Purpose: DEXA measurements are performed to assess bone health in patients with low impact fractures. IBEX's Multi-Absorption Plate (MAP) allows generation of BMD information on standard DR systems without compromising diagnostic image quality. This study compares bone composition measurements from DEXA and IBEX systems to assess IBEX BMD measurement as a potential replacement for DEXA.
Methods and Materials: A Hologic "Discovery" DEXA machine was compared with an IBEX MAP-equipped DR system (x-ray tungsten target source, Rayence 1417 FPD, 115cm source to detector distance). Phantoms were constructed of tissue- and bone-equivalent materials giving a "ground truth" against which to compare the two measurements. Phantoms ranged in total thickness from 3cm to 6cm with 50% to 100% tissue-equivalent material giving a BMD range from approximately 0 to 1 g/cm^2.
Results: Bone thickness was compared to BMD values obtained from each system. A set of DEXA data produced a simple calibration to align the output of the IBEX system to the DEXA results, allowing BMD values to be compared directly. Plotting BMD against bone simulant thickness we find agreement between linear models associated with BMD outputs from both machines. A standardised distance between model gradients of 0.9389 suggests no evidence that IBEX's methodology does not give an unbiased estimator for DEXA BMD. The residual standard error of the IBEX system is calculated to be 0.0434g/cm^2.
Conclusion: IBEX technology enables BMD to be measured on a DR system, and therefore presents a potentially viable alternative to further patient referral and use of DEXA.

Gridless scatter removal on standard digital radiography systems using the IBEX material identification technology

P.D. Scott[1], B. Lopez[1], A. Ratcliffe[1], J. Cowling[1], I. Argyridis[2], K. Robson[2]; [1]*Sedgefield/UK*, [2]*Newcastle Upon Tyne/UK (p.scott@ibexinnovations.co.uk)*

Purpose: A process has been developed for accurate scatter prediction and removal using materials information generated by IBEX materials identification technology. This enables scatter to be removed without the dose impact of an anti-scatter grid (ASG) and also provides quantitative materials information required for diagnostic techniques such as bone mineral density (BMD). Currently, ASGs are used to remove scattered x-rays when imaging larger body parts. ASGs improve feature contrast at the cost of increased radiation dose or increased Poisson noise. This study compares IBEX's scatter removal method (SRM) to a standard ASG, for a range of phantoms and cadavers and shows the potential for gridless x-ray imaging and BMD measurements on a standard DR detector.
Methods and Materials: The technology has been applied to a standard FPD (Rayence 1417) and GE VMX+ mobile x-ray source with an accompanying simulator developed in GEANT4. The model provides information relating to sample specific scattering characteristics which is used to identify materials and remove scatter present within the x-ray image. The technology has been demonstrated on both x-ray phantoms and cadaveric donors.
Results: Early data demonstrates removal of scatter to a level equivalent to that of an ASG. This results in a factor six CNR improvement when compared to an uncorrected image as well as providing quantitative materials information.
Conclusion: A gridless scatter removal method using the IBEX materials identification technology has demonstrated improvements in CNR and a reduction in patient dose. This offers clear benefits to both patients and clinicians in medical diagnostics.

B-0313 15:12

Novel segmentation method using absorption- and phase-contrast x-ray images

A. Yoneyama[1], R. Baba[1], K. Hyodo[2]; [1]*Kokubunji/JP*, [2]*Tsukuba/JP (akio.yoneyama.bu@hitachi.com)*

Purpose: To finely identify inner structures of biomedical samples and precisely distinguish between normal and tumour tissues, a novel segmentation method based on absorption- and phase-contrast x-ray images was tested using three-dimensional images of a phantom and a rat tail obtained under ideal conditions.
Methods and Materials: Three-dimensional absorption- and phase-contrast images were obtained using a Talbot interferometric imaging system with 17.8-keV monochromated synchrotron radiation. A phantom composed of small spheres made of five kinds organic material (glass, polyurethane, polypro pine, acryl, and nylon) and a formalin-fixed rat tail were used as demonstrative samples. The obtained images were segmented using the proposed method, which uses a ratio of absorption and phase-shift CT values at the same pixel in each image.
Results: The segmented image of the phantom clearly depicts each sphere made of different materials, which cannot be distinguished using the absorption- and phase-contrast imaging method only. Artefacts caused by heavy material was also identified clearly and removed easily. The segmented image of the rat tail also shows hair, muscle, and bone clearly.
Conclusion: These results show that the proposed segmentation method effectively identifies organic materials and biomedical regions, and therefore, is expected to provide a new way to finely segment biomedical samples, especially to precisely distinguish between normal and tumour tissues.

Application of a single-energy electron-density reconstruction in radiation therapy planning

A. Ritter, B. Schmidt, R. Raupach; *Forchheim/DE (andre.ritter@siemens.com)*

Purpose: In radiation therapy, a tube-voltage-dependent conversion from CT value (HU) to electron density is needed for dose calculation on CT images. It is common practice to use a fixed tube voltage. A new single-energy electron-density reconstruction, can remove the need for a tube-voltage-dependent conversion. We discuss properties of this reconstruction and their implications for the application in radiation therapy planning.
Methods and Materials: The reconstruction is based on a material decomposition, which takes place partly in image and projection domain, to compute the effective thicknesses of water and bone in the projection domain. Both effective thicknesses are used to synthesize line integrals of electron density, from which images of electron density are reconstructed. The reconstruction is tested with the Gammex 467 Tissue Characterisation Phantom using different arrangements of the tissue substitutes and different tube voltages. Additionally, this method is compared to a conventional conversion from CT value to electron density.
Results: The accuracy of the electron density reconstruction increases with higher tube voltage and tends to be at least as high as for tube-voltage-dependent conversion from standard images. Additionally, effects of beam hardening, such as streaks between high-density bone-like tissues or systematic changes of image values due to different substitute arrangements, are decreased.
Conclusion: The improved stability of electron density estimation might be advantageous for the accuracy of dose calculation in radiation therapy. Systematic changes of image values due to changes in tube voltage are reduced, which opens the opportunity to introduce the benefits of tube-voltage-adaption to radiation therapy.

Short-term effects during examinations in an actively shielded 7T MR

B. Hansson[1], P. Höglund[1], O. Johan[1], K. Markenroth-Bloch[1], M. Nilsson[1], J. Frankel[2], J. Wilén[2], T. Owman[1], J. Arborelius[1]; [1]*Lund/SE*, [2]*Umeå/SE (boel.hansson@med.lu.se)*

Purpose: To evaluate frequency and quality of short-term effects reported by research persons after research examinations performed in an actively shielded 7T MR.
Methods and Materials: 124 research persons undergoing 154 7T MR examinations (77% brain) answered a web-based questionnaire on occurrence (n) and strength (VAS, visual-analogue-scale) of inconsistent movement, dizziness, nausea, headache, metallic taste, twitches and light flashes, and regarding temperature, noise, communication system, information status, motion sickness and willingness to repeat a scan. Scanner output on predicted peripheral nerve stimulation (PNS) values was recorded in 85 research persons.
Results: Short-term effects reported were dizziness (84% of examinations), inconsistent movement (70%), nausea (53%), headache (53%) and metallic taste (43%). Mixed model analyses showed in all positions (in, inside, out, outside) significantly higher VAS values for inconsistent movement ($p<0.001$) and dizziness ($p<0.002$) when scanned head first compared to feet first, but no significant differences were found for nausea, headache and metallic taste. Twitches, an expression of PNS, was reported in 67% of examinations, occurred primarily in torso, hand and arm, and tended to increase with higher predicted PNS values. 23% of the research persons experienced light flashes. Scanner noise levels were well tolerated. The communication system was well perceived. Willingness to undergo a future 7T MR was high both as research person and patient (90%, 96%).
Conclusion: Actively shielded 7T MR examinations are well tolerated, although short-term effects such as inconsistent movement, dizziness and twitches are more commonly reported compared to literature on passively shielded 7T MRs.

B-0316 14:08

Assessment of incidental findings detected on research MRI scans of healthy volunteers

A. Ljimani, H.-J. Wittsack, J. Aissa, G. Antoch, R. Lanzman; *Düsseldorf/DE (alexandra.ljimani@med.uni-duesseldorf.de)*

Purpose: To assess the frequency and clinical significance of incidental findings in healthy volunteers undergoing research MRI scans.
Methods and Materials: Research MRI scans of 324 healthy subjects (178 male, 146 female, mean age 31.5±11.6 years) performed in our department over a two year period were considered for this analysis. Research scans of the brain (n=92), spinal cord (n=149), kidneys (n=20), liver (n=3), hands (n=22), hips (n=34) and knees (n=4) were systematically reviewed by board certified radiologists for incidental findings. Incidental findings and subsequent recommendations were analysed.
Results: Incidental findings were reported in 19 of 324 (5.9%) subjects in scans of the spinal cord (n=15), brain (n=3) and knee (n=1). Most frequently prolapsed vertebral discs (n=7), enlarged ovarian cysts (n=3) and inguinal lympadenopathies (n=3) were reported. Furthermore, dilated bile ducts (n=1), a meniscus tear in the knee (n=1), microangiopathic changes in the brain (n=1), a state following hip necrosis (n=1), a retroperitoneal mass/metastasis (n=1) and a lesion in the clivus that was suspicious for a chondroma (n=1) were reported. Further medical examination or treatment based on the incidental findings was required in 8 of 19 (42%) subjects.
Conclusion: Incidental findings may occur in up to 6% of healthy volunteers undergoing research MRI scans and might often (42%) require further examinations. Therefore, MRI research scans should be systematically evaluated for incidental findings.

B-0317 14:16

Artefact evaluation in MRI of new materials for hip prostheses: a phantom study

D. Sousa[1], P. Martins[1], C. Ferreira[2], S. Francesco[1], M. Castelo-Branco[2], R. Silva[1]; [1]*Aveiro/PT*, [2]*Coimbra/PT (pmartins@ua.pt)*

Purpose: MRI is a well-established imaging method for diagnostic purposes. Nevertheless, it is prone to several artefacts like those coming from magnetic susceptibility ones, which can compromise image quality. Development and use of new materials is a promising alternative concerning the reduction of this type of artefacts. Silicon nitride ceramics coated with nanocrystalline diamond (SND) developed by CICECO-Aveiro University show excellent characteristics of wear resistance and biocompatibility. Our aim is to evaluate the magnetic susceptibility artefacts caused by this prosthesis and compare it with others available on the market.
Methods and Materials: Cobalt-chromium (CC), oxinium (Ox), zirconia-toughened alumina (ZTA), silicon nitride (SN) and SND femoral head prosthesis placed in a custom-made plastic phantom were used to compare image artefacts. T1-weighted images were acquired with spin-echo and gradient-echo sequences at 3 and 1.5Tesla. Quantitative analysis of the images and 3D reconstruction of the artefact was performed with MeVisLab2.7.1 using region-growing method to calculate artefact volume.
Results: All prosthesis showed higher artefact volumes at 3Tesla when compared with 1.5Tesla, as expected. At 3Tesla, artefact volume was 445.14cm^3, 60.39cm^3, 3.67cm^3, 2.45cm^3, 2.52cm^3 for CC, OX, ZTA, SN and SND, respectively, with a similar pattern at 1.5Tesla. Ceramic materials (ZTA,SN and SND) present considerably smaller artefacts than metallic ones (CC and OX) both at 1.5 and 3Tesla. SND produce comparable artefacts (even lower) than ZTA prosthesis, the gold standard in clinical practice.
Conclusion: Our preliminary results pointed to an excellent performance (reduced artefact volume) of diamond-coated ceramic prosthesis, even in high-field imaging. However, a more comprehensive evaluation should be carried out.

B-0318 14:24

Investigation of radiographer and radiologist ability to manage MR image quality issues for abdomen and pelvis examinations in Saudi Arabian and Irish centres

S. Al Dahery, A. McGee, L. Rainford; *Dublin/IE (shrooq_talal@hotmail.com)*

Purpose: The study aimed to identify the current knowledge and confidence of MR radiographers and radiologists from Saudi Arabia and Ireland with regard to image quality management for MR abdomen and pelvis examinations. Findings would inform any future training requirements needed to ensure high-quality imaging standards.
Methods and Materials: A qualitative approach was applied. Public, private, military and academic hospitals in the western region of Saudi Arabia (SA) were invited to participate, as were Irish centres. Institutional review board ethical approval was attained. Semi-structured interviews were designed to investigate both the radiographer's and radiologist's professional role in the two countries, how they dealt with image quality issues and perceived personal development in MR and what they viewed as required regarding image quality training to support their work. Chief radiographers, radiographers, and radiologists working in MR were included. Coded interviews were recorded and then transcribed.
Results: Nvivo 10 files (n=87): Saudi Arabia (n=10 centres); Ireland (n=12 centres) were created. Coding resulted in 2071 references grouped into nodes, later becoming three themes: healthcare professional: factors affecting image quality, image quality, and departmental policy. An interrelationship across and between data was identified. A variety of experience and participant knowledge of image quality was noted, as where the challenges of achieving optimal quality levels. Differences between countries were identified as was the impact of experience and education level.
Conclusion: Image quality training and subsequent assessment of professional skills are required to support radiographers and radiologist in the routine management of MR image quality.

B-0319 14:32

Magnetic resonance imaging of anterior cruciate ligament tears: evaluation of standard orthogonal and tailored paracoronal imaging

L.M. Deguara, P. Demicoli, F. Zarb; *Msida/MT (ldeg0010@um.edu.mt)*

Purpose: To evaluate the diagnostic efficiency of using the standard magnetic resonance planes with an additional paracoronal plane in the diagnosis of anterior cruciate ligament (ACL) tears.
Methods and Materials: Ten MR examinations of the knee using proton density fat saturated sequences were prospectively compiled. The visibility of anatomical structures was used for the evaluation of image quality. Repeat MR examinations facilitated intra and inter rater reliability. Two radiologists performed absolute visual grading analysis (VGA). Data was analysed using

visual grading characteristic curves (VGC) and the area under the curve (AUC) determined which plane offers the best image quality for each anatomical structure. The one sample t-test was performed to establish significant differences in image quality.
Results: Overall image quality scores were higher for coronal (VGC_{AUC} 0.76) and sagittal (VGC_{AUC} 0.51) over the paracoronal plane, whilst the paracoronal showed better image quality over the axial plane (VGC_{AUC} 0.48). The coronal plane was significantly better in the visualization of 3 anatomical structures: anteromedial bundle of the ACL (p-value 0.04), posterolateral bundle of the ACL (p-value 0.04) and lateral insertion of the collateral ligament (p-value 0.02). The paracoronal plane was significantly better than the axial plane in the visualization of the distal insertion of the ACL (p-value 0.02). None of the structures showed significant image quality differences (p&gt0.05) on the sagittal plane.
Conclusion: The addition of the paracoronal plane might be of added benefit when used in conjunction with the orthogonal planes for further investigations concerning the distal insertion of the ACL.

B-0320 14:40

Assumed factor analysis of MRI safety processes by MRI personnel: a FMEA approach

A. De Bock, A. Stadler, W. Schima; *Vienna/AT (anke.de.bock@live.be)*

Purpose: Due to the broadening, the field of MRI applications using high-field scanners and the growing number of examinations, hazardous events in MR units do occur. The role of MR safety officers in the MR environment and the perceived level of safety among MRI personnel was assessed.
Methods and Materials: A questionnaire was designed with q-set.at, and sent out to MR institutions. Reply from MRI personnel (n=175) was analysed regarding subjective feeling of safety in MR institutions, objective occurrence of adverse events in the MRI suite, and the role of MR safety officers. The statistic tests used were contingency coefficient and the Mann-Whitney-U-test (significance level 0.05, test power with a probability ≥ 0,8).
Results: MRI personnel feels safe (scale 0-20) with a value of 16.6. There is a higher level of safety feeling in an MRI department with an MRI safety officer present (p=0.002). However, there is no association between the presence of an MRI safety officer and the amount of serious events regarding MR safety (C=0,014; p=0,894). There is no association between the number of educated radiographers and the safety feeling if working in the MRI department (C=0,239; p=0,101).
Conclusion: The presence of MRI safety officers causes a higher level of subjective safety feeling of the MRI personnel, which, however, does not correlate with a lower number of hazardous events. The results of this survey show the importance of an MRI safety education to ensure safety for patients and personnel.

B-0321 14:48

Brain imaging: comparison of T1 FLAIR BLADE with conventional T1 SE

E. Lavdas[1], E. Giankou[2], A. Tsikrika[3], E. Kapsalaki[3], G. Batsikas[3], S. Kostopoulos[1], D. Glotsos[1], K. Ninos[1], D. Kavouras[1], P. Mavroidis[4]; [1]*Athens/GR*, [2]*Paros/GR*, [3]*Larissa/GR*, [4]*Chapel Hill, NC/US (eleonoragiankou@gmail.com)*

Purpose: The objective of this study is to compare the quality of T1W-FLAIR BLADE images and the quality of T1W-SE images in the MR imaging of the brain.The goal is to highlight which sequence can better eliminate artifacts and visualise lesions and surrounding tissues.
Methods and Materials: Brain examinations with T1W-FLAIR BLADE images and T1W-SE were performed on 55 patients using 1.5T SIEMENS (AVANTO) scanner.These techniques were evaluated by two radiologists for a) qualitative analysis i.e. presence of artifacts, CSF nulling, and b) quantitative analysis of signal-to-noise ratios (SNR), contrast-to-noise ratios (CNR) and relative contrast (ReCon).The evaluation was performed by the Kruskal-Wallis non-parametric system.
Results: In the quantitative analysis, T1W-SE appeared to have higher values in the majority of cases regarding the SNR measurements, whilst T1W-FLAIR BLADE had higher values on CNR and ReCon measurements. In the qualitative analysis BLADE sequences had a higher scoring than the conventional sequences in all the cases.The overall image quality was better on T1W-FLAIR BLADE.Motion and flow-related artifacts, as well as susceptibility errors were lower in T1W-FLAIR BLADE.T1 FLAIR BLADE offered a better imaging for metastases, AVMs, ischaemic strokes, multiple sclerosis and vessels.
Conclusion: T1W-FLAIR BLADE sequence is superior to T1W-SE in overall image quality, reduction of motion and flow-pulsation artifacts, susceptibility errors and in nulling CSF. T1W-FLAIR BLADE is preferred by the clinicians and may be an alternative approach to brain MRI imaging. We suggest the use of T1 FLAIR BLADE in AVM's, metastases, ischaemic strokes and multiple sclerosis.

B-0322 14:56

Patients' MRI acoustic noise exposure in different protocol exams

V.M.F. Silva, I.M. Ramos, J.A. Moreira, M. Marques; *Porto/PT (vitorsoft@gmail.com)*

Purpose: Time-varying gradient fields are the main source of acoustic noise associated with an MRI procedure. Lorenz forces are produced during each procedure, deforming and vibrating the three main gradient coils. Various types of acoustic noise are produced in each protocol exam. Problems associated from this hazard for patients include annoyance, anxiety, verbal communication difficulties, psychological distress, temporary hearing loss, headaches and, in extreme cases, the potential for permanent hearing impairment. Acoustic noise may pose a particular and substantial problem to specific patient groups. There is legislation to rule acoustic noise levels that are divided in two types of exposure: equivalent continuous sound level (Lex, 8h) and peak sound pressure level (Lc peak).
Methods and Materials: Different exam protocols used in brain, spine and abdominal MRI were tested in a 1.5T scanner, with a sound level meter. It was used ISO 9612:2009 for determination of acoustic noise exposure.
Results: Lex, 8h ranged from 58.6 dB(A) in T2 FLAIR sequence used in brain and 80.3 dB(A) used in time of flight (TOF) 2D sequence used in MRI angiography.While Lc peak ranged from 98.63 dB(C) in T2 FLAIR sequence and 118.84 dB(C) used in abdominal echo planar imaging (EPI) diffusion sequence.
Conclusion: Lex, 8h is higher in TOF 2D sequences used in brain MRI and EPI sequences used in abdominal MRI, while Lc peak is higher in EPI sequences used in all diffusion and perfusion MRI protocols. Manipulating some MRI parameters, maintaining image quality, it is possible to lower exposure noise levels.

B-0323 15:04

Application of the tractography method in the study of magnetic resonance imaging in paediatric patients in selected clinical situations

A. Przepióra; *Poznań/PL (agnieszkaprzepiora@gmail.com)*

Purpose: Correlation of the impact of technical conditions on quality of the images obtained using diffusion tensor imaging (DTI) in the study of magnetic resonance imaging (MRI) of paediatric patients' heads.
Methods and Materials: From January to November 2015, in the department of paediatric radiology of the K. Jonscher Clinical Hospital No. 5 in Poznań, MRI of brain has been performed with the use of DTI and visual representations of nerve fibres have been made using the tractography technique. 25 patients have been examined. The patients were from 3 days to 17 years old. The study has been performed with the 3T scanner. The dependency between age, clinical condition of a child, size of the imaged area and resulting image quality has been analysed.
Results: The objective of the study was to analyse the technical conditions of the study taking into account patient's individual features. It has been shown that in most of studies (84%) tractography was possible to perform from the data collected during diffusion imaging. For the operator of the study an important factor is age of an examined patient and size of the imaged area. Examination of the youngest patients needed a significant modification of existing technical settings.
Conclusion: For the operator who performs the examination, information on the individual characteristics of the patient is important for the selection of appropriate technical conditions for the sequence. Proper technical settings are in correlation with the obtained image quality of the tractography.

B-0324 15:12

Patients knowledge about ultrasound, computed tomography and magnetic resonance

P. Ferreira, R.P.P. Almeida, A.F. Abrantes, L.P.V. Ribeiro, N. Pinto, K.B. Azevedo, J.P. Pinheiro; *Faro/PT (lpribeiro@ualg.pt)*

Purpose: To study the level of patients knowledge about ultrasound (US), computed tomography (CT) and magnetic resonance imaging (MRI) and to assess patients understanding of the main general aspects of these examinations.
Methods and Materials: A self-applied questionnaire developed by Chesson, Mckenzie and Mathers (2001) in UK was validated for the Portuguese population with permission of the authors and assigned to 143 outpatients who perfomed US (55), CT (48) and MRI (40) examinations. The questionnaires used 15 main questions, an answer scale with 3 options (True, False or Don't Know) and were interpreted and statistically analysed through descriptive statistics, Phi and Cramer's V tests.
Results: Only 22,4% of the patients indicated they sought information about the type of investigation they had been referred for and 63,6% had performed US, CT or MRI examinations before. Considering the three mentioned techniques, patients answered more accurately to questions related to situations experienced during the examination (darkness of the examination

room, presence of the radiographer in the examination room and viewing images on a monitor) than items related to specific issues (use of ionizing radiation, use of contrast media, preparations and respiratory instructions).
Conclusion: Patients were not well informed regarding these examinations, especially relating to specific issues. Since this could have implications in the information-giving strategies, it becomes necessary to raise awareness and educate patients, allowing the social development of information on this topic as well as radiographer intervention in the exam procedure.

B-0325 15:20

MRI safety procedures during the dismantling of one scanner

T. De Bondt, F. Vanhevel, M. Geldof, F. Deferme, P.M. Parizel; *Antwerp/BE (timo.debondt@gmail.com)*

Purpose: To describe issues regarding MRI safety during the unusual situation of the dismantling of an MRI scanner, and to identify potential associated risks.
Methods and Materials: Our hospital received the Joint Commission International (JCI) accreditation in 2015. To achieve this, MRI safety procedures were put in place, following the American College of Radiology (ACR) guidance document. Two capital aspects of these measures are the screening procedure and the site-access restriction through the zoning system. Zone 1 is accessible for the general public, Zone 2 is the reception and screening area, Zone 3 is only accessible for patients under supervision of MR personnel and Zone 4 is the scanner room. Our MRI facility had 4 MRI systems, 3 of which are still operational and 1 was dismantled by Hegele Logistics.
Results: The normal access door for unscreened patients needed to be removed because of the scanner size. This door was removed for 2 days; after working hours, wooden plates were put in place to prevent free access. Additionally, during transportation of the scanner, all physical barriers between Zone 1 and Zone 3 were not in place. Therefore, radiographers were instructed to increase alertness when unscreened patients moved throughout the MRI-site Zone 3. No incidents occurred during the dismantling.
Conclusion: During the unusual situation of a scanner dismantling, several established safety precautions can temporarily be rendered useless. These events need special attention in terms of improvised safety measures, and need to be discussed and communicated in advance.

Rapid functional cardiac imaging between gadolinium injection and late enhancement: evaluation of a highly accelerated sequence with sparse data sampling and iterative reconstruction

J. Budjan, H. Haubenreisser, S. Sudarski, C. Doesch, T. Henzler, M. Borggrefe, S.O. Schönberg, U.I. Attenberger, T. Papavassiliu; *Mannheim/DE*

Purpose: To create and evaluate a time-efficient, patient-friendly cardiac magnetic resonance imaging (CMRI) protocol that uses the idle time between gadolinium injection and late enhancement acquisition for volumetric assessments.
Methods and Materials: 20 consecutive patients (14 male, 56±19 years) underwent a CMRI examination including a fully-sampled multi-breath-hold sequence as gold standard (Ref) as well as an highly accelerated real-time CINE TrueFISP sequence based on sparse data-sampling with iterative reconstruction (SSIR) acquired in single-breath-hold (SSIR-BH) and under free breathing (SSIR-nonBH). SSIR sequences were acquired 4 minutes after gadolinium injection (0.2mmol/kg body weight Gd-DOTA). Right (RV) and left ventricular (LV) volumetric parameters as well as regional wall movement (RWM) were evaluated and compared between Ref and SSIR.
Results: Despite reduced contrast between myocardium and intra-ventricular blood, volumetric as well as regional wall movement assessment revealed high agreement between both SSIR sequences and Ref. For the volumetric LV assessment, excellent correlation and narrow limits of agreements were found for both SSIR-BH and SSIR-nonBH when compared to Ref (mean LV ejection fraction [EF] Ref: 52.8%, SSIR-BH 52.3%, SSIR-nonBH 52.5%). For the RV analysis, both SSIR sequences showed an excellent correlation and high agreement with Ref (mean RV EF Ref: 52.7%, SSIR-BH 52.0%, SSIR-nonBH 52.2%). In the RWM analysis, 314/320 segments (98%) received identical ratings in all three sequences.
Conclusion: Even when acquired in the idle time between gadolinium injection and LGE acquisition, the highly accelerated SSIR sequence delivers accurate volumetric and regional wall movement information. It thus seems ideal for very time-efficient CMRI protocols.

Cross-modality accuracy of dual-step prospective ECG-triggered dual-source CT compared with echocardiography and cardiac MR in the follow-up of heart-transplanted patients

D. Curione, C. Rutigliano, D. Di Molfetta, C. Grippo, B. Merlino, L. Natale, R. Marano, L. Bonomo; *Rome/IT*

Purpose: To evaluate the role of dual-step prospective ECG-triggered dual-source CT (pECGdualstep-DSCT) in the follow-up of heart-transplanted-patients (HTPs) for the assessment of both left ventricular function (LVF), in comparison with Echocardiography (Echo) and Cardiac Magnetic Resonance (CMR), and the coronary arteries.
Methods and Materials: Prospective blinded evaluation of 11 HTPs: 1. left ventricular ejection fraction (EF), end-diastolic (EDV), end-systolic (ESV), stroke volume (SV), cardiac output (CO), and mass on pECGdualstep-DSCT (2 independent readers), Echo (single operator) and CMR (single reader) performed on the same day (heart-rate (HR) recorded during all exams); 2. coronary arteries on pECGdualstep-DSCT. pECGdualstep-DSCT technique: sequential scan (10-90% R-R interval) applying variable tube current (full during systole (35-45%) and reduced (20%) during the remaining acquisition).
Results: 1. EF was slightly lower on pECGdualstep-DSCT (55.7%±5.0) than Echo and CMR, but without a statistically significant difference. pECGdualstep-DSCT showed statistically significant higher EDV (153.7±24.2mL), ESV (67.8±11.5mL), SV (85.9±17.6mL), CO (6.4±1.2L/min), and mass (120.6±28.7g/m2) ($p<0.01$) compared with Echo and CMR, but with a high correlation coefficient (rho), mainly with CMR ($p<0.05$ up to <0.001) and particularly for CO (rho=0.959). HR was statistically significant lower on pECGdualstep-DSCT (75.6±7.8bpm, $p<0.001$). Inter-reader agreement on pECGdualstep-DSCT was excellent for all parameters (concordance correlation coefficient≥0.97, $p<0.001$). 2. No significant coronary artery disease was detected. Mean effective radiation dose was 6.4±1.9mSv.
Conclusion: pECGdualstep-DSCT allows reliable and reproducible LVF assessment in HTPs, with good correlation with Echo and CMR, and with simultaneous coronary artery evalutation in one single fast acquisition with a limited radiation dose.

The effect of contrast administration on the treshold-based cardiac magnetic resonance (CMR) evaluation

F. Suhai, I. Csécs, C. Czimbalmos, A. Tóth, Z. Dohy, B. Horváth, B. Szilveszter, B. Merkely, H. Vágó; *Budapest/HU (suhaiimi987@gmail.com)*

Purpose: The aim of our study was to investigate the effect of the contrast administration on left and right ventricular (LV,RV) parameters evaluated by a threshold-based quantification software (MassK).
Methods and Materials: We prospectively evaluated CMR data of 19 patients without any functional, structural abnormalities or delayed contrast enhancement (mean age:38±4 years) and 14 patients with previous myocardial infarction (mean age:57±15 years). The CMR scans were performed on a 1.5T Philips Achieva, assessements were performed using Medis, QMASS 7.6 software. We performed precontrast short axis cine images (SACI) before iv. Gadovist administration (0.15 mmol/kg) and postcontrast SACI which were taken 2 minutes after the contrast administration. We assessed the LV, RV volumes and masses using the conventional and the MassK method.
Results: With the MassK algorithm the LV, RV volumes were significantly higher and LV, RV masses were lower on the postcontrast compared to the precontrast evaluation in both groups.
The median LV end-diastolic volume index (LVEDVi) was in the control group:71 ml/m^2 [67-87] vs. 67ml/m^2[60-81], LV mass:141g[62-88] vs. 149g[112-180] ($p<0.002$). Median LVEDVi in the infarction group:74.5 ml/m^2[61-95] vs. 64.5 ml/m^2[62-88] LV mass:152g[130-184] vs. 164g[135-189] ($p<0.002$).
With the conventional method there were no differences in LV, RV volumes and masses in control group. In the infarction group the postcontrast LVEDVi was lower compared to the precontrast (median LVEDVi:92.4 ml/m^2[77.7-114] vs. 93.4 ml/m^2[79.6-113.6] ($p=0.0023$).
Conclusion: These preliminary results show that contrast administration has a significant effect on the threshold-based quantification method which have to take into account during the post-processing evaluation.

B-0329 14:24

Assessment of left ventricular deformation in patients with ebstein's anomaly by cardiac magnetic resonance tissue tracking

X. Liu, Z.-G. Yang, Y.-K. Guo, R. Li, K.-Y. Diao; *Chengdu/CN (liuxihsd@163.com)*

Purpose: The aim of this study was to clarify the feasibility of myocardial strain using cardiovascular magnetic resonance (CMR) for the evaluation of left ventricular (LV) deformation in patients with Ebstein's anomaly (EA).
Methods and Materials: We recruited 32 EA patients and 30 controls for CMR examination and measured LV function, dimension and tissue tracking parameters (the global and regional radial, circumferential and longitudinal peak strain), together with the right ventricle (RV) dimension. LV strain parameters were compared among the controls, patients with preserved LV ejection fraction (LVEF; ≥55%), and patients with reduced LVEF (<55%).
Results: The global strain parameters all decreased significantly in the EA group compared with the control group (all $P < 0.05$). Furthermore, the global radial and circumferential peak strain (PS) were obviously even lower in the reduced LVEF group than the strain measured in preserved LVEF groups (28.64% vs. 37.39%, $p< 0.05$; and -8.20% vs. -17.89%; $p< 0.05$). The regional strain abnormalities in EA patients were mainly involved in basal and middle segments. The results also demonstrated a significant correlation between the ratio of the RV end-diastolic dimension to the LV end-diastolic dimension (RVEDD/LVEDD index) with the global circumferential PS ($r = 0.508$) and the longitudinal PS ($r =0.474$), as well as a good correlation between radial PS and LVEF ($r = 0.465$).
Conclusion: LV strain serves an earlier and more comprehensive measurement of LV dysfunction than LVEF in EA, which could potentially be included as a supplementary diagnostic procedure in the evaluation of EA.

Non-invasive evaluation of left ventricular function using CT and MRI: a meta-analysis

M. Kaniewska[1], G.M. Schütz[1], S. Willun[1], P. Schlattmann[2], M. Dewey[1]; [1]*Berlin/DE*, [2]*Jena/DE (malwina.kaniewska@ksb.ch)*

Purpose: To compare the diagnostic accuracy of CT in the assessment of global and regional left ventricular function with MRI established as the gold standard examination.
Methods and Materials: We have systematically reviewed databases of MEDLINE, EMBASE, and ISI Web of Science. Evaluation included: ejection fraction, end-diastolic volume, end-systolic volume, stroke volume, and left ventricular mass. Differences between modalities were analysed using limits of agreement. Publication bias was measured by Egger's regression test. Heterogeneity was evaluated using Cochran's Q test and Higgins I2 statistic. In the presence of heterogeneity the DerSimonian-Laird method was used for estimation of heterogeneity variance.
Results: 53 studies including 1814 patients were identified. The mean difference between CT and MRI was -0.56% (-11.6 to 10.5%) for EF, 2.62 ml (-34.1 to 39.3 ml) for EDV and 1.61 ml (-22.4 to 25.7 ml) for ESV, 3.21 ml (-21.8 to 28.3 ml) for SV and 0.13 g (-28.2 to 28.4 g) for LVM. CT detected wall motion abnormalities on a per-segment basis with 90% sensitivity and 97% specificity.
Conclusion: CT is accurate for assessing global LV function parameters but the limits of agreement in comparison to MRI are moderately wide. However, in CT examination wall motion deficits are detected with high accuracy.

Left ventricular absolute wall thickening: a unifying theory of heart failure?

J.C.L. Rodrigues[1], B. Rooms[1], K. Hyde[1], S. Rohan[1], M.C.K. Hamilton[1], A.K. Nightingale[1], J.F.R. Paton[1], N.E. Manghat[1], D.H. MacIver[2]; [1]*Bristol/UK*, [2]*Taunton/UK (jonrodrigues@doctors.org.uk)*

Purpose: No single well-established hypothesis for the mechanisms of heart failure exists. Left ventricular ejection fraction (LVEF) is widely used to dichotomise heart failure into reduced and preserved LVEF cohorts. We hypothesised that a common myocardial mechanism occurs in heart failure regardless of cause. We quantify the relationship of absolute wall thickening (AWT) with LVEF across a range of global cardiac pathology with varying degrees of end-diastolic wall thickness (EDWT) using cardiac magnetic resonance (CMR).
Methods and Materials: 183 subjects underwent 1.5T CMR: 53 idiopathic dilated cardiomyopathy (DCM), 36 amyloid cardiomyopathy, 55 hypertensives (HTN) and 39 normal controls. LV volumes and LVEF were calculated. EDWT and end-systolic wall thickness (ESWT) were measured in basal and mid-myocardial segments from long-axis cines. AWT (ESWT-EDWT) and relative AWT (rAWT=AWT/LV end-diastolic internal diameter) were calculated. Longitudinal and circumferential strain were measured.
Results: There was a range of LVEF: normal (controls 64±7% and HTN 66±8%), moderately reduced (amyloid 49±16%) and severely reduced (DCM 30±11%). There were significant differences in EDWT between subgroups (controls: 8±1mm, DCM: 8±1mm, HTN: 11±3mm and amyloid: 14±3mm, $P<0.0001$). Reduced longitudinal ($R=-0.457$, $P<0.0001$) and circumferential strain ($R=-0.710$, $P<0.0001$) were associated with reduced AWT. AWT was strongly related to LVEF ($R=0.812$, $P<0.0001$). Changes in rAWT accounted for >75% LVEF variability across the entire cohort ($R^2=0.766$).
Conclusion: LVEF is determined by changes in rAWT across a range of global LV disease of varying EDWT. Our findings offer a unifying mechanism to explain heart failure with preserved and reduced LVEF.

B-0332 14:48

Value of post contrast Cine-SSFP images for visual assessment of global left ventricular function at 3T

A. Preuß[1], S. Wyschkon[1], M. Elgeti[2], B. Hamm[1], T. Elgeti[1]; [1]*Berlin/DE*, [2]*Los Angeles, CA/US*

Purpose: At higher field strengths, B0-inhomogeneitis and the resulting dark-band artefacts can degrade delineation of myocardial contours on steady-state free precession (SSFP) magnetic resonance (MR) images and thus impair visual assessment of myocardial functional abnormalities. We therefore tested if gadobutrol (Gd)-enhanced post-contrast Cine- SSFP images allow visual assessment of global cardiac function on cardiac long-axis views.
Methods and Materials: Pre- and post-contrast (single standard dose of gadobutrol) Cine-SSFP loops in the four-chamber view of 20 patients who underwent contrast-enhanced cardiac MR imaging at 3T (Magnetom Trio, Siemens) were evaluated. Contrast-to-noise ratios (CNR) were calculated. Standard deviation (SD) of left ventricular (LV) signal intensity was measured to quantify signal heterogeneity of LV blood pool. Presence of artefacts (dark band, flow) in both ventricles and delineation of the endocardial LV border were rated by two observers in consensus using a four-point Likert scale (lower=better). Results are given as mean±SD. Measurements were compared using Student´s t-test and qualitative results were assessed using the non-parametric Wilcoxon signed-rank test.
Results: Pre- and post-contrast CNR was 33±17 and 40±18 ($p=0.052$), SD of LV blood pool was 43±32 and 31±15($p=0.062$). Presence of artefacts was rated 3±0.9 in pre- and 1.9±0.9 in postcontrast images ($p=0.001$). Endocardial delineation was rated 2.7±0.9 (precontrast) and 1.7±0.6 (postcontrast) ($p=0.002$).
Conclusion: If Gd-based contrast medium is used (e.g., for delayed Gd-enhancement imaging), post-contrast Cine-SSFP images show comparable CNR by significantly reduced dark band and flow artefacts thus improving the visual assessment of global cardiac function.

Left ventricular diastolic function estimation from magnetic resonance real-time cine imaging

C. Reiter[1], G. Reiter[1], A. Schmidt[1], A. Greiser[2], M. Fuchsjäger[1], U. Reiter[1]; [1]*Graz/AT*, [2]*Erlangen/DE (Clemens.Reiter@medunigraz.at)*

Purpose: To evaluate if cardiac magnetic resonance (CMR) cine real-time imaging-derived volumetric parameters of the left heart allow grading of left ventricular diastolic dysfunction similar to routinely used early-to-late diastolic transmitral (E/A) and systolic-to-early diastolic pulmonary venous (S/D) flow ratios.
Methods and Materials: Eleven patients with coronary heart disease without aortic and mitral insufficiencies (age = 66±9 years; male/female = 8/3) underwent 3T CMR 4D flow and cine real-time imaging covering the left heart in 4-chamber orientation. E/A and S/D ratios were derived from 4D flow data. Left ventricular and atrial volumes were semi-automatically segmented in cine images to determine the ratios of early-to-late diastolic left ventricular peak filling rates (volumetric E/A) and of systolic atrial peak filling to early-diastolic peak emptying rate (volumetric S/D). Relations between flow and volumetric ratios were analysed by correlation and regression analysis; means were compared with paired t test.
Results: Whereas mean values of E/A and volumetric E/A did not differ (0.87±0.34 vs. 0.76±0.20; p=0.11), mean values of S/D and volumetric S/D differed (0.98±0.42 vs. 1.55±0.40; p<0.0001). Flow and volumetric ratios correlated strongly (E/A, r=0.87; S/D, r=0.92). Standard deviations from the regression lines of flow against volumetric ratios were small (0.10 in case of E/A and 0.17 in case of S/D).
Conclusion: A close relationship between flow and volumetric-derived E/A ratio and S/D ratio was found. Cine real-time imaging of the left heart might present a fast alternative in the assessment of diastolic dysfunction.

Subclinical changes in cardiac functional parameters as determined by MRI in patients with sleep apnea and snoring: findings from UK Biobank

A. Curta[1], H. Hetterich[1], R. Schinner[1], W. Sommer[1], N. Aung[2], M.M. Sanghvi[2], S. Neubauer[3], S.K. Piechnik[3], S.E. Petersen[2]; [1]*Munich/DE*, [2]*London/UK*, [3]*Oxford/UK (adrian.curta@med.uni-muenchen.de)*

Purpose: Obstructive sleep apnoea (OSA) is a common disorder that shows an increased risk for left ventricular (LV), more rarely right ventricular (RV) dysfunction. We explored subclinical alterations in cardiac MRI in patients participating in the UK biobank study.
Methods and Materials: We analysed data from 5000 subjects. Patients with known heart disease were excluded. The rest was divided into three groups: a) individuals with OSA, b) individuals with snoring and c) individuals with no OSA or snoring (n=35, 2049 and 2666 respectively). We researched demographic parameters, cardiovascular risk factors, LV and RV functional parameters.
Results: Our analysis showed significantly increased LV mass (109±25g vs 94±25g vs 85±23g, p<0.001), LV end diastolic volume (167±29ml vs 148±35ml vs 139±32ml, p<0.001), LV end systolic volume (67±18ml vs 61±21ml vs 57±19ml, p<0.001), LV stroke volume (100±19ml vs 87±20ml vs 82±18ml, p<0.001), RV end diastolic volume (179±34ml vs 157±38ml vs 147±36ml, p<0.001), RV end systolic volume (80±20ml vs 70±23ml vs 65±22ml, p<0.001) and RV stroke volume (100±20ml vs 88±20ml vs 82±18ml, p<0.001) in patients with OSA and snoring compared to the control group. There was no significant difference in LV or RV ejection fraction.
Conclusion: Our results indicate that not only sleep apnoea but also snoring, although at a smaller degree, could be associated with dilation of both ventricles and LV hypertrophy. A differentiation between alterations caused by OSA and by associated cardiovascular risk factors such as hypertension and obesity still remains a challenge.

Cardiac MRI correlates of patient functional improvement after advanced pharmacotherapy for pulmonary arterial hypertension (PAH)

S. Terpenning, L. Melendres, M. Boivin, C. Bunn, L. Ketai;
Albuquerque, NM/US (STerpenning@salud.unm.edu)

Purpose: To identify cardiac MRI correlates of improved patient functional capability in response to advanced pharmacotherapy for pulmonary arterial hypertension (PAH).
Methods and Materials: Retrospective analysis identified 28 patients with PAH who underwent cardiac MRI and 6-minute walk testing before initiating or intensifying vasodilator treatment. Ten of these patients underwent repeat cardiac MRI and six-minute walk testing > 4 months after change in therapy. Two cardiothoracic radiologists independently analysed the pre and post-treatment MRIs masked from walk results. Cardiac outputs (CO) were calculated from right (RV) and left (LV) ventricular volumes. Relationship between walk distance and cardiac parameters was analysed with linear regression.
Results: Mean change in six-minute walk distance was 18m±57m, p>.05, with a range of -106m to +100m. Measurements from one reader showed significant positive correlation between change in RVCO and change in walk distance (R=.79, R2=.62, p<.01), while correlation between other reader's RVCO measurements and walk distance did not achieve significance. (R=.62, R2=.38, p = 0.6). Both readers measurements demonstrated significant correlation between change in LVCO and change in walk distance, (R=.75, R^2=.56, p=.01) and (R=.65, R^2=.42, p<.05). For both readers change in LVEDV showed the strongest correlation with change in walk distance (R=.89, R^2=.80, p=.001) and (R=.82, R^2=.68, p<.01). Neither reader's measurements of change in RVEDV correlated significantly with changes in walk distance.
Conclusion: Changes in patient functional capability after advanced pharmacotherapy for PAH correlate with changes in CO and may be more strongly associated with changes in LV rather than RV morphology.

B-0336 15:20

Evaluation of myocardial strain by cardiac MRI: correlation with myocardial iron overload and echocardiography speckle tracking

C. Tudisca[1], A. Meloni[2], F. Pizzino[3], C. Gerardi[4], M. Midiri[1], A. Pepe[2]; [1]*Palermo/IT*, [2]*Pisa/IT*, [3]*Messina/IT*, [4]*Sciacca/IT (chiaratudisca@gmail.com)*

Purpose: Magnetic resonance (MR) tagging analyzed by dedicated tracking algorithms allows precise measurements of myocardial motion and characterization of regional myocardial function.Our aim was to quantitatively assess regional myocardial contractility in thalassemia major (TM) patients and correlate it with myocardial iron overload, global biventricular function and strain values in speckle tracking ehocardiography (STE).
Methods and Materials: One-hundred and one TM patients (59 F; 3.3±9.0 yrs) enrolled in the MIOT network underwent MR (1.5T). Among these, 25 patients underwent STE on the same day. Three short-axis tagged MR-images were analyzed offline using harmonic-phase methods, and circumferential shortening (Ecc) was evaluated for all the 16 myocardial segments.The same short-axes were acquired by a T2* GRE-multiecho technique to assess myocardial iron overload.Bi-ventricular function parameters were quantitatively evaluated by cine-images. In the patients that underwent STE was evaluated the strain in the 3 directions.
Results: Global-Ecc and T2* values were -12.2±2.6 and 27.2±13.2, respectively, not significantly correlated. Global-Ecc value was not associated to left ventricle (LV) volumes and ejection fraction (with a P> 0.5 in all the comparisons), while was significantly correlated with LV mass and cardiac output (p<0.05).Mean-Ecc was significantly different among 4 cardiac regions (anterior, septal, inferior and lateral; p<00001). In the 25 patients who underwent STE we found a significant correlation between the mean Ecc value and the mean global longitudinal deformation (GLD) value, (R= 0.593, p=0.002).
Conclusion: In TM patients mean global Ecc is significantly correlated with LVmass and cardiac output, and with the GLD evaluated with the STE.

Differential diagnosis of ovarian tumours: value of multiparametric MRI
A.E. Solopova, A.D. Makatsaria, S.K. Ternovoy; *Moscow/RU (dr.solopova@mail.ru)*

Purpose: The objective was to evaluate the value of magnetic resonance imaging with quantitative DCE and DWI analysis for differential diagnosis of complex ovarian tumours (OT).
Methods and Materials: MRI was performed in 141 patients (173 OT) using the following protocol: Sg T2, Ax T2, Co T1, DCE using dynamic T1-FS, and DW MRI (b-values 0, 1000 v/vv2). Following quantitative parameters were evaluated: amplitude of contrast agent accumulation (ACAA), period of rise of signal intensity (HRSI), the maximum curvature (MC), apparent diffusion coefficient (ADC). All MRI results were compared with histological verification.
Results: The tumour grade distribution: benign tumours (BTs)—49%, borderline (BrTs)—12%, malignant (MTs)—39%. ACAA was significantly higher in MT—165% (118.5-211.1%) than in BTs—68.2% (40.5-96.2%) (P<0.001) and BrTs—82.7% (59.1-141.5%), (P=0.05); HRSI was significantly higher in BTs—35.1 s (31.0-41.2 s) than the BrTs—27.6 s (23.1-29.4 s), (P=0.05), and BTs—23.6 s (21.9-30.2 s) (P = 0.01). MC was 1.75 (1.0-2.4), 2.8 (2.04-3.7) and 6.04 (4.25-9.26) for BTs, BrTs and MTs, respectively, and was significantly higher in MTs (P<0.01). Mean ADC values of MT's solid component were significantly lower than in BTs (1.013 ± 0.12 and 1.41 ± 0.3, respectively (P<0.05)). The diagnostic efficiency of multiparametric MRI was as follows: the accuracy of 93.4%, sensitivity of 92.9% and specificity of 95.1%.
Conclusion: Quantitative multiparametric MRI should be obligatorily included into preoperative assessment of indeterminate adnexal masses, allowing clear distinction the degree of OT malignancy, to optimise the treatment strategy.

B-0338 14:08

Delayed detection of recurrence on postoperative PET-CT in patients with advanced ovarian cancer: a study of initially missed lesions on MDCT
H. Bae, D.C. Jung, S.Y. Park, Y.T. Oh; *Seoul/KR (hbae07@yuhs.ac)*

Purpose: To describe patterns of erroneous postoperative multi-detector row CT (MDCT) interpretation of recurred peritoneal lesions in patients with advanced ovarian cancer (AOC).
Methods and Materials: Between 2011 and 2016, we reviewed postoperative follow-up PET-CT images of 223 patients with suspected recurrence based on images, who had a history of initially diagnosed AOC (International Federation of Gynaecology and Obstetrics (FIGO) stage IIIC-IV) and underwent primary cytoreduction. Under the awareness of the recurred location, we re-evaluated MDCT images taken right before the recurrence was detected on PET-CT and categorised the cases as either absence of lesion or presence of lesion (missed case). We performed region-based comparisons of the missed cases according to predefined peritoneal locations. In the same period, preoperatively neglected lesions in AOC patients were analysed for comparison.
Results: Re-evaluation of follow-up MDCT revealed that 42.6 % (95/223) of recurrent lesions were missed. According to region-based comparisons of the missed cases, the most commonly missed site was pelvic cavity (18.9%, 18/95) followed by porta hepatis (14.7%, 14/95) and para-aortic/aortocaval lymphadenopathy (12.6%, 12/95). Compared to postoperative images, the most commonly neglected site in preoperative staging evaluation was porta hepatis followed by small bowel mesentery and pelvic cavity.
Conclusion: The most commonly missed location on post-op CT imaging was pelvic cavity followed by upper abdominal lymphadenopathy while porta hepatis was equally overlooked on both pre- and postoperative evaluations. Compared to preoperative evaluations, missed rate of mesenteric implants was lower in relapsed cases. Familiarity with these imaging features may aid in detection of recurrence.

B-0339 14:16

Diagnostic efficiency of DW MRI in detection of peritoneal carcinomatosis
I.Y. Sychenkova, N.A. Rubtsova; *Moscow/RU (sichiu@rambler.ru)*

Purpose: To determine the diagnostic efficiency of DW MRI in detection of abdominal and pelvic peritoneal dissemination in oncological patients.
Methods and Materials: The study included 32 patients of both sexes with cancer of various localizations. In case of suspicion for the peritoneal implants presence patients underwent MRI, which was performed in two stages: the first one was carried out with the use of a protocol that included Sg T2, Ax T2, Cor T2 FatSat, Obl-Ax T2, Obl-Cor T2 and Co T1; the 2nd - with addition of DWI.
Results: When carrying out MRI under the standard protocol full compliance of MRI data with histopathological examination was determined in 18 (56,2%) cases, which were considered as true positive (TP) results, false positive (FP) results were obtained in 2(6,3%) cases. True negative (TN) results were determined in 4(12,5%) patients, false negative (FN) - in 8(25,0%) patients. The indicators of MRI diagnostic efficiency when using the standard protocol were the following: accuracy 69%, sensitivity 69%, and specificity 67%. During the assessment of diagnostic value of DW MRI, 25(78,1%) cases demonstrated TP results, 1(3,1%) - FP results, TN results were obtained in 4(12,5%) cases, and FN results were shown in 2(6,3%) cases. The informativity measures when using the DWI method increased to: 91% for accuracy, 93% for sensitivity and 80% for specificity.
Conclusion: The use of DWI significantly increases the diagnostic efficiency measures of MRI in detection of abdominal and pelvic peritoneal dissemination for cancer of various localizations.

B-0340 14:24

Dedicated diffusion-weighted MR imaging for staging peritoneal metastases: a preoperative selection tool for cytoreduction surgery (CRS) candidates
I. van't Sant-Jansen, S. Chandrasegaram – Shanmuganathan, D.M.J. Lambregts, W. van Driel, N.F.M. Kok, R.G.H. Beets-Tan, G.L. Beets, A.G.J. Aalbers, M.J. Lahaye; *Amsterdam/NL (MJ.Lahaye@gmail.com)*

Purpose: The peritoneal cancer index (PCI) quantifies the extent of peritoneal metastases found at surgery. To prevent unnecessary surgical staging procedures in patients whose peritoneal tumourburden is too extensive to benefit from CRS/HIPEC, patient selection based on preoperative imaging would be ideal. Computed tomography is inaccurate in predicting the PCI. Therefore, we compare the PCI estimated preoperatively by DW-MRI with the PCI found at surgery to assess whether DW-MRI can be used to select CRS/HIPEC candidates.
Methods and Materials: In this ongoing study eighteen consecutive patients (April-September 2016, M/F=3/15) with histologically proven peritoneal carcinomatosis from either colorectal (n=13) or ovarian (n=5) origin were included. Patients were scheduled for exploratory laparoscopy and/or CRS/HIPEC and underwent preoperative dedicated DW-MRI (scan time=30min). Two independent readers prospectively determined the PCI on DW-MRI. Patients were categorised as low-risk (PCI 0-21) versus high-risk (PCI 22-39); in our center considered operable versus non-operable. Reference standard was PCI found at surgery. Quadratic weighted kappa was used to evaluate the interobserver agreement.
Results: At surgery the mean PCI was 11.3 (range 0-26). For reader 1 the mean PCI was 11.5 (0-29) and for reader 2 9.8 (0-29). Both readers categorized 17 out of 18 patients correctly (accuracy 94%) when compared to surgical findings. Both readers understaged the same patient.
The interobserver agreement was perfect (k=1.0).
Conclusion: These data suggest that DW-MRI is an accurate selection tool to noninvasively select patients who could potentially benefit from CRS/HIPEC. No overstaging occurred with DW-MRI, meaning no patients would have been denied potential curative surgery if DW-MRI would have been used as a selection tool.

B-0341 14:32

The usefulness of preoperative radiological assessment of peritoneal cancer index (PCI) as predictive factor for optimal debulking and survival: a preliminary study
G. Avesani[1], M. Arshad[2], J. Liang[2], A. Thornton[2], H. Lu[2], A.G. Rockall[2]; [1]*Bolzano/IT*, [2]*London/UK (giacomo.avesani@gmail.com)*

Purpose: To evaluate if the radiological assessment of PCI on preoperative CT of patients with ovarian cancer can be predictive of complete surgical debulking and whether the radiological PCI (rPCI) is correlated with Overall Survival (OS) and Progression Free Survival (PFS).
Methods and Materials: We considered all patients with a diagnosis of ovarian cancer, a preoperative CT, up-front cytoreductive surgery at a single institution between 2004 and 2009 and a complete clinical follow-up after surgery, to December 2015 (51 patients). We recorded the surgical outcome and the OS and PFS after surgery. An expert radiologist retrospectively evaluated the CT examinations and assigned rPCI following Sugarbaker's diagram. We correlated rPCI score with the results of surgery using ROC curve analysis and with OS and PFS using Kaplan-Meier curve.
Results: 32 (62.7%) patients had complete cytoreduction and 31 (60.8%) died due to the cancer; the median value of OS was 42 months (2-113) and of PFS was 15 months (7-56). The median value of rPCI was 11 (0-31). ROC curve analysis identified a PCI of 18 as significant threshold useful to predict complete surgical cytoreduction (p=0,05). Patients with a rPCI >16 has a

shorter OS (p=0.02; Hazard Ratio=2.13). Similarly, patients with a rPCI >7 has a shorter PFS (p=0.03; HR=1.9).
Conclusion: rPCI on preoperative CT could help in predicting surgical outcome and seems to correlate positively with both OS and PFS. This may be helpful in better evaluating prognosis in patients with high FIGO stage who may have very different peritoneal extension.

B-0342 14:40

Diagnosis of peritoneal metastases: comparison of DWIBS MR imaging with FDG 18PET CT

R. Balaji; *Chennai/IN (ravikanthbalaji@gmail.com)*

Purpose: Assess diagnostic performance and accuracy of diffusion weighted imaging with background signal suppression (DWIBS) compared with ^{18}Fluorodeoxyglucose positron emission tomography (FDG-PET) in detection of peritoneal metastases.
Methods and Materials: The study included 64 patients with ovarian and colonic malignancies and lymphomas with peritoneal deposits. DWIBS imaging was performed on a 1.5T scanner (Achieva, Philips Medical Systems, Netherlands) within mean period of two days after ^{18}FDG-PET/CT study. b-value of 800 s/mm^2 was used. ^{18}FDG-PET/CT was performed on Philips, Gemini PET/CT system after intravenous injection of FDG. Axial images and coronal MIP images of MR and PET CT images were obtained and blinded review of PET/CT and DWIBS images was performed separately to avoid bias and all lesions detected were recorded. DW MR images were also assigned colour scale based on diffusion restriction and ADC values to display PET like images. The findings detected on DWIBS and PET/CT images were compared on a per-lesion basis using PET/CT as gold-standard.
Results: FDG-PET/CT revealed 380 malignant lesions in 64 patients. DWIBS showed 368 lesions with a detection rate of 96% compared with ^{18}F FDG-PET/CT which was the gold standard. The study exhibited relatively good concordance between detection rates of DWIBS and FDG-PET/CT irrespective of primary pathology.
Conclusion: DWIBS allows for fast and robust imaging with low technical and operational efforts and is cost effective. Patients are comfortable as there is no injection of contrast and no exposure to radiation. DWIBS is as accurate as FDG PET/CT in assessment of peritoneal metastases.

B-0343 14:48

Added value of diffusion-weighted magnetic resonance imaging in the staging of cervical carcinoma

S.M. Mansour, S. Fakhry; *Cairo/EG (shery4@yahoo.com)*

Purpose: Assess the diagnostic accuracy of diffusion-weighted imaging (DWI) versus dynamic contrast-enhanced MRI (DCE-MRI) and T2 fast spinecho-weighted images (T2WI) in the preoperative staging of cervical carcinoma.
Methods and Materials: MRI pelvis using T2WI, DCE sequence and DWI were done for 50 cases with cancer cervix after initial biopsy confirmation for pre-management staging. In dynamic imaging we used T1 THRIVE (High Resolution Isotropic Volume Examination) technique that enables images acquisition at one pre-contrast, and six sequential post-contrast phases at 40, 80, 120, 160, 200 and 240sec. On DWI, scanning acquired by b values: 0, 500, 1000 and 1500.Analysis considered signal intensity (SI) at b1000 and the mean ADC values for the solid components of the masses. Surgical staging was the standard reference.
Results: The staging accuracy in all cases were 66.6% for T2WIs, 83.3% for DCE-MRI and 91% for DW-MRI.Upon assessment of parametrial infiltration, T2 detected 36%(n=18), DCE-MRI detected 35.4% (n=17) and DWI detected 32% (n=16). Assessment of locally advanced and advanced stages was comparable among T2WIs, DWI and DCE-MRI.While on assessing metastatic lymph nodes T2WIs was positive for lymphadenopathy in 15 cases (30%), DWI in 14 cases (28%) and DCE-MRI in 7 cases (14.6%).The overall accuracy of T2WIs, DW-MRI and DCE-MRI in staging cervical carcinomas was 74%, 88% and 83.3% respectively.
Conclusion: DWIs supported by conventional MRI data can improve detection of small tumours, increase overall accuracy, increase reader's confidence in evaluation of parametrial infiltration and help in proper detection of locally advanced and advanced stages of cancer cervix.

B-0344 14:56

Histological type of cervical cancer: can it be evaluated with mpMRI

E. Tarachkova, M. Shorikov, V. Panov, I. Tyurin, B. Dolgushin; *Moscow/RU (tarachkovaelenavlad@gmail.com)*

Purpose: To show if combined MRI data can improve differential diagnostics of the histological type of cervical cancer (CC).
Methods and Materials: 91 patients with histologically verified diagnosis of CC (cervical squamous cell carcinoma, CSCC: 74; cervical adenocarcinoma, CAC: 17); for some grade of the tumour had been determined: SCCC: G1-6, G2-23, G3-24; CAC: G1-5, G2-5, G3-4) MRI (1.5 & 3T): T2WI TSE native/fat saturated (fs); DWIfs+ADC-maps; T1WIfs VIBE before and 4 min after i.v. injection of MRCA (1.0 M; 0.1 ml/kg); 35 series DCE T1WIfs TWIST after MRCA injection, time resolution=5s. Signal intensity (SI) and standard deviation (SD) in CC and the gluteus maximus muscle (15-30 pixels) were measured (SD, SI/SD for heterogeneity; SI(CC), SI(CC)/SI(muscle) for intensity).
Results: DCE: both types showed active SI increase at first 10-20 s after the occurrence of MRCA in pelvic arteries with following change of signal (inflection point), after relative SI (rSI) for DCE was calculated as rSI(t)= 100%* (SI(t)-SI (inflection))/SI (inflection); CAC was more heterogeneous at 110 s ($p < 0.03$) and had higher rSI ($p < 0.003$-0.04). Additionally areas under DCE curves were significantly different: CAC>CSCC, $p < 0.005$, CSCC curve had an additional inflection point before plateau at about 60-70th second while CAC continually accumulated MRCA, rSI (60s) had maximum accuracy (Sen/Sp=0.75/0.76) or Sen/Sp=0.27/0.95 T2WIfs: CAC was brighter, less heterogeneous ($p<0.05$). A regression model showed that T2WIfs and DCE combined data significantly differentiate CSCC and CAC: $p<0.0015$, Sen/Sp=0.80/0.85 or 0.67/0.95. SD of SI of the tumours on postcontrast T1WI-VIBE for CAC of G1 and G3 grades were significantly different from each other and from all other types of CC: SD(CAC(G1)) > SD (SCCCs,CAC(G2)) > SD (AC(G3)), $p<0.02$. Sp/Sen (CAC(CAC(G1)) = 0.75/0.95;Sp/Sen (CAC(G3)) = 1.00/0.83.
Conclusion: T1WI after MRCA injection, T2WI with fat saturation can be used to estimate histological type of CC.

B-0345 15:04

Invasive stromal cancer cervix post-therapy: MRI pulse sequences comparative diagnostic merits

S.A. Hussein, M.K.A. Asran, M.H. El Naggar, R.M. Kamal, T.A. Raafat; *Cairo/EG (samar.ahmad@nci.cu.edu.eg)*

Purpose: The aim of the study was to assess the diagnostic merits of each of the applicable MRI pulse sequences in the evaluation of tumour residual, recurrence or post treatment complications of cervical cancer aiming to assess the possibility of use of Diffusion weighted imaging instead of Contrast enhanced studies especially in patients with deteriorated renal functions.
Methods and Materials: Our study included 48 patients with histopathologically proven cancer cervix and a control group of 20 patients. All patients underwent post treatment Contrast Enhanced and Diffusion weighted MRI examinations to assess, confirm or exclude the presence of residual/recurrence mass lesions or post therapy complications.The reported MRI findings of both studies were correlated with histopathology results and/or with follow -up imaging.
Results: The sensitivity and specificity of DWI were 96.8 % and 100% respectively as compared to sensitivity and specificity of 87.5 % & 87.5% respectively calculated for contrast enhanced MRI studies. The mean ADC value of malignant post-treatment tumour (1+/- 0.18 x 10-3 mm2/sec) was significantly different than those of benign post -treatment changes (1.56 +/- 0.03 x 10-3 mm2/sec) and from values calculated for the control group (1.57 +/- 0.2 x 10-3 mm2/sec) (P value< 0.0001). The initial mean ADC value of complete responders were also significantly less than that of partial responders and those with recurrent disease (P value< 0.0001).
Conclusion: Quantitative DW imaging provides a better assessment tool than Contrast enhanced MRI in the characterisation of post-treatment changes.

B-0346 15:12

DW-MRI: an early predictive assay for treatment outcome in locally advanced cervical cancer

A.M. Telesca, M. Miccò, B. Gui, M. Giuliani, E. Rodolfino, F. Cambi, P.P. Grimaldi, A.L. Valentini, L. Bonomo; *Rome/IT (annamariatelesca@gmail.com)*

Purpose: The purpose of this study was to investigate the clinical value of DW-MRI as early predictor of treatment response in patients with locally advanced cervical cancer (LACC) receiving preoperative chemoradiotherapy (CRT) through the measurement of ADCm. Correlation with histopathological findings.
Methods and Materials: This prospective study was approved by our Ethical Committee. 88 patients receiving CRT for LACC (FIGO staging IB2 or more advanced) were enrolled and underwent 1.5 T pelvic MRI including DWI before CRT (baseline) and after 4 weeks (early). ADCm (b-values: 0-800 s/mm^2), determined at baseline and early MRI, were compared with histopathologic findings after radical hysterectomy (good responders (R) vs. poor-R). For ADCm values, differences between good-R and poor-R were assessed by T-test. Its discriminatory capability for detection of good-R was compared with receiver operating characteristics (ROC) analysis.
Results: Early ADCm values were significantly higher for good-R than for poor-R (1.12×10^{-3} mm^2/sec vs 1.04×10^{-3} mm^2/sec; p=0.02), but no significant differences were observed for ADCm at baseline MRI (p= 0.40) between the two groups. The area under the ROC curve for prediction in treatment response was higher for early ADCm comparing to baseline ADCm (0.63 vs 0.52). A cut-off value of 1.10×10^{-3} mm^2/sec was determined for early ADCm

with a sensibility, specificity, VPP, VPN and accuracy of 74%, 67%, 50%, 85% and 90%.
Conclusion: Early evaluation of ADCm might provide useful information for predicting outcome and selecting high-risk patients for more aggressive therapy.

B-0347 15:20

Factors affecting inferior vena cava retrieval: 5-year experience from a district hospital

H. Lee, W. Wong, C. Chan; *Hong Kong/HK*

Purpose: This study aims to evaluate factors related to IVC filter (IVCF) retrieval rate and factors that affect success rate in retrieval attempts.
Methods and Materials: All patients with IVCF insertion in a district hospital from 10/2011 to 8/2016 were retrospectively included. Data regarding patient demographics, comorbidities, indications for and type of IVCF, IVCF tilting, and time to retrieval were obtained.
Results: 75 patients with 76 IVCF placement were included. IVCF retrieval rate was 30% (23 out of 76). IVCF retrieval success rate was 82% (23 out of 28 attempts). In patients with DVT and contraindicated for anticoagulation due to operation, the rate of IVCF retrieval was significantly higher than that of patients with IVCF placed for other indications (63% vs 17%, p<.05). Patients with malignancy had a significantly lower rate of IVCF retrieval compared to patients without malignancy (17% vs 39%, p<.05). IVCF angulation >15 degree was observed more in patients with failed retrieval attempt (3/5), compared to patients with successful retrieval (0/23). This difference was statistically significant (p<.05). There were no significant differences between successful and failed attempts in terms of age, sex, history of malignancy, placement route, type of filter, and time to filter retrieval.
Conclusion: IVCF retrieval is more likely in patients with IVCF placed for DVT and contraindication for anticoagulation due to operation, and in patients with no known malignancy. Unsuccessful IVCF retrieval attempts are more likely to occur in IVCF which are angulated.

Independent component and seed-based analyses in localisation and lateralisation of Broca's and Wernicke's areas with resting state fMRI

L. Makovskaya[1], R. Vlasova[2], E. Mershina[1], E. Pechenkova[1]; [1]*Moscow/RU*, [2]*Los Angeles, CA/US (lmak@fbm.msu.ru)*

Purpose: To compare SCA and ICA methods in mapping Broca's and Wernicke's areas with resting-state fMRI (rsfMRI) data in healthy volunteers.
Methods and Materials: Each of 52 volunteers (25 left-handed) performed two task-based and one rsfMRI session in the Siemens Avanto 1.5T scanner. Each of the Broca's and Wernicke's areas was localised by three methods: using one of the speech tasks (SPM12 software); ICA analysis of rsfMRI data and the language network mask (GIFT v4.0); and SCA analysis of the rsfMRI data with a seed region in the other speech area revealed by the independent speech task (Conn v.14). Location and laterality index (LI) of the speech areas identified with the two rsfMRI methods were cross-validated with the task-based data.
Results: The average overlap of the speech areas localized by task-based and rsfMRI (either SCA or ICA) has not exceeded 25%. However, correlation between LI across SCA and task-based analyses was moderate for Broca's area (r=0.67, p<0.001) and high in Wernicke's area (r=0.71, p<0.001). The ICA showed no LI correlation with the task-based data: r=0.26 (p=0.06) for Broca's area and r=0.08 (p=0.57) for Wernicke's.
Conclusion: Unlike task-based and SCA-based results, the speech areas localized by ICA analysis of rsfMRI were bilateral in all volunteers. Therefore, speech areas are better lateralized by SCA method of rsfMRI rather than ICA. It is still to be empirically tested whether the flexible adjustment of the statistical thresholds on the individual basis may improve the consistency of task-based and rsfMRI data.

B-0349 14:08

Functional connectivity analysis in differential diagnostics of chronic disorders of consciousness

E.I. Kremneva, E. Zmeykina, L. Legostaeva, A. Poidasheva, A. Chervyakov, D. Sergeev, J. Ryabinkina, N. Suponeva, M. Piradov; *Moscow/RU (moomin10j@mail.ru)*

Purpose: To perform functional connectivity analysis based on resting-state fMRI data for differential diagnostics between vegetative (VS) and minimal consciousness states (MCS).
Methods and Materials: In 14 patients with chronic disorders of consciousness (DOC) (CRS-rVS=4, CRS-rMCS-=5, CRS-rMCS+=5, mean age 26+-2.0) rsfMRI (3T Siemens Verio) was performed followed by data preprocessing in SPM8 and connectome construction in CONN. As regions of interest (ROI) we accepted full standard brain atlas. We obtained connectome with functional connections showing correlation of BOLD signal in ROIs. Also, we analysed correlation coefficients in default mode network's (DMN) nodes. Statistical results were thresholded using a combination of a connection-level threshold (FDR-corrected p values on individual ROI-to-ROI connections) and seed-level thresholds (F test on multivariate connectivity strength for each seed ROI).
Results: MCS- group showed appearance of three connections with a positive correlation, and MCS + group showed significant increase of the amount of connections. Improving of the level of awareness is associated with increase of the correlation coefficient between medial prefrontal cortex (MPFC) only and other areas outside the DMN. Values of correlation coefficients between MPFC and left lateral parietal cortex were: -0.01 (VS), 0.05 (MCS-), 0.05 (MCS+); between MPFC and posterior cingulate cortex: -0.01 (VS), 0.1 (MCS-), 0.1 (MCS+); between MPFC and right lateral parietal cortex: -0.12 (VS), 0.1 (MCS-), 0.14 (MCS+).
Conclusion: The connectoms' number of connections in ROI multiplies with the level of consciousness increase. MPFC may be of most important value for further investigations because of its relations with other DMN zones.

Altered interactions of cortical cores in patients with type 2 diabetes mellitus: a resting state functional MRI study

D. Liu; *Chongqing/CN (liudaihong121@163.com)*

Purpose: To investigate the change patterns of cortical cores and their interactions in type 2 diabetes mellitus (T2DM) patients using combined degree centrality (DC) and Granger Causality Analysis approaches.
Methods and Materials: Forty-seven T2DM patients and 47 healthy controls (HCs) matched for age, sex, education and BMI were enrolled in the blood biometric measurement, neuropsychological tests and resting-state brain MRI scanning. DPARSF v4.1 software was applied to preprocess the MRI data. REST v1.8 software was applied to analyse the difference of DC pattern between the two groups and verify the candidate cortical cores influenced by T2DM. Granger Causality effect among these cores was also calculated with REST v1.8 software. Proportion was examined with χ^2 test. Independent samples *t* test and Mann-Whitney U test were applied to normally distributed continuous data and to non-normally distributed data, respectively. P<0.05 was considered as statistically significant.
Results: In T2DM patients, significantly higher DC values were observed in left anterior cingulate gyrus (ACG), and significantly lower DC values in bilateral superior/middle occipital gyrus (S/MOG) and right precentral gyrus. There was negative causal effect from left ACG to left S/MOG that negatively correlated with fasting insulin (r=-0.360, P=0.013) and C-peptide (r=-0.363, P=0.012) in T2DM patients. No effective connectivity was found among the cores in HCs.
Conclusion: The altered interactions of cortical cores may provide insights into the neurological mechanisms underlying the T2DM-associated cognitive impairment. Patients may benefit from anti-diabetic therapy to prevent brain function decrement.

Physiological artefacts correction at pre-surgical task-related functional MRI

M. Kiss, J. Martos, V. Gál; *Budapest/HU (kissmate20@gmail.com)*

Purpose: Pre-surgical functional MRI (fMRI) is rapidly becoming a standard method to detect the eloquent brain areas. Breathing and pulsation cause significant artefacts, which are decreasing the localisation sensitivity and specificity. We would like to demonstrate the effectivity of physiological artefact removal - based on physiological parameter recordings - on the sensitivity and selectivity of the fMRI mapping.
Methods and Materials: Siemens Magnetom Verio 3T MRI system was used to collect data. The physiological parameters (breathing, pulse and ECG) were recorded with the built-in devices. 20 patients - with brain tumour - data were evaluated with SPM12. RETROICOR/RVHR was applied to detect the relevant physiological artefacts. We compared the statistical maps before and after the physiological correction.
Results: The physiological correction improved the specificity: we found false-positive activation around the main brain vessels. The main relative activation value of the eloquent areas did not change significantly after the correction, albeit the standard deviations were lower. The correction improved the statistical maps in 11 patients. We detected minimal changes in 5 patients as a result of low pulse and slow breathing.
Conclusion: The physiological correction increased the specificity of statistical maps, so we are able to detect the eloquent regions more reliably, which allows more reliable pre-surgical planning.

B-0352 14:32

Repeated application of realtime-fMRI neurofeedback in tobacco dependent patients after smoking cessation

M. Paolini, D. Keeser, S. Gschwendtner, A. Reckenfelderbäumer, H. Jeanty, B. Rauchmann, B. Ertl-Wagner, T. Rüther, S. Karch; *Munich/DE (Marco.Paolini@med.uni-muenchen.de)*

Purpose: To evaluate the effect of repeated application of real-time(rt)-fmri neurofeedback in patients with tobacco dependency with respect to smoking cessation success.
Methods and Materials: Tobacco-dependent patients (n=43) were randomized into two groups receiving either real feedback (n=26) of an addiction associated brain region (ACC, insula, DLPFC) or sham feedback. The aim was to reduce neural activity in the region of interest during nicotine cue exposure in 3 sessions within a period of 4 weeks after professionally assisted smoking cessation. Preprocessing and statistical analysis of functional images were conducted in BrainVoyagerQX taking patients' smoking status after 6 months into account (persistent tobacco abstinence/ significant reduction or complete relapse). Clinical data were assessed by established questionnaires (QSU, BDI, BIS, FTND).
Results: The fixed effect analysis of all patients with known smoking status after 6 months (real feedback, group) revealed brain activity reduction in addiction associated brain region in both abstinent/ less smoking patients (n=17) and completely relapsed patients (n=7) during neurofeedback sessions (3rd versus 1st run, $p<0.05$, Bonferroni corrected). However, in contrast to relapsed patients, abstinent/ less smoking patients had reduced brain activity in the ACC and the nucleus caudatus in several runs and enhanced brain activity in thalamic and parietal regions, especially in the 2rd and 3rd run of each session (between-group-comparison, $p<0.05$, Bonferroni corrected).
Conclusion: Neurofeedback based on rt-fmri may reveal and induce specific anti-addiction changes of brain state in tobacco dependent patients after smoking cessation and probably be used as a diagnostic and therapeutic tool.

B-0353 14:40

Assessment of executive functions in bipolar disorder: a voxel-based meta-analysis of fMRI studies

F. Tian, Z. Jia; *Chengdu/CN (1534748929@qq.com)*

Purpose: To identify executive function deficits assessed in functional magnetic resonance imaging (fMRI) studies of bipolar disorder (BD) through a voxel-based meta-analysis.
Methods and Materials: Web-based publication databases were searched to perform this meta-analysis of whole brain fMRI studies up to July 2016. A new improved voxel-based meta-analytic method, signed differential mapping (SDM), was developed to examine regions of activated or deactivated grey matter regions in the BD patients vs. healthy controls during a variety of executive functioning tasks.
Results: Eighteen datasets comprising 461 people with BD and 423 healthy controls met the inclusion criteria. Compared with age-matched healthy control participants, participants with BD showed reliable patterns of hyperactivation in bilateral gyrus rectus, extending to bilateral anterior cingulate cortex (ACC) and right middle temporal gyrus; hypoactivation in left cerebellum crus I, left precentral gyrus, right precuneus, right dorsolateral prefrontal gyrus (DLPFC). A sensitivity analysis as well as analyses of subgroups further confirmed these findings. Meta-regression analyses showed that studies that included individuals with older age of onset were significantly more likely to report hyperactivation area in the right ACC.
Conclusion: These findings suggest that BD pts show greater activation mainly in the prefronto-temporal gyrus during executive function tasks which could represent a major neural functional correlate of their illness as defined in DSM-V.

B-0354 14:48

Stroke-related brain plasticity of the human mirror-neuron system during audio-motor transformation: fMRI and DTI study

O. Omelchenko; *Kiev/UA (ol.omelchenko@gmail.com)*

Purpose: Audio-motor transformation (AMT) is a good model for perception to action information flow. Human mirror-neuron system (MNS) consisted of ventral premotor and inferior parietal cortices and was shown to participate in AMT. We propose brain activation, structural and functional connectivity analysis for the focal-stroke-related plasticity changes in AMT.
Methods and Materials: Three groups (G1, G2, G3) of right-handed subjects were studied. G1: 5 healthy subjects (3F, 45-63 y.o.), G2: 3 primary sensorimotor stroke patients (1F, 41-76 y.o.), G3: 2 left supramarginal gyrus stroke patients (1F, 44-58 y.o.). We used 1.5T SIGNA (GE, USA) for DTI and fMRI. Finger tapping was used for activation. EPI was used for BOLD imaging (TR/TE=3000/71ms, voxel 4x4x5mm) and DTI (b=1000, TR/TE=8000/100ms, voxel 0.9x0.9x4mm, encoded directions =25). Data processing was done using FSL (Oxford, GB) and BrainWavePA (GE, USA).
Results: Decrease of FA (G3=0.08, G1=0.4) and fiber density was shown for G3 at ischaemic focus location. Altered AMT-related brain activation was found in G3, in comparison to G1, G2. G1, G2 AMT activation pattern: primary sensorimotor cortex, supplementary motor area, bilateral temporal cortex, suparamarginal, inferior frontal cortices (MNS). G3 showed altered AMT-related activation: lesion nearby left supramarginal gyrus slight activation, bilateral temporal cortices. Thus, one of the mirror-neuron nodes' impairment led to the decrease of MNS AMT functioning, resulting in decreased auditory stimulus response and voice command execution.
Conclusion: fMRI and DTI could reveal stroke-related brain plasticity. Left supramarginal gyrus plays important role in MNS functioning during AMT.

B-0356 14:56

Mapping of brain regions associated with deception by functional magnetic resonance

M. Perez, H. Ferreira, N. Pereira; *Lisbon/PT (mafaldaperez13@gmail.com)*

Purpose: Functional magnetic resonance imaging (fMRI) had been used for lie perception. Our study prompts to reproduce these studies and also to test a novel paradigm, which consists of displaying images of the stolen object amongst images of various other objects.
Methods and Materials: Nine healthy subjects, aged 21 to 36, were studied after given their consent and being screened for their aptitude to understand the paradigms. The subjects were asked to commit a mock crime: stealing only one of two objects, a watch or a ring, and hiding it in a specific locker. Two fMRI experiments were done: a slideshow with ten images of various objects including the watch and the ring; and a mixed-design questions paradigm where subjects were instructed either to confirm or deny (lie about) the theft. The data was collected in a 1.5 Tesla MRI scanner with a button box to record the subjects' responses in the second experiment. The fMRI data analysis was done using FEAT and response times were evaluated.
Results: In the first and second experiments it was possible to correctly identify the stolen object in 67% and 87.5% of subjects, respectively. The parietal area showed overall higher brain activity in both experiments, and response times denounced 87.5% of subjects in the second experiment.
Conclusion: The questions paradigm together with time reaction analyses seems to play an important role to perception of brain activity areas associated with the action of lying.

B-0357 15:04

Functional and structural changes in brain's default mode network in early stages Parkinson's disease patients according to voxel-based morphometry and resting-state fMRI comparison

E. Seliverstova, Y. Seliverstov, M. Krotenkova, R. Konovalov, S. Illarioshkin, I. Krotenkova; *Moscow/RU*

Purpose: To assess pattern of functional and structural changes in neurodegeneration comparing to physical examination and healthy controls by resting-state fMRI (RsfMRI) and voxel-based MRI (VBM) is very prospective nowadays study, especially changes within default mode network (DMN).
Methods and Materials: We have exanimated, compared 3 independent right-handed groups - 41 patients with PD in early steps in pharmacological treatment and newly diagnosed, 20 healthy volunteers were investigated

summary and underwent 1.5 T RsfMRI, T1-MPR MRI scanning for fMRI, VBM data acquisition.
Results: We had some results (p<0,005): in group of newly diagnosed PD patients we observed significant greater volume of right precuneus (part of DMN) comparing to patients in pharmacological treatment and healthy volunteers, in group of patients in treatment we marked volume loss in right precuneus comparing to newly diagnosed PD patients and healthy volunteers. Comparing fMRI data and volume changes in precuneus in group of newly diagnosed PD patients we observed direct correlation (than higher volume of precuneus that greater areas of spontaneous neuronal activity in precuneus), in group of patients in treatment we observed inversed correlation (than smaller precuneus volume that significant greater areas of spontaneous neuronal activity in precuneus).
Conclusion: Our findings may indicate about compensatory hypertrophia of precuneus as compensatory mechanisms of neuroplasticity phenomena in early stages of PD, at that time volume loss of precuneus in PD patients in treatment may reflect increasing atrophy in neurodegenerative process. Correlation between fMRI and VBM-analysis data may be demonstration of multivariants of compensatory mechanisms in neurodegeneration.

Mirror imaging

A. Sharma[1], J. Lay[1], I.Q. Grunwald[2], A.L. Kühn[3], P. Harman[1], S. Bowman[1], S. Kelavkar[1], R. Aspinall[2], C. Law[4]; [1]*Southend-on-Sea/UK*, [2]*Chelmsford/UK*, [3]*Worcester, MA/US*, [4]*Palo Alto, CA/US*

Purpose: Mirror therapy is an effective rehabilitation therapy after stroke. A mirror is placed between the patient's arms or legs so that the image of the non-affected limb gives the illusion of normal movement in the affected limb. Despite the overwhelming evidence of adult brain's capacity to reorganize after stroke, it remains unclear whether and to what extent specific peri-lesional or full brain adaptation is responsible for motor-function recovery.
Methods and Materials: In a randomised study, starting with either conventional or Mirrorbox Therapy, we used a repetitive task specific approach (forearm, wrist and hand) 3x15 minutes/day) for 3 weeks at which time patients switched therapy group. Resting-state-fMRI was performed at baseline, crossover (3 weeks) and 6 weeks.
Results: Resting-state fMRI showed changes in inter-hemispheric synchronization of neuronal signalling and reorganization of the motor execution network after stroke rehabilitation. This was more pronounced after Mirror therapy compared to conventional rehabilitation. There was specific activation of the temporal gyrus, precuneus and the posterior cingulate cortex (PCC).
Conclusion: It appears that alterations in functional brain networks are interrelated to the structural plasticity of the underlying neuronal architecture. Activation of the temporal gyrus, precuneus and the PCC might be related to improved self-awareness and spatial attention.

The role of quantitative analysis on T2WI and DWI in differentiating haemangiomas from malignant liver tumours

K. Ozturk, E. Soylu Ozturk, C. Bilgin, G. Savci; *Bursa/TR*
(keremov54@hotmail.com)

Purpose: To determine if haemangiomas and malignant liver tumours could be differentiated on the basis of T2-weighted imaging (T2WI) and diffusion-weighted imaging (DWI) by using quantitative measures.
Methods and Materials: 384 patients with liver tumours (250 haemangioma, 134 malignant tumours) underwent 3-T MRI examination with breath hold turbo spin echo T2WI (TR = 3,000 ms; TE = 80 ms) and respiratory-triggered DWI (b = 0, 500, 1000). The both T2WI and DWI images were evaluated with independent and blinded technique. The measurement of lesion to liver signal intensity ratios (SI) for T2WI and b1000/ b0 true diffusion signal intensity ratios for DWIs were assessed quantitatively. Histopathologic evaluation, contrast-enhanced MR images and long period follow-up images were used as the gold-standard.
Results: The mean SI ratio of the haemangiomas and malignant tumours on T2WI found to be 2.9 ± 0.5 and 1.5 ± 0.3 (P < .001) and on DWI 0.22 ± 0.10 and 0.36 ± 0.09 (P < .001) respectively. A cut-off value of 3.1 on T2WI images gave a performance (100% sensitivity, 92% specificity) which is better than DWI with cut-off value of 0.25 (92% sensitivity, 95% specificity). Combination of two sequences didn't provide additive diagnostic performance (90% sensitivity, 88% specificity) (P < 0.05).
Conclusion: Our results indicate that quantitative analysis of both sequences offers high diagnostic performance separately in distinguishing haemangiomas from malignant liver tumours (T2WI is better than DWI) which may have impact on adaption of non-contrast MR techniques.

Usefulness of a multi-arterial phase protocol for MRI characterisation of hypervascular liver lesions using Gadoxetic Acid

L. Grazioli[1], R. Ambrosini[1], R. Faletti[2], B. Frittoli[1], G. Battisti[3]; [1]*Brescia/IT*, [2]*Turin/IT*, [3]*Spoleto/IT (lgrazioli@yahoo.com)*

Purpose: To assess the usefulness of a multi-arterial phase MRI technique (Controlled Aliasing In Parallel Imaging Results in Higher Acceleration - CAIPIRINHA) for assessment of enhancement characteristics of hypervascular liver lesions using Gadoxetic Acid, in comparison to a single arterial phase protocol.
Methods and Materials: 148 consecutive patients have been examined: 70 with a single phase protocol and 78 using the CAIPIRINHA multi-arterial technique. MRI exams were carried out using a 1.5T scanner with a phased array coil and automated contrast injection of Gadoxetic Acid (Primovist - Bayer, 0.025 mmol/kg @1ml/sec). We analysed SI from Aorta, Portal vein, Liver parenchyma and Lesions on both protocols and classified lesions identified on triple arterial phase CAIPIRINHA protocol as follows: A=maximum lesion-to-liver contrast ratios (LLCR) at 1st phase, B=maximum LLCR at 2nd phase and C=maximum LLCR at 3rd phase of the examination.
Results: The single-phase protocol detected 33 hypervascular lesions, the CAIPIRINHA protocol showed 50 hypervascular lesions. The comparison between the two protocols showed that Aortic enhancement resulted significantly higher with the single-phase technique if compared to the 1st arterial phase of the CAIPIRINHA protocol (p<0.0001). All the other measured values resulted in between the observed ones in the first two arterial phases of the CAIPIRINHA protocol, and significantly lower to the values measured in the latest arterial phase (p=0.0003).
Conclusion: The possibility to obtain and assess three arterial phases allows to detect more hypervascular lesions and to better assess lesions enhancement respect to a single phase protocol.

B-0360 10:46

A breakthrough in non-contrast MR characterisation of hepatic focal lesions

W.R.A. Abdel Hamid, R. Salah Eldein, Y. Abbas; *Cairo/EG*
(w.gforever@yahoo.com)

Purpose: Our work aimed at evaluating the role of intravoxel incoherent motion (IVIM) as a non-contrast imaging biomarker in the characterisation of hepatic focal lesions (HFLs) as an attempt to reduce health care cost and introduce an alternative for patients with contraindications for IV contrast.
Methods and Materials: This retrospective study includes 130 patients with a total of 200 HFLs. They were assessed using a 3T MR scanner adding IVIM to the established MR protocol. Post-processing analysis was performed to measure IVIM parameters of D, D*, fp & ADC. fp was compared to percent of arterial enhancement of hepatic focal lesions using Pearson correlation test. MedCalc Software was used to assess sensitivity, specificity, PPV and NPV.
Results: Moderate correlation between fp & % of arterial enhancement of hepatic focal lesions (r= 0.686). fp showed high sensitivity (86.27%), low specificity (60.71%), PPV (80%) and NPV (70.83%) to % of enhancement. D showed high sensitivity (83.02%), low specificity (65.38%), PPV (83.02%) and NPV (65.38%). ADC showed lower sensitivity (72.9%) and PPV (77.78%), yet comparable specificity (65.52%), and NPV (63.38%) when compared to D.
Conclusion: fp and D values are promising non-contrast MR tools in the characterisation of hepatic focal lesions that can readily replace IV contrast.

B-0361 10:54

Role of 3-Tesla diffusion-weighted magneic resonance imaging in differentiation between benign and malignant hepatic lesions

M.T.A.A. Ali, D.M. Nabil, M.F. Osman, M.D. Homos; *Cairo/EG*
(mtalatali@hotmail.com)

Purpose: To evaluate the ability of DWIs to distinguish between benign and malignant focal hepatic lesions (FHLs) using 3T MR.
Methods and Materials: A total of 73 FHLs in 48 patients were evaluated. There were 28 benign lesions including 13 hemangiomas (17.8%), 8 hepatic cysts (10.9%), 4 regenerating hepatic nodules (5.4%), 2 adenomas (2.7%) and 1 focal fatty infiltration (1.3 %). The others 45 lesions were malignant including 28 hepatocellular carcinoma (38.3%), 15 metastases (20.5%) and 2 cholangiocarcinoma (2.7%). The study used two b values (0 and 800 sec/mm2) and the ADC values were calculated.
Results: The mean ADC value for simple liver cysts was 2.58 ± 0.35 x 10^{-3} mm^2/sec, for solid benign lesions was 1.63 ± 0.41 x 10^{-3} mm^2/sec and for malignant lesions was 1.21 ± 0.38 x 10^{-3} mm^2/sec with statistical difference (p<0.0001). We found that the best cut off was 1.49 x 10^{-3} mm^2/sec ADC value with accuracy of 83.6% in differentiation between the all benign and malignant FHLs. While with exclusion of the cystic hepatic lesions, the best cut off was reduced to be 1.35 x 10^{-3} mm^2/sec ADC value, with accuracy of 78.5%.
Conclusion: DWI can be used to differentiate between the benign and malignant FHLs.

B-0362 11:02

Visibility of hepatic focal lesion: comparison between kupffer phase images of sonazoid-enhanced ultrasound and hepatobiliary phase images of gadoxetic acid-enhanced MRI

W. Yang, H. Park, Y. Kim, M. Yu, S. Jung, H. Jeon; *Seoul/KR*
(20130094@kuh.ac.kr)

Purpose: To assess the agreement between Kupffer phase images of Sonazoid-enhanced ultrasound and hepatobiliary phase images of gadoxetic acid-enhanced MRI in the visibility assessment of hepatic focal lesions.
Methods and Materials: One hundred and fifty eight hepatic focal lesions in 158 patients who underwent both Sonazoid-enhanced ultrasound and gadoxetic acid-enhanced liver MRI were included in this retrospective study. Visibility of hepatic focal lesions on Kupffer phase images of Sonazoid-enhanced ultrasound was graded as 0 (invisible; isoechoic), 1 (vaguely visible; vaguely hypoechoic), and 2 (clearly visible; clear hypoechoic), while that on hepatobiliary phase images of gadoxetic acid-enhanced MRI was graded as 0 (invisible; high/iso SI), 1 (vaguely visible; weak low SI), and 2 (clearly visible; strong low SI). Pairwise comparison of lesion visibility between the two modalities was performed and inter-modality agreement was assessed.
Results: On Kupffer phase imaging, 38 (24.1%) lesions were invisible, 14 (8.9%) were vaguely visible, and 106 (67.1%) were clearly visible. On hepatobiliary phase of MR, 5 (3.2%) lesions showed high SI, 4 (2.5%) lesions showed iso SI, 45 (28.5%) lesions showed weak low SI, and 104 (65.8%) showed strong low SI. Regarding the visibility, 77.8% (123/158) of the lesions showed agreement between the two modalities. Among the 35lesions showing the discrepancy, 32 (91.4%) visible lesions on MR images were invisible on US

images, while only three(8.6%) visible lesions on US images were invisible on MR images. Overall inter-modality agreement regarding the lesion visibility was fair (weighted *k*=0.213).
Conclusion: Visibility of hepatic focal lesion showed discrepancy in approximately22% between the Kupffer phase images of Sonazoid-enhanced ultrasound and hepatobiliary phase images of gadoxetic acid-enhanced MRI.

B-0363 11:10

Radiological-pathological correlation of hepatocellular adenoma and focal nodular hyperplasia with atypical clinical or radiological features on Gd-BOPTA enhanced MRI

B. Gest, R.L. Miclea, M.G.J. Thomeer, F.E.J.A. Willemssen, R.S. Dwarkasing; *Rotterdam/NL (b.gest@erasmusmc.nl)*

Purpose: The typical radiological features of HCA and FNH on MRI allow for confident diagnosis. However, little data is available when these tumours have an atypical presentation. The aim of this retrospective study was to investigate HCA and FNH with atypical findings on gadobenate dimeglumine (Gd-BOPTA) enhanced MRI (GB-MRI).
Methods and Materials: Between 2008 and 2016, 451 patients underwent GB-MRI of the liver. Patients with histopathological (PA) proven lesions (n=110) were included. Indication for PA was reviewed in the patient dossier. Exclusion criteria were patients with unequivocal HCA or FNH, preexistent liver disease, history of malignancy. Lesions with atypical findings were reviewed by 2 radiologists blinded to the PA result. Interobserver agreement was measured using kappa statistics.
Results: 31 patients (all women, mean age 42.3±10 yrs) with 33 lesions were included. Indications for biopsy were: possible malignancy (n=14, 42.4%), unable to differentiate between HCA and FNH (n=11, 33.3%), interval lesion growth (n=3, 9.1%), HCA >5 cm, (n=3, 9.1%) and miscellaneous (n=2, 6.0%). Interobserver agreement between the 2 readers was good (kappa=0.77, 95% CI=0.58-0.96).
Pathological diagnosis revealed inflammatory HCA (n=15, 45.4%), FNH (n=7, 21.2%), HCA not otherwise specified (n=4, 12.1%), steatotic HCA (n=3, 9.1%), chronic autoimmune hepatitis (n=1, 3.0%), β-catenin mutated HCA with foci of HCC (n=1, 3.0%), HCC (n=1, 3.0%), and cholangiocarcinoma (n=1, 3.0%). All malignant lesions (n=3, 9.1%) were initially characterized as “possible malignancy” on GB-MRI.
Conclusion: Inflammatory HCA represents the majority (45%) of HCA and FNH cases with an atypical presentation. Almost one in ten cases is malignant.

B-0364 11:18

Intra-patient comparative MRI study of MultiHance and Primovist to differentiate HCA from FNH

I.J.S.M. Vanhooymissen, M.G. Thomeer, B. Gest, S. van Koeverden, L.M.M. Braun, R.S. Dwarkasing, R.A. De Man, J. IJzermans; *Rotterdam/NL (ingevanhooymissen@hotmail.com)*

Purpose: At present, imaging guidelines do not recommend which hepatobiliary contrast agents should be used preferably to differentiate hepatocellular adenoma (HCA) from focal nodular hyperplasia (FNH). We analysed the intra-patient differences of the hepatobiliary phase using gadobenate dimeglumine (Gd-BOPTA, MultiHance) and gadoxetate disodium (Gd-EOB-DTPA, Primovist)-enhanced magnetic resonance imaging (MRI) to characterise a benign liver lesion in non-cirrhotic patients.
Methods and Materials: We reviewed the hepatobiliary phase of 43 patients with 112 lesions (69 HCA; 43 FNH). All patients underwent Gd-BOPTA and Gd-EOB-DTPA-enhanced MRI. Signal intensities, inter-observer correlation and degree of certainty for scoring lesions in the hepatobiliary phase were assessed by two observers. Sensitivity and specificity to diagnose HCA and FNH were calculated for both contrast agents.
Results: Almost perfect agreement was found between the two observers for scoring signal intensities with both contrast agents. In 25 out of 112 lesions (22%) there was a difference in signal intensity in the hepatobiliary phase between both contrast agents. For distinguishing HCA from FNH with Gd-BOPTA sensitivity was 55% (38/69) and specificity was 93% (40/43). With Gd-EOB-DTPA sensitivity was 83% (57/69) and specificity was 98% (42/43). We found no significant difference between the two contrast agents in the degree of certainty for scoring a lesion by the observers.
Conclusion: These results indicate that there is a difference in the usefulness of both contrast agents to differentiate HCA from FNH in the hepatobiliary phase. According to our findings, Gd-BOPTA-enhanced MRI would misclassify a significant proportion of HCAs as FNH.

B-0365 11:26

Role of CT perfusion in differentiating haemangiomas from liver metastasis in patient with known primary tumour: initial experience

J. Singh[1], S. Sharma[2], K. Kaur[3], S. Singh[2], N. Aggarwal[2], S. Sood[2]; [1]*New Delhi/IN*, [2]*Shimla/IN*, [3]*Chandigarh/IN (drjagjeetsingh86@gmail.com)*

Purpose: The purpose of the study was to determine whether CT perfusion shows any difference in perfusion parameters in haemangiomas and metastatic hepatic lesions in patients with known primary malignancy.
Methods and Materials: This study was approved by the institutional review board. All the patients provided informed consent. CT perfusion was performed on 64 MDCT in 72 patients with 54 cases of metastasis, 18 cases of haemangiomas. Data was analysed to calculate BF, BV, PS, MTT, HAF and IRFTO. CT perfusion parameters at the periphery of lesions and background liver parenchyma were compared.
Results: Significant changes were observed in the perfusion parameters at the periphery of haemangiomas and metastatic lesions. Of all the perfusion parameters BF, HAF and IRFTO showed most significant changes. BF cut-off value of more than 400ml/100g/min at the periphery of the lesions showed sensitivity of 88.9%, specificity of 83.3%, PPV of 57.1% and NPV of 96.7% in differentiating haemangiomas from hepatic metastasis. HAF cut-off value of more than 60% showed sensitivity of 77.8%, specificity of 86.1%, PPV of 58.3% and NPV of 93.9% in differentiating haemangiomas from hepatic malignancy. IRFTO cut-off value of more than 3 seconds showed sensitivity of 77.8%, specificity of 86.1%, PPV of 58.3% and NPV of 93.9% in differentiating haemangiomas from hepatic malignancy .
Conclusion: Perfusion CT is a helpful tool in differentiating haemangiomas from hepatic metastasis by determining changes in perfusion parameters at the periphery of the lesions.

B-0367 11:34

Detection and viability of colorectal liver metastases after neoadjuvant chemotherapy: a multiparametric PET/CT-MR study

V. Dunet[1], N. Halkic[1], A. Anaye[2], J.O. Prior[1], C. Sempoux[1], A. Denys[1], S. Schmidt[1]; [1]*Lausanne/CH*, [2]*Vevey/CH (sabine.schmidt@chuv.ch)*

Purpose: To compare the value of combined gadoxetic-acid-enhanced (Gd-EOB-DTPA) and diffusion-weighted (DW) MRI, with intravenously (IV) contrast-enhanced 18-F-FDG-PET/CT for the detection and viability assessment of colorectal liver metastases (CLMs) after neoadjuvant chemotherapy (NAC).
Methods and Materials: Following NAC forty-five patients with CLMs were prospectively enrolled and underwent combined Gd-EOB-DTPA-enhanced and DW-MRI and contrast-enhanced 18-F-FDG-PET/CT. Forty patients subsequently underwent surgery including peroperative ultrasound (US), which served as reference standard. The number of metastases detected by each technique was compared. In 69 resected metastases, SUVmean, SUVmax, maximum target-to-background ratio (TBR), TBRmean, total lesion glycolysis (TLG), metabolic tumour volume (MTV), ADCmean and ADCmin were correlated to corresponding tumour viability (TV) assessed on histological specimens.
Results: Peroperative US revealed 153 CLMs of whom 122 were resected. Detection rate of MRI and contrast-enhanced 18-F-FDG-PET/CT were similar (p>0.31) while detection rate of 18-F-FDG-PET was lower (p=0.0005). SUVmax and ADCmin were negatively correlated (r=-0.34, p=0.005) on preoperative imaging after NAC. However, TV was significantly correlated with TBRmax (r=0.33, p=0.006) and TBRmean (r=0.37, p=0.002), unlike with ADCmin (r=-0.02, p=0.9) or ADCmean (r=0.01, p=0.9).
Conclusion: While both combined Gd-EOB-DTPA-enhanced and DW-MRI and contrast-enhanced 18-F-FDG-PET/CT allow confident detection of CLMs, only 18-F-FDG-PET metrics are able to predict TV after NAC.
Author Disclosures:
S. Schmidt: Research/Grant Support; Bayher Healthcare, Switzerland.

B-0368 11:42

Prediction and response assessment after chemotherapy of colorectal liver metastases: can ADC values evaluated at 3T MRI represent a reliable biomarker?

F. Pacciardi, F. Donati, P. Boraschi, R. Cervelli, M. Castagna, L. Urbani, R. Gigoni, D. Caramella; *Pisa/IT (federica.pacciardi@libero.it)*

Purpose: To determine the usefulness of ADC values at 3T MRI as a biomarker for prediction and response assessment after neoadjuvant chemotherapy (nCT) in colorectal liver metastases.
Methods and Materials: Eighteen patients with colorectal liver metastases underwent MR imaging at 3T device (GE DISCOVERY MR750; GE Healthcare) before and after nCT. Diffusion-weighted-MRI (DW-MRI) was performed using a spin-echo echo-planar sequence with multiple b-values (150,500,1000,1500 sec/mm²), obtaining an ADC map. Fitted ADC values were calculated by two observers in conference for each liver lesion (more than 1cm of diameter) in both examinations drawing two ROIs: the former

around the entire tumour (eADC) and the latter in the peripheral area of the lesion (pADC). Pre- and post-nCT e- and pADC values and the difference between the eADC values (ΔeADC) and the pADC values (ΔpADC) before and after nCT were histopathologically related to tumour regression grading (TRG) of surgically resected liver metastases. Statistical analysis was performed on a per-lesion basis.
Results: In our 18 patients e- and pADC values were calculated in 43 and 35 colorectal liver metastases before and after nCT, respectively. The e- and pADC values obtained in the post-nCT and the ΔeADC and ΔpADC were statistically related to TRG classification ($p<0.0052$, $p<0.0001$, $p<0.222$ and $p<0.0203$, respectively). On the contrary, the e- and pADC values obtained in the pre-nCT MRI were not related to the pathologic staging.
Conclusion: ADC values at 3T MRI can be helpful as a biomarker for response assessment after nCT in colorectal liver metastases.

B-0369 11:50

Posttherapeutic changes of the liver parenchyma on hepatobiliary MR imagigng after radioembolisation
R. Seidel, M. Mehrmann, P. Fries, G. Schneider, A. Buecker, A. Massmann; *Homburg/DE (melina.mehrmann@uks.eu)*

Purpose: To investigate changes in the uptake of liver specific contrast media after radioembolization (RE) in correlation to liver function.
Methods and Materials: In 31 patients with various tumours undergoing RE the signal intensity of the liver in correlation to the spleen (liver- spleen ratio, LSR) was determined in the hepatobiliary phase 60 to 90 minutes after administration of Gd-BOPTA. Imaging was performed on a 1.5 T scanner before and 3 to 4 months after RE. Image analysis was processed on a separate workstation based on a fat suppressed T1 w GRE Sequence (TR/TE 108/4.76ms, flip angle 70°, matrix 256x256) by two readers in consensus. 5 regions of interest (ROI) were placed in the treated liver volume and 3 ROI in the splenic parenchyma avoiding vessels and tumour. LSR and laboratory findings (i.e. gamma glutamyl transpeptidase (GGT), international normalized ratio (INR) and Bilirubin) were statistically analyzed.
Results: LSR before RE with a mean of 1.39 (SD 0.33; CI1.27 to 1.50) and LSR post RE with a mean of 1.18 (SD 0.27; CI 1.08 to 1.28) differed significantly ($p=0.0003$). Difference mean was -0.21 (CI -0.11 to -0.31). A significant increase of GGT was observed with a mean 279.3 U/l (SD 264.4, CI 180.6 to 378.1) before and 349.3 U/l (SD 324.2; CI 223.6 to 475.0) after RE ($p=0.0074$). No correlation for laboratory values and LSR was found.
Conclusion: Liver specific imaging reflects parenchymal changes after RE. This might be useful to determine tissue at risk for further interventional procedures.

Increasing efficiency of MRE for detecting Crohn's disease activity through proper sequence selection
J. Rimola[1], A. Cofiño[2], I. Alfaro[1], S. Rodríguez[1], I. Ordás[1], J. Panes[1]; [1]*Barcelona/ES*, [2]*Gijón/ES (jrimola@clinic.cat)*

Purpose: The aim of this study is to compare different Magnetic Resonance Enterogrphy (MRE) sequence strategies for grading activity in patients with Crohn's disease (CD).
Methods and Materials: MRE and ileocolonoscopies performed within 1 month were compared. Intestinal segments were assessed using, T2, Diffusion Weighted Imaging (DWI) or combination of both, and categorically classified as inactive, active or severe. The findings were matched with those obtained using contrast-enhanced gadolinium sequences using MaRIA score. Simplified Endoscopy Score for CD (SES-CD) was considered the gold standard.
Results: 224 segments were included. Sensitivities of T2, DWI or combination of both for detecting activity were 0.81, 0.83, 0.76; and specificities were 0.97, 0.69, 0.96 respectively. For severity, sensitivities were 0.93, 0.7, 0.93; and specificities 0.88, 0.90, 0.83, respectively. For detecting active inflammation, T2 sequence had a similar sensitivity but superior specificity and accuracy to DWI. T2 had higher sensitivity than DWI for identifying severe disease. Compared with T2 sequence, the MaRIA had higher specificity and accuracy for identifying severe inflammation.
Conclusion: Our results support the use of a T2 sequence as a first screening step, and proceed with a full MRE examination only when abnormal findings are identified in the initial T2 sequence.

B-0371 10:38

Magnetic resonance enterography in the evaluation of anti-TNF alpha therapy response
I. Martini, C. Briani, F. Landolfi, G.M. Barelli, E. Iannicelli; *Rome/IT (isabella.martini88@gmail.com)*

Purpose: Identify possible correlations between magnetic resonance enterography (MRE) parameters and endoscopic data, in patients with Crohn's disease, with the aim to evaluate anti-TNF alpha therapy response.
Methods and Materials: 40 patients with Crohn's disease underwent MRE and ileo-colonoscopy before and after 1 year of anti-TNF alpha therapy. Different MRE parameters were analysed: pathological segment extension, bowel wall thickening, pattern and degree of contrast enhancement, presence of hyperaemia of mesenteric vessels (comb sign). CDEIS was used to evaluate endoscopic activity.
Results: After 1 year of treatment, 50% of patients had ileo-colonoscopy suggestive for active disease and an MRE stable and unchanged. Meanwhile, 50% of patients had ileo-colonoscopy suggestive of non-active disease. In the last group of patients we found statistically significant correlations between pathological segment extension ($p=0.001$), bowel wall thickening ($p=0.001$), comb sign ($p=0.011$) and endoscopic data. In particular, 80% of patients had regression of disease extension and bowel wall thickening and 60% of patients had also disappearance of comb sign.
Conclusion: In patients with non-active Crohn's disease, bowel wall thickening, comb sign and pathological tract extension are the MRE findings that statistically significantly correlate with endoscopic data. Finally, evaluation of these parameters before and after 1 year of anti-TNF alpha treatment can be useful to assess therapy response.

B-0372 10:46

Detectability of inflammatory bowel disease in Diffusion-weighted MR imaging (DWI): which imaging plane and b-values should be preferred?
C. van Rijswijck[1], T. Lauenstein[2], S. Kinner[1]; [1]*Essen/DE*, [2]*Düsseldorf/DE (Christine.Lipponer@uk-essen.de)*

Purpose: MR imaging (MRI) plays an important role in the diagnostic work up of patients with inflammatory bowel disease (IBD). Diffusion-weighted imaging (DWI) has gained more importance in body MRI including IBD, but has been performed differently in different institutions. The aim of this study was to evaluate which imaging planes and b-values are most helpful for DWI to differentiate inflammatory lesions.
Methods and Materials: 50 consecutive patients with known/suspected IBD and a standard MR of the bowel including DWI in axial and coronal planes with b-values of 50, 500 and 1000 were included. Standard bowel MR sequences served as reference for inflammatory lesions. 2 radiologists reviewed axial and coronal DWI images and scored on a 3-point Likert scale the detectability of lesions (1: not detectable, 2: weakly detectable, 3: clear detectable). Best b-value for detectability was evaluated in consensus. A Wilcoxon rank sum test was used for statistical analysis.
Results: According to the standard MRI sequences suspected bowel lesions in DWI were detected in 46/50 patients. In coronal DWI radiologists were able to detect 32/29 lesions clearly and 14/17 lesions weakly. In axial DWI readers rated 32/33 lesions respectively as clearly detectable, and rated 14/13 as weakly detectable. There was no significant interobserver difference (Kappa-value=0.79). A b-value 1000sec/mm^2 was noted to be best in lesion-detection.
Conclusion: DWI offers a high detectability of abnormal bowel parts in patients with IBD. Axial DWI was rated higher than coronal DWI. High b-values turned out to present the pathology most clearly in both orientations.

Bowel distention degree does influence DWI ADC values throughout the whole bowel length: results from two consecutive studies in healthy subjects
I. Apine, S. Atteka, J. Pokrotnieks, M. Leja, G. Krumina; *Riga/LV (dr.ilze.apine@gmail.com)*

Purpose: To compare ADC values in different bowel distention degrees in MR Enterography (MRE) examinations to assess reliability of DWI ADC in diagnosis of inflammatory bowel disease (IBD) in subjects with various bowel distention degrees.
Methods and Materials: ADC values of bowel walls with high SI in DWI images at b=600 grading bowel filling level as “distended”, “partially distended” and “collapsed” were measured in two consecutive studies (for small and large bowels separately) including 406 small bowel segments from 42 patients and

269 large bowel segments from 26 patients with no evidence of IBD were included. Bowel distention was maintained with 1-1.5 l of 2.5% mannitol solution orally and MRE were performed by 1.5T MR systems using DWI of b=0, 100 and 600. ADC differences between bowel filling grades were assessed with t-test and Wilcoxon signed-rank test.
Results: There were statistically significant differences ($p<0.05$) among ADC values of different bowel distention degrees being 1.84×10^{-3} mm^2/s and 2.73×10^{-3} mm^2/s for collapsed and distended state of jejunum, 2.46×10^{-3} mm^2/s and 2.89×10^{-3} mm^2/s for collapsed and distended state of ileum. In large bowel the mean ADC values were 1.45×10^{-3} mm^2/s, 1.79×10^{-3} mm^2/s and 2.49×10^{-3} mm^2/s for collapsed, partially distended and distended bowel walls, respectively.
Conclusion: Bowel distention degree has influence on ADC and ADC values of collapsed and inflamed bowel walls can overlap which has to be considered in diagnosis of IBD.

B-0374 11:02

Semi-automatic assessment of the small bowel and colon in Crohn's disease patients using MRI (the VIGOR++ project)
C.A.J. Puylaert[1], P.J. Schüffler[2], R.E. Naziroglu[3], J.A.W. Tielbeek[1], Z. Li[3], L.J. van Vliet[3], J. Stoker[1], S.A. Taylor[4], F.M. Vos[3]; [1]*Amsterdam/NL*, [2]*New York, NY/US*, [3]*Delft/NL*, [4]*London/UK (c.a.puylaert@amc.uva.nl)*

Purpose: MRI scores show promise for evaluation of Crohn's disease (CD) activity, although reported reproducibility is variable. Potentially, reproducibility could be improved using software assisted semi-automated measurements. The aim of this study was to develop and validate a predictive MRI activity score for ileocolonic CD activity based on software assisted semi-automatic measurement of MRI features.
Methods and Materials: 104 patients (59 female, median age 32) patients with known CD were prospectively recruited from two centres to undergo consecutive MRI and ileocolonoscopy. An MRI-based disease activity score (the "VIGOR" score) was developed based on both subjective radiologist observations and semi-automatic measurements of bowel wall thickness, excess volume and contrast enhancement (initial slope of increase; ISI) using a retrospective cohort of 27 patients with known CD and endoscopic reference standard (CDEIS). A second score was developed based only on the subjective radiologist observations. For validation, both scores were applied to the prospective dataset, along with two existing MRI activity scores (MaRIA and the London score) by two observer groups. Interobserver agreement was evaluated using the intraclass correlation coefficient (ICC).
Results: The VIGOR score (20.5*ISI+0.2*excess volume+2*mural T2) and the subjective model had comparable correlation to CDEIS as the MaRIA and London score (Ob1/2, r=0.55/0.60, 0.40/0.53, 0.38/0.47 and 0.37/0.49, respectively). The VIGOR score however had a significantly higher ICC compared to the other activity scores (0.82 vs 0.45-0.58, $p<0.001$).
Conclusion: The new VIGOR score achieves comparable accuracy to conventional MRI activity scores, but with significantly improved reproducibility.

Comparative study with magnetic resonance of bowel and perianal disease between adult and paediatric patients affected by Crohn's disease
D. Bencardino, F. Maccioni, V. Buonocore, F. Mazzamurro, C. Catalano; *Rome/IT*

Purpose: Perianal disease is considered a disabling complication and a negative prognostic factor in patients with Crohn's disease (CD), particularly in children. Comparative studies are necessary to mark any distinguishing features between paediatric and adult population.
Methods and Materials: 350 consecutive 1.5 Tesla MRI examinations performed on adult (>20 yo) and paediatric (<20 yo) patients affected by CD were retrospectively reviewed. Main inclusion criteria: CD confirmed with endoscopy and biopsy; no previous intestinal resections or surgical treatments for perianal fistulas. MR-enterography and high-resolution pelvic MRI were considered as gold standard. Nine intestinal localisations were considered, from jejunum to rectum. Disease activity grading was obtained considering the following activity parameters: wall thickening, overall length of CD lesions, wall Gd-enhancement, T2w wall signal and local active lymph nodes, according to published papers. Perianal fistulas were staged using Parks and St James's Hospital classification.
Results: 219 patients were selected (54% adult). The prevalence of perianal disease in paediatric and adult population was 35.6% and 17.8% (OR 2.5, $p=0.0031$ with Fisher exact test). Children have a higher risk of rectum involvement ($p=0.0042$), as well as of perianal disease in the presence of rectal involvement, than adults ($p=0.0007$). Paediatric patients with severe colorectal CD have a significantly increased risk of perianal disease ($p=0.0274$). No significant differences emerged regarding fistulas staging.
Conclusion: Paediatric patients with CD have a higher incidence of colorectal involvement and higher risk of perianal fistulas than adult patients. Evaluation of the perianal region should be always performed during MRI-enterography, particularly in children.

B-0376 11:18

Time is money: ultrashort protocol of MRI fistulogram for perianal fistulae
A. Balani[1], S. Shaikh[2], A. Kumar[1], S. Alwala[1], S. Marda[1], C. Chatur[2]; [1]*Secunderabad/IN*, [2]*Hyderabad/IN (drankitbalani@gmail.com)*

Purpose: To formulate state of art ultra-short protocol for imaging perianal fistulae and to evaluate its accuracy by correlating imaging findings with intraoperative findings.
Methods and Materials: 45 patients with suspicion of perianal fistula were included. Ultra-short protocol was done utilizing phased-array coil on GE 1.5T machine which included only two sequences, i.e. 3D-T2 fat suppressed FSE (4 min 55 sec) and T2 axial (4 min 24 sec). Observations were tabulated under headings of age, gender, patterns of abnormalities [types of fistulas,branching tracts,inflammatory collections] and surgical findings. Accuracy was assessed by correlating with surgical findings.
Results: The most common age group was 31-50 years with 82.2% males. Intersphincteric fistula was the most common type (25 cases, 55.5%), followed by transsphincteric type (17 cases, 37.7%). 1 patient(2.2%) had extrasphincteric fistula and 2 (4.4%) had no perianal fistula. In 23 (51.1%) patients, MRI showed additional findings like branching tracts (22.2%) or inflammatory collection (8.8%) or both (20%). Of the 45 patients, MRI correctly identified the fistulous tract in 44. In one patient, only one amongst the two fistulas was identified. Of 21 patients having secondary tracts intraoperatively, MRI correctly identified them in 19. All inflammatory collections were correctly identified. Thus the sensitivity was 93%, specificity was 100% and the accuracy was 93.3%. This is comparable to the previously reported sensitivity of 91% by Buchanan etal, 97% by Beckingham et al.
Conclusion: Ultra-short MRI protocol (9 min 19 sec) is highly accurate in mapping perianal fistulae with results comparable to studies done utilizing detailed protocols. The protocol significantly reduces scan time, improving patient co-operation and patient throughput and obviates the need of contrast administration.

B-0377 11:26

Virtual monoenergetic dual-energy CT enterography: optimisation of KeV settings and the added value for small bowel diseases
S. Lee, S. Kim, S. An, H.-J. Kang, J. Kang, J. Han; *Seoul/KR (twin393@hanmail.net)*

Purpose: To find the optimal keV setting for obtaining maximum contrast-to-noise (CNR) on dual-energy CT enterography (DE-CTE) and to investigate the added value of virtual monoenergetic image for the diagnosis of small bowel (SB) diseases.
Methods and Materials: Forty-five consecutive patients who underwent DE-CTE were prospectively enrolled. Images were reconstructed with iterative reconstruction algorithm (iDose[4]) and virtual monoenergetic settings at 40 keV, 55 keV, and 70 keV. For quantitative analysis, CNR for normal and abnormal bowel wall were measured and compared. Thereafter, two successive review sessions for the diagnosis of SB diseases were independently performed by three radiologists with different expertise using a 5-point confidence scale. At the first session, reviewers interpreted DE-CTE images reconstructed with iDose[4]. At the second session, monoenergetic images were additionally provided to the reviewers. To assess improvement in radiologists' performance, the multi-reader multi-case receiver operating characteristic method was used.
Results: CNR for both normal (16.1, 7.6, 3.0, 2.5; $P<0.001$) and abnormal (9.1, 6.5, 5.0, 3.5; $P=0.005$) bowel wall was significantly greatest on 40 keV images, followed by 55 keV, 70 keV, and iDose. When 40 keV images were added on iDose[4] images, mean area-under-the-curve (AUC) of three radiologists was significantly improved from 0.926 to 0.954 for the diagnosis of Crohn's disease ($P=0.028$). For SB tumours, AUC was improved from 0.708 to 0.954, but statistical significance was not achieved ($P=0.423$).
Conclusion: Lowest (40 keV) monoenergetic images provide best CNR on DE-CTE. Regardless of radiologists' expertise, diagnostic performance for the diagnosis of Crohn's disease can be significantly improved with the addition of 40 keV monoenergetic images.

The value of CT enterography in predicting the need of surgery in Crohn's disease: what advises can radiologists give to gastroenterologists in advance?

M. Jiang, X. Li, Z. Li; *Guangzhou/CN (1063345769@qq.com)*

Purpose: When to perform a surgery and how to choose the right lesions needed for surgery are critical for CD patients, in order to reduce surgical complications and avoid "short bowel syndrome". Thus, the purpose of this study was to assess the efficacy of CTE in predicting the need of surgery for CD patients.
Methods and Materials: 156 consecutive CD patients were evaluated and stratified as surgery group (n=83) and non-surgery group (n=73) according to clinical outcome in observation time. Compared between the two groups, the CTE findings with statistical significance were listed as risk factors. According to the number of CTE risk factors, the patients were divided as low-risk group, median-risk group and high-risk group. Survival analysis was used to predict the need for surgery.
Results: The CTE findings with significant differences between surgery and non-surgery group included number of lesion, fibrofatty proliferation of the mesentery, mesenteric lymph nodes, bowel thickness, enhanced density, proximal bowel dilation, perienteric stranding , ulceration, comb sign, abscess and fistulas (all P<0.05). All these risk factors were analysed using a cumulative risk-score shown as surgery-free survival curve. An enterography-based cumulative risk-score (low-risk, 1-4 CTE risk factors; median-risk, 5-8 CTE risk factors; high-risk,>8 CTE risk factors) derived from multivariate analysis was able to differentiate at different risk for surgery (P=0.001).
Conclusion: CTE helps pick out high-risk CD patients to closely monitor and can accurately predict the need for surgery for CD patients.

Correlation study of quantitative parameters derived from a dual-layer spectral CT with endoscopic and clinical indicators for evaluation of Crohn's disease

Y. Tang, Y. Jiang, F. Yan, Q. Han; *Shanghai/CN (yanjiangcs@hotmail.com)*

Purpose: To investigate the correlation of quantitative parameters derived from a dual-layer spectral CT with endoscopic and clinical indicators for evaluation of Crohn's disease.
Methods and Materials: 24 patients with diagnosed Crohn's disease underwent dynamic abdomen CT using a dual-layer spectral CT (IQon spectral CT, Philips Healthcare) and gastrointestinal endoscopy with an interval not more than 2 days. Bowel wall thickness, CT attenuation and iodine concentration (IC) in the areas with the greatest thickening of different phases were recorded. Difference of CT attenuation and IC between arterial and venous phases was calculated. Clinical disease activity index (CADI) and Crohn's disease endoscopic index of severity (CEDIS) were evaluated for analysis. The correlation between spectral CT parameters with CADI and CEDIS was analysed by Pearson coefficients.
Results: Only bowel wall thickness presented significant correlation with CADI (r=0.492, p=0.017), no other CT quantitative parameters presented correlation with CADI. No CT quantitative parameters presented significant correlation with CEDIS. A significant correlation presented between CADI and CEDIS (r=0.567, p=0.005).
Conclusion: Bowel wall thickness is an important indicator for evaluation of Crohn's disease, which exhibits significant correlation with CADI.

CT enterography: farewell to colonoscopy? - diagnostic accuracy of qualitative predictors of inflammatory bowel disease and its activity (prospective study from a tertiary centre)

S.T. Laroia, A. Rastogi, K. Yadav, M. Haroon, A.S. Bhadoria, G. Kumar, S.K. Sarin; *New Delhi/IN (thaparshalini@gmail.com)*

Purpose: To study the CT Enterography (CTE) findings in inflammatory bowel disease (IBD) for accuracy of qualitative imaging features of primary disease and its activity in comparison to histopathology of the affected segment
Methods and Materials: A prospective study on patients who underwent CTE followed by enteroscopy/colonoscopy and histopathology within one week was conducted during 2010-16 at a tertiary hospital. Parameters such as mural thickening, stratification, pericolonic congestion, lymph nodes and extra-intestinal manifestations were assessed for diagnostic accuracy and qualitative predictors of IBD and its activity
Results: Out of 203 patients, 106 (67 males, age 41.9±14.6, range 12-73 years) were found to have IBD (Ulcerative colitis 47%, Crohn's disease 42.5%, indeterminate disease 10.4% patients) on histopathology. Most common site of involvement was sigmoid colon (65.1%) followed by rectum (60.4%). Increased mucosal enhancement (53%Vs27%) and mural thickening (71.1%Vs30%) were found to be predictors of IBD with odds of 3.13 (95%CI, 1.03-4.91) and 3.16 (95%CI, 1.07-5.72), respectively. Pericolonic vascular congestion (58.5%Vs19.7%) showed borderline significance with OR of 2.74 (CI 0.91-5.23). Other indices were not significant. Toxic megacolon was seen in 5%Vs0.9%7.5%Vs3.1% patients underwent surgery for emergency and elective management. CTE revealed a sensitivity and positive predictive value (PPV) of 83.3% and 86.2% respectively in diagnosis of IBD. Sensitivity and PPV for determination of disease activity was 83.7% and 88.5% respectively
Conclusion: Our study revealed that CTE and its qualitative indices are accurate in diagnosis of IBD and its activity and have the potential to replace invasive scopic studies and histopathology

Percutaneous varicocele embolisation: a retrospective cohort study of recurrence, pain and fertility on follow-up in a single centre 7-year study

H. Shiwani[1], S. Shaikh[2]; [1]*Leeds/UK*, [2]*Bradford/UK (hshiwani@gmail.com)*

Purpose: A varicocele is a collection of dilated and tortuous veins due to dilation of the spermatic vein caused by impaired drainage of blood. Varicoceles impair spermatogenesis, are painful and appear unsightly. Radiologic embolisation of the spermatic vein is an alternative to surgical varicocele ligation which is linked to hydrocele formation and testicular atrophy. In this study, we aimed to determine the outcomes in patients following percutaneous varicocele embolisation.
Methods and Materials: A retrospective single-group cohort study included patients who underwent percutaneous varicocele embolisation in a 7-year period between 1st January 2009 to 1st January 2016 in a single centre at the Bradford Royal Infirmary, Bradford, UK. All patients were followed up and questioned on pain (on a scale of 1 to 10), unsightly appearance (Not at all, A little, Moderately, Extremely) and the outcome of successful pregnancy.
Results: A total of 26 patients underwent percutaneous varicocele embolisation. Follow-up information was obtained for 21 of the 26 patients. There was 1 recurrence (This patient underwent re-embolisation 6 years later) and no reported side-effects. Median length of follow-up was 2.1 years (IQR= 3.1 years). There was a median decrease of 4 in the pain score (out of 10) after the procedure compared to before the procedure. All recorded an improvement in appearance. For those that attempted pregnancy after the procedure, 8 (50%) had a successful pregnancy and 8 (50%) did not.
Conclusion: Varicocele embolisation is an effective treatment for improving pain and the unsightly appearance of a varicocele with minimal complications.

B-0382 10:38

Salvage cryoablation after curative treatment in locally recurrent prostate cancers

M. Barat, L. Colleter, P. Mongiat Arthus, F. Desgrandchamps, E. de Kerviler; *Paris/FR (maxime.barat89@gmail.com)*

Purpose: 20 to 30% of patients have a local recurrence after a curative treatment in prostate cancer. We report our series of salvage cryoablation in locally recurrent prostate cancers.
Methods and Materials: 28 patients underwent cryoablation for intra-prostatic (n=21) or extra-prostatic (n=7) locally recurrent prostate cancers.
Results: Mean follow-up was 428 days. Among the 21 intra-prostatic recurrent patients, Procedure was successful in 13 patients with a PSA blood level drop of -3.72ng/L. Two patients had an insufficient treatment. Six patients had a biological recurrence (average time: 15 months) among them 3 had bones metastasis that required hormone deprivation therapy. Among the 7 patients with extra-prostatic recurrence, (4 seminal vesicle, 3 lymph nodes), 4 procedures were successful with a PSA blood level drop of 1.33ng/ml, and the remaining 3 had an early biological recurrence (3 seminal vesicles) that required hormonotherapy.
Conclusion: Salvage cryoablation of locally recurrent prostate cancer after a curative treatment is a safe and efficient technique allowing delay initiation of hormone deprivation therapy.

B-0383 10:46

Leiomyoma-based selection of patients for uterine artery embolisation: which leiomyomas are best suited for embolisation?

N.N.N. Naguib, N.-E.A. Nour-Eldin, T. Gruber-Rouh, M. Al-Subhi, T.J. Vogl; *Frankfurt a. Main/DE (nagynnn@yahoo.com)*

Purpose: To study which leiomyomas are best suited for uterine artery embolization (UAE) based on pre-embolization MRI for proper selection of patients.
Methods and Materials: The study was retrospectively performed on 38 females (mean: 45.5+/-4.43) with 108 leiomyomas. The following leiomyoma characteristics were studied: leiomyoma enhancement (ratio leiomyoma: piriform muscle enhancement), leiomyoma location (pedunculated submucous, submucous, interstitial, subserous and pedunculated subserous), leiomyoma position (fundal, anterior, posterior and cervical) and size (maximal diameter <3 cm, 3 to <6 cm, 6 to <9 cm, 9 to <12 cm and 12 cm or more). Individual parameters were tested for significance against leiomyoma volume change at 3-month follow-up.
Results: No significant difference between patients was found regarding the size, enhancement or location of leiomyomas. The mean initial leiomyoma volume was 66.38 ml+/-131.61 (range: 1.23-987.34). The maximal diameter was 4.27 cm+/-2.42 (range: 1.4-14.4). At follow-up, the mean volume was 43.69 ml+/-110.45 (range: 0.03-875.05). The mean percentage volume change at follow-up was 55.58% [reduction]+/-26.1 (range: 40.05% [increase]-99% [reduction]). No significant correlation was seen between the leiomyoma position and volume change at follow-up (p=0.79). Degree of enhancement, location and size showed statistically significant correlation with percentage volume change at follow-up (p=0.043, p<0.001 and p<0.001, respectively).
Conclusion: Leiomyoma location, maximal diameter and degree of enhancement correlate significantly with the volume changes of leiomyoma at follow-up and can be used for proper patient selection.

B-0384 10:54

To evaluate the effectiveness and the safety of magnetic resonance-guided focused ultrasound (MRgFUS) in the treatment of submucosal uterine fibroids

S. Iafrate, I. Capretti, M. Di Luzio, F. Arrigoni, S. Mascaretti, G. Mascaretti, C. Masciocchi; *L'Aquila/IT (sonia.iafrate87@gmail.com)*

Purpose: To evaluate the effectiveness and the safety of magnetic resonance-guided focused ultrasound (MRgFUS) in the treatment of submucosal uterine fibroids.
Methods and Materials: From December 2013 to December 2015, we submitted to MRgFUS treatment 17 patients (age range 23-52 years) affected by submucosal uterine leiomyomas, studied with MRI and classified with the FIGO staging system. Twenty-one submucosal fibroids of type 0, 1 and 2 were treated, measuring between 1 and 3.5 cm (7 of type 0, 5 of type 1, 9 of type 2). After treatment, an evaluation of the non-perfused-volume (NPV), representing the treated area, was performed on the c.e. T1-weighed sequences (MRI). Symptoms severity score questionnaire (UFS-QOL) was used to assess the severity of clinical features.
Results: Each patient was treated in one session alone. After MRgFUS treatment, a mean NPV extension of 93% was observed without major complications or side effects. At control studies up to 2-years, 7 out of 17 patients showed progressive reduction of the volume with regularisation of the uterine wall. Ten out of 17 patients showed significant reduction of fibroid volume (about 80%). All the patients experienced a reduction of UFS-QOL symptoms severity score, when compared with the pre-treatment score.
Conclusion: MRgFUS is a valid mininvasive and radical approach in the treatment of submucosal fibroids.

B-0385 11:02

Pre-abortion uterine arterial embolisation in high haemorrhage risk pregnancies

P. Venetucci[1], F. Venetucci[2], S. Pizzetta[1], R. Basile[1], F. Pane[1], A. Brunetti[1]; [1]*Naples/IT*, [2]*Rocchetta Sant'Antonio/IT (pierovenetucci@gmail.com)*

Purpose: Interventional radiology has a well-defined role in the management of many gynaecological conditions (postpartum haemorrhage, fibromas, placentation abnormalities). Through our experience, we wanted to analyse the pre-abortion interventional radiology role in high haemorrhage risk pregnancies such as caesarean scar pregnancy (CSP) and vesicular mola.
Methods and Materials: In the past two years, we performed 12 pre-abortion precautionary embolisation procedures: 10 patients with CSP and 2 with vesicular mola. All the patients came for a planned therapeutic procedure, except one (CSP) who arrived unstable, with an uterus laceration. Embolisation was achieved through a right common femoral artery access with a 5F catheter. Left uterine artery was embolised before the right one using temporary embolisation material.
Results: Significant bleeding reduction has been obtained; less than 500 ml blood loss in 11 patients, and between 500 and 1000 ml in only 1 patients. In CSP group menstrual function has been preserved in 6 patients while one is still in the 6-month follow-up term; hysterectomy has been performed on 3 patients, 1 due to procedure complications. Interventional radiology techniques proved to be, in our experience, an important and successful step in the therapeutic planning of high haemorrhage risk pregnancies that cannot be carried to full term. Between the two patients with vesicular mola, 1 is still in the 6-month follow-up for menstrual function recovery and 1 underwent hysterectomy.
Conclusion: Interventional radiology techniques proved to be an important and successful step in the therapeutic planning of high haemorrhage risk pregnancies that cannot be carried to full term.

B-0386 11:10

Uterine fibroids treated with MRI-guided high-intensity focused ultrasound (MRgFUS): clinical outcomes in comparison to current therapeutic strategies

A. Napoli, R. Scipione, M. Anzidei, F. Andrani, S. Dababou, C. Catalano; *Rome/IT (alessandro.napoli@uniroma1.it)*

Purpose: To prospectively evaluate clinical outcomes in patients affected by uterine fibroids and treated using MRI-guided focused ultrasound (MRgFUS), uterine artery embolisation (UAE) or surgery.
Methods and Materials: 570 women affected by symptomatic uterine fibroids referred our department for MRgFUS treatment. Pre-treatment evaluation assessed fibroids MR characteristics and MRgFUS eligibility. 166 of 182 eligible patients (group A) were treated with MRgFUS, while 388 resulted ineligible. Of these, 33 patients underwent UAE (group B), 140 myomectomy (group C) and 58 hysterectomy (group D). Clinical efficacy for each treatment was determined by symptoms severity score (SSS) reduction from baseline to 3- and 12-month follow-up. Further data concerning number and type of complications, days of hospitalisation and days of convalescence were also compared.
Results: MRgFUS group showed a mean SSS decrease of 24.6% at 3 months and 55.8% at 12 months. SSS drop for UAE was 51.2% and 57.4%, respectively, for myomectomy 71.5% and 66.0%, for hysterectomy 96.6% and 94.5%. MRgFUS group had the least number of adverse events (1.8%), while UAE group experienced the major rate (26.4%). MRgFUS patients were treated in outpatient setting, while mean days for hospitalisation and convalescence for other groups were, respectively, 3.1±2 and 12.4±9 days for group B, 4.5±2 and 17.2±12 for group C, 4±1 and 26.3±14 for group D.
Conclusion: MRgFUS clinical efficacy for uterine fibroids treatment is comparable to UAE and slightly lower than myomectomy. However, MRgFUScan be performed in an outpatient setting and complication rate is significantly inferior to other treatments.

B-0387 11:18

Role of embolisation with N-butyl cyanoacrylate in recurrent post-surgical varicoceles

M.M. Zaitoun, E.R. Elsayed, S.B. Elsayed; *Zagazig/EG (zaitoun2015@gmail.com)*

Purpose: To evaluate the role of n-butyl cyanoacrylate (NBCA) embolisation in recurrent post-surgical varicoceles and to detect the most common cause of recurrence after surgery.
Methods and Materials: During 2 years, 36 consecutive patients with recurrent post-surgical varicoceles were embolised with n-butyl Cyanoacrylate (NBCA) emulsified in lipidol using a 4-F hydrophilic catheter. Mean age was 23 years. Follow-up with Doppler US was performed after 1 month then every 3 months for 1 year.
Results: The technical success was 100%. Neither major complications nor non-targeted embolisation were detected. Only 6 patients had pain following the embolisation and were treated medically for 10 days. In the follow-up by the Doppler US, all the patients showed complete resolution of the varicocele. Duplication of the gonadal veins was the main observation in this study as a cause of recurrent varicocele after surgery.
Conclusion: Embolisation with n-butyl cyanoacrylate (NBCA) is ideal for post-surgical recurrence of varicoceles with 100% technical success and no major complications as well as it is an inexpensive and safe technique. Duplication of the gonadal vein is the most common cause of varicocele recurrence after surgery.

B-0388 11:26

Renal angiomyolipoma: effects of selective arterial embolisation on glomerular filtration rate

A.M.K. Abdel Aal, R. Oser, S. Saddekni, S. Moawad, A. Abouarab, K. Mahmoud, A. Almehmi; *Birmingham, AL/US (akamel@uabmc.edu)*

Purpose: Selective arterial embolisation (SAE) is a surgery-sparing treatment for renal angiomyolipoma (AML). However, limited data are available on the effects of SAE on glomerular filtration rate (GFR). The outcomes of contrast exposure on GFR during SAE procedure remain unknown. The aim of this study is to evaluate the change in serum creatinine and GFR in patients with AML who underwent SAE.
Methods and Materials: Retrospective review of AML cases that were treated with SAE procedure at our center from 2004 to 2015. Data on demographics, tumour side and size, and other laboratory values were collected. Serum creatinine and calculated GFR were assessed immediately prior and 3 months after SAE procedure.
Results: This study included 42 patients. The indications for SAE included back pain, haematuria and retroperitoneal haemorrhage. Baseline characteristics were: median age 42 (32-64) years; 81% females; 66% whites. Hypertension and tuberous sclerosis were present in 33% and 42.9% of patients, respectively. Tumour size was median 5.9 (4.7-8.5) cm. Acute kidney injury (AKI) was encountered in 2 patients (4.7%) following the SAE procedure. However, both cases had a full renal recovery. Although the mean serum creatinine increased from 0.98 to 1.15 mg/dl (p=0.001), no statistically significant difference was noted in GFR (70 vs 60 ml/min;p=0.125).
Conclusion: SAE is a safe, surgery-sparing treatment for renal AML. Despite contrast exposure and partial parenchymal loss, renal function did not change after SAE procedure. AKI is a rare complication after SAE that occurred in only 4.7% of the patients with complete renal recovery.

Comparison of radiofrequency and cryoablation for renal masses exceeding 3cm

J. Gregory, C. Delavaud, J. Dbjay, A. Khairoune, O. Helenon, J.-M. Correas; *Paris/FR (jgregory111@gmail.com)*

Purpose: To compare the efficacy and complications of cryoablation and radiofrequency in the treatment of renal masses larger than 3cm.
Methods and Materials: The study was approved by our institution's local Ethics. Patients were included in two groups: group 1 with all patients referred for cryoablation treatment of renal tumours exceeding 3cm from September 2013 to March 2015. Group 2 with all patients referred for radiofrequency treatment of renal tumours exceeding 3cm from December 2010 to August 2013, when radiofrequency was the treatment of choice. Clinical and laboratory data were collected from medical records. All patient underwent constant CT and MRI during a one-year follow-up.
Results: Forty-three patients were included in each group. The mean tumour diameter was significantly higher in the cryoablation group (4.0 ± 0.8 cm) than in the RF ablation group (3.5 ± 0.6 cm) ($p < 0.01$). Tumours treated by cryoablation were of higher complexity according to the RENAL score than those treated by RFA ($p < 0.01$). Local recurrence-free survival rates at 12 months for cryoablation and RFA were 72.1% (95% CI, 60-87) and 76.7% (95% CI, 65-91) respectively ($p = 0.65$). According to the Clavien-Dindo classification, 29 (67%) of the cryoablation and 35 (81%) of the RF ablation procedure lead to no complication at all. ($p = 0.18$).
Conclusion: The efficacy and safety of radiofrequency and cryotherapy for renal tumours larger than 3 cm are not different in our study.

Trans-rectal- ultrasound (TRUS) guided biopsy with MRI-TRUS fusion: feasibility study using a multipurpose magnetic tracking system

G. Bizzarri[1], A. Bianchini[1], D. Valle[1], L. Di Vito[1], L. Velari[1], L. Lodigiani[1], A. Dell'Era[1], V. Anelli[2]; [1]*Albano Laziale/IT*, [2]*Rome/IT (bizzarrigiancarlo@libero.it)*

Purpose: Purpose. TRUS guided biopsy with MRI fusion is a promising technique as it combines the accuracy of prostate multiparametric MRI (mpMRI) with TRUS guided biopsy that is well recognized to be friendly, well-tolerated and inexpensive. We report a feasibility study using a multipurpose Virtual Navigation (VN) system based on magnetic tracking technology for TRUS guided biopsy with MRI-TRUS fusion.
Methods and Materials: Methods and Materials. A MyLabTwice ultrasound scanner equipped with VN software and hardware was used (ESAOTE, Italy). The procedure was performed on 20 patients (mean age 75) with EC123 (3-9 MHz) endfire transrectal probe with single use guiding system and reusable tracking brackets for magnetic sensor (CIVCO Medical Solutions,Kalona,Iowa,USA).For each patient prostate mpMRI performed within one month was loaded on the VN system. After periprostatic local anesthesia, US-MRI coregistration was performed on the sagittal plane and NV modality activated. Fusion accuracy was evaluated using internal markers (seminal vesicles and retention cysts). Targeted and systematic biopsies were performed using a 18G trucut needle.
Results: Results. TRUS and mpMRI fusion was a rapid procedure (mean time 4 minutes). The use of the magnetic tracking system did not required any change in the standard TRUS biopsy technique. The error of TRUS-mpMRI fusion, checked using internal markers, never exceeded 5 mm.. The learning curve required 5 procedures.
Conclusion: Conclusion. Our experience demonstrates that TRUS guided prostate biopsy with mpMRI-TRUS fusion is easy, reliable and accurate despite the use of a multipurpose VN system available in a large number of radiological departments.

Renal sympathicolysis by transaortic periarterial ethanol injection in pigs with the use of an experimental injections catheter: a feasibility study

P. Freyhardt[1], J. Schütze[2], R. Donners[2], J. Schnorr[2], N. Stolzenburg[2], J.-L. Rinnenthal[2], R.W. Günther[2], F. Streitparth[2]; [1]*Krefeld/DE*, [2]*Berlin/DE (patrick.freyhardt@helios-kliniken.de)*

Purpose: Evaluation of feasibility, safety and efficacy of renal sympathetic denervation after transaortic periarterial ethanol injection with an experimental injection catheter in pigs.
Methods and Materials: Percutaneous unilateral periarterial transaortic injection of 10 ml of an ethanol-bupivacaine-accupaque-mixture (7:2:1) was performed in 11 normotensive pigs. Catheter advancement and injections were performed under fluoroscopic guidance in all animals. CT scans of the kidneys and perirenal structures and blood pressure measurements were performed immediately pre- and post-intervention and 4 weeks after treatment. After euthanasia the norepinephrine (NE) concentration of both kidneys was determined. A histopathologic analysis of the renal arteries and the surrounding tissue was performed to assess induced nerve fibre degeneration.
Results: All procedures were technically successful with good periarterial injectant distribution. In two animals, a slight distribution to the contralateral side was observed. One animal died immediately after the intervention due to cardiac arrest. NE concentration of the renal parenchyma was significantly lower on the treated side in eight of ten pigs with a decrease of up to 68% and an average decrease of 37%. Histopathological analysis revealed mild to severe circumferential nerve degeneration correspondingly.
Conclusion: Renal sympathetic denervation by transaortic periarterial ethanol injection was feasible, effective and safe in a pig model. This approach may be an alternative to catheter-based RFA or other methods of renal denervation.

Subsolid and part-solid nodules in lung cancer screening: comparison between visual and computer-aided detection

M. Silva[1], G. Capretti[1], N. Sverzellati[1], C. Jacobs[2], F. Ciompi[2], B. van Ginneken[2], C.M. Schaefer-Prokop[2], A. Marchianò[3], U. Pastorino[3]; [1]*Parma/IT*, [2]*Nijmegen/NL*, [3]*Milan/IT (mario.silva@unipr.it)*

Purpose: To compare visual detection and computer aided diagnosis (CAD) for detection of non-solid nodules (NSN) and part-solid nodules (PSN), in a lung cancer screening trial.
Methods and Materials: Baseline low-dose computed tomography (LDCT) of 2303 subjects were assessed by 2 independent operators: a) visual detection (VD); b) CAD software (CIRRUS Lung Screening). CAD was run also on first and second incidence round. Rate of agreement was calculated by weighted k test. Sensitivity and negative predictive value (NPV) were calculated according to cumulative number of subjects with detected nodules (VD and CAD). LDCT features were compared between CAD-only and VD-only detected nodules.
Results: Nodules were detected in 215/2303 subjects (dominant nodule: 171/215 NSN and 44/215 PSN), notably 149 were CAD-only detected (113 NSN and 36 PSN), 27 were VD-only detected (25 NSN and 2 PSN), and 39 were CAD and VD detected (33 NSN and 6 PSN). The agreement was fair

(weighted k=0.276). Sensitivity and NPV for CAD 87.4% and 98.7%, and for VD 30.7% and 93.3%. Automatic and manual caliper were similar for the assessment of maximum diameter (p=0.111). CAD-only and VD-only detected nodules showed similar nodule diameter (p=0.727) and proportion of PSN (p=0.073). Volume of CAD-only detected nodules was significantly smaller (p=0.019). Among the 27 VD-only detected nodules, 11 NSN were subsequently detected by CAD at the incidence rounds.
Conclusion: Detection of NSN and PSN showed only fair agreement between VD and CAD. Combined assessment of LDCT by both VD and CAD is needed to achieve optimal sensitivity.

B-0393 10:38

'Non-nodule' appearance of early lung cancer in CT screening: retrospective evaluation of 281 lung cancers detected

M. Minotti, S. Calloni, C. Rampinelli, M. Bellomi; *Milan/IT*
(marta.minotti@alice.it)

Purpose: Pulmonary nodule is the typical presentation of lung cancer. However, there is a spectrum of focal lesions that cannot be defined as pulmonary nodule, but really represent early manifestation of lung cancer. Therefore, we aimed to evaluate the features of early stage lung cancers which are depicted on low-dose CT as 'non-nodule' lesion.
Methods and Materials: Two experienced radiologists in lung CT screening retrospectively reviewed the radiological features of 281 lung cancers detected during 10 years of screening trial (5203 heavy smokers, >50-year-old). The readers in consensus assessed if lung cancer appearance at time of diagnosis was consistent ('nodule') or not ('non-nodule') with the Fleischner Society definition of 'pulmonary nodule'. 'Non-nodule' lung cancers were further classified as: 1) bulla-like, 2) scar-like, 3) endobronchial, 4) other. In case of disagreement, a third radiologist (>15-year experience) resolved the discrepancies.
Results: Twenty-four lung cancers (24/281, 8.5%) were defined as 'non-nodule' lesions: 7 (2.9%) were bulla-like, 9 (3.7%) scar-like, 4 (1.6%) endobronchial and 4 (1.6%) other. The mean diameter at time of diagnosis was 16.2 mm (range: 7.5-65 mm). Nineteen were adenocarcinomas, two SCC, two NSCLS non-otherwise-specified, and one SCLC. Nineteen were diagnosed in stage I, four in stage III and one in stage IV.
Conclusion: A non-negligible proportion (8.5%) of screening-detected lung cancers has a 'non-nodule' appearance. Bulla-like and scar-like lesions are predominant and should be carefully evaluated. The awareness of these atypical lung cancer presentations can avoid missed diagnosis and should be considered in management of screening-detected focal lesions.

B-0394 10:46

The implications of internal vessel and bronchial changes within pure ground-glass opacity lung adenocarcinoma on CT

Z. Shaohong, Y. Nie, X. Jin, Y. Yang; *Beijing/CN*
(cjr.zhaoshaohong@vip.163.com)

Purpose: To investigate the implications of vessel and bronchial changes within lesion on CT by comparing with histopathologic subtypes of lung adenocarcinoma with pure ground-glass nodule (pGGN).
Methods and Materials: One hundred and ninety patients (201 lesions) of lung adenocarcinomas with pGGN who underwent curative resection were included. All patients were categorized into two groups according to the abnormalities of vessel and bronchus: abnormal group and normal group. Histopathologic subtypes were classified into preinvasive lesions (atypical adenomatous hyperplasia [AAH] and adenocarcinoma in situ [AIS]), minimally invasive adenocarcinoma (MIA) and invasive pulmonary adenocarcinoma (IPA). Pearson Chi square test was used to analyze the relationships between vessel and bronchial abnormalities and histopathologic subtypes. Mann-Whitney rank test and t-test were used to identify the correlation of vessel and bronchial abnormalities with the density and diameter of pGGN.
Results: There were 4 with vessel abnormalities and 1 with bronchial abnormalities in 35 preinvasive lesions, 26 and 18 in 53 MIAs, 80 and 55 in 113 IPAs, respectively. There were statistically significant differences of vessel and bronchial abnormalities among histopathologic subtypes (P=0.000, 0.000). There were significant differences in vessel and bronchial abnormalities with pGGN diameter (P=0.000, 0.000), but not with density (P=0.303, 0.966). There were no significant difference between vessel convergence and vessel dilation or distortion among these three subtypes (P=0.115).
Conclusion: Vessel and bronchial abnormalities within the pGGN may indicate the invasiveness of lung adenocarcinoma and were correlated with the lesion diameter.

B-0395 10:54

Quantitative analysis for determining the optimal computed tomography threshold value to detect invasive foci in subsolid nodules

D. Lee, C. Park, T. Kim; *Seoul/KR (edahyunle@gmail.com)*

Purpose: To establish the optimal CT threshold value for detecting the solid components of subsolid nodules, using invasive foci as reference.
Methods and Materials: Thin-section non-enhanced chest CT scans were retrospectively reviewed for 25 patients (M:F=7:18; age, 55.9±12.7 years) with pathologically confirmed MIA. The solid portion was assumed as the surrogate marker of invasive foci of MIA. It was defined as the area with higher attenuation than the threshold and measured using the maximum diameter on multiplanar reconstruction images with various HU thresholds ranging from −600 to −100 HU in 50-HU intervals. A linear mixed model for considering repeated measures from various thresholds was used to evaluate bias in each threshold, using the pathological size of invasive foci as the reference.
Results: The size of the 25 MIA was 9.2±1.33 mm, with mean attenuation of −539.1±96 HU. The size of the pathologically invasive foci was 3.56±1.33 mm. The maximum size (mm) of the solid portion was 0.31±0.87 on −100 HU, 0.55±1.06 on −150 HU, 0.93±1.31 on −200 HU, 1.39±1.6 on −250 HU, 2.00±1.67 on −300 HU, 2.76±2.22 on −350 HU, 3.58±2.39 on −400 HU, 4.52±2.39 on −450 HU, 5.44±2.47 on −500 HU, 6.67±2.34 on −550 HU, and 7.75±2.56 on −600 HU. At the threshold of −400 HU, the bias was lowest (−0.0176) between the solid portion and invasive foci, showing an insignificant difference (p=0.963).
Conclusion: For quantitative analysis, −400 HU might be the optimal threshold to define the solid portion of subsolid nodules as a surrogate marker of invasive foci.

B-0396 11:02

Small pulmonary nodules on negative mode lung window images

M.U. Nasir, G. Masood, A. Iqbal, I.K. Niazi; *Lahore/PK*
(dromernasir@gmail.com)

Purpose: To compare normal and negative mode axial images of lung windows of multi detector computed tomographic CT data for detection of small intrapulmonary nodules.
Methods and Materials: Prospective analysis of 500 oncology patients who underwent standard dose thoracic multi detector CT was done. Axial thin slice CT images were reviewed on standard workstations. Two consultant radiologists and registrars were involved in data collection and analysis.Parameters observed included mean, minimum and maximum reading time per examination and per radiologist. The nodules detected and confirmed by two consensus of two observers served as the reference standard. Descriptive statistics were calculated with P value of 0.05 indicating a significant difference. The McNemar's test and confidence intervals for differences between methods were used to compare the sensitivities.
Results: Negative mode images of lung windows were superior to the normal images. There was significant difference in detection rate and reporting time of nodules smaller than 10 mm in diameter for both set of observers. Sensitivity of negative mode images ranged from 89 % to 98% while the sensitivity of normal axial images of lung windows was 70 to 84 %.
Conclusion: Negative mode images of lung windows are the superior to normal axial lung widows for the detection of small intrapulmonary nodules.

B-0397 11:10

Comparison of lung nodule detection performance on 3D CAD system among filtered back projection and iterative reconstruction methods at different radiation-dose levels

Y. Ohno[1], K. Aoyagi[2], Q. Chen[3], S. Kaminaga[2], Y. Fujisawa[2], N. Sugihara[2], Y. Kishida[1], S. Seki[1], T. Yoshikawa[1]; [1]*Kobe/JP*, [2]*Otawara/JP*, [3]*Beijing/CN*
(yosirad@kobe-u.ac.jp)

Purpose: To compare the nodule detection capability on a 3D computer-aided detection (CAD) system among filtered-back projection (FBP) and iterative reconstruction (IR) methods at standard-, reduced- and ultra-low-dose CTs (SDCT, RDCT and ULDCT).
Methods and Materials: Forty patients prospectively underwent chest CT examinations with SDCT (250mA), RDCT (50mA) and ULDCT (10mA) protocols, and CT data were reconstructed into 1-mm-thick images with and without commercially available IR method (i.e. AIDR 3D). Therefore, the following CT data set in each patient was reconstructed: SDCT with and without AIDR 3D, RDCT with and without AIDR 3D, and ULDCT with and without AIDR 3D. Then, nodule detections were automatically performed by our proprietary CAD software. To determine the utility of IR method for improving nodule detection capability, sensitivity and false positive rate (/case) of the CAD system were also compared among all protocols by means of McNemar's test or signed rank test.
Results: Although there were no significant difference of false-positive rate among all protocols, sensitivities of RDCT and ULDCT with AIDR 3D (RDCT:

72.3%, ULDCT: 66.3%) were significantly higher than that without AIDR 3D (RDCT: 56.4%, p<0.0001; ULDCT: 35.6%, p<0.0001). Sensitivity of SDCT with and without AIDR 3D (with AIDR 3D: 73.3%, without AIDR 3D: 76.2%) were significantly higher than that of RDCT without AIDR 3D (p<0.0001) and ULDCT with and without AIDR 3D (p<0.0001).
Conclusion: Iterative reconstruction method is useful for improving nodule detection performance on a 3D CAD system at reduced- and ultra-low-dose CTs as compared with filtered-back projection method.

B-0398 11:18

Effect of detectability of pulmonary nodules with lowering dose based on nodule size, type and body mass index with different iterative reconstruction algorithms

V. Vardhanabhuti[1], C.-L. Pang[2], S. Tenant[2], J. Taylor[2], C.J. Hyde[3], C.A. Roobottom[2]; [1]*Hong Kong/HK*, [2]*Plymouth/UK*, [3]*Exeter/UK*

Purpose: To determine the diagnostic accuracy of lung nodule detection in thoracic CT using 2 reduced-dose protocols comparing 3 available CT reconstruction algorithms (filtered back projection-FBP, adaptive statistical reconstruction-ASIR and model-based iterative reconstruction-MBIR) in a western population.
Methods and Materials: A prospective single-center IRB-approved study recruited 98 patients with written consent. Standard-dose (STD) thoracic CT followed by 2 reduced-dose protocols using automatic tube current modulation (RD1) and fixed tube current (RD2) were performed and reconstructed with FBP, ASIR and MBIR with subsequent diagnostic accuracy analysis for nodule detection.
Results: 108 solid nodules, 47 subsolid nodules and 89 purely calcified nodules were analysed. RD1 was superior to RD2 for assessment of solid nodules ≤4mm, and subsolid nodules ≤5mm. Deterioration of RD2 is correlated to patient's body mass index and least affected by MBIR. For solid nodules ≤4mm, MBIR area under curve (AUC) for RD1 was 0.935/0.913 and AUC for RD2 was 0.739/0.739, for rater 1/rater2 respectively. For subsolid nodules ≤5mm, MBIR AUC for RD1 was 0.971/0.986 and AUC for RD2 was 0.914/0.914, for rater 1/rater2 respectively. For calcified nodules excellent detection accuracy was maintained regardless of reconstruction algorithms with AUC >0.97 for both readers across all dose and reconstruction algorithms.
Conclusion: Diagnostic performance of lung nodule is affected by nodule size, protocol, reconstruction algorithm and patient's body habitus. The protocol in this study showed that RD1 was superior to RD2 for assessment of solid nodules ≤4mm, and subsolid nodules ≤5mm and deterioration of RD2 is related to patient's body mass index.

B-0399 11:26

Influence of reconstruction methods to measurement accuracy for computer-aided volumetry (CADv) at standard-, reduced-, low-dose and ultra-low-dose CT in QIBA phantom study

T. Sekitani[1], E. Suehiro[1], N. Negi[1], K. Fujii[2], Y. Fujisawa[2], N. Sugihara[2], K. Aoyagi[2], T. Yoshikawa[1], Y. Ohno[1]; [1]*Kobe/JP*, [2]*Otawara/JP (atieinks-toshi@nifty.com)*

Purpose: To directly compare the capability of three reconstruction methods using forward projected model-based iterative reconstruction (FIRST), adaptive iterative dose reduction using 3D processing (AIDR 3D) and filtered back projection (FBP) for radiation dose reduction and accuracy of computer-aided volumetry (CADv) measurements on chest CT examination in the QIBA recommended phantom study.
Methods and Materials: An thoracic phantom with 30 simulated nodules of three density types (100, -630, and -800 HU) and five different diameters was scanned with an area-detector CT at tube currents of 270, 80, 40, 20, and 10 mA. Each scanned data was reconstructed with three methods. CT value and image noise were measured, and compared among three reconstruction methods at each tube current by Tukey's HSD test. For comparison of the capability for CADv at each tube current, Tukey's HSD test was used to compare the percentage of absolute measurement errors for three reconstruction methods.
Results: Image noises of FIRST and AIDR 3D for each nodule type were significantly lower than that of FBP at each tube current (p<0.05). In addition, image noises of FIRST were significantly lower than that of AIDR 3D at all tube currents except 270mA (p<0.05). Mean absolute measurement errors of AIDR 3D and FIRST for each nodule type were significantly lower than those of the FBP method at 20mA and 10mA (p<0.05).
Conclusion: FIRST and AIDR 3D methods are more effective than the FBP method for radiation dose reduction, while yielding better measurement accuracy of CADv for chest CT examination.

B-0400 11:34

Effect of image reconstruction with ADMIRE in low-dose and ultra-low-dose CT volumetry of solid pulmonary nodules: a phantom study

M. Eberhard, D. Stocker, T. Nguyen-Kim, M. Wurnig, T. Frauenfelder, S. Baumüller; *Zurich/CH (matthias.eberhard@usz.ch)*

Purpose: To investigate the influence of ultra-low-dose CT and iterative reconstruction with ADMIRE on volumetry of solid lung nodules.
Methods and Materials: CT scans were obtained with third-generation dual-source CT at standard dose, 1/8, 1/20 and 1/70 of standard dose using an anthropomorphic chest phantom containing solid microspheres (4-10mm). An extension ring was used for different phantom sizes (M, L). Image reconstruction was performed with FBP, ADMIRE3 and 5. Three oberservers independently measured nodule volumes semi-automatically. Relative percentage error (RPE) was computed to evaluate measurement accuracy. To assess influence of various parameters on RPE univariate ANOVA with post hoc Bonferroni-Test was applied. P<.05 was considered significant.
Results: Intra-class correlation coefficient for RPE between observers was 0.862 (95%CI: 0.838-0.883). Phantom size, nodule diameter, CT dose protocol and reconstruction algorithm significantly contributed to RPE (all p<.001). Underestimation of mean nodule volume among all dose protocols was -5.3±6.0% with ADMIRE3,-7.0±5.6% with ADMIRE5, and-2.7±8.5% with FBP (all p<.001). Overall scanning with 1/70 dose protocol showed higher underestimation of mean volume (-7.3±10.3%) compared with standard dose (-4.1±4.0%), 1/8 (-4.6±4.3%) and 1/20 (-4.1±7.3%) dose (all p<.001). There were no significant differences between other dose values. Overall volume underestimation was highest in 6mm nodules (-10.3±5.4%), compared to 4 (-1.3±10.3%), 8 (-3.2±2.8%) and 10mm (-4.7±1.9%) nodules. Phantom size L (-5.8±7.9%) showed significant lower overall mean RPE compared to size M (-4.2±6.0%; p<.001).
Conclusion: Our study indicates that image reconstruction with ADMIRE3 and 5 and scanning with 1/70 dose leads to little but significant underestimation of solid nodule volume.

B-0401 11:42

Comparison of the effect of model-based iterative reconstruction (MBIR) and filtered back projection (FBP) algorithms on software measurements in pulmonary ground-glass nodules

J.G. Cohen[1], H. Kim[2], S. Park[2], B. Van Ginneken[3], C. Lee[2], J. Goo[2], C. Park[2]; [1]*Grenoble/FR*, [2]*Seoul/KR*, [3]*Nijmegen/NL (jcohen@chu-grenoble.fr)*

Purpose: To evaluate the differences between filtered-back-projection (FBP) and model-based iterative reconstruction (MBIR) algorithms on semi-automatic measurements in subsolid nodules (SSNs).
Methods and Materials: Unenhanced CT-scans of 73 SSNs obtained using the same protocol and reconstructed with both FBP and MBIR algorithms were evaluated by two radiologists. Diameter, mean-attenuation, mass, and volume of whole nodules and its solid components were measured. Intra-, inter-observer variability and differences between FBP and MBIR were then evaluated using Bland-Altman method and Wilcoxon tests.
Results: Longest diameter, volume and mass of nodules and those of its solid component were significantly higher using MBIR (p<0.05) with mean differences of 1.1% (limits of agreement, -6.4 to 8.5%), 3.2% (-20.5 to 27%), 3.2% (-20.9 to 27.3%), 6.3% (-51.9 to 64.6%), 2.9% (-16.9 to 22.7%), and 6,6% (-50.1 to 63.3%), respectively. The limits of agreement between FBP and MBIR were within the range of intra- and inter-observer variability for both algorithms with respect to the diameter, volume and mass of nodules and its solid components. There were no significant differences in intra- or inter-observer variability between FBP and MBIR (p>0.05).
Conclusion: Semi-automatic measurements of SSNs significantly differed between FBP and MBIR, however, the differences were within the range of measurement variability.

B-0402 11:50

Deep learning applied to automated chest x-ray screening

B. Fos Guarinos[1], A. Alberich-Bayarri[2], A. Ten-Esteve[2], I. Bosch-Roig[2], L. Martí-Bonmatí[2]; [1]*Sueca/ES*, [2]*Valencia/ES (befogua@etsii.upv.es)*

Purpose: One of the most performed examinations by radiologists is chest radiography, providing information of important anatomical structures of the body. Reporting chest x-rays is a demanding task and very important medical-legally, sometimes neglected. The aim is setting up a screening tool for giving priority to the abnormal radiographs and facilitate the reporting task. New techniques based on artificial intelligence have emerged (field of computer vision). We propose to use deep learning (convolutional neural networks, CNN) in a computer-aided diagnostic (CAD) system to help radiologists to perform automated screening of chest radiographs.
Methods and Materials: A database of chest x-ray images (7470) from the Indiana University was used for the study. A subset of cases was selected consisting of 2242 A-P, divided into different groups (abnormal, cardiomegaly, nodule, opacity, atelectasis, pleural effusion, each one versus normal). The AlexNet CNN (pretrained with ImageNet) was implemented to extract features from the different groups needed to train binary support vector machine classifiers. An NVIDIA Tesla K40 GPU was used to optimize the computing performance.
Results: A software tool was successfully implemented obtaining an area under curve (AUC) of 0.86 for abnormal, 0.91 for cardiomegaly, 0.92 for pleural effusion, 0.70 for nodule, 0.90 for atelectasis group and 0.86 for opacity.
Conclusion: Using a pretrained CNN as an automatic feature extractor for training an SVM classifier is a good approach to get relevant results in chest x-ray screening tasks.

Sarcopenia assessed using preoperative CT-scans as a predictor of postoperative complications following radical cystectomy

B.J.U. Hensen[1], M. Kramer[2], M. Jansen[1], M. Hennig[2], M. Hupe[2], H. Tezval[1], M. Kuczyk[1], A. Merseburger[2], F. Wacker[1]; [1]*Hannover/DE*, [2]*Lübeck/DE (hensen.bennet@mh-hannover.de)*

Purpose: Urothelial carcinoma is usually treated with radical cystectomy (RC). However, patients face a relevant risk of postoperative complications on variable factors. Recent reports described that sarcopenia, which is defined by a loss of sceletal muscle body composition may enhance risk stratification.
Methods and Materials: Our retrospective study includes 200 patients (154 men, 46 women, mean age: 68 years) which were treated with RC (2005-2014). Median follow-up time was 26 months. Computed tomography (CT) scans were performed within 60 days prior to surgery. Skeletal muscle index (SMI) were measured with MeVisLab 2.7 by manually segmentation of preoperative CTs. The fat mass index (FMI) was calculated based on the same CT slides. Cut off points were developed for men and women separately. Additionally, complications were assessed using the Clavien-Dindo-Classification.
Results: SMI (cm^2/m^2), FMI (kg/m^2) and BMI (kg/m^2) for men were calculated with median scores of 50.6, 9.7 and 26.8, respectively. The corresponding calculated means for women were 38.6, 9.2 and 24.8. The SMI for mid-term complications (<Grade IIIa) were statistically significant (p = 0.017).
Conclusion: The presence of sarcopenia may improve risk stratification in patients undergoing radical cystectomy. BMI and FMI may not be used in risk stratification models. Further research is needed to validate the current findings. Noninvasive and semiautomatic calculation of SMI in preoperative CT scans may improve risk stratification in patients undergoing radical cystectomy and thus could reduce mortality.

B-0404 10:38

Stiffness of benign and malignant prostate tissue measured by shear-wave elastography

O. Rouviere[1], C. Melodelima[2], A. Hoang-Dinh[1], F. Bratan[1], G. Pagnoux[1], T. Sanzalone[1], S. Crouzet[1], M. Colombel[1], F. Mège-Lechevallier[1], R. Souchon[1]; [1]*Lyon/FR*, [2]*Grenoble/FR (olivier.rouviere@netcourrier.com)*

Purpose: To measure benign and malignant prostate tissue stiffness using shear-wave elastography (SWE).
Methods and Materials: Thirty consecutive patients underwent transrectal SWE in axial and sagittal planes before prostatectomy. After reviewing prostatectomy specimens, two radiologists measured stiffness in regions corresponding to cancers, lateral and median benign peripheral zone (PZ) and benign transition zone (TZ).
Results: Cancers were stiffer than benign PZ and TZ. All tissue classes were stiffer on sagittal than on axial imaging, in TZ than in PZ, and in median PZ than in lateral PZ. At multivariate analysis, the nature of tissue (benign or malignant; P<0.00001), the imaging plane (axial or sagittal; P<0.00001) and the location within the prostate (TZ, median PZ or lateral PZ; P=0.0065) significantly and independently influenced tissue stiffness. On axial images, the thresholds maximizing the Youden index in TZ, lateral PZ and median PZ were respectively 61.5 kPa, 32.8 kPa and 48.9 kPa. On sagittal images, the thresholds were 76.4 kPa, 49.5 kPa and 72.4 kPa, respectively.
Conclusion: SWE can distinguish prostate malignant and benign tissues. Tissue stiffness is influenced by the imaging plane and the location within the gland.

B-0405 10:46

Chronic prostatitis: retrospective cohort-study of persistence of signs on T2-weighted MR-images

U.G. Mueller-Lisse[1], M.K. Scherr[2], U.L. Mueller-Lisse[1], A. Meister[1], M.F. Reiser[1], M. Kuhn[1]; [1]*Munich/DE*, [2]*Murnau am Staffelsee/DE (ullrich.mueller-lisse@med.uni-muenchen.de)*

Purpose: Chronic prostatitis may elevate prostate-specific-antigen-levels (PSA) in patients with negative prostate-biopsy (NBX) and show at T2-weighted MR-imaging (T2WI) with diffusely-low (DLSI), focally-non-nodular-low (FLSI), nodular-low (NLSI), or unremarkable signal-intensity (UNSI). Persistence of T2WI-signs of chronic prostatitis was analysed in a retrospective cohort from a prospective data-base.
Methods and Materials: With ethics-committee-approval, 19 patients with prior prostate-MR-examinations 3.7+/-2.7 years ago (average+/-standard-deviation) showing signs of chronic prostatitis, age, 63.7+/-7.4 years, PSA, 9.4+/-2.6 ng/ml, median 2 NBX (range, 1-5), median 12 samples/NBX (2-20), without previous prostate-therapy except for antibiotics, were identified in a prospective database of 210 prostate-MR-examinations. All current and 4/19 prior MR-examinations were at 3.0T with multi-channel-surface-coils; 15/19 prior MR-examinations were at 1.5T with phased-array/endorectal-coil-systems. Presence and temporal/spatial persistence of DLSI, FLSI, NLSI, and UNSI on T2WI were compared in peripheral-zone-(PZ)-regions and central-zone-(CZ)-regions, applying the PI-RADSv2-39-region-prostate-scheme. McNemar's-chi-square-test was significant for p<0.05 in two-by-two-tables (first-second T2WIs, changed-unchanged); Cohen's kappa was substantial >0.60.
Results: DLSI persisted in 194/225 (86%) and newly developed in 41/113 regions (36%, chi-square, 1.125, 0.25<p<0.50, agreement, 79%, kappa 0.51), FLSI in 34/51 (67%), new in 15/287 (5%, 0.0313, p>0.5, 91%, 0.62), NLSI in 0/1, new in 3/337 (1%, 0.25, p>0.5, 98.8%, 0), and UNSI in 34/61 (56%), new in 17/277 (6%, 2.0511, 0.1<p<0.25, 87%, 0.53). Four CZ-regions were non-evaluable.
Conclusion: DLSI appears to be the most frequent, most persistent, and most often newly-developing sign of chronic prostatitis at T2WI. Both FLSI and UNSI appear to decrease insignificantly over time, while NLSI appears to be an infrequent finding.

B-0406 10:54

Interobserver agreement in the volumetric assessment of peri-prostatic fat, a marker of prostate tumour aggressiveness

D. Nörenberg[1], C. Kelly-Morland[2], V. Goh[2], G. Cook[2], D. Cahill[2]; [1]*Munich/DE*, [2]*London/UK (dominik.noerenberg@med.uni-muenchen.de)*

Purpose: Previous studies have shown peri-prostatic fat volume is associated with prostate cancer Gleason score and outcome. This study aimed to assess the inter-reader reliability of measurements of peri-prostatic fat volume.
Methods and Materials: The pelvic MRI scans of 100 men (mean age 60 (41-75)) with prostate cancer who subsequently underwent a robotically assisted radical prostatectomy were reviewed. The following measurements were performed by two independent radiologists with 6 and 3 years of pelvic MRI experience; the peri-prostatic fat volume (PPFV), ischio-anal fossa fat volume (IAFV), anterior prostatic fat depth (APFD), subcutaneous fat depth (SCFD)

and prostate volume (PV).Intra-class correlation coefficients (ICCintra) and Bland-Altman analysis were performed.
Results: ICC results showed substantial agreement for PPFV 0.61 (0.42-0.74) and IAFV 0.72 (0.62-0.8) excellent for SCFD 0.87 (0.79-0.91) and PV 0.94 (0.88-0.96) and moderate for APFD 0.48 (0.32-0.62).
Conclusion: Excellent or substantial agreement was found for all parameters with the exception of the anterior prostatic fat depth indicating assessment of peri-prostatic fat is reproducible.

B-0407 11:02

Effectiveness of intramuscular hyoscine butylbromine compared with intravenous administration in improving image quality in pelvic MRI

M.B. Taylor, A. Kilburn, L. McDaid, C. Shepherd, D. Ryder, S. Bonington, B. Carrington; *Manchester/UK (ben.taylor@christie.nhs.uk)*

Purpose: To determine whether intramuscular (IM) hyoscine butylbromide (HBB) is as effective as intravenous (IV) HBB in reducing movement artefact during pelvic MRI.
Methods and Materials: Institutional ethical approval and patient consent were obtained. 321 patients attending for pelvic MRI on 400 occasions were recruited to this prospective study. At each attendance the patient was randomised to receive 20 mg HBB either IM or IV. T2-weighted image series were anonymised and assessed for image quality (IQ) and lesion visualisation using a 4 point scale by 3 radiologists blinded to the route of injection. The primary aim was demonstration of similar proportions of median IQ scores for the 3 observers of 3 or 4 (slight or no artefact) for both sagittal and transverse series between the IM and IV groups. A one tail non inferiority test with an inferiority margin (IM-IV) of -10% was used.
Results: There were 385 attendances included in the analysis (15 examinations not completed to protocol). Non-inferiority of IM was demonstrated with 169/194 (87.1%) having both IQ scores of 3 or 4 in the IM arm compared to 165/191 (86.4%) in the IV arm (point estimate for the difference (IM - IV) of 0.7% with 95% CI (-6.0%, 7.5%) (p=0.001). Interobserver agreement for image scoring was fair to moderate (k=0.383-0.537).
Conclusion: IM HBB is as effective as IV injection in reducing movement artefact in pelvic MRI. IM HBB may be preferred as an antiperistaltic in pelvic MRI due to patient preference and ease of administration.

B-0408 11:10

Effect of hyoscine butylbromide on prostate multiparametric MRI anatomical and functional image quality

I. Caglic[1], N. L. Hansen[2], A. J. Patterson[1], T. Barrett[1]; [1]*Cambridge/UK*, [2]*Aachen/DE (iztokcaglic@gmail.com)*

Purpose: To evaluate the effect of the spasmolytic agent hyoscine butylbromide (HBB) on the quality of anatomical and functional prostate multiparametric (mp) MRI.
Methods and Materials: 87 patients received 20mg intravenous hyoscine butylbromide (HBB group), 86 patients did not (non-HBB group) in this retrospective study. 3T-MRI was performed using a 32-channel body coil. Quality of T2WI, diffusion-weighted imaging (DWI) and ADC maps, was evaluated using a 5-point Likert scale. DWI was further assessed for distortion and artefact, and T2WI for motion or blurring. Dynamic contrast-enhanced (DCE) sequences were assessed by recording the number of corrupt data-points on the contrast curve.
Results: HBB group T2W image quality was significantly higher than the non-HBB group (3.63±1.11 versus 2.84±0.899); p<0.001. The HBB group showed significantly less T2W motion and blur than the non-HBB group (23.0% and 51.7% versus 53.5% and 83.7%, respectively; p<0.001). However, there was no significant improvement in DWI/ADC image quality, distortion or artefact. There was a trend towards fewer corrupted DCE data points in the HBB group (2.47±2.44 versus 3.68±2.64), but this did not reach significance (p=0.052). Substantial inter-reader agreements were achieved for T2W Image Quality (k=0.670), DWI distortion (0.741) and ADC Image Quality (0.630). Agreements for T2W Motion (k=0.514), DWI image quality (0.441) and DWI artefact (0.427) were moderate, agreement for T2W Blur was fair (0,341).
Conclusion: Administration of HBB significantly improves the image quality of T2-weighted images. These results provide evidence for the use of HBB in routine patient preparation prior to prostate mpMRI.

B-0409 11:18

Screening of prostate cancer by means of fast MR protocol: feasibility study

G. Foti, E. Demozzi, F. Cavicchioli, A. Molinari, S. Cavalleri, G. Carbognin; *Negrar/IT (gfoti81@yahoo.it)*

Purpose: To compare diagnostic accuracy of different magnetic resonance (MR) protocols in diagnosing prostate tumour.
Methods and Materials: Multiparametric MR (mpMR) of 185 consecutive patients (mean age 62.3 years) with elevated serum level of prostate-specific antigen (PSA) studied with 1.5 Tesla scanner were retrospectively reviewed by two experienced radiologists. Four reading sessions separated by 1 month gap were performed, starting by reading only axial T2+DWI (PR-1), and progressively including coronal and sagittal T2 (PR-2), pre-contrast T1 (PR-3) and dynamic contrast-enhanced sequences (PR-4), respectively. Sensitivity (se), specificity (sp) and accuracy (acc) values in diagnosing prostate cancer were assessed using radical prostatectomy as reference standard and compared by using Mc-Nemar test, A value of p<0.05 was considered statistically significant. Inter-observer variability was calculated by using k-statistics.
Results: At pathology, prostate cancer was diagnosed in 115/185 patients (mean size index lesion 12 mm). Best accuracy was achieved by reading PR-4 for reader 1 and 2 (se 85.2% and 83.4%, sp 87.1% and 84.2%, acc 85.9% and 83.7%, respectively). For both readers, accuracy did not drop significantly by reading PR-3 (se 83.4% and 83.4%, sp 85.7% and 83.4%, acc 84.3% and 83.2%, respectively), PR-2 (se 83.4% and 82.6%, sp 82.8% and 81.4%, acc 83.2% and 82.1%, respectively) and PR-1 (se 82.6% and 80.9%, sp 81.4% and 77.1%, acc 82.2% and 79.4%, respectively). Inter-observer variability was excellent (k=0.92).
Conclusion: Fast PR-1 MR protocol did not give significant drop in overall accuracy if compared to mp-MR protocol (p<0.05).

B-0410 11:26

Multiparametric magnetic resonance imaging of the canine prostate gland as an animal model prior to MRgFUS

K. Lorenc, K. Skierbiszewska, T. Jasinski, K. Siewruk, Z. Gajewski; *Warsaw/PL (kamil_lorenc@sggw.pl)*

Purpose: Multiparametric magnetic resonance imaging (mp-MRI) is an evolving technique used in the diagnostic protocol for prostate cancer (PCa) detection, localisation, risk stratification and staging of clinically significant prostate cancers in humans. It has also opened up opportunities for focal treatment of PCa. PCa in dogs and humans share similar features: extracapsular extension, pulmonary and bone metastases, as well as are diagnosed at later age. Wherefore, dogs are used as a pre-clinical, animal model for PCa diagnosis and therapy management. The aim of the study was to create and apply an mp-MRI protocol for PCa imaging in dogs based on the PI-RADS™ v2 human protocol and its implementation on a 3.0T MR scanner before future ablation procedures (MRgFUS).
Methods and Materials: 10 male dogs, age 4-14, with confirmed prostatic gland pathologies with ultrasound examination were enrolled into the study. Anaesthetised dogs were positioned (prone, feet first) on the MRI table. Protocols were validated with MR imaging on clinical scanner discovery MR750w 3.0T, coils GEM anterior array and GEM large flex depending on canine size.
Results: Final protocol consisted of: T1WI axial FSE, T2WI sagittal FRFSE, T2WI axial FRFSE, T2WI coronal FRFSE, DWI focus axial: b-value 0, 50, 200, 800 s/mm^2.
Conclusion: MRI examination including mp-MRI in canine model is challenging due to a small field of view and thin slices, which increases scan time, distortion, and noise level. Canine model is particularly useful for the study of diagnostic and therapeutic methods used in PCa in humans.

B-0411 11:34

Comparison of the Likert score and a quantitative model in characterising prostate focal lesions on pre-biopsy multiparametric MRI

A. Hoang-Dinh[1], R. Souchon[1], C. Melodelima[2], F. Bratan[1], F. Mège-Lechevallier[1], A. Ruffion[3], S. Crouzet[1], M. Colombel[1], O. Rouviere[1]; [1]*Lyon/FR*, [2]*Grenoble/FR*, [3]*Pierre Bénite/FR (olivier.rouviere@netcourrier.com)*

Purpose: To assess in patients referred for pre-biopsy multiparametric MRI (mpMRI) a quantitative model trained at characterising Gleason ≥7 cancers.
Methods and Materials: We trained a model combining the 10th percentile of ADC and the time-to-peak for distinguishing Gleason ≥7 cancers in 106 retrospectively-selected patients treated by prostatectomy who had pre-operative 3T mpMRI (T2-weighted, diffusion-weighted and Dynamic Contrast-enhanced imaging) on a General Electric (n=72) or a Philips (n=34) scanner.Then, we prospectively selected 131 consecutive patients referred for prostate biopsy who had pre-biopsy mpMRI on the same GE (n=108) or Philips (n=23) scanners. The uroradiologist performing the biopsy prospectively assigned a 5-level Likert score of suspicion to each targeted lesion (cognitive guidance). The model was then used to estimate the probability the lesion was a Gleason ≥7 cancer.
Results: Using targeted biopsy as reference, the model outperformed the Likert score at per-patient (AUC=0.94 [95% confidence interval (CI): 0.90-0.98] versus AUC=0.81 [(CI): 0.75-0.88]; p=0.0002), per-lobe (AUC=0.90 [CI: 0.84-0.95] versus AUC=0.84 [CI: 0.78-0.89]; p=0.015) and per-lesion (AUC=0.88 [CI: 0.83-0.93] versus AUC=0.80 [CI: 0.74-0.86]; p=0.01) analysis. The model significantly outperformed the Likert score at the three levels of analysis for PZ lesions and for radiologists with <1 year of experience, and at per-patient analysis for radiologists with >1 year of experience. It was outperformed by the Likert score in the 15 patients with suspicious lesions of the transition zone.

Conclusion: The quantitative model outperformed the Likert score in PZ lesions. This approach may help less experienced readers characterising focal lesions seen on mpMRI.

B-0412 11:42

T2 correlated PSA density

K. Ozturk, Y. Kordan, G. Savci; *Bursa/TR (keremov54@hotmail.com)*

Purpose: To evaluate the value of new tool such as T2-correlated PSA (prostate specific antigen) density (T2-correlated PSAD) in detecting prostate cancer (PCa) on 3-Tesla magnetic resonance (MR) system.
Methods and Materials: Eighty-five patients with a negative DRE and PSA level between 4-20 ng/ml suspected for PCa underwent TRUS-guided cognitive biopsies with the result of multiparametric-MRI including T2-Weighted (T2-WI), diffusion weighted, and spectroscopy imaging. Total volume and mean signal intensity of the prostate gland were determined in axial T2-WI. PSAD was obtained by dividing serum PSA level to the prostate volume. Mean T2 signal intensity of the prostate gland was adjusted with signal intensity of internal obturator muscle. T2-Weighted PSAD was calculated by multiplying PSAD with the mean T2 signal intensity of the prostate gland. Accuracy of PSAD and T2-correlated PSAD were analyzed using the receiver operating characteristic curve while relationship between two method was assessed using the un-paired t-test.
Results: PCa was detected in 12 patients (14%) with TRUS biopsies. The positive predictive value of PSAD with cut-off level of 0.12 ng/mL/cm and T2-correlated PSAD with cut-off level of 0,023 ng/ml/cm for detection of PCa were found to be 28% and 39%, respectively. The performance of T2-correlated PSAD was better than that of PSAD alone (P<0.01).
Conclusion: In patients who have negative DRE and PSA levels between 4-20 ng/ml, the application of T2-correlated PSAD would have prevent 63% of patients from an unnecessary biopsy, without missing any PCa. T2-correlated PSAD is better indicator of detecting PCa compare to PSAD.

B-0413 11:50

Efficacy of PSA density for predicting prostate cancer utilising volumes from mpMRI and TRUS

A. Ushinsky, S. Fardin, M. Nguyentat, C. Green, E. Uchio, C. Lall, T.B. Nguyen, R. Houshyar; *Orange, CA/US (tbnguyen@uci.edu)*

Purpose: To compare the efficacy of prostate-specific antigen (PSA) density based on prostate volume from mpMRI versus transrectal ultrasound (TRUS).
Methods and Materials: We retrospectively reviewed 137 patients who underwent prostate mpMRI and subsequent MRI/TRUS fusion biopsy. For each patient, MRI prostate volume was estimated using measurement technique per PI-RADS version 2, and US prostate volumes were obtained during fusion biopsy. Two PSA densities were then calculated by dividing serum PSA concentration by prostate volume using each modality. MRI-based and US-based PSA densities were compared using paired and independent T test. The classification function was evaluated with ROC analysis, and then areas under the curves (AUCs) were compared.
Results: Based on histopathology, 53 patients had clinically significant prostate cancer (Gleason score ≥ 7) and 84 patients had non-clinically significant cancer. PSA density was significantly higher in patients identified with clinically significant cancer versus non-clinically significant cancer when calculated with both MRI (0.22 vs 0.12, p=0.001) and US (0.19 vs 0.12, p=0.001). MRI-based versus US-based PSA density was not statistically different in patients with clinically significant cancer (p= 0.057) nor in those with non-clinically significant cancer (p= 0.439). Also, the AUCs were not statistically different (0.681 vs. 0.671, P= 0.87) between the two methods of PSA density in diagnosing clinically significant cancer.
Conclusion: These results suggest that US and MRI-based PSA density calculations are not significantly different and the two modalities' estimates of prostate volume are consistent. Therefore, PSA density calculations may likely be performed with either US or MRI.

Radiomics of primary staging diffusion-weighted MRI to predict neoadjuvant treatment response in rectal cancer

J.J.M. van Griethuysen[1], S. Trebeschi[1], D.M.J. Lambregts[1], M.J. Lahaye[1], F.C.H. Bakers[2], R.F.A. Vliegen[3], E. Voest[1], R.G.H. Beets-Tan[1], H.J.W.L. Aerts[4]; [1]*Amsterdam/NL*, [2]*Maastricht/NL*, [3]*Heerlen/NL*, [4]*Boston, MA/US (j.v.griethuysen@nki.nl)*

Purpose: Assessing robust radiomics signature of rectal carcinoma most likely to respond to neoadjuvant chemoradiation (nCRT).
Methods and Materials: We assessed primary staging (pre-treatment) diffusion-weighted MRI scans (b-values 0-1000/1100) of 140 patients with locally advanced rectal carcinoma, treated with nCRT. Tumours were semi-automatically segmented on b1000-DWI by a region-growing algorithm and then manually adapted by 4 readers (2 expert; 2 non-expert), adding to a total of 5 segmentations. Radiomics features were extracted from these segmentations. Feature stability was assessed using the intraclass correlation coefficient (ICC) across different readers/segmentations. Predictive performance to distinguish between complete tumour regression and residual tumour was assessed by ROC-curve analysis with False Detection Rate (FDR) 10%.
Results: 112 features were identified, of which 1010 were stable across readers (ICC ≥0.75, mean 0.82, range 0.76-0.88). For the manually-adjusted delineations 129/1129 features per reader showed significant performance after FDR-correction, however, none of these remained significant after FDR-correction for the semi-automated segmentation. A final subset of 60 features remained stable and performant across all readers. These 60 features resulted in a mean AUC of 0.67 (range 0.65-0.69) to predict a complete response and a mean ICC of 0.83 (range 0.73-0.88).
Conclusion: Robust radiomics features exist that can aid in predicting a complete tumour response to nCRT. Features extracted from semi-automated segmentation show inferior performance compared to features extracted from manually adjusted segmentations, emphasising the need for adequate tumour segmentation. Interestingly, delineations by inexperienced and experienced readers showed comparable results, suggesting that highly expert input is not required.

B-0415 10:47

T2-weighted MR image registration of rectal tumours and mesorectum during radiotherapy

A. Bani Yassien[1], G. Ghobadi[2], M. Staring[2], B. van Triest[1], D.M. Lambregts[1], A. Betgen[1], C.A.M. Marijnen[2], U.A. van der Heide[1]; [1]*Amsterdam/NL*, [2]*Leiden/NL (a.baniyassien@nki.nl)*

Purpose: To monitor tumour changes in rectal cancer patients undergoing sequential MRI during radiotherapy, deformable image registration (DIR) is required. However, applying DIR may result in unrealistic tissues expansion or folding, particularly in the case of tumour shrinkage. We developed and evaluated two registration approaches of T2-weighted (T2W) MRI for spatial mapping of tumour and mesorectum.
Methods and Materials: Thirteen patients received weekly repeated T2W-MRI (3T) for five weeks (n=62 scans). Both approaches were implemented in Elastix, using a B-splines transformation and mutual information as a similarity metric. For registration of non-tumour structures in the mesorectum manually selected landmarks and/or rectum contours were utilized to refine the registration when needed. For tumour mapping, the transit point from tumour to normal rectum wall was used for tumour alignment assuming tumour volume preservation.
Results: Registration of non-tumour structures resulted in average dice similarity coefficient (DSC) of 90±6% and mean surface distance (MSD) of 1.53±0.48 mm between mesorectum segmentations. Refinement using landmarks was required for one patient improving MSD and DSC, from 18.0 to 1.27 mm and 62% to 96% respectively. Refinement using rectum contours was required for another patient improving MSD form 3.0 to 2.7 mm. Tumour mapping resulted in satisfactory alignment when evaluated visually. For an

average-sized tumour (~30cc) with 44% volume shrinkage MSD was 1.5 mm between rectum delineations.
Conclusion: We obtained accurate registrations between T2W-MRIs over time within the mesorectum. This can be used for monitoring tumour response and toxicity of normal tissue in radiotherapy of rectal tumours.

B-0416 10:55

Pathological complete responders after chemoradiotherapy in rectal cancer, what can be learned from imaging for the selection?
M. Maas[1], M. van der Sande[1], B. Hupkens[2], M. Martens[3], D. Lambregts[1], S. Breukink[2], F. Bakers[2], G. Beets[1], R.G.H. Beets-Tan[1]; [1]*Amsterdam/NL*, [2]*Maastricht/NL*, [3]*Sittard/NL (moniquemaas@live.nl)*

Purpose: Many complete responders(CRs) after CRT for rectal cancer are missed, leading to overtreatment of CRs.Aim is to assess what can be learned from operated pathological CRs who were missed on post-CRT MRI+DWI+endoscopy.
Methods and Materials: Patients with a pCR after CRT and surgery were retrospectively selected.The MRI+DWI+endoscopy were re-evaluated by expert readers (MRI: radiologist and endoscopy: surgeon) who scored likelihood for CR by following updated (according to current knowledge) selection criteria for a CR.Patients were categorised into groups:(1) residual tumour at reassessment and (2) (near) CR.Several other imaging parameters about the primary tumour, volume and morphology/aspect were assessed.At endoscopy aspect of the scar (normal/ulcer/polyploid) was noted.
Results: 32 patients were included with a pCR after surgery.Main reason for missing CR were heterogeneous T2W-MRI signal, residual focal/massive diffusion-restriction, massive fibrosis ycN+ disease and residual mucosal lesions at endoscopy.In distal rectal tumours CRs are more easily missed.20/32 (63%) were deemed to have residual tumour (non-CR group), the remaining 12 (37%) had (near) CR (CR group).In the non-CR group heterogeneous signal on T2W-MRI was present more often than in the CR group (75% vs 25%,p=0.01), just as massive/spicular fibrosis (90% vs 58%,p=0.07) and residual diffusion restriction (58% vs 27%,p=0.11). Nodes were scored false positive in 7/32 patients, mostly due to irregular morphology.
Conclusion: Reasons for missing a CR after CRT are heterogeneous T2W-MRI signal, massive/spicular fibrosis, residual focal/massive diffusion-restriction, ycN+ disease, residual mucosal lesions at endoscopy and distal tumour. Knowledge about these features can help improve selection of patients for a watch-and-wait strategy.

B-0417 11:03

Nodal staging in complete responders (ypT0) after CRT for rectal cancer, how can we better select the ypN0 patients for organ preservation?
M. Maas[1], M. van der Sande[1], B. Hupkens[2], M. Martens[3], D. Lambregts[1], F. Bakers[2], S. Breukink[2], G. Beets[1], R.G.H. Beets-Tan[1]; [1]*Amsterdam/NL*, [2]*Maastricht/NL*, [3]*Sittard/NL (moniquemaas@live.nl)*

Purpose: To evaluate nodal staging accuracy and identify factors that might improve nodal staging in patients with ypT0 after CRT.
Methods and Materials: 42 patients with ypT0 after surgery were identified. Nodes were re-evaluated by one expert reader, who scored a confidence level for likelihood of residual N+ disease and described the morphology of the nodes after CRT. Diagnostic performance was assessed by ROC curves and area under the curve (AUC). Differences between pN+ and pN0 patients and between incorrectly staged patients and correctly staged patients were assessed.
Results: Nine patients had ypT0N+ disease, the remaining 33 had ypT0N0. AUC for nodal staging was 0.91 (0.81-1.00). Sensitivity was 100%; specificity was 75%, PPV was 53%, NPV was 100%. 8 patients were overstaged, of which 7 had irregular nodal morphology. Of the 9 patients with ypN+ disease 6 had irregular nodes. All patients with normalised nodes (n=10) were ypN0.
Conclusion: Nodal staging in the subset of patients with a complete response (ypT0) after CRT is more accurate than nodal staging in the general post-CRT population. No residual ypN+ disease was missed but overstaging was found in almost 50%, mostly due to the irreliable feature of irregular morphology. Irregular morphology was encountered in almost all patients with ypN0, but also in 67% of patients with ypN+ disease. Normalisation of nodes was associated with ypN0 in 100%.

B-0418 11:11

Evaluation of rectal cancer response to therapy: role of MR-tumour regression grade to predict pathological complete response
S. Picchia[1], M. Rengo[2], D. Bellini[2], D. Caruso[2], T. Biondi[2], A. Laghi[2]; [1]*Latina/IT*, [2]*Rome/IT (lisiva@alice.it)*

Purpose: To evaluate the accuracy of magnetic resonance tumour regression grade (MR-TRG) for the identification of complete responders after chemoradiotherapy in a population of patients with locally advanced rectal cancer.
Methods and Materials: 65 patients, diagnosed with locally advanced rectal cancer were prospectively enrolled in the study. All patients underwent MRI on a 3-Tesla before, during and after chemoradiotherapy (CRT). All patients underwent total mesorectal excision (TME). MR-TRG was evaluated on TSE T2-weighted axial images as the fibrosis/tumour ratio. Results were grouped into favourable (>75% fibrosis) and unfavourable (<74%) classes. Measurements were performed on the entire tumour volume using a dedicated software. MR-TRG was compared to pathologic TRG. Disease-free survival (DFS) and overall survival (OS) were compared between MR-TRG classes. Sensitivity and specificity for the detection of CR were evaluated with ROC analysis.
Results: A complete pathological response was observed only in patients with favourable MR-TRG. A good correlation with pathologic TRG was observed (r2=0.874). Good sensitivity (96%) and specificity (78%) were observed on ROC analysis (AUC =0.947). A significant difference was observed between MR-TRG classes in terms of DSF (p=0.028) and OS (p=0.012).
Conclusion: MR-TRG is an accurate predictor of complete response after CRT and correlates with patients survival. When an unfavourable MR-TRG is observed the persistence of disease should be suspected. This method, applied also during therapy, may reduce the time to surgery.

B-0419 11:19

Rectal cancer: comparison of MR-TRG, volume ratio and signal intensity decrease for the identification of complete responders after radiochemotherapy
S. Picchia[1], M. Rengo[2], D. Caruso[1], D. Bellini[1], M. Zerunian[1], A. Laghi[1]; [1]*Latina/IT*, [2]*Rome/IT (lisiva@alice.it)*

Purpose: To compare three methods to identify complete responders after CRT in a population of patients with locally advanced rectal cancer.
Methods and Materials: 65 patients, diagnosed with locally advanced rectal cancer were prospectively enrolled in the study. All patients underwent MRI on a 3-Tesla before, during and after chemoradiotherapy (CRT). All patients underwent total mesorectal excision (TME). MR-TRG, volume reduction ratio (VR) and signal intensity percentage decrease (SI) were compared. Measurements were performed on the entire tumour volume using a dedicated software. MR-TRG, VR and SI were compared with histology. DFS, OS and ROC analysis were evaluated and compared among the three groups. Patients were stratified according to the histology result in complete responders (CR) and partial or non-responders (PNR).
Results: MR-TRG and VR were significantly different in CR and PNR patients (P=0,0005) while no significant differences were observed for SI (p=0.14). Significantly higher sensitivity and specificity were observed for MR-TRG compared to VR and SI (p=0.001). MR-TRG was also more accurate to predict the OS and DFS (p=0.002).
Conclusion: MR-TRG is more accurate than VR and SI for the identification of CR and correlates with patients' survival.

B-0420 11:27

The value of diffusion kurtosis imaging to assess pathological complete response to neoadjuvant chemoradiation therapy in rectal cancer
F.-X. Hu, T. Tong, W.-J. Peng; *Shanghai/CN (fxhu14@fudan.edu.cn)*

Purpose: The aim of this study was to compare diffusion kurtosis imaging (DKI) with conventional diffusion-weighted imaging (DWI) for assessing the pathological complete response (pCR) to neoadjuvant chemoradiation therapy (CRT) in locally advanced rectal cancer (LARC).
Methods and Materials: Fifty-six consecutive patients diagnosed with LARC were prospectively enrolled and underwent MRI before and after CRT on 3T MRI. The DWI and DKI parameters were compared between patients with pCR and non-pCR, using the nonparametric Mann-Whitney U test. Receiver operating characteristic (ROC) curve analyses were performed to characterize each parameter in terms of its value for predicting the CRT outcome.
Results: The MK_{pre} and MK_{post} values were significantly lower for the pCR patients (mean±SD, 0.72±0.09 and 0.56±0.06, respectively) than for the non-pCR patients (0.89±0.11 and 0.68±0.08, respectively) ($p<0.001$). The ADC_{post} and the ratio of apparent diffusion coefficient (ADC_{ratio}) values were significantly higher for the pCR patients (mean±SD, 1.31±0.13 and 0.64±0.34, respectively) than for the non-pCR patients (1.12±0.16 and 0.33±0.27, respectively) ($p<0.001$ and $p=0.001$, respectively). In addition, the MD_{post} and MD_{ratio} (2.45±0.33 vs 1.95±0.30, $p<0.001$; 0.80±0.43 vs 0.35±0.32, $p<0.001$, respectively) were also increased. The area under the receiver operating characteristic curve (AUROC) for the assessment of pCR were greater using MK_{post} (0.908, cut-off value=0.6196) compared with other parameters.
Conclusion: Both DKI and conventional DWI exhibited potential for predicting treatment response to neoadjuvant chemoradiation therapy in rectal cancer. The DKI parameters, especially MK_{post}, showed higher specificity than did conventional DWI for assessment of pCR and non-pCR in patients with LARC.

B-0421 11:35

DW MRI by 3T in the response assessment of locally advanced rectal cancer after chemioradiotherapy: apparent diffusion coefficient value as an imaging biomarker

R. Cervelli, P. Boraschi, F. Donati, F. Pacciardi, A. Cacciato Insilla, D. Campani, D. Caramella; *Pisa/IT (rosa.cervelli@virgilio.it)*

Purpose: To investigate the usefulness of the apparent diffusion coefficient (ADC) value by 3T-device in response assessment of locally advanced rectal cancer after neoadjuvant chemoradiotherapy (n-CRT).
Methods and Materials: Twenty-one patients affected by locally advanced rectal cancer underwent 3.0T MRI (GE DISCOVERY MR750; GE Healthcare) before and after n-CRT. After the conventional preliminary acquisition of high-resolution T2-weighted sequences, diffusion-weighted MR images (DW-MRI) were acquired using a spin-echo echo-planar sequence with multiple b-values (150, 500, 1000, 1500 sec/mm2) and an ADC map was obtained. Fitted ADC values were calculated for each rectal lesion before and after nCRT, by drawing a hand-made ROI around the tumour outline. All patients underwent surgery and the pathologic staging (classified according to TNM and to tumour regression grading, TRG) represented the reference standard. Pre-treatment ADC value (p-ADC), ADC value obtained after n-CRT (n-ADC) and the difference between p-ADC and n-ADC (ΔADC) were correlated with both the TNM and the TRG staging systems, in each patient.
Results: The ADC value obtained in the post-nCRT examination was statistically related both to TRG and TNM stages by histopathology (p=0.0019; p=0.0497, respectively). On the contrary, the ΔADC and the p-ADC values were not related to the pathologic staging.
Conclusion: DW-MRI, using ADC map and value, can be useful to assess the efficacy of neoadjuvant chemoradiation therapy in locally advanced rectal tumours; in fact post-nCRT ADC value improves the MR capability in the evaluation of nCRT response assessment.

B-0422 11:43

Role of MRI and added value of diffusion-weighted and gadolinium-enhanced MRI for the diagnosis of local recurrence from rectal cancer

V. Molinelli, N. Tarallo, F. Piacentino, E. Macchi, M. Angeretti, E. Bracchi, C. Fugazzola; *Varese/IT (va.la@hotmail.it)*

Purpose: To evaluate whether the addiction of gadolinium-enhanced and diffusion weighted (DWI) MRI improves standard pelvic MRI performance for diagnosis of local recurrence (LR) from rectal cancer; to asses which one is better in formulating this diagnosis and interobserver agreement among readers with different experienc.
Methods and Materials: 43 patients with suspected LR from rectal cancer underwent pelvic MRI with T2 weighted (T2) sequences, gadolinium fat-suppressed T1 weighted (T1mdc) and DWI MR sequences. Three readers (expert:G, intermediate:E, resident:V) scored the likehood of LR on T2, T2+DWI and T2+T1mdc.
Results: 18 Patients had LR; on T2 images the expert reader achieved AUC 0.916, se 88,9%, sp 96%; for intermediate reader were 0.890, 88.8% and 92%, respectively; for resident 0.852, 88.8% and 88%. DWI significantly improved AUCs value for expert radiologist up to 0.999 (p=0,0492), while T1mdc significantly improved AUC for resident up to 0.950 (p=0,0432). For intermediate reader, both T2+DWI AUC and T2+T1mdc AUC were better than T2 AUC (0.976 and 0.980 respectively), but with no statistical difference. No statistically significant difference was achieved from comparison between T2+DWI AUCs and T2+T1mdc AUCs in none of three readers.
Conclusion: Both DWI and gadolinium-enhanced MRI increase diagnostic performances for LR diagnosis compared to T2, in particular, DWI may be helpful in patients with contraindications to i.v. administration of gadolinium.

B-0423 11:51

Diffusion-weighted MRI and ADC value: their role in detection of metastatic lymph nodes in patients with primary rectal cancer

A. Ferrari[1], F. Schirru[1], G.F. Satta[1], A. Restivo[1], F. Scintu[1], L. Zorcolo[1], M. Cerci[1], J. Suri[2], L. Saba[1]; [1]*Cagliari/IT*, [2]*Pocatello, CA/US (ferrant.1986@gmail.com)*

Purpose: The aim of our study is to demonstrate the diagnostic value of DWI and ADC value in detection of metastatic lymph nodes in patients with primary rectal cancer.
Methods and Materials: In this retrospective study, 9 patients with rectal cancer were studied with MRI morphological T2W and DWI sequences. Surgical treatment and lymphadenectomy was performed successively on all patients. Total 68 lymph nodes were included in the study. Lymph nodes were classified as suspected and no-suspected considering dimension (diameter greater than 4 mm), morphology and T2 signal inhomogeneity. ADC values were then compared with the histopathological data.
Results: Of the 68 considered nodes (36 metastatic and non-metastatic 32), we excluded 11 lymph nodes with clear necrotic characteristics that showed extremely high ADC values (mean value of 1,57 ± 0:47 × 10-3 mm2/s). The mean ADC of the metastatic LNs (0.75 ± 0.29 × 10−3 mm2/s) was lower than that of the non-metastatic LNs (1.08 ± 0.26 × 10−3 mm2/s); the area under the ROC curve was 0,715 (95% confidence interval, 0,58-0,83 P < 0,002). Choosing an ADC value of 0,95 × 10−3 mm2/s as the cut-off, we got a sensitivity of 76% and a specificity of 68%.
Conclusion: Although T2W nodes characteristic is still the gold standard in defining the N Stage of a tumour, ADC value could be useful in differentiating between benign and metastatic pelvic lymph nodes in patients with rectal carcinoma, especially in doubtful nodes.

Non-invasive monitoring of therapeutic response in sorafenib-treated orthotopic hepatocellular carcinoma mouse models using photoacoustic and fluorescence imaging

S. Lee, J. Kim, J. Lee, J. Han; *Seoul/KR (seunghyun.lee.22@gmail.com)*

Purpose: To investigate the changes in oxygen saturation (sO_2) and radiant efficiency (R_E) in sorafenib-treated hepatocellular carcinoma (HCC) mouse models using photoacoustic (PI) and fluorescence imaging (FI).
Methods and Materials: BALB/c nude mice, implanted with human HepG2-RFP cells in left lobe of the liver, were randomized to the sorafenib-treated group (n = 21), or the control group (n = 20). Sorafenib (30 mg/kg) was administered orally to the treated group during 1-week. The changes in tumour volume, sO_2 of HCC and liver parenchyma, and R_E were measured at baseline and after 1-week. Pathologic changes including necrotic fraction and microvessel density were compared using unpaired t-test and correlation analysis.
Results: In the sorafenib-treated group, tumour volume and R_E showed lower values than those in the control group at 1-week (94.77 ± 42.24 vs. 159.10 ± 77.32 mm^3 and 4.89 ± 2.57 vs. 7.02 ± 3.89 x 10^{11} [p/sec/cm^2/sr]/ [μW/cm^2], P = .003 and P = .044). The sO_2 of HCC and liver parenchyma were also lower in the treated group than in the control group at 1-week (42.89 ± 8.16% vs. 49.40 ± 8.52% and 54.16 ± 7.91% vs. 59.14 ± 5.29%, P = .017 and P = .023). The sO_2 change in HCC showed a significant correlation with higher necrotic fraction (r = .427, P = .005) and lower microvessel density (r = -.421, P = .006) in the treated group.
Conclusion: The changes in sO_2 and R_E by sorafenib can be useful markers for non-invasive monitoring of therapeutic response in orthotopic HCC mouse models.

B-0425 10:38

Hyperpolarised MRS using 13-C-pyruvate reveals alterations in the metabolic phenotype of DEN-induced HCC in a rat model not revealed by 18F-FDG-PET

G. Kaissis, E. Bliemsrieder, D. Keim, L.S. Gebrekidan, G. Topping, F. Schilling, M. Schwaiger, E.J. Rummeny, R. Braren; *Munich/DE (g.kaissis@tum.de)*

Purpose: The propensity of tumour cells for aerobic glycolysis as opposed to mitochondrial oxidative phosphorylation, termed the "Warburg-Effect", is a potential target for oncologic pharmacotherapy in HCC. Magnetic Resonance Spectroscopy (MRS) with hyperpolarized substances such as C-13-Pyruvate allows non-invasive evaluation of tumour metabolism to identify candidate tumours.
Methods and Materials: HCC was induced in Wistar rats with oral Diethyl Nitrosamine. 20 HCCs were imaged using high-resolution T2w imaging and Free Induction Decay-Chemical Shift Imaging (FID-CSI) after i.v. injection of Hyperpolarised 13-C-Pyruvate. 6 healthy control animals were also imaged. A subset of 5 tumours was also examined with 18F-FDG-PET. Tumours and livers were excised and histologically examined. Tumour-ROI and liver spectra were generated and label exchange between C13-pyruvate, lactate and alanine was evaluated.
Results: Ratios of 13-C-pyruvate to lactate and 13-C-pyruvate to alanine label exchange (lac/ala-ratio) were significantly higher in HCC than in normal liver tissue (1.69±0.44 in HCC vs 1.05±0.12 in normal liver, p=0.002). There was marked intertumoural heterogeneity in lac/ala-ratio (σ^2=0.19) compared to normal liver (σ^2=0.016). Tumours with similar standardised uptake values in PET demonstrated markedly different lac/ala ratios.

Conclusion: C-13-Pyruvate-MRS allows in vivo visualisation of HCC metabolics and offers an imaging correlate to the "Warburg-phenotype" by directly demonstrating increased lactate production from pyruvate in HCC compared to normal liver. This technique could offer additional information about tumour biology compared to PET, since tumours with similar SUVs were found to demonstrate distinctly heterogeneous lactate/alanine production.

B-0427 10:46

Time-lapse MRI: single-cell tracking in experimental autoimmune encephalomyelitis

M. Masthoff, S. Gran, X. Zhang, L. Wachsmuth, L. Sorokin, J. Roth, M. Eisenblätter, M. Wildgruber, C. Faber; *Münster/DE (max.masthoff@ukmuenster.de)*

Purpose: Time-lapse MRI was recently introduced for MRI cell tracking studies. Here, via repetitive acquisition of the region of interest not only a static, single impression but also dynamic observation of cell migration can be obtained. Our purpose was to optimise the temporal resolution of time-lapse MRI and evaluate this technique in a specific disease model.
Methods and Materials: After inducing experimental autoimmune encephalomyelitis (EAE) in C57BL/6J mice via myelin oligodendrocyte glycoprotein injection, iron nanoparticles (Resovist®, 1.3ml per kg/BW) were injected i.v. 24h prior to MRI scan. MRI of the brain was performed on a 9.4T small animal MRI at different EAE disease levels (symptomatic n=8, presymptomatic n=2, healthy control n=3) using a T2* multi-gradient echo sequence with following scan parameters: TR 649ms, TE: 8.0ms, FA: 60°, averages 4, slice thickness 300µm, scan time 8min 12s (single time frame), respectively, 2h 44min with 20 repetitions. After MRI mice were sacrificed and brains prepared for histology.
Results: Time-lapse MRI sequence was improved to a temporal resolution of 8 minutes per time frame covering the entire brain. The technique allowed for tracking of patrolling leukocytes labelled with iron nanoparticles. The number of detected events changed significantly in EAE mice compared to healthy control mice.
Conclusion: By optimising time-lapse MRI towards an improved temporal resolution this technique is now applicable for single-cell tracking in animal models. Application in EAE disease shows the feasibility of detection of alternated immune cell dynamics.

B-0428 10:54

High resolution magnetic resonance imaging of HPF-labelled mouse natural Killer cell

L. Zheng[1], Z. Zhang[2], A. Larson[2]; [1]*Shanghai/CN*, [2]*Chicago, IL/US*

Purpose: To develop and optimise clinically translational protocol using US FDA approved drugs ferumoxytol, heparin and protamine to form HPF nanocomplexes and label specific mouse NK cell line (LNK) and determine in vitro and in vivo quantitative MRI properties.
Methods and Materials: LNK cells were labelled with self-assembled HPF nanocomplexes and optimise by varying the amount of HPF-nanocomplex. Labelling was confirmed the iron uptake with TEM, Prussian blue staining and ICP-MS. Cell viability and function were evaluated with Trypan blue staining and flow cytometry. Using a 7 Tesla MRI scanner, the labelled LNK MRI properties including signal intensity, R2* value and SNR were assessed with T2*W sequence. Finally, in Panc02 C57BL/6 mice model, changes of T2* signal, R2* value and SNR of labelled cells injection area were analysed by serial MRI detection after delivery of these labelled cells via percutaneous and intra-tumoural injection procedures, respectively.
Results: The HPF nancomplexes were internalised and encapsulated in labelled LNK cell as electron-dense nanoparticles. No significant difference between labelled LNK and control(unlabelled) LNK cells($p<0.05$, n=6) . No influence of HPF on both dead cell and early apoptosis were observed with exception of 200 µg/ml HPF-labelled LNK cells ($p<0.05$, compared with control).There is statistical significance between labelled and unlabelled LNK cells for both SNR and R2* in vivo and in vitro, respectively (all $p<0.05$).
Conclusion: LNK can be labelled with clinical applicable HPF-nanocomplex for MRI imaging in vitro and in vivo and has the potential to translate for longitudinal monitoring during NK cell immunotherapy.

B-0429 11:02

Directing neuronal differentiation of stem cells with a small interfering RNA-complexed MRI-visible cationic polymersome to counteract inhibitory microenvironment in stroke

L. Lu, J. Shen, X. Duan, F. Zhang, W. Young, M. Chen; *Guangzhou/CN (luliejingsysu@163.com)*

Purpose: Poor neural differentiation limits therapeutic prospects of exogenous neural stem cells (NSCs) to stroke,myelin associated inhibitory factors played critical inhibitory roles in axonal regeneration and neuronal differentiation of NSCs. A MRI-visible cationic polymersome system was used to delive siRNA targeting NgR gene, a common receptor of myelin associated inhibitory factors to direct neuronal differentiation of NSCs.
Methods and Materials: Superparamagnetic iron oxide nanoparticles loaded polyethyleneimine polylactic acid polymeric vesicle was synthesized and used to deliver NgR-siRNA into NSCs.Then, we assess the capability of this MRI-visible cationic polymersome to deliver siRNA targeting NgR into NSCs and the consequent effectiveness of directing neuronal differentiation of NSCs. The therapeutic benefits, long-term biological behaviour and safety of such epigenetic modification of NSCs are further tracked by the structural and functional changes of the host brain.
Results: This multifunctional nanocarrier enables efficient and safe blockage of NgR gene and can efficiently direct neuronal differentiation of NSCs both in vitro and in vivo. Meanwhile, this nanosystem can non-invasively monitor the migration and retention of NSCs in real time, without affect their therapeutic benefits.
Conclusion: These results demonstrate that the cationic polymersome-based multifunctional nanocarrier can provide robust epigenetically control over stem cell differentiation via RNA interference to counteract inhibitory microenvironment in stroke. This nanosystem will offer an opportunity for delivery of proneurogenic genes and simultaneous real-time monitoring of dynamics of stem cells, which will facilitate develop new stem cell therapy paradigm for stroke.

B-0430 11:10

Alanine loaded HMSNs: a potential contrast agent for MRS imaging

J. Wang, Z. Yao; *Shanghai/CN (jingwang_hs@foxmail.com)*

Purpose: To explore distinctive exogenous MRS contrast agents (CAs) to reliably distinguish brain glioma from other diseases.
Methods and Materials: Herein, β-alanine loaded hollow mesoporous silica nanospheres (AMSNs) have been synthesised and used as exogenous CAs for contrast-enhanced MRS based on the following two major merits: (1) β-alanine (ALA) is a kind of safe nutrition that is absent in the central nervous system. In the characteristic MRS spectrum, the peak of ALA at 2.562ppm should not be interfered by other metabolites in brain; (2) Hollow mesoporous silica nanospheres (HMSNs) can serve as nanocarriers to encapsulate large amounts of ALA with remarkable bio-safety and flexible facile modification.
Results: Our investigations have demonstrated that AMSNs with high biosafety could serve as specific MRS CAs for brain glioma's detection both ex-situ and in-situ, which helps to greatly enhance the diagnostic accuracy in comparison with the conventional MRS.
Conclusion: In summary, the constructed AMSNs with a characteristic MRS spectrum have been synthesised and used as remarkably efficient MRS CAs for brain glioma diagnosis. Our investigations show that the outstanding contrast-enhanced MRS using the biocompatible AMSNs can substantially promote the diagnostic efficiency and improve the diagnostic confidence of glioma. To our best knowledge, this is the first time to study on the exogenous specific MRS CAs. Similarly, specific MRS CAs may find a universal application in the accurate diagnosis of other diseases, which is hopeful to further accelerate the progress and break the shackle of current MRS technology.

B-0431 11:18

Histological correlation of dGEMRIC and T2 mapping in an ovine femoroacetabular impingement model: preliminary results

F. Schmaranzer[1], L. Arendt[2], N. Wolfer[2], C. Zurmühle[1], T. Lerch[1], K. Nuss[2], P. Kircher[2], B. von Rechenberg[2], M. Tannast[1]; [1]*Berne/CH*, [2]*Zurich/CH (schmaflo@gmail.com)*

Purpose: DGEMRIC and T2 mapping are increasingly used to judge prearthritic cartilage quality in femoroacetabular impingement (FAI) but the correlation between histology and both techniques is not well established. We asked whether dGEMRIC and T2 indices correlate with histological cartilage degeneration in a validated, experimental ovine FAI model.
Methods and Materials: This experimental, controlled, prospective study on 5 sheep (10 hips) was conducted after IRB approval. Five sheep underwent surgical induction of FAI by varus intertrochanteric osteotomy unilaterally, which rotates the naturally aspherical ovine femoral head into the acetabulum, inducing typical focal chondrolabral damage as seen in humans. Correction of the deformity was performed after 70 days. No surgery was performed in the 5 contralateral hips. Sheeps were sacrificed after further 70 days. One hour before sacrifice sheep received i.v gadolinium-DTPA and roamed free. Hips were dissected to fit into the coil. dGEMRIC and T2 maps were obtained at 3T using inversion recovery techniques. Histologic samples were stained with toluidine blue and cartilage degeneration was graded with the Mankin score. DGEMRIC and T2 indices of acetabular and femoral cartilage were radially measured at the 12 clock-face positions and correlated to Mankin scores (linear regression analysis; $p< 0.05$).
Results: Overall and regional (up to $R= -0.742$; $p<0.007$) inverse correlation was found between dGEMRIC indices and Mankin scores. No overall correlation was found between T2 indices and Mankin scores.

Conclusion: dGEMRIC correlates well with histological cartilage degradation, while we could not find such a correlation between T2 indices and Mankin scores.

Whole-body imaging of mice using a long circulating blood pool tracer to perform multi-patch MPI
C.S.L. Jung[1], J. Salamon[1], P. Szwargulski[1], M.G. Kaul[1], G. Adam[1], K.M. Krishnan[2], A. Khandahr[2], T. Knopp[1], H. Ittrich[1]; [1]*Hamburg/DE*, [2]*Seattle, WA/US*

Purpose: The purpose was to perform multi-patch MPI using LS-008 as long circulating blood tracer to achieve mice whole body imaging in a high-spatial resolution.
Methods and Materials: MPI Scans of FVB mice (n=4) were carried out using a 3D imaging sequence (2.5T/m gradient strength, 14mT drive-field strength). Ten minutes after the iv injection of 60µl of LS-008 six different drive-field patches (two cranial, two median and two caudal) each taking 1.5min were performed. As MPI delivers no anatomic information, MRI scans at 7T ClinScan (Bruker) were performed using a T2-weighted 2D turbo spin echo sequence. Fiducial markers were used to enable MRI/MPI image fusion. Image reconstruction was performed offline using a custom reconstruction framework developed in the programming language Julia using the join formulation.
Results: The combined MRI/MPI measurements were carried out successfully. The reconstruction of the drive-field patches generated no artefacts at the margins resulting in a whole mice body MP imaging. Compared to previous experiments using a lower gradient strength of 1T/m the multi-patch method with a gradient strength of 2.5T/m resulted in a higher spatial resolution. Therefore we were able not only to visualise the inferior vena cava, the heart and the liver but also the cerebral vessels, the thoracic aorta and the kidneys.
Conclusion: In vivo whole-body imaging of mice using multi-patch MPI is feasible. The long circulating blood tracer enabled us to visualize whole mice without motion artefacts that would occur using short half-life contrast agents.

Insulin-dependent triglyceride-rich lipoprotein uptake into brown adipose tissue visualised by 7T MRI and intravital microscopy
C.S.L. Jung, M. Heine, N. Mangels, M.G. Kaul, G. Adam, H. Ittrich, J. Heeren; *Hamburg/DE*

Purpose: The aim was to determine the activity of brown adipose tissue (BAT) and its dependence on signalling pathway mediated by insulin using superparamagnetic iron oxide nanoparticles (SPIO) or quantum dots (QD) embedded into triglyceride-rich lipoproteins (TRL).
Methods and Materials: BAT activity of C57BL/6J wild-type was stimulated by treatment with the β3 receptor agonist CL316, 243. Inhibition of insulin secretion was induced using the potassium channel agonist diazoxide. MRI at 7T ClinScan (Bruker) was performed before and 20min after iv injection of TRL-SPIOs using a T2*w Multiecho-GRE sequence (TR/TE_{first} 400/2ms, ETL 12, ES 1ms, FA 25°). ΔR2* in BAT was estimated. In addition intravital microscopy (IVM) analysis was performed for real time imaging of TRL-QD uptake. In order to quantify TRL clearance, the fate of radioactively labelled TRLs was analysed.
Results: For control mice no signal difference in BAT before and after the injection of TRL-SPIO was detectable, while a significant signal drop and increase of ΔR2* ($82.9s^{-1}$; $p<0.001$) was estimated for CL treated, BAT activated mice. Inhibition of insulin signalling resulted in a significant lower uptake of TRL-SPIO into BAT ($\Delta R2^* = 21.1s^{-1}$; $p<0.001$). IVM analysis and quantitative metabolic studies using radioactive lipid tracers confirmed MRI results. In both set-ups inhibition of insulin secretion using diazoxide diminished TRL uptake into BAT.
Conclusion: β3-receptor activation via CL with following acute insulin release lead to BAT activation, which can be visualized *in vivo* by MRI using TRL-SPIO and estimating ΔR2*. Accordingly, the inhibition of insulin signalling blocks TRL uptake into BAT.

Single nucleotide polymorphisms in relation to mammographic density in women with breast cancer
H. Sartor, J. Brandt, O. Melander, S. Zackrisson; *Malmö/SE (hannasartor@med.lu.se)*

Purpose: Certain single nucleotide polymorphisms (SNPs) are associated with mammographic density and breast cancer. Our purpose was to investigate whether certain SNPs known from literature (i.e., candidate SNPs) were associated with mammographic density in women with breast cancer in a large Swedish cohort - the Malmö Diet and Cancer Study (MDCS).
Methods and Materials: From 1991-2007 a total of 826 women with breast cancer have been identified in the MDCS and radiological parameters for those women have been registered. Genotyping was performed on 762 nonrelated women with breast cancer. 15 SNPs in relation to mammographic density (fat involuted and moderately dense vs dense) were analysed with logistic regression yielding odds ratios (OR) with 95% confidence intervals (CI) adjusted for age at diagnosis, body mass index, and hormone replacement therapy (at baseline).
Results: For SNP rs6557161, the minor homozygote allele showed a significant relation to high mammographic density as compared to the major homozygote (OR_{adj} 1.91 (1.12-3.26)). For SNP rs7289126, the minor homozygote (OR_{adj} 0.60 (0.37-0.97)) and the heterozygote allele (OR_{adj} 0.65 (0.45-0.94)) showed a significant relation to low mammographic density. For 13 of the selected SNPs no relation to mammographic density was observed.
Conclusion: We have found that two SNPs were associated with mammographic density in a large Swedish cohort, the MDCS, and further analyses on breast cancer survival will be performed. Increased knowledge regarding a potential shared genetic basis for mammographic parameters such as density could potentially help in the development of breast cancer risk scores including SNPs.

Determining factors of radiation dose in digital breast tomosynthesis (DBT) and full-field digital mammography (FFDM) utilising automated breast density and volumetric measurements
L.H.Y. Sinn, C.S.Y. Lo, E.Y.W. Chan, M.W.M. Law, W. Wong, T.P.W. Lam, W.W.M. Lam; *Hong Kong/HK (lorriesinn@gmail.com)*

Purpose: To determine the factors affecting the radiation dose of stand-alone DBT versus FFDM.
Methods and Materials: IRB-approved study on women attending their surveillance mammography from February 2015 to March 2016 were performed. All women had both FFDM and DBT performed at same time under same degree of compression.The breast density and volumetric measurements were generated Quantra software (version 2.2, Hologic Inc, USA). The correlation between average glandular dose (AGD) per view with age, compressed thickness, and volumetric data of both FFDM and stand-alone DBT were performed with regression analysis.
Results: Retrospective analysis performed on 4283 study sets with mean AGD per view of FFDM and DBT equals 1.58mGy and 1.53mGy respectively.On regression analysis, there is positive correlation of AGD with compressed thickness, volume of fat, fibroglandular tissue and total breast volume for both FFDM and DBT, and negative correlation with age. All these parameters show stronger correlation in FFDM compared to DBT with better goodness of fit (R^2) values, as well as larger regression coefficients. Among all, compressed breast thickness and volume of fibroglandular volume demonstrated largest regression coefficient measuring 0.039 and 0.0057 respectively, R^2 = 57% and 32% respectively in FFDM, while for DBT the regression coefficient measured 0.021 and 0.0029 respectively.

Conclusion: The increase in compressed thickness and volume of fibroglandular tissue resulted in more significant increment in radiation dose in FFDM than in DBT, indicating that there was relatively less radiation dose in patients having stand-alone DBT compared to FFDM in population with predominantly dense breasts.

B-0436 10:46

Comparison of automated volumetric breast density measurements by two different applications

A. Shimauchi[1], Y. Machida[1], M. Yakabe[2], K. Nii[2], H. Namba[3], A. Saita[1], E. Fukuma[4]; [1]*Chuo-ku/JP*, [2]*Minato-ku/JP*, [3]*Miyazaki/JP*, [4]*Kamogawa/JP (akikoshima@gmail.com)*

Purpose: To compare automated volumetric breast density measured by two different applications.
Methods and Materials: Mammograms of 110 women using a spectral photon-counting scanner (MicroDose mammography SI; Philips), from Jan 2015 to Feb 2016, were used. Breast volume (BV) (cm^3), glandular volume (GV) (cm^3), and volumetric breast density (VBD) (%) of two views of each breast were obtained from spectral energy data at the time of acquisition, using Breast Density Measurement (Philips). Three parameters were also obtained by Volpara (version 1.5.1; Volpara Solutions) using the raw data. Correlation coefficients (R) between MLO and CC views of the same breast for each system, and between two systems for each view were calculated. Weighted κ analyses were performed for density scores between the two systems, and between visual assessment and each system.
Results: Both systems showed very strong correlations between CC and MLO, for BV, GV and VBD (R=0.970, 0.977, 0.990 by Philips, R=0.963, 0.898, 0.864 by Volpara). BV and GV of two systems showed very strong correlations (R=0.993-0.997, 0.865-0.880), whereas VBD showed strong correlation (R=0.775-0.794). Density scores between Philips and Volpara, visual assessment and Philips, and visual assessment and Volpara showed moderate agreement (κ=0.510, 0.523, and 0.419).
Conclusion: Volumetric measurements of BV, GV, and VBD by both systems showed good precision. Philips system showed slightly better performances in correlation of VBD between CC and MLO, and agreement of density scores with visual assessment, which may be because direct measurements of spectral energy data are undertaken instead of processing of raw digital data.

B-0437 10:54

Reproducibility of automated mammographic density measures between two digital mammography device vendors

M. Abdolell, K.M. Tsuruda, P. Brown, J.S. Caines, C.B. Lightfoot, S.E. Iles; *Halifax, NS/CA (sian.iles@nshealth.ca)*

Purpose: This study examined the reproducibility of automated mammographic density measures for mammograms acquired from two digital mammography device vendors during a one year period. Continuous measures of mammographic density included percent breast density, dense breast area, and total breast area; categorical measures of mammographic density included a 3-category scale and the 4th edition BI-RADS density scale.
Methods and Materials: Pairs of "for presentation" digital mammography images were obtained from two mammography units for 128 women who had a screening mammogram on one vendor unit followed by a diagnostic mammogram on a different vendor unit. All exposures occurred within a single department by the same group of mammography-certified technologists and under the direction of a single medical director, technical manager, and quality assurance officer. A fully-automated density software was used to generate mammographic density measures from all available standard screening view images from the two vendors. Intra-class correlation coefficients (ICC), Pearson's correlation coefficient (PCC), weighted kappas, and scatter plots were used to evaluate mammographic density measures between vendors.
Results: ICCs of 0.94, 0.90, and 0.98 and PCCs of 0.94, 0.92, and 0.99 were observed for percent density, dense breast area, and total breast area measurements respectively. Weighted kappas for a 3-category scale and the 4th edition BI-RADS scales were 0.85, 0.83 respectively.
Conclusion: Overall agreement of mammographic density measures automatically generated from pairs of "for presentation" digital mammography images was almost perfect between the two vendors.

B-0438 11:02

Reliability of automated breast density measurements vs visual assessment in mammography

C.S.Y. Lo, L.H.Y. Sinn, K.W.M. Wong, T.P.W. Lam, W.W.M. Lam; *Hong Kong/HK (chrissy.lo@gmail.com)*

Purpose: To compare the reliability of automated breast density (ABD) measurements and visual assessment in terms of reproducibility.
Methods and Materials: 159 women (excluding those with previous breast operation) attending surveillance mammography at least once with digital breast tomosynthesis (DBT) from October 2014-June 2016 recruited with IRB approval. Breast density assigned using BIRADS 5th edition (Fatty: a, scattered fibroglandular tissue: b, heterogeneously dense: c, markedly dense: d). Simply dense (category c+d) and non-dense breast (category a+b) grouping done and analysed. Quantra software [version2.2; Hologic Inc, USA] utilised for ABD. For visual assessment, two blinded radiologists (Readers 1&2) assigned breast density to same group of patients for visits 1 and 2. Kappa statistics used to assess agreement between different comparison groups.
Results: [Same visit] Agreement of Quantra ABD of both breasts (assuming symmetrical) compared: Kappa coefficient 0.8 (CI 0.6-0.9). As only one measurement was given to each patient in visual assessment, agreement of Readers 1 and 2 assigned breast density assignment compared for same visit, but kappa coefficient was only 0.27 (CI 0.13-0.41). [Same patient, different visits] Agreement of Quantra assigned breast density category at two visits compared: Kappa co-efficient 0.82 (CI 0.73-0.91). For visual assessment reproducibility, the agreement of the Reader 1 in the first visit was compared with Reader 2 in the second visit, but kappa coefficient was only 0.16 for visual assessment (CI 0-0.3).
Conclusion: Automated breast density is more reliable in terms of reproducibility of breast density assessment than visual assessment, which has high inter-observer variability.

B-0439 11:10

Accuracy of fully automated volumetric FGT measurement with MRI of the breast: correlation with anthropomorphic breast phantoms

G.J. Wengert, K. Pinker, T.H. Helbich, W.-D. Vogl, S. Spijker, H. Bickel, S. Polanec, P.A.T. Baltzer; *Vienna/AT (georg.wengert@meduniwien.ac.at)*

Purpose: To investigate the accuracy of fully automated measurements of the amount of fibroglandular tissue (FGT) with magnetic resonance imaging (MRI) using different MRI sequences based on anthropomorphic breast phantoms as the ground truth.
Methods and Materials: In this study, ten anthropomorphic breast phantoms that consisted of different known fractions of adipose and fibroglandular tissue, which closely resembled normal breast parenchyma, were developed. Anthropomorphic breast phantoms were imaged with a 1.5 Tesla unit (Siemens, AvantoFit) using an 18-channel breast coil. The sequence protocol consisted of an isotropic Dixon sequence (Di), an anisotropic Dixon sequence (Da), and T1 3D FLASH sequences with and without fat saturation (T1). Fully automated, quantitative, volumetric measurement of FGT for all anthropomorphic phantoms and sequences was performed and correlated with the amount of fatty and glandular components in the phantoms as the ground truth.
Results: Fully automated quantitative measurements of FGT with MRI were performed successfully in all phantoms 6.71-59.72% (mean 32.82%) and for all sequences; Di, Da, and T1 ranged from 6.98-58.05% (mean 32.89%), 7.43-61.05% (mean 34.76%), and 6.44-54.69% (mean 34.67%), respectively. All sequences yielded good correlation with actual FGT content. However the best correlation of FGT measurement results and anthropomorphic breast phantoms was identified for Dixon sequences; Di (R2=0.998), Da (R2=0.997), and T1 (R2=0.910).
Conclusion: Fully automated quantitative measurements of FGT with MRI provide accurate information on the actual amount of FGT. Dixon type sequences showed the highest correlation and reproducibility of automated, quantitative FGT measurements on anthropomorphic breast phantoms, compared to conventional sequences.

B-0440 11:18

Breast MRI background parenchymal enhancement: a potential bridge to molecular cancer subtype?

G. Dilorenzo, M. Telegrafo, V. Ranieri, A. Cirilli, C. Giardina, A.A. Stabile Ianora, G. Angelelli, M. Moschetta; *Bari/IT (giuseppedlr@live.it)*

Purpose: To evaluate the distribution of MRI BPE among different breast cancer subtypes searching for any correlation with immunohistochemical and receptorial panel (Estrogen Receptor -ER, Progesterone Receptor - PR, Human Epidermal Growth Factor Receptor 2 - HER2).
Methods and Materials: 41 consecutive patients affected by breast cancer underwent breast DCE-MRI. Two radiologists evaluated all subtracted MR enhanced images for classifying normal BPE. ER, PR and HER2 expression was assessed by immunohistochemical analysis. ER and PR status was evaluated using Allred score (positive values: score ≥3). The intensity of the c-erbB-2 staining was scored as 0, 1+, 2+, or 3+ (positive values: ≥ 3+; negative: 0 and 1+; 2+ value assessed with silver in-situ hybridisation). Patients were subdivided into four categories based on cancer subtypes: ER/PR+HER2+, ER/PR+HER2-, ER/PR-HER2+, ER/PR-HER2- (triple negative). Distribution of BPE into the four categories was assessed and any significant difference was

calculated with the comparison of proportions, with p≥0.05 considered as significant.
Results: 6/41 (14.5) patients were ER/PR+Her2+, 24/41 (58.5%) were ER/PR+HER2-, 2/41 (5%) were ER/PR-HER2+, 8/41 (19.5%) were ER/PR-HER2-. No significant correlation between BPE pattern and receptor expression among breast tumours was found (p>0.05). Mild/moderate BPE were the most prevalent patterns in ER/PR+HER2+, ER/PR+HER2-, ER/PR-HER2+ groups; in the ER/PR-HER2- (triple negative) group, moderate/marked BPE prevailed.
Conclusion: BPE shows no significant correlation with breast tumour receptorial panel, except for triple negative breast tumours, in which an atypical trend for moderate/marked BPE prevalence could be supposed. Further studies need to be performed to confirm this preliminary data.

B-0441 11:26

Association of breast density and region of interest size with apparent diffusion coefficient value of normal fibroglandular tissue at MRI

N. Radovic, G. Ivanac, M. Crnogorac, E. Divjak, T. Cicvara-Pecina, J. Petrovic, B. Brkljacic; *Zagreb/HR (niko.radovic@gmail.com)*

Purpose: To determine association of breast density and region of interest (ROI) size with apparent diffusion coefficient (ADC) value of normal fibroglandular tissue on diffusion-weighted imaging (DWI) at MR.
Methods and Materials: The retrospective study included 28 women who underwent clinical MR exams. Breast density was evaluated at MRI and divided into low and high density category, the former including breasts interpreted as being fatty or having scattered fibroglandular tissue, and the latter including heterogeneously dense and dense breasts. DWI was performed at 1.5T using b = 0, b = 400 and b = 800. ADC of normal fibroglandular tissue was calculated by manually drawing two sets of multiple circular ROI´s of sizes equalling 15 mm^2 and 30 mm^2. Areas of fibroglandular tissue not large enough to encompass the larger ROI were excluded from measurements to avoid partial volume averaging. Intrasubject mean ADC values for the two ROI sizes were compared by Pearson's correlation coefficient. Association between mean ADC and breast density level was assessed using Student's t-test.
Results: Mean ADC of fibroglandular tissue was 1.79 ±0.18 $x10^{-3}$ mm^2/s and 1.8±0.2 $x10^{-3}$ mm^2/s on smaller and larger ROI respectively. Intrasubject ADC measurements for the two ROI sizes were highly correlated (r=0.954, p<0.001). ADC was not associated with breast density level (p>0.5).
Conclusion: ADC reflects microstructural characteristics of fibroglandular tissue unrelated to breast density or ROI size. Contrast between lesions and fibroglandular tissue on DWI will not be affected by breast density.

B-0442 11:34

Effect of parenchymal pattern in women with dense breasts, variation with age and impact on screening outcomes: observations from a UK screening programme

L. Ward[1], S. Heller[2], S. Hudson[1], L. Wilkinson[1]; [1]*London/UK*, [2]*New York, NY/US (lauraward@doctors.org.uk)*

Purpose: To analyse mammographic parenchymal pattern (PP) in women with densest breasts; to determine how tissue pattern varies with age and impacts recall and cancer detection.
Methods and Materials: Breast density data (Volpara™, 5th ed.) was obtained in a subset of women screened in a regional programme (April 2013-March 2015). Cases with densest breasts (Volpara Grade d [VGd]) were selected for PP categorization. All assessed VGd cases and 100 randomly selected VGd cases from non-assessed women were reviewed. Ten readers classified PP on a 1-5 scale (1-very smooth to 5-very nodular). Mean PP classification was compared between age groups and for assessed vs non-assesed women. Reader agreement was analysed using intraclass correlation. Likelihood of biopsy, cancer diagnosis and cancer characteristics were analysed by age and PP.
Results: 4,331/40,760(10.6%) screened women were VGd. Proportions of PP categories were similar at all ages for controls (p = 0.145) and for 280 assessed women (p=0.657). Inter-rater reliability for scoring PP in controls was good (ICC = 0.6302). 155 women underwent biopsy of which 34 had cancer. PP (1-5) ratios did not vary significantly with age in these groups (p = 0.580). There was significant correlation between cancer and nodular PP (p = 0.043). Cancer characteristics did not differ by age or PP.
Conclusion: Ratio of smooth to nodular pattern in women with the densest breasts did not vary with age. PP did not affect likelihood of recall to assessment or biopsy. There was a significant association between nodular PP and cancer diagnosis.

B-0443 11:42

Positive predictive values by breast density in the Norwegian Breast Cancer Screening Programme

N. Moshina, M. Roman, S. Sebuodegard, S. Hofvind; *Oslo/NO (nataliia.moshina@kreftregisteret.no)*

Purpose: To investigate the trends of PPV-1 (the percentage of screening detected breast cancers among the recall examinations due to abnormal mammographic findings) and PPV-2 (the percentage of screening detected breast cancers among the recall examinations that include an invasive diagnostic procedure) by categories of subjectively assessed mammographic density (MD).
Methods and Materials: We used information from 6363 recall examinations obtained from 5666 women screened with full field digital mammography in the Norwegian Breast Cancer Screening Programme, 2003-2010. The radiologists who performed the recall examination classified the mammograms into three categories based on MD: MD-1 (<30% of fibroglandular tissue), MD-2 (30-70%), and MD-3 (>70%). We used chi-square trend statistics to estimate trends of PPVs across MD categories. Logistic regression was used to estimate the odds ratio (OR) of screening detected breast cancer associated with MD among recalled women, adjusting for age.
Results: PPV-1 and PPV-2 decreased by increasing MD category (p<0.05 for the trend). MD-2 and MD-3 were associated with lower odds of breast cancer among recalled women compared with MD-1. Adjusted OR was 0.79 (95% CI: 0.68-0.92) and 0.75 (95% CI: 0.58-0.97) for MD-2 and MD-3, respectively.
Conclusion: High MD was associated with a higher amount of false positive results, and thus decreased radiologists' performance, compared with low MD in the national screening programme in Norway.

B-0445 11:50

Reliability of 5th edition vs 4th edition BI-RADS mammographic density scales

M. Abdolell[1], K.M. Tsuruda[1], P. Brown[1], J.S. Caines[1], G. Schaller[2], C.B. Lightfoot[1], S.A. Raza[2], S.E. Iles[1]; [1]*Halifax, NS/CA*, [2]*Sydney, NS/CA (pbpete@gmail.com)*

Purpose: This study examined the variability in inter-rater reliability between radiologists assessments of mammographic density using the 4th and 5th edition of the BI-RADS density classification scales.
Methods and Materials: Six radiologists assessed mammographic density for 375 cases using the 4th and 5th editions of the BI-RADS density scale. A consensus assessment was calculated based on the majority assessment. Chance-corrected inter-rater agreement was evaluated using the weighted kappa statistic for all pairs of radiologists and between each radiologist and the consensus measure.
Results: Inter-rater agreement between all pairs of radiologists was moderate to almost perfect for the 4th edition scale (mean Kappa=0.76, range=0.53-0.90), and substantial to almost perfect for the 5th edition scale (mean Kappa=0.79, range=0.71-0.83). Inter-rater agreement between each radiologist and the consensus measure was substantial to almost perfect for the 4th edition scale (mean Kappa=0.85, range=0.69-0.92) and almost perfect for the 5th edition scale (mean Kappa=0.86, range=0.81-0.91).
Conclusion: In the absence of strict percent density cut-points in the BI-RADS 5th edition density scale, inter-rater agreement is significantly better than for the BI-RADS 4th edition density scale. The range of inter-rater variability between pairs of raters and between raters versus the consensus measure was considerably less for the 5th edition BI-RADS density scale compared to the 4th edition scale. Visual assessment of density using the BI-RADS 5th edition density scale may be more reliable than using the BI-RADS 4th edition density scale.

Iatrogenic complications during mechanical thrombectomy for acute ischaemic stroke: potential mechanisms, rescue strategies, and clinical outcomes in a multicentre study
C. Parra-Fariñas, A. Tomasello Weitz, P. Cardona Portela, M. de Miquel, M. Gomis Cortina, C. Castaño Duque, J. Blasco, X. Urra, M. Ribó Jacobí; *Barcelona/ES (carmenparrafarinas@gmail.com)*

Purpose: Mechanical thrombectomy has emerged as valuable armamentarium for acute ischaemic stroke. Complications due to arterial rupture and dissection have not been formally described. This study aimed to report our intra-procedural vessel damage and discuss its technical details and clinical significance.
Methods and Materials: We studied patients prospectively included in SONIIA registry (2011-2015), a mandatory, externally audited registry that monitors the quality of reperfusion therapies in Catalonia during practice. Successful recanalisation (TICI grade ≥2b), procedural time, symptomatic intracranial haemorrhage (SICH), dramatic neurological improvement (≥10 points decrease in the NIHSS score at 24 hours), independent functional outcome (mRS ≤2) at three months, and iatrogenic arterial injury were recorded.
Results: Among the 1640 patients included, iatrogenic complications occurred in 3.6% (2.0% dissection, 1.6% perforation, 40% middle cerebral artery occlusion, 52.1% left side, 21.7% posterior circulation). Median NIHSS score was 17 (12-21) on arrival and 9 (3-18) at 24 hours. Complications were not related to general anaesthesia: 26.7% vs. 73.3% (RR, 1.7; 95% CI, 1.0-3.0; p=0.061). Complications were associated with less successful recanalisation: 36.7% vs. 79.3% (RR, 6.0; 95% CI, 3.6-10.1; p=0.000) and longer procedural time: 108.1±55.2 min vs. 87.4±73.32 min (p=0.031). SICH: 18.3% (81.8% perforation vs. 18.2% dissection, p=0.002) vs. 2.5% (p=0.000). Good early response: 15.1% vs. 71.0% (p=0.000). Functional independence: 18.4% vs. 48.9% (p=0.000). Mortality: 60.0% vs. 17.4% (p=0.000).
Conclusion: Intra-procedural vessel damage was rare, but when it occurred was associated with high unfavourable outcome. However, 18.4% had functional independence, suggesting that in some complicated patients good neurological recovery is achievable.

B-0447 10:47

Should mechanical thrombectomy be considered in patients with M2 occlusion?
I.Q. Grunwald[1], M. Sneade[2], B. Bock[1], V. Janardhan[3], L. Ammar[4], A. Kühn[5], S. Shah[6], C. Goncalves[6], S. Sit[4]; [1]*Chelmsford/UK*, [2]*Oxford/UK*, [3]*Dallas, TX/US*, [4]*Alameda, CA/US*, [5]*Worcester, MA/US*, [6]*Southend-on-Sea/UK*

Purpose: The preponderance of evidence suggests that vessel location is an important predictors of outcomes in acute ischemic stroke. However, few studies have examined the natural history of a cohort of patients with persistent M2 vessel occlusion who would have been eligible for, but remained untreated with mechanical thrombectomy.
Methods and Materials: The SOS and FIRST trials were prospective, multicenter studies evaluating the natural history of a stroke cohort eligible for mechanical thrombectomy but did not receive the treatment. Enrolled patients presented with symptoms of acute ischaemic stroke due to large vessel occlusion and were refractory or ineligible for rtPA treatment. Functional independence was defined as a mRS score 0-2 at 90 days. Incidence of death, intracranial hemorrhage, serious adverse events, and mortality were assessed for association with vessel location.
Results: 238 patients (median age: 71) met study criteria. Occlusions of the M2 alone were reported in 8.9%. At 90 days only 75% of Middle Cerebral Artery M2 patients did not achieve functional independence as defined by a mRS score of 0-2. Mortality rate was 10%.
Conclusion: Persistent occlusion of the M2 MCA is associated with a low rate of functional independence and a high mortality, posing the question if this patient group should be considered for mechanical thrombectomy.

Manual aspiration thrombectomy using penumbra catheter in patients with acute migrated MCA occlusion
S. Baik; *Jeonju/KR (mdshbaik@gmail.com)*

Purpose: Our study aimed to retrospectively assess the efficacy and safety of a manual aspiration thrombectomy (MAT) using Penumbra in patients with acute migrated middle cerebral artery (MCA) occlusion.
Methods and Materials: We conducted a retrospective review of patients who underwent MAT using Penumbra 4 or 5 MAX reperfusion catheters for treatment of acute MCA occlusion between January 2012 and December 2015. Migrated thrombus was defined as distal migration above> 1cm on initial cerebral angiography compared with preprocedural angiographic findings. We evaluated immediate angiographic results and clinical outcomes through reviewing of patient's electrical medical records. We compared with clinical outcomes between migrated MCA occlusion and non-migrated MCA occlusions.
Results: During this period, 98 patients underwent MAT using Penumbra catheters for treatment of acute MCA occlusions. Of these patients, 19 (19.4%) had a migrated MCA thrombus on initial cerebral angiography compared with preprocedural angiographic findings. The overall rate of successful recanalisation (TICI grade ≥ 2b) was 90.8%. The rate of successful recanalisation on migrated thrombus group was 94.7% (18/19). Overall favourable clinical outcomes (mRS score at 3 months ≤ 2) were seen in 64 patients (65.3%). Although it is not significant, favourable clinical outcomes in migrated thrombus group was higher compared with non-migrated thrombus groups (78.9% vs. 60.8%, p = .231).
Conclusion: MAT appears to be safe and is capable of achieving high rate of successful recanalisation and favourable clinical outcomes in patients with acute MCA occlusion. A migrated thrombus group was more favorable clinical outcomes.

Single-centre experience using the 3MAX reperfusion catheter in the treatment of acute ischaemic stroke with distal arterial occlusion
K. Premat, B. Bartolini, E. Shotar, F. Barronet-Chauvet, V. Degos, N. Sourour, F. Clarençon; *Paris/FR*

Purpose: Recently published data reported promising results with tromboaspiration devices such as the Penumbra System (Penumbra, Alameda, California) combined with the Penumbra MAX series reperfusion catheters by using the ADAPT technique. The aim of this study was to report our initial experience with the 3MAX (3.8F) reperfusion catheter for the recanalisation of occluded distal intracranial arteries.
Methods and Materials: From August 2015 to December 2016, 28 consecutive patients (15 women [54%] and 13 men [46%]; mean age=69±18.7y, [range: 22-94]) for 34 distal occlusions underwent mechanical thrombectomy (MT) using the 3MAX catheter. The occluded vessels were: M2 (n=24; 70.6%), M3 (n=2; 5.9%), P1 (n=2, 5.9%), P2 (n=2, 5.9%), P3 (n=2, 5.9%), A3 (n=1, 2.9%) and superior cerebellar artery (SCA) (n=1, 2.9%). The primary endpoint was the Thrombolysis In Cerebral Infarction (TICI) score after thromboaspiration attempts alone using the 3MAX.
Results: In 1/34 (2.9%) cases, the 3MAX could not be navigated into the target artery. Successful recanalisation (TICI 2b/3) after aspiration with the 3MAX alone was achieved in 59% of the cases. Overall recanalisation rate was 76%. Six (17.6%) procedure-related complications occurred, including four (11.8%) 3MAX-related complications (two clot migration in the same territory; 2 clot migration in another territory). Overall mortality rate was 15.8%. No procedure-related mortality was recorded. mRS 0-2 was observed in 47.3% of the cases at last follow-up (average delay: 108±70 d).
Conclusion: The 3MAX reperfusion catheter is a safe device and provides interesting results for recanalisation of distal occlusions.

Comparison of dual-layer spectral CT with MRI in differentiation between haemorrhage and extravasation of iodinated contrast medium after endovascular treatment of ischaemic stroke

I. Riederer, A. Sauter, M. Renz, J. Dangelmaier, J.S. Kirschke, A.A. Fingerle, E.J. Rummeny, P.B. Noel, D. Münzel; *Munich/DE (isabelle.riederer@tum.de)*

Purpose: To evaluate the advantages of dual-layer spectral omputed tomography (CT) for distinguishing between intracerebral haemorrhage and iodine extravasation due to disruption of the blood brain barrier in ischaemic stroke patients after mechanical thrombectomy.
Methods and Materials: Twenty patients who had received mechanical thrombectomy, were examined with a dual-layer spectral CT (IQon spectral CT, Philips Healthcare, USA) 11 +/- 3h after revascularisation. Virtual non-contrast (VNC) images and iodine overlay maps (IOM) were calculated and evaluated using a dedicated software (IntelliSpace Portal, Philips Healthcare, USA). Region of interests (ROIs) analyses were performed within the hyperdense areas in the conventional CT, IOM and VNC images. As a standard of reference data from Magnetic Resonance Imaging (MRI), acquired during the follow-up procedure, are utilised. Sensitivity, specificity and positive predictive value (PPV) for the presence of haemorrhage in dual-layer spectral CT are calculated.
Results: A total of twenty hyperdense areas in twelve patients were seen in dual-layer spectral CT. In comparison to follow-up MRI as a gold standard, it was possible to correctly classify haemorrhage (n=8), extravasation of iodine (n=8), or both (n=4) in spectral CT images. The ROI analysis showed HU of 64 +/- 2 (“conventional CT”) and 51 +/-2 (VNC) for haemorrhage and 61 +/- 3 (“conventional CT”) and 22 +/-2 (VNC) for iodine, respectively.
Conclusion: Dual-layer spectral CT improves the capability to distinguish between intracerebral haemorrhage and extravasation of iodinated contrast medium due to disrupted blood brain barrier in patients with acute stroke after intra-arterial thrombectomy.

Catheter thrombo-aspiration in acute ischaemic middle cerebral artery stroke: first results

M. Voormolen, T. van der Zijden, O. d'Archambeau, L. Yperzeele, T. Menovsky, P.M. Parizel; *Antwerp/BE (maurits.voormolen@uza.be)*

Purpose: To assess the efficacy and safety of thrombo-aspiration (TA) using Penumbra catheters in patients with acute middle cerebral artery (MCA) occlusion.
Methods and Materials: We evaluated immediate angiographic results and prospective clinical outcomes after treatment of 33 consecutive patients undergoing endovascular treatment of MCA occlusions, treated with Penumbra aspiration catheters and pump system, between January 2015 and July 2016, involving 12 men and 21 women, with a median age of 69 years (range 25-88). Seventeen patients had left MCA arterial occlusion (52%). Inclusion criteria were defined as: patients with neurological symptoms (NIHSS≥6), treatment within 6 hours after symptom onset, brain CT scan showing infarct <50% MCA territory and catheter angiography showing thrombo-embolic MCA occlusion.
Results: Recanalisation by TA was achieved in 24 patients (73%), with successful recanalisation (TICI 2b/3) in 22 patients. Seven patients were additionally treated with stent retrievers (21%). In 9 patients TA was unsuccessful, because of access difficulties in tortuous arteries (n=4) or shortness of catheters (n=2), or impossibility to aspirate thrombus (n= 3). Except one carotid artery dissection and a thrombo-embolus in another vascular territory, no procedure related complications occurred. At admission, median NIHSS was 16 (range 6-29), with decrease to 10 at discharge (range 1-29). Median mRS at 3 months was 1 (range 0-6). Favorable clinical outcome at 3 months (mRS≤2) was seen in 21 patients (64%).
Conclusion: In our experience, catheter thrombo-aspiration is a safe procedure, with high rates of successful recanalisation and favorable clinical outcomes in patients with acute ischemic MCA stroke.

B-0452 11:27

Primary aspiration technique in acute stroke treatment with ACE 64 in 121 patients

M. Alexandrou, M. Politi, L. Meyer, C. Roth, P. Papanagiotou; *Bremen/DE (mariapoliti@hotmail.com)*

Purpose: To evaluate the safety and affectivity of primary aspiration technique in endovascular stroke treatment.
Methods and Materials: Between July 2014 and December 2015 107 acute ischaemic stroke patients with large vessel occlusion and mean NIHSS 14 were treated with primary aspiration technique. The ACE 64 aspiration catheter (Penumbra inc.) was used in all patients. Procedural and clinical data were selected for analysis.
Results: The primary aspiration technique was successful in achieving thrombolysis in cerebral infarction (TICI) 2b or 3 revascularization in 65% of cases. In 60% of these cases procedure time was <40min. The additional use of stent retrievers in 37 cases improved the TICI 2b/3 revascularisation rate to 89%. The functional outcome (modified Rankin Scale (mRS) 0-2) at discharge was 49.5 %, mRS 6 in 14%.
Conclusion: Primary aspiration technique is an alternative strategy for mechanical thrombectomy as it allows high recanalisation rates with small procedure times.

B-0453 11:35

Endovascular treatment of basilar artery occlusion: RELOBA study group experience

A. Giorgianni[1], F. Biraschi[2], D. Mardighian[3], G. Pero[4], M. Crispino[5], M. Pavia[3], S. Strocchi[1], L. Valvassori[4]; [1]*Varese/IT*, [2]*Rome/IT*, [3]*Brescia/IT*, [4]*Milan/IT*, [5]*Cremona/IT (f.biraschi@gmail.com)*

Purpose: Acute basilar artery (BA) occlusion is considered among the most severe medical conditions, with very high morbidity and mortality. The aim of this study is to present 5 years experience of 12 centers of the Lumbardy area of Italy, in BA occlusion endovascular treatment (EVT) and to evaluate prognostic factors that may improve clinical outcomes and recanalisation rate.
Methods and Materials: The RELOBA registry is a retrospective multicenter collection of basilar artery occlusion undergone to EVT in the period 2010-2015. 102 patients (mean age 65 years) with proven basilar artery occlusion treated with EVT were included. Clinical, procedure and neuroradiological data were collected. Recanalisation (TICI score 2b-3) was assessed by local interventional neuroradiologist. Good (moderate) outcome was defined as a mRS score of 0 to 2 (0-3) assessed at 3 months.
Results: 39% patients had good and 46% had moderate mRS clinical outcome at 3 months. Mortality was 30%. TICI 2b-3 recanalisation was achieved by 62%. Univariate analysis showed that age, NIHSS at onset, total time to recanalisation, recanalisation TICI grade were all statistically significant ($p<0.05$) in predicting clinical outcome. Multivariate logistic regression showed total time, age, NIHSS at onset as significant independent predictors of good outcome.
Conclusion: Mechanical thrombectomy is feasible and effective in patients with acute basilar artery occlusion. A better understanding of the factors that influence the prognosis could dramatically improve patient outcome. These initial results must be confirmed by further prospective studies within a randomised-controlled settings.

B-0454 11:43

Low admission blood glucose favours good neurologic outcome and smaller final infarct size in stroke thrombectomy

T. Huber[1], M. Kaesmacher[1], J.F. Kleine[2], C. Zimmer[1], J. Kaesmacher[1]; [1]*Munich/DE*, [2]*Berlin/DE (thomas.huber@med.uni-muenchen.de)*

Purpose: High levels of peripheral blood glucose on admission (AG) are associated with a deteriorated outcome in stroke. Different pathophysiologies have been suggested, including inhibitory effects on the efficacy of IV rtPA, blood-brain barrier breakdown and reduced salvage of the penumbra. The association of AG in the context of stroke thrombectomy has not been evaluated in detail up to date.
Methods and Materials: 325 consecutive patients with acute MCA occlusion undergoing mechanical thrombectomy (MT) between 2008 and 2016 were included in this retrospective study. AG was classified on an ordinal scale ranging from normoglycaemia to severe hyperglycaemia. Final infarct volume (FIV) was segmented on postinterventional, diffusion-weighted MR images. Short-term neurologic outcome was assessed using dichotomised NIHSS variables (good outcome: discharge-NIHSS <5; substantial improvement: compound criterion of either NIHSS at discharge ≤1 or NIHSS-improvement ≥8).
Results: Higher levels of AG were associated with older age, higher admission-NIHSS, larger FIV and more severe neurologic disability (all $p<0.05$). These associations were present in all subgroups, irrespective of recanalisation results, time to recanalisation and administration of IV rtPA bridging. Higher AG was found to be an independent risk factor for lower rates of good neurologic outcome and substantial neurologic improvement (aOR 0.744, 95%-CI: 0.568-0.975 and aOR 0.745, 95%-CI 0.600-0.925, respectively).
Conclusion: Higher levels of AG are significantly associated with a poor neurologic outcome in patients undergoing MCA-thrombectomy. These findings challenge the hypothesis that an association between acute hyperglycaemia and patients' outcome may be mediated through altering the efficacy of thrombolysis and thereby favours others pathophysiologic explanations.

Impact of thrombectomy maneuver count on recanalisation and clinical outcome in patients with ischaemic stroke

F. Seker, J. Pfaff, M. Wolf, S. Nagel, S. Schönenberger, C. Herweh, M.A. Möhlenbruch, M. Bendszus, M. Pham; *Heidelberg/DE*

Purpose: The effectiveness of thrombus retraction in patients with acute stroke using stent retrievers is variable. Here, we studied the impact of thrombectomy maneuver count on recanalisation and clinical outcome.
Methods and Materials: We retrospectively analysed data of 99 consecutive patients with acute occlusion of the terminal internal carotid artery or M1 segment of the middle cerebral artery treated with thrombectomy. Successful recanalisation was defined as TICI score of 2b or 3. Good clinical outcome was defined as mRS score of ≤2 at 90 days after stroke onset.
Results: Median thrombectomy maneuver count was 3 (range 1-10). Multivariate logistic regression analyses identified increasing maneuver count as an independent predictor of both unsuccessful recanalisation (adjusted OR 0.39, 95% confidence interval 0.22 to 0.59, P<0.001) and unfavorable clinical outcome (adjusted OR 0.56, 95% confidence interval 0.34 to 0.88, P=0.018). In cases where the thrombectomy procedure was finished within two maneuvers, a good outcome was significantly more likely compared to cases where three or four maneuvers or even more than four maneuvers were required (P<0.001). Besides, maneuver count was not associated with the occurrence of intraprocedural complications (unadjusted OR 1.01, 95% CI 0.99-1.03, P=0.436).
Conclusion: The number of thrombectomy maneuvers is strongly associated with the probability of successful recanalisation and good clinical outcome. A good outcome appears to be unlikely, if recanalisation is not achieved within four maneuvers.

One step beyond contrast-enhanced spectral mammography: malignancy potential score as a new diagnostic tool in mammography

E. Nikolentzou, C. Tzimas, E. Gioutlaki, E. Feida, A.N. Chalazonitis; *Athens/GR (christostzimas@yahoo.com)*

Purpose: To propose a new score estimated quickly by the sum of BIRADS score and Contrast Enhanced Spectral Mammography strength enhancement, termed as “Malignancy Potential Score” (MPS).
Methods and Materials: From September 2014 to September 2015, 216 females underwent diagnostic mammograms, followed by CESM. 10 of these females had bilateral findings; so, 226 lesions were examined in total. We collected data from women only with BIRADS 3-5 findings. CESM findings were evaluated based on the intensity of lesion enhancement compared with background breast enhancement (-1 to 2). The score of BIRADS was added to the score of CESM. This new score served as the final diagnostic score. Histopathology reports were compared with imaging assessment. Receiver-operating characteristic (ROC) curves were used to determine the sensitivity and specificity and also to extrapolate the optimum cut-off value for MPS.
Results: 98 of 226 lesions were malignant and 128 of 226 lesions were benign. The sensitivity, specificity and accuracy rates were 91.83, 80.47 and 85.40%, respectively, when a best MPS cut-off point of 4, to distinguish benign from malignant, was used. The diagnostic accuracy and specificity of MPS were superior to that of digital mammography or CESM alone.
Conclusion: Combining the well-documented experience of digital mammography with the power of type of enhancement of CESM into one score improves diagnostic accuracy and specificity compared with digital mammography or CESM alone.MPS seems to be an efficient tool in clinical management in every-day practice serving as an additional problem-solving method in breast imaging.

Contrast-enhanced spectral mammography for the evaluation of breast calcifications: diagnostic performance and impact on surgical planning

M.B.I. Lobbes[1], I. Houben[1], S. Vanwetswinkel[1], V. Kalia[2], P. Nelemans[1], E. Heuts[1], M. Smidt[1], J.E. Wildberger[1]; [1]*Maastricht/NL*, [2]*Reykjavik/IS (marclobbes@planet.nl)*

Purpose: To evaluate the diagnostic accuracy of contrast-enhanced spectral mammography (CESM) in breast (micro)calcifications and its impact on surgical decision making.
Methods and Materials: All screening recalled patients with suspicious microcalcifications that underwent CESM in the period October 2012 till September 2015 were included. First, radiologists provided a BI-RADS classification for the low-energy (mammographic) images only. In a session simulating a tumour board meeting, two breast surgeons (in consensus) decided on the preferred surgical treatment (breast conservative (BCT) versus mastectomy, blinded for final histopathology) for all (pre)malignant cases. After eight weeks, the evaluation was repeated for the entire CESM exam (i.e. including the recombined image with contrast information). Sensitivity, specificity, PPV and NPV were calculated using BI-RADS>4 being malignant as cut-off value. In addition, differences in surgical decision making were analysed and compared using the McNemar test.
Results: In total, 147 women were included in this study (mean age 61 years). Pathology showed 82 benign and 32 malignant lesions, with 33 ductal carcinoma in situ cases. Diagnostic performances of CESM (with differences compared to low-energy images in brackets) were: sensitivity 94% (+3%), specificity 38% (-3%), PPV 56% (0%), NPV 88% (+4%). Based on low-energy images, surgeons suggested BCT in 89% of the cases. Based on the CESM exam, their decision making did not change statistically significant (86% BCT).
Conclusion: CESM is not of added value in breast (micro)calcifications, as it neither improve their evaluation, nor helpful in guiding surgical decision making.

B-0458 10:46

The added value of contrast-enhancing mammography in assessment of breast asymmetry

R.W. Abdel Rahman; *Cairo/EG (rashakao@yahoo.com)*

Purpose: To evaluate the clinical performance of CEDM on asymmetries detected on mammogram.
Methods and Materials: This study is a retrospective analysis that included 125 females, 33 (26.4%) were presented for screening and 92 (73.6%) were presented for diagnostic mammogram in the period from March, 2015 to March, 2016 .Their age ranged from 25-81 years (mean 48.87). None of them were treated with hormonal replacement therapy. Enhanced spectral mammography (CESM) was performed using Senographe Essential; (Seno DS; GE, Buc, France) that is adapted to obtain low- and high-energy images for each mammography view. Reference stander was histopathology after core or surgical biopsy, as well as follow-up (6months) for non-enhanced asymmetry classified as normal variants.
Results: The study included 125 females. 9/125 (7.2%) had asymmetry, 92/125 (73.6%) had focal asymmetry, 23/125 (18.4%) had global asymmetry and 1/125 had developing asymmetry (0.8%). There is a significant correlation between focal and global asymmetries showing mass or non-mass enhancement and malignancy (p value ≤0.001), while asymmetry showing non-mass enhancement has significant correlation with benign pathology (p value ≤0.001). There is significant correlation between non-enhancing asymmetrical findings and benign pathology provided no associated suspicious mammographic finding (p value ≤0.001).
Conclusion: Contrast enhanced mammography provided clinical impact on breast asymmetrical density by figuring out underlying lesions and high lightening the management of asymmetry whether to be followed-up or to biopsied .

3T multiparametric MR: contrast-enhanced (DCE) MR with DWI and single-voxel spectroscopy could predict the assessment of prognostic indicators in breast cancer?

L. Camera, C. Cavedon, I. Baglio, G. Meliadò, G. Barbazeni, S. Montemezzi; *Verona/IT (camera.lfmad@gmail.com)*

Purpose: To test whether 3T multiparametric magnetic resonance could predict the assessment of prognostic indicators in breast cancer.
Methods and Materials: 318 patients were prospectively studied with a 3T MR. We considered lesion volume, dynamic curve, apparent diffusion coefficient (ADC) provided by DWI and total choline (tCho) peak obtained from spectroscopy (single-voxel technique, volume 10x10x10mm^3). tCho signal-to-noise ratio (SNR) was used as an index of tCho concentration. The pathologic examination of surgical specimens was the standard reference. For each lesion we considered: histological type, nuclear grade, the expression of oestrogen receptor [ER], progesterone receptors [PgR], HER2 and Ki-67, categorised as subtypes luminal A, luminal B, HER2 enriched, triple negative as reported by Perou et al. [Nature(2000); 406:747-752]. Correlations were investigated by logistic regression analysis.
Results: 320 invasive malignant lesions with volume >1cm^3 were included. DCE-MRI and DWI were successfully performed in all patients; regarding spectroscopy, the spectrum quality was considered acceptable in 281/320 lesions with 83 cases that showed tChoSNR≥2. The distribution in the prognostic categories was: 112/320 luminal A; 136/320 luminal B, 39/320 HER2 enriched, 33/320 triple negative lesions. We found that high volumes were correlated with triple-negative group (P=0.002); similar results were obtained with type of curve (type 3 was correlated with triple-negative lesions, P=0.008). No statistically significant correlation was found between ADC values and the different categories. tCho was significantly correlated with the aggressiveness of cancer (P=0.003). Tumours with high volume, curve III and tCho≥2 were more likely triple-negative cancers.
Conclusion: Multiparametric breast MR could predict the assessment of breast cancer prognostic indicators.

B-0460 11:02

Role of magnetic resonance spectroscopy using choline peak as a malignancy marker in diagnosis of breast lesions classified BIRADS III and IV

M.M.K.M. Barakat, N. Chalabi; *Cairo/EG (nivine.chalabi@gmail.com)*

Purpose: To assess the diagnostic value of MR spectroscopy using choline peak as a malignancy marker in diagnosis of breast lesions categorised by mammography and/or ultrasound as (BIRADS III,IV) and correlation with histopathological findings or follow-up.
Methods and Materials: 35 female patients underwent breast MRI with single-voxel MRS performed, on a 1.5 T Philips machine. All patients included had lesions classified as BIRADS III and IV by Mamography+/- US.Single-voxel MR spectroscopic data were collected. MR spectroscopic findings were defined as positive if the signal-to-noise ratio of the choline resonance peak was 2 or greater and as negative in all other cases. MR spectroscopic results were then compared with histologic findings or at least 1 year follow-up , and statistical analysis was performed.
Results: 18 out of 35 patients had BIRADS III Lesions and 17 were BIRADS IV. 25 lesions were benign (71.4%) (7 of them were BIRADS IV lesions and 18 were BIRADS III lesions), and 10 were malignant (28.6%) (all of them BIRADS IV lesions). A choline peak was present in 13 lesions (37.1%) of 35 and in 3 of 18 benign lesions. Calculated MR spectroscopy sensitivity was 100% and specificity 88%. Positive predictive value was 76.9%, false positive rate was 12.0%, correct classification was 91.4%, misclassification was 8.6%.
Conclusion: Breast single MR scan increase the specificity of the conventional dynamic MRI in evaluating breast lesions classified as (BIRADS III and BIRADS IV) and hence reduced the number of unnecessary biopsies.

B-0461 11:10

Adjunct screening with 3-D functional infrared imaging in women with dense breasts: interim-analysis of a prospective study

R. Hellgren[1], A. Sundbom[1], P. Dickman[1], K. Czene[1], P. Hall[1], D. Izhaky[2]; [1]*Stockholm/SE*, [2]*Air Port City/IL (karmakamera99@gmail.com)*

Purpose: 3D functional infrared imaging (3DIRI) has shown high accuracy in assessment for the likelihood of breast cancer based on multiparametric evaluation of metabolic imaging biomarkers1. In this prospective study, we conducted a trial of adjunct screening with 3DIRI in women with dense breasts to evaluate the incremental cancer detection rate.
Methods and Materials: Women with breast density greater than 7.5% on their most recent mammogram were recruited at the time of their subsequent routine screening mammography to undergo additional 3DIRI. The 3DIRI findings were classified into healthy or possibly suspicion of cancer. Women with a negative mammography, but positive 3DIRI result, were referred to contrast-enhanced MRI. Diagnosis of breast cancer was verified after biopsy or surgery and histopathologic examination.
Results: 1728 women (median age 56 years) underwent digital mammography and 3DIRI screening procedures. Mammography detected 7 cancers in 7 women. Two of these 7 women had a positive 3DIRI score and 5 had a normal score. Of 1692 women with negative mammography, 225 women had a positive 3DIRI result and were referred to contrast-enhanced MRI, of which 219 completed the MRI. An additional 6 cancers were identified in 5 women, increasing cancer detection rate from 0.4% to 0.7%, demonstrating incremental cancer detection rate of 86%
Conclusion: The use of 3DIRI to select women for an MRI can result in the detection of additional cancers in women with mammographically dense breasts. Additional studies are necessary to evaluate the role of 3DIRI as adjunct to mammography for women with dense breast.

Detection of breast masses in dense breast tissue with a contrast-enhanced cone-beam breast CT

S. Wienbeck, V. Stahnke, E. von Fintel, J. Lotz, U. Fischer; *Göttingen/DE*

Purpose: To evaluate the conspicuity of breast lesions in dense breasts with a contrast-enhanced cone-beam breast-CT (CE-CBBCT) in comparison to noncontrast CBBCT and mammography in the diagnostic setting.
Methods and Materials: In this prospective, institutional review board approved clinical trial, women with ACR density types c and d and a BI-RADS 4 or 5 assessment in mammography and/ or ultrasound of the breast, underwent noncontrast and CE-CBBCT (Koning Corp.). Two radiologist independently scored lesion conspicuity for the different imaging modalities. Patient age, breast density type, lesions size and histopathological results were recorded. Mean lesion voxel intensity was measured in Hounsfield units (HU) of each mass and the surrounding tissue with three measurements within the same coronal slices before and after administration of contrast media.
Results: In this ongoing study non-contrast and CE-CBBCT has be done in 30 women with 49 lesions (12 benign, 18 semimalignant, 29 malignant). All malignant lesions were seen at CE-CBBCT, with a better visibility in comparison to noncontrast CBBCT or mammography. Benign lesions enhanced in median 38.9±3.5 HU. Semimalignant lesions enhanced in median 42.8±2.5 HU and malignant lesions enhanced in median 66.2±3.2 HU after contrast administration.
Conclusion: The first results with CBBCT show that the lesion detection is improved at CE-CBBCT for women with ACR types c and d in comparison to mammography and noncontrast CBBCT. Semimalignant and malignant lesions show a higher density after contrast administration in comparison to benign lesions. Quantifying lesion enhancement may aid in the detection and diagnosis of breast cancer.

B-0463 11:26

Quantitative optoacoustic imaging detects increased haemoglobin in malignant lesions

O. Abeyakoon, S. Morscher, M. Wallis, P. Moyle, S. Bohndiek, F.J. Gilbert; *Cambridge/UK (oshi.creativity@googlemail.com)*

Purpose: Optoacoustic imaging is an emerging technology, which has the potential to differentiate between benign and malignant breast tissue by exploiting the differential absorption characteristics of endogenous chromophores. Our study aims to detect quantitative changes in haemoglobin concentration/oxygenation to facilitate the differentiation of benign and malignant breast lesions
Methods and Materials: Optoacoustic images from 12 solid malignant lesions (9 no specific type NST, 2 ductal carcinoma in-situ DCIS and 1 invasive lobular carcinoma ILC) and 8 benign lesions (5 fibroadenomas, 1 post-op scar, 1 fibrocystic change, 1 sclerosing-adenosis) were analysed using Matlab. Images taken from the total haemoglobin-weighted (800nm) and deoxyhaemoglobin-weighted (700nm) images were analysed.
A region of interest was drawn around the outline of breast lesion based on anatomical information from ultrasound. All results are presented as mean and standard deviation.
Results: The lesion size ranged from 0.5-3cm. The depth range was 0.3-2.5cm. Lesion signal intensity in the total haemoglobin-weighted image increased from 11.54±1.037 in benign lesions to 15.09±1.221 in malignant lesions (p=0.0398). The result was statistically significant. An increase was also observed in the deoxyhaemoglobin-weighted image, with a rise from 13.94±0.9145 in benign lesions to 15.34±1.258 in malignant lesions. However, the increase was not statistically significant.
Conclusion: Preliminary results from the quantitative analysis of optoacoustic images are encouraging. Development of algorithms for depth correction (fluence correction) and multispectral unmixing algorithms have the potential to further refine the clinical value of quantitative optoacoustic imaging.

B-0464 11:34

Systematic review: translation of optoacoustic imaging into the breast clinic

O. Abeyakoon, S. Morcher, S. Bohndiek, F.J. Gilbert; *Cambridge/UK (oshi.creativity@googlemail.com)*

Purpose: Optoacoustic imaging is an emerging technology that measures endogenous-chromophores relevant in breast cancer. These include total haemoglobin, oxy- and deoxy-haemoglobin, water and collagen. Our systematic review (PRISMA Guidelines) evaluates the current status of clinical translation.
Methods and Materials: Four data-bases (PubMed, Scopus, Biosis, Web of Science) and one search-engine (google-scholar) were searched using the terms “optoacoustic” “photoacoustic” “photo-acoustic” “opto-acoustic” AND “breast” “mamm*”. Eligibility criteria included studies performed in humans and use of histopathology as the gold standard for diagnosing malignancy. Data extracted included prototype design, scan protocol, demographics of women scanned, cancer detection rate and correlation with other modalities where available and reasons for failure.
Results: Nine eligible publications were found with 7 prototype machines (6 with 2D probes, 1 3D probe). One prototype used a single wavelength, 4 prototypes used two wavelengths and two prototypes used four wavelengths. The resolution ranged from 0.25-4mm with depths of 2.6-6cm. In the four studies published between 2007-2014 45/73 (61.7%) invasive cancers were detected. As the technology evolved in the 5 studies published from 2014-2016 68/79 (86%) invasive breast cancers and 7/7 (100%) cases of DCIS were seen. The most common reasons for non visualisation were position of the lesion within the breast, technical and operator errors/limitations. 5 mammographically occult cancers were seen. 9/11 cancers had good co-localisation with MRI.
Conclusion: Optoacoustic imaging is a promising technique that could enhance breast cancer diagnosis. The molecular information provided has the potential to be a prognostic biomarker of outcome.

Study of the nipple-areola complex with MRI and microcoils

M.E. Munoz, M.S. Munoz, L. Mignini, A.M. Pendino; *Rosario/AR (memf@fibertel.com.ar)*

Purpose: To evaluate Magnetic Resonance Imaging with microcoils in the study of the nipple-areolar complex.
Methods and Materials: MR with commercially available microcoils were acquired from 52 patients. The type of secretion, dilated duct (>3 mm) and 4 types of enhancements, defined as unifocal, multifocal in scattered nodes, non-mass enhancement of clustered rings (volume reconstructions showed them as sponges), and mixed pattern (nodes, rings and cyst), were registered. Three-dimensional reconstruction, with the high resolution provided by microcoils, was shared with the surgeon and pathologist.
Results: The duct diameter showed dilated in 66.7% of the cases, which was related to mass enhancement or mixed pattern (p &lt 0.0001). Of the 17 cases with non-dilated duct diameter, 13 showed hematic secretion. Among 34 cases with dilated duct, 28 had serohematic secretion (p &lt 0.0001). Unifocal enhancement was found in 38.8% of the cases, mixed enhancement in 24.5%, rings in 22.4%, and nodes in 12.2%. Of the 16 cases with non-dilated duct diameter, 10 presented enhancement as rings (sponges). 36 patients were referred to surgery; the pathologists found 13 instances of cancer and 10 papillomas. The remaining 13 cases did not present cancer. 9 of 10 papillomas presented dilated conducts and mass enhancement. 11 of the 19 cases with hematic secretion showed no dilated ducts and ring enhancement (sponges) representing micropapillary and cribriform carcinoma
Conclusion: The method is simple and effective, and claims to be used as a first line treatment of thelorrhagia and in the examination of the nipple-areolar complex.

B-0466 11:50

Performance of deep artifical neural networks in the diagnosis of breast cancer in mammography

A.S. Becker, M. Marcon, S. Ghafoor, M.C. Wurnig, T. Frauenfelder, A. Boss; *Zurich/CH*

Purpose: To evaluate the diagnostic performance of a deep artificial neural network (ANN) for the detection of breast cancer in an independent, dual-centre mammography dataset.
Methods and Materials: Mammographies from 2012 at our institution were reviewed (n=3271). Patients diagnosed with cancer or borderline lesions were identified (n=143). I) A matched control cohort was selected from the remaining patients. The ANN was trained with this dataset. From a publicly available dataset, patients with cancer and a matched control cohort were selected (n=35x2). The performance of the trained ANN was tested with this external dataset by receiving operator characteristic (ROC) analysis. II) Cases from Jan-Sept were used for training, from Oct-Dec for testing. Three radiologists (3, 5 and 10 years of experience) evaluated both test datasets. The area under the ROC curves (AUC) between readers and the ANN were compared. A Bonferroni-corrected p value of <0.016 was considered statistically significant.
Results: Mean age of patients with a lesion was 59.6 years (range: 35-88y), and in controls 59.1y (35-83y). Diagnoses were invasive ductal carcinoma in 90, ductal in situ carcinoma in 13, invasive lobular carcinoma in 13, mucinous carcinoma in 3 and borderline lesion in 12 patients. I) AUC of the trained ANN was 0.81 and comparable on the test cases 0.79 (p=0.63). One of the radiologists showed comparable performance (0.83, p=0.17), while two were significantly better (0.91 and 0.94, p<0.016). II) The ANN (0.82) performed comparable to the radiologists (0.77-0.87, p>0.016).
Conclusion: Cancer detection in mammographies with ANN shows similar diagnostic performance when compared to radiologists.

Dose reduction in MDCT-based bone mineral density and microstructure assessment: effects of low-dose simulation and sparse sampling

B.J. Schwaiger[1], K. Mei[1], F.K. Kopp[1], R. Bippus[2], A.S. Gersing[1], E.J. Rummeny[1], J.S. Kirschke[1], P.B. Noël[1], T. Baum[1]; [1]*Munich/DE*, [2]*Hamburg/DE*

Purpose: To evaluate whether in-vivo quantitative bone mineral density (BMD) and microstructure assessment after simulated dose reduction and sparse sampling combined with statistical iterative reconstruction (SIR) is still feasible for differentiating subjects with and without vertebral fractures.
Methods and Materials: In 12 subjects with osteoporotic vertebral fractures and 12 controls pairwise-matched for age and sex undergoing routine thoracic/abdominal MDCT examinations, lower radiation doses were simulated by virtual lower tube current (10, 25 and 50% of the original current) and sparse sampling (10, 25 and 50% of the original raw data). All images were reconstructed with SIR. BMD and trabecular bone microstructure parameters (including bone fraction and trabecular thickness) were extracted from the reconstructed images in T10 to L5.
Results: Effective dose of the original scan was 10 mSv, and 5, 3, 1 mSv for the 50, 25, 10% sparse sampled/low-dose simulated data, respectively. All BMD measurements calculated from different virtual lower tube currents and different sparse samplings were significantly lower in subjects with fractures compared to controls (range: 89-110 vs. 125-187 mg/ml; $P<0.003$ for all). Analogously, bone fraction (0.31-0.47 vs. 0.50-0.52, $P<0.004$ for all), and trabecular thickness were consistently lower in subjects with fractures (1.1-1.3 vs. 1.7-2.4 mm; $P<0.011$ for all).
Conclusion: After simulated dose reduction and sparse sampling, BMD and microstructure parameters obtained from MDCT examinations and processed with statistical iterative reconstruction were still significantly different in subjects with and without vertebral fractures, suggesting osteoporosis diagnosis to be feasible in low-dose protocols.

Establishing a method to measure bone density using spectral CT

M. Ramyar[1], C. Leary[2], R. Aamir[1], N. de Ruiter[1], A.P.H. Butler[1], T.B.F. Woodfield[1], N.G. Anderson[1]; [1]*Christchurch/NZ*, [2]*Portland, OR/US (mohsenramyar@gmail.com)*

Purpose: Combining bone structure and density measurement in 3D is required for site-specific bone quality assessment. Spectral molecular imaging can measure bone density in relation to bone structure by quantifying calcium hydroxyapatite (CaHA) in 3D space. This study aimed to optimise spectral CT methodology to measure bone density in excised human bone samples.
Methods and Materials: MARS CT with CdTe Medipix3RX detector was used with brass filter in four energy binds between 26 and 118 keV for following experiments. Two energy protocols were tested using a Perspex phantom containing four concentrations of CaHA (50, 200, 800 and 1200 mg/cm^3) to assess the linear relationship between attenuation and density and to detect anomalies in measured mass attenuation curve. Using the chosen protocol, linear response and mass attenuation curves were compared with theoretical values for CaHA and $CaCl_2$ phantoms. Two parts of the same human femoral

head were prepared in two conditions (in air and in PBS) then scanned to assess the effect of intra-osseous air on trabecular bone density measurement.
Results: The protocol with energy bins [30-45, 45-60, 60-78 and 78-118 keV] displayed linear response and anticipated mass attenuation behaviour for both CaHA and $CaCl_2$. Due to partial volume effect at bone-air interface, trabecular CaHA density measured 172 ± 46 mg/cm^3 (air present) versus 319 ± 20 mg/cm^3 (prepared in PBS).
Conclusion: We established a bone density protocol for quantifying bone density with spectral CT. In future, this method could be combined with bone structure measurement to study site-specific bone quality.

L1 vertebra CT density measurements are too variable with different scanning protocols to be used as a simple screening test for osteoporosis

E.-L. Gerety, M.A. Hopper, P.W.P. Bearcroft; *Cambridge/UK (emma@dormand.com)*

Purpose: Osteoporosis is an increasing problem in the aging population, with insufficiency fractures causing significant morbidity and mortality. CT density of the L1 vertebral body has previously been found to correlate with bone mineral density. There has been recent interest in screening for osteoporosis in patients undergoing CT by measuring their L1 density. We aimed to determine the feasibility of a simple L1 density threshold to identify patients with osteoporosis. We investigated some of the parameters causing variability in L1 density measurements.
Methods and Materials: Retrospective study of 200 randomly selected patients from a previous audit of CT reporting of vertebral fractures. The L1 density was measured on 864 CT scans with a variety of scanners, kVp and iv contrast protocols.
Results: L1 densities for the same patient with multiple scans within 6 months varied by a mean of 27.5 HU (95%CI 23.8-31.1 HU). Iv contrast resulted in a mean increase of 24.5 HU (95%CI 21.6-27.4 HU). Changing the scan kVp from 100 kVp to 130 kVp lead to a mean decrease of 24.1 HU (95%CI 13.45 - 34.8 HU). Increasing age decreased the L1 density by approximately 1.7 HU per year.
Conclusion: There is too much variation in L1 CT density due to patient and scanning parameters to define a single threshold to identify those at risk of osteoporosis. Previous studies have been performed on more defined subsets of patients. Patient age and scanning protocol have significant effects on the measured CT density of the L1 vertebral body.

CT-based bone strength prediction using finite element analysis: how much dose is needed?

T. Baum[1], D. Anitha[2], K. Mei[1], F.K. Kopp[1], P. Foehr[1], P.B. Noel[1], J.S. Kirschke[1], K. Subburaj[2]; [1]*Munich/DE*, [2]*Singapore/SG (thbaum@gmx.de)*

Purpose: Multi-Detector Computed Tomography (MDCT) image-based finite-element (FE) analysis has shown significant improvement in prediction of vertebral bone strength beyond bone mineral density (BMD). However, high radiation exposure limits its use in clinical routine. This study aimed to evaluate the effect of dose reduction, by means of tube exposure reduction, on bone strength prediction from FE analysis.
Methods and Materials: Fresh thoracic midvertebral specimens (n = 11) were imaged in a water bath to simulate the soft tissue environment using MDCT with different x-ray tube exposures (80, 150, 220 and 500 mAs). Differences in image quality and geometry of each specimen were measured. FE analysis was performed on all specimens to predict fracture load. Paired t-tests were used to compare the results obtained, using the highest MDCT dose (500 mAs) as reference.
Results: Dose reduction had no significant impact on FE-predicted fracture loads, with significant correlations obtained with reference to 500 mAs, for 80 mAs (R^2 = 0.997, p < 0.001), 150 mAs (R^2 = 0.998, p < 0.001) and 220 mAs (R^2 = 0.987, p < 0.001). There were no significant differences in volume quantification between the different doses examined.
Conclusion: MDCT radiation dose could be reduced substantially with no impact on strength estimates obtained from FE analysis. This finding may enable early diagnosis and advanced monitoring of osteoporosis and associated fracture risk.

B-0471 11:02

Femoral neck strength prediction in osteoporosis patients: trabecular bone analysis using tomosynthesis images

M. Fujii, T. Aoki, S. Yamaguchi, Y. Hayashida, K. Nakano, Y. Okada, K. Saito, Y. Tanaka, Y. Korogi; *Kitakyushu/JP*

Purpose: Although bone mineral density (BMD) by dual x-ray absorptiometry (DXA) has been used for the diagnosis of osteoporosis, bone marrow quality also has important implications in bone strength prediction. The purpose of this study is to determine the value of trabecular bone analysis using tomosynthesis (TS) images to BMD in femoral neck strength prediction of osteoporosis patients.
Methods and Materials: Forty-seven consecutive osteoporosis patients were included in this study. They underwent DXA, TS, and CT covering the hip joints within a week. We extracted the trabecular patterns of TS images, and obtained the total strut length (TSL), the bone volume per tissue volume (BV/TV) and the textural features (HOM: homogeneity, ENT: entropy, COR: correlation, CON: contrast, VAR: variance) as the indices of TS images. Failure load of the femoral neck, determined by the CT-based finite-element method (FEM), was used as the gold standard for bone strength. Stepwise multiple regression analysis for evaluating the availability of the TS image indices was performed.
Results: Amongst the combinations of the BMD and each index of TS images, the combination of BMD with the TSL and the VAR showed the highest correlation to the failure load by CT-FEM. The correlation between the failure load and the BMD with the TSL and the VAR (r^2=0.72) was significantly higher than that between the failure load and the BMD alone (r^2=0.67; p=0.0397).
Conclusion: TS-based trabecular bone analysis in combination with BMD measurements can potentially be used in predicting bone strength in osteoporosis patients.

B-0472 11:10

Validation of bone volume percentage and pore size measurements extracted from MR and MDCT against synthetic bone phantom

A. Ten-Esteve[1], R. García-Marcos[1], F. García-Castro[1], L. Martí-Bonmatí[1], M. Pérez[2], A. Alberich-Bayarri[1]; [1]*Valencia/ES*, [2]*Zaragoza/ES (ten_ama@gva.es)*

Purpose: The characterisation of the bone microarchitecture from MR or CT is significantly relevant to predict the risk of bone fracture. Our purpose was to evaluate the accuracy of the bone analysis methodology and compare it to the reference standard under different imaging modalities.
Methods and Materials: The reference is based on synthetic bones, consisting of 10 samples, 5 with 15% and 5 with 30% of material density that were acquired from SAWBONES® (Washington, USA) with known mass, density and pore size and were scanned using MDCT and MR. The voxel size in MDCT was of 0.234x0.236x0.67mm. The MR sequence was a T2-GRE with a voxel of 0.146x0.146x0.5mm. The image processing steps were different in MDCT and MR, according to a methodology developed in our group. Bone volume to total volume (BV/TV) was measured to define the bone percentage in the volume. Trabecular separation (Tb.Sp) was quantified by taking into account consecutive voxels corresponding to marrow cavities.
Results: Mean relative errors of 9% and 27% were obtained for MDCT and MR measurements of BV/TV, with a tendency to overestimate the parameter in 15% density samples but underestimate in 30% density samples with similar errors. Mean relative errors for Tb.Sp were of 4% and 34% for MDCT and MR, respectively.
Conclusion: MR and MDCT measurements of trabecular bone volume percentage and pore size were calibrated against the known ground truth from synthetic bones. These results add insight into the validation of bone microarchitecture imaging biomarkers.

B-0473 11:18

Characterisation of sharp force trauma and thermal injuries on human bone samples: a forensic MicroCT study

G. Pelletti[1], G. Cecchetto[1], D. Miotto[1], G. Viel[1], P. Fais[2], M. Montisci[1], S.D. Ferrara[1], C. Giraudo[3]; [1]*Padua/IT*, [2]*Bologna/IT*, [3]*Vienna/AT (chiara.giraudo@meduniwien.ac.at)*

Purpose: Identification of sharp force and thermal injuries is a main challenge in forensic medicine.Thus, aim of this study was to investigate the role of MicroCT for the detection of experimentally produced saw marks and the characterization of bone structural parameters after fire exposure.
Methods and Materials: Saw-marks were experimentally produced on eight human bone samples using either a 24-teeth-per-inch (TPI) with alternating-set or a 18-TPI with wavy-set rip-cut-saw (ie.,four samples each). Each sample was then examined by MicroCT before and after exposure to open-flame fire for two and ten minutes. For all investigated conditions, saw-marks' detectability and structural cortical (bone volume (BV_c), bone surface (BS_c), bone surface/bone volume (BS/BV_c)) and trabecular bone parameters (BV_t,

BS_t, BS/BV_t, structural model index, anisotropy degree, trabecular thickness, -spacing, -number, -pattern factor) were collected and compared using a one-way-repeated measures ANOVA with Greenhouse-Geisser correction and Bonferroni post-hoc tests.
Results: All saw-marks (n=8) were recognizable at each investigated condition (i.e., fresh, after two and ten minutes of fire exposure). BV_t and BS_t significantly decreased comparing two (BV_t mean±SD=5.16±2.96 mm^3; BS_t=133.40±69.13 mm^2) and ten (BV_t=3.48±2.23 mm^3;BS_t=97.15±56.72 mm^2) minutes exposure ($p<0.05$, each). BV_c decreased whereas BS/BV_c increased at all tested condition (BV_c values: 139.95±67.18 mm^3,131.66±71.64 mm^3,119.89±68.91 mm^3; BS/BV_c values: 5.30±1.06%, 5.48±1.29%, 5.94±1.17%, respectively fresh, at two and at ten minutes fire exposure; $p<0.05$,each). All other cortical and trabecular parameters did not show any significant difference ($p>0.05$).
Conclusion: MicroCT demonstrated to be an accurate forensic tool to investigate bone saw marks, even after thermal injuries, providing information about heat-induced bone modifications. Future studies including prolonged fire exposure are necessary to further assess these evidences.

The effect of vertebral osteoarthrosis (VO) and vertebral fractures (VF) on trabecular bone score (TBS): preliminary results
A. Poloni[1], C. Monaco[1], S. Rapisarda[1], G. Di Leo[2], C. Messina[1], L.M. Sconfienza[1]; [1]*Milan/IT*, [2]*San Donato Milanese/IT (alessandropoloni.md@gmail.com)*

Purpose: TBS is a textural score that provides an indirect index of trabecular microarchitecture from lumbar spine (LS) dual energy x-ray absorptiometry (DXA). We evaluated the effect of VO and VF on bone mineral density (BMD) and TBS.
Methods and Materials: We retrospectively identified all patients that performed an LS DXA in January-March 2015 together with an LS x-ray/MRI (maximum interval with DXA=6 months). Among them, we included patients with VO or VF diagnosed on LS x-ray/MRI with a maximum of two vertebrae involved. We calculated the BMD/TBS difference between vertebrae affected by VO/VF and the adjacent vertebrae with the greater values of BMD/TBS; between vertebrae affected by VO/VF and the average L1-L4 BMD/TBS (average value included the vertebrae with VO/VF).
Results: Out of 258, we included 20 patients (19 females, age=72±10y) with VO (n=13) or VF (n=7). Mean BMD (g/cm2): vertebrae with VO/VF = 1.004±0.167; adjacent-vertebrae = 0.935±0.154; L1-L4 = 0.946±0.127. Mean TBS: vertebrae with VO/VF = 1.300±0.122; adjacent-vertebrae = 1.252±0.122; L1-L4 = 1.261±0.091. Considering VO+VF together, all differences were significant ($p<0.05$), except for BMD difference between vertebrae with VO/VF and adjacent-vertebrae ($p=0.082$). Considering only VO vertebrae, all differences between vertebrae were significant ($p<0.05$). Considering only VF vertebrae, no differences were found with adjacent-vertebrae/L1-L4 for BMD and TBS ($p>0.119$). Correlations between BMD and TBS for vertebrae with VO/VF were all significant ($p<0.05$): R=0.5247 (VO+VF), R=0.6194 (only VO), R=0.9224 (only VF).
Conclusion: Compared to adjacent vertebrae and L1-L4, VO significantly impacts both on BMD and TBS, while no differences were found for VF. BMD and TBS are positively correlated, especially for VF.

B-0475 11:34

Lumbar bone marrow perfusion in osteoporosis rabbit with dynamic contrast enhancement MRI: correlation with BMD and MVD
H. Yang, Y. Li, F. Lv, O. Yu; *Chongqing/CN (frankyang119@126.com)*

Purpose: To use dynamic contrast enhancement (DCE-MRI) to assess lumbar spine bone marrow blood perfusion in osteoporosis rabbit and correlate perfusion with bone mineral density (BMD) and microvessel density (MVD).
Methods and Materials: 22 New Zealand white rabbits were randomly divided into 2 groups, including experimental group (n=12) and control group (n=10). Bilateral ovariectomies (OVX) were applied in experimental group. DCE-MRI, DEXA and immunohistochemistry exam were respectively performed both groups in 3, 5, 7 moths after OVX. Vertebral maximum percentage of enhancement (Emax), enhancement slope (ES), BMD and MVD were measured from them.
Results: BMD of lumber spine in OVX group in postoperative 7m was obviously decreased compared to control group ($P<0.05$). In postoperative 3 and 5m lumber spine bone marrow Emax and ES had no difference both groups($P>0.05$), however the significant difference were found in postoperative 7m ($P<0.05$), Emax and ES were significantly decreased in OVX group. MVD of vertebral marrow was 67.58±11.6 in control group and 39.32±9.54 in OVX group, which were significant difference between them ($P<0.05$).Vertebral marrow Emax and ES were significant positive correlation with BMD and MVD in 7m OVX group (r=0.714, 0.820, 0.866 and 0.771,$P<0.05$).
Conclusion: Lumbar bone marrow perfusion is significantly decreased in osteoporosis rabbit, similarly vertebral MVD obviously reduce too. DCE-MRI can provide more information about osteoporosis blood perfusion. Emax and ES are significant correlation with BMD and MVD. This result may suggest a vascular component in the pathogenesis of OP and is helpful to diagnosis and treatment of OP.

B-0476 11:42

Prediction of fracture non-union healing using clinical scores, contrast-enhanced ultrasound (CEUS) and dynamic contrast-enhanced MRI (DCE-MRI)
M.-A. Weber, T. Bruckner, G. Schmidmaier, H.-U. Kauczor, C. Fischer; *Heidelberg/DE (marcandre.weber@med.uni-heidelberg.de)*

Purpose: To assess whether dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) and contrast-enhanced ultrasound (CEUS) can predict fracture non-union consolidation after revision surgery.
Methods and Materials: Perfusion within non-unions of extremities was prospectively quantified in 205 patients (mean, 51.5 years; 76 female) before revision surgery and at 6, 12, 26, 52 and more weeks follow-up. 3-Tesla DCE-MRI derived signal-intensity-curves obtained from a region-of-interest analysis were normalized to adjacent muscle tissue and non-unions were classified as vascularised or not depending on the contrast uptake within the non-union. Potential infection was measured by positive microbiologic culture of the resected non-union tissue. In addition, CEUS was performed in 43 patients (mean, 46.8 years; 14 female). The ability to predict successful outcome with osseous consolidation at CT of DCE-MRI and CEUS parameters, body mass index (BMI), and the non-union scoring system (NUSS) was estimated by receiver-operating-characteristic analysis.
Results: 103/169 (61%) non-unions eventually healed and demonstrated higher perfusion than in failed consolidation at 6 ($p=0.023$), 12 ($p=0.025$) and 26 ($p=0.009$) weeks follow-up (sensitivity/specificity of DCE-MRI at 26 weeks for prediction of consolidation: 75%/87%, false classification rate: 19%). 50% of all non-unions consolidated within 14 months after revision surgery. Both a low BMI ($p=0.041$) and NUSS ($p<0.0001$) were associated with eventual consolidation. CEUS detected preoperatively increased perfusion kinetics in infected non-unions (n=16/43, rise time ($p=0.024$), time to peak ($p=0.011$), sensitivity/specificity: 93%/65%).
Conclusion: DCE-MRI at 26 weeks after revision surgery of non-unions predicts successful outcome. Preoperative vascularity in CEUS, NUSS and BMI are important prognostic factors concerning consolidation.

B-0477 11:50

Quantitative MR T_2* relaxometry in osteoporosis of ovariectomised rabbits
H. Yang, Y. Li, F. Lv, Y. Ouyang; *Chongqing/CN (frankyang119@126.com)*

Purpose: To establish a primary osteoporosis rabbit model by ovariectomy (OVX) and measure lumbar spine T_2* and R_2* MR relaxation parameters in osteoporosis rabbit and compare them with bone mineral density (BMD) and histomorphology.
Methods and Materials: 22 New Zealand white rabbits were randomly divided into 2 groups, including experimental group (n=12) and control group (n=10). Bilateral ovariectomies were applized in experimental group. MRI, DEXA and pathohistology exam were respectively performed both groups in 3, 5, 7 moths after OVX. T_2*, R_2* and BMD of lumber spine were obtained.
Results: BMD of lumber spine in OVX group in postoperative 7m was obviously decreased compared to control group ($P<0.05$). In postoperative 3m lumber spine T_2* and R_2* value had no difference both groups; but the significant difference were found in postoperative 5m ($P<0.05$) and 7m ($P<0.001$), T_2* was significantly increased and R_2* was obviously decreased. Histomorphological characteristics showed the trabecular bone were thinner, interrupted and trabecular spaces enlarged and trabecular number lessened in OVX group. Lumber spine T_2* value was significant inverse correlation with BMD in OVX group ($r=-0.599$, $P< 0.001$), and R_2* was positive association with BMD ($r=0.746$, $P< 0.001$).
Conclusion: T_2* and R_2* MR relaxation time can sensitively detect trabecular bone micro-architecture changes in osteoporosis rabbit and are significant correlation with BMD. Combination with T_2*, R_2* and BMD can better reflect bone strength and bong quality variation in early OP.

Dose evaluation in dental, interventional and radiotherapy CBCT: the EFOMP-IAEA-ESTRO guidelines
H. de las Heras[1], R.M. Sánchez Casanueva[2], K. Mair[3], A. Baumgartner[4], F. Schöfer[1]; [1]*Zorneding/DE*, [2]*Madrid/ES*, [3]*Kempten/DE*, [4]*Munich/DE*
(hugo@quart.de)

Purpose: Investigate the applicability of the dose action levels provided in the recent EFOMP-IAEA-ESTRO guidelines for quality control of CBCT devices, and introduce one measure for patient dose estimation.
Methods and Materials: Empty scans of the most common protocols were performed in a linac, C-arm and dental scanner. The incident air kerma ($K_{a,i}$) at the flat panel was measured using a solid-state probe. The dose in the field of view D_{FOV} and the average $K_{a,i}$ at the skin of a hypothetical patient head $K_{a,i}$(skin) were subsequently calculated. A kerma-area product (KAP) meter was attached to the exit of the tube and the scan was repeated with the same exposure parameters.
Results: The KAP meter attenuates the beam intensity by 8 % (125 KVp) up to 13 % (80 KVp). The corresponding D_{FOV}, KAP and $K_{a,i}$(skin) were respectively for the dental scanner 23.1±1.4 mGy, 0.86±0.05 Gycm^2 and 3.3 ±0.2 mGy; for the interventional C-arm (high-dose protocol) 42±2 mGy, 19.8±1.2 Gycm^2 and 23.4±1.3 mGy; and for the linac (full-trajectory head protocol) 8.8±0.5 mGy, 2.74±0.16 Gycm^2 and 5.0±0.3 mGy.
Conclusion: The action level for the D_{FOV} (50 mGy) seems appropriate for common CBCT protocols (excluding high resolution). The three suggested quantities can be used for constancy tests accompanied by image quality evaluations. The $K_{a,i}$(skin), as opposed to the other quantities, represents actual patient exposure and it is sensitive to changes in the field of view and the scanning geometry. Therefore, it can be useful for both quality control and patient dose estimations.

Patient dose in CT: what is the impact of the generation of the CT scanner? Results of a decade of patient dose collection in France
P. Roch, D. Celier, S. Dreuil, C. Etard; *Fontenay-aux-Roses/FR*
(serge.dreuil@irsn.fr)

Purpose: To assess evolution of patient dose in CT since implementation of diagnostic reference levels (DRLs) in France in 2004.
Methods and Materials: Volume Computed Tomography Dose Index ($CTDI_{vol}$) and Dose Length Product (DLP) per sequence are annually collected from all CT departments by the French national institute for radiation protection (IRSN) in order to update national DRLs, defined as the 75th percentile of the distributions ($CTDI_{vol,75}$ and DLP_{75}). Evolution of $CTDI_{vol,75}$ and PDL_{75} from 2006 to 2015 was analyzed for chest, head and abdomen/pelvis CTs, based on 500 to 12700 patient dose data per examination per year. The influence of the age of the CT scanner on DLP_{75} was studied on 2013 to 2015 data.
Results: The $CTDI_{vol,75}$ for chest, head and abdomen/pelvis CTs decreased by 36%, 38% and 24% respectively, whereas the reductions in DLP_{75} were evaluated to 28%, 27% and 20%. The DLP_{75} increased significantly with the age of the CT scanner. For abdomen/pelvis CT, an increase by 35% was noticed between CT scanners commissioned in 2015 and 5 year old ones, all brands taken together.
Conclusion: Recent CT scanners enable effective patient dose reduction, mainly due to iterative reconstruction algorithms and detectors' improvement. Based on these results, French DRLs per sequence in CT (published in 2011) should be consequently reduced by 34% in average. Nevertheless, in order to optimize the global exposure of the patient, clinical DRLs taking into account all the sequences of an examination, remain necessary.

Dental scan MDCT: comparison of dose levels and image quality assessment between three centres in two European countries
S. Puggina[1], S. Galo[2], M. Calderone[3], L. Best[4], K. Katsari[5], R. Illing[5]; [1]*Monselice/IT*, [2]*Évora/PT*, [3]*Padova/IT*, [4]*London/UK*, [5]*Amsterdam/NL*
(stefano.puggina@affidea.it)

Purpose: To analyse the relationship between radiation exposure and diagnostic image quality of dental multidetector Computed Tomography (MDCT) protocols, to determine best practice and compare to published dose figures from cone beam CT (CBCT).
Methods and Materials: Data was collected for 90 anonymised, unenhanced dental MDCT examinations from three centres in two European countries. Protocols from three MDCT scanner models were compared; Discovery 750 HD 128 with ASiR, LightSpeed VCT 64 with ASiR (GEHC, Mil. USA) and Somatom Sensation 64 with Care Dose option (Siemens Healthineers, Erlangen, Germany). GEHC DoseWatch recorded and analysed protocol parameters, gender, age, CTDIvol, DLP and Effective Dose. Images were evaluated by three radiologists using a 5-level scale for subjective quality. For visualisation of pathology, a 3-level scale was used. VGA, VGC and inter-rater reliability analysis were used in correlation with statistical analysis of the dose values. Dose values were compared to those published for dental CBCT.
Results: None of the centres were deemed to produce significantly inferior image quality on blinded assessment, but one of the three centres did give significantly less dose. Published Effective Dose figures for CBCT varies between 11µSV and 1073µSV.
Conclusion: It is possible to significantly reduce dose while maintaining image quality for dental MDCT. Work is underway to reproduce the lowest dose CT protocol on the other systems across the network. Although historical dose figures for CBCT may be lower than MDCT, without assessment of comparative imaging, conclusions as to the best method of examination cannot be drawn.

B-0481 11:03

Effective and equivalent organ doses conversion factors in coronary angiography and percutaneous coronary interventions with a radial access
M. Brambilla, B. Cannillo, R. Mathoeud, A. Bongo, A. Carriero; *Novara/IT*
(marco.brambilla@maggioreosp.novara.it)

Purpose: To derive Effective dose (ED), organ dose (H_T) and conversion factors with the Dose Area Product (DAP) in Coronary angiography (CA) and percutaneous coronary intervention (PCI) with a radial access.
Methods and Materials: The patient population included 34 patients referred for CA and 31 for PCI. ED, HT and risks were derived from in-the-field DAP measurements using Monte Carlo methods embedded in the PCXMC software.
Results: Median DAP of 23.2 and 56.8 Gy cm2 and ED of 6.9 and 20.0 mSv were found for CA and PCI, respectively. Conversion factors between DAP and effective dose were 0.30±0.04 mSv Gy-1 cm-2 for CA and 0.33±0.05 mSv Gy-1 cm-2 for PCI. The correlation between E and DAP was excellent for both CA (r= 0.99) and PCI (r=0.96). The correlation between HT and DAP for different organs/tissues ranged from r=0.87 to r=1 and from r=0.71 to r=0.98 for CA and PCI, respectively.
Conclusion: A single factor, the total DAP, can be used to reliably estimate ED and H_T without the need of a detailed analysis for each patient. While this circumstance favorably solves the issues of reliability in the estimation of ED and H_T using conversion factors, the issues of accuracy of such estimates still remains challenging. The disparities in ED/DAP and H_T/DAP conversion factors (a factor of 3) predominantly arose from differences in the phantoms used. This is of concern also considering that specific methods for organ dose estimation are being embedded in software for radiation dose data collection and reporting.

B-0482 11:11

Radiation exposure during CT-guided interventional procedures for adults
N. Guberina, S. Suntharalingam, K. Nassenstein, J. Theysohn, A. Ringelstein, M. Forsting, A. Wetter; *Essen/DE*

Purpose: The purpose of this study was to examine radiation dose levels of CT-guided interventional procedures at a large multicenter institute.
Methods and Materials: In a retrospective study design altogether 1219 CT-guided interventional procedures of different organ regions ((A) abdomen (n= 516), (B) chest (n= 528), (C) spine (n= 134) and (D) extremities (n= 41)) at different CT-scanner generations ((I) SOMATOM Definition AS+, (II) Somatom Definition Volume Zoom, (III) Emotion 6) were included in the time period from 2013-2016. Important CT-parameters, as well as standard dose descriptors like $CTDI_{vol}$ and DLP were examined. Additionally, effective and organ doses

were calculated using Monte Carlo simulation, following recommendations by ICRP103.
Results: The mean effective dose [$CTDI_{vol}$; DLP] for each of the four procedures is summarised as follows: (A) (I) 9.3 mSv [10.8 mGy; 655 mGy*cm; SSDE12.2 mGy]; (II) 13.9 mSv [13.3 mGy; 813 mGy*cm; SSDE13.2 mGy]; (B) (I) 7.3 mSv [7.8 mGy; 440 mGy*cm; SSDE8.8 mGy]; (III) 11.4 mSv [9.5 mGy; 684 mGy*cm; SSDE11.9 mGy]; (C) (I) 6.3 mSv [13.3 mGy; 460 mGy*cm]; (II) 7.4 mSv [14.4 mGy; 620 mGy*cm]; (D) (I) 4.3 mSv [9.1 mGy; 257 mGy*cm]; (II) 10.8 mSv [14.7 mGy; 777 mGy*cm].
Conclusion: This is the first data acquisition of radiation exposure during various CT-guided interventional procedures at a large interventional and diagnostic radiological centre in Germany. The assessment of radiation exposure is crucial for the determination of diagnostic reference levels. Employment of newer CT-scanner generations is recommended for CT-guided interventions in order to reduce radiation exposure.

B-0483 11:19

Monte-Carlo evaluation of mean glandular dose in spot compression mammography

A. Sarno[1], D.R. Dance[2], R.E. van Engen[3], K.C. Young[2], P. Russo[1], F. Di Lillo[1], G. Mettivier[1], K. Bliznakova[4], I. Sechopoulos[3]; [1]*Naples/IT*, [2]*Guildford/UK*, [3]*Nijmegen/NL*, [4]*Varna/BG (ioannis.sechopoulos@radboudumc.nl)*

Purpose: To characterise the dependence of mean glandular dose (MGD) on image acquisition and breast model parameters and evaluate alternative dose-related metrics in spot compression mammography.
Methods and Materials: Using a previously validated Geant4-based Monte Carlo simulation, three different previously-proposed dose related metrics for spot compression mammography were characterised: the standard normalised glandular dose to the entire breast (DgN), the normalised MGD to only the directly irradiated portion of the breast (DgN_v), and the DgN weighted by the ratio of irradiated breast mid-height area to the entire breast area (DgN_m). The variation of each with field-of-view size, spot area thickness, x-ray energy, spot area and position, breast shape and size, and system geometry using a standard breast model was studied. Comparison of the simple model results to estimates with patient-based heterogeneous breast models was also performed.
Results: As expected, DgN is lower than DgN_v for all partial breast irradiation areas, especially so for clinically used spot compression areas. DgN_m underestimates DgN by up to 14%. In spot compression, unlike in full field mammography, DgN varies considerably with breast area. Neither the difference in breast thickness between the spot compressed area and the uncompressed area, nor the position and size of the compressed area introduce a variation in DgN.
Conclusion: The results provide insight in how DgN and two alternative dose metrics behave with various image acquisition and model parameters. This will be used as part of the development of a new breast dosimetry model undertaken by the AAPM and EFOMP.

SSDE calculations in thoracoabdominal CT: comparison of different approaches

C. Aberle[1], M. Obmann[1], B. Stieltjes[1], S. Schindera[2]; [1]*Basle/CH*, [2]*Aarau/CH (christoph.aberle@usb.ch)*

Purpose: To evaluate SSDE (Size Specific Dose Estimate) calculations for thoracoabdominal CT compared to the recommended method described in the AAPM Report 220.
Methods and Materials: SSDE values of 115 adult thoracoabdominal exams (52 male, 63 female, BMI-range 15.8 to 42.9 kg/m^2) from three CT scanners (Siemens Somatom Definition AS+, Flash and Edge) were evaluated using three methods. First, the study's reference was calculated according to the AAPM Report 220. A dedicated reconstruction with non-overlapping slices and a 500 mm field of view was used. Slice by slice, the water-equivalent diameter (WED) was calculated excluding the patient table, the $CTDI_{vol}$ was extracted and the SSDE was determined. The average over all slices was used as the reference SSDE. Secondly, the WED of only one slice at the center of the scan region was calculated and the SSDE was obtained using the mean $CTDI_{vol}$. Thirdly, the SSDE value was extracted from a dose-monitoring software (Radimetrics, Bayer HealthCare).
Results: The ratios of the SSDEs from the central slice method to the reference SSDEs averaged 0.96 with a standard deviation of 0.04. The ratios of the SSDEs from the dose-monitoring software to the reference SSDEs averaged 0.95 with a standard deviation of 0.04.
Conclusion: The SSDE values from the dose-monitoring software and from the central slice method are in good agreement with the reference SSDEs. They both have a root mean square deviation of less than 10% relative to the reference, which is a quality criterion proposed in the AAPM Report 220.

Accuracy of size specific dose estimate (SSDE) calculation from water-equivalent diameter of the center slice in computed tomography

J. Boos, P. Kröpil, O.T. Bethge, J. Aissa, G. Antoch, C. Thomas; *Düsseldorf/DE (Johannes.Boos@med.uni-duesseldorf.de)*

Purpose: To quantify the impact of patient size on accuracy of SSDE calculation from central slice with water-equivalent diameter (Dw).
Methods and Materials: 1812 CT scan series (1583 adult: 1195 abdominal, 388 chest, 61.5±15.7years, BMI 26.0±5.6kg/m²; 229 paediatric: 26 abdominal, 203 chest, 9.3±5.0years, BMI 17.6±4.3kg/m²) were included in this retrospective study. Dw was automatically calculated for all slices of each CT using a self-developed Matlab tool (The Mathworks, Natick, MA). SSDE were calculated: 1. based on Dw from the centre slice and overall CTDIvol; and 2. based on Dw and CTDIvol from all slices of the volume, which was regarded as the reference standard. Impact of patient weight, height and BMI on SSDE accuracy was assessed.
Results: The mean absolute relative difference between overall SSDE and the centre slice approach was 3.9±3.4% (range 0-30.5%) for adult abdominal, 5.0±3.2% (0-17.2%) for adult chest, 3.1±2.6% (0-9.2%) for paediatric abdominal and 2.0±1.7% (0-15.5%) for paediatric chest CT. Accuracy of the centre slice SSDE approach correlated with patient size (BMI: r=0.15 in paediatric chest to r=0.43 in adult abdominal CT; body weight r=0.26 in paediatric chest to r=0.49 in paediatric abdominal CT) with a tendency for dose overestimation in small and underestimation in large patients.
Conclusion: SSDE calculation using the centre slice approach leads to a mean relative absolute error of 2-5% compared to SSDE calculation with all slices of the scan volume. Accuracy of the centre slice approach is related to patient size with SSDE underestimation in large and overestimation in small patients.

Initial estimation of an optimal dose protocol for evaluation of the lumbar spine of human cadaveric specimens in the upright position with a novel 3D x-ray system

R.M. Benz[1], D. Harder[1], J. Voigt[2], A. Fieselmann[2], F. Amsler[1], R. Menz[1], A.L. Falkowski[1], B. Stieltjes[1], A. Hirschmann[1]; [1]*Basle/CH*, [2]*Erlangen/DE (robyn.benz@usb.ch)*

Purpose: To estimate the optimal dose protocol and assess image quality and radiation dose of the lumbar spine of cadaveric specimens with a different BMI in the upright position using a prototype 3-D x-ray system and compare it to conventional CT.
Methods and Materials: The lumbar spine of five formalin-fixed cadaveric human specimens (BMI 22-35) was assessed in the upright position using 3D tomography (Multitom Rax/Siemens Healthineers/Erlangen/Germany). Specimens were scanned at a detector surface dose (DSD) of 0.696µGy with varying kV-levels (70/81/90/100/109/121kV). With the optimal kV DSD was varied (0.278/0.435/0.548/0.87/1.09µGy). Conventional CT (Somatom Definition Flash/Siemens Healthineers/Erlangen/Germany) was performed. Images were rated qualitatively (visibility of cortex/end plates/facet-joints/trabeculae/neuroforamina/posterior alignment/spinal canal/nerve roots). Noise and radiation dose were assessed quantitatively. Descriptive statistics were used ($p<0.05$).
Results: For specimens with a BMI<32 81kV and for BMI≥32 121kV and 0.87uGy yielded the best image quality. In specimens with a BMI<32, depiction of all structures was good and comparable to CT except for nerve roots. For specimens with a BMI≥32, image quality was limited. Noise did not differ significantly (1.3 vs 0.8). Dose measurements were higher in 3D tomography (mean DLP; 984±412 vs 387±102 mGycm).
Conclusion: An optimal dose protocol for 3D-tomography in the upright position of the lumbar spine in cadaveric specimens was estimated. Image quality is comparable to CT in specimens with BMI<32 and limited for soft tissue structures and specimens with BMI≥32. Patient dose is higher in 3D tomography than CT.

How contrast data management complements dose data management: preliminary results

L. Pyfferoen[1], K. Van De Moortele[1], F. Zanca[2], M.-S. Walgraeve[1], C. Lafay[2], J.W. Casselman[1]; [1]*Bruges/BE*, [2]*Buc/FR (lotte.pyfferoen@azsintjan.be)*

Purpose: Increasingly medicine is being defined and evaluated based on patient outcome. The aim of this study was to assess how implementation of a contrast data management software can help in achieving best practices and better patient outcome.
Methods and Materials: In June 2015, an existing dose tracking system (DoseWatch, GE Healthcare) was upgraded with a contrast tracking module. Contrast administration data of CT-protocols using intravenous Iodine administration were collected from a GE-Revolution CT-scanner for a 7-months period. The injected volume per patient was analysed and compared to hospital specific used volume (fixed volume, adapted to patient habitus, kidney function and age) for thorax, abdomen, thorax-abdomen and neck CTs. Image quality was quantified by measuring Hounsfield Units (HU) of selected organs. The operator's impact on the administered volume was also assessed.
Results: Non-standard procedures for the investigated CT-protocols were identified. For CT-thorax-abdomen exams the contrast volume was infrequently adapted to patient habitus, resulting in large variations in image quality (e.g. liver, 351% variation in HU). The contrast volume was adapted to patient age only in 62% of patients above 80 years. Operator dependence was also observed, with less trained operators using fixed contrast volumes more often.
Conclusion: The implementation of contrast data management as a complementary tool to dose management, allows identifying unwanted variations in the administered contrast volume and therefore image quality for the same CT-protocol. As a consequence, contrast protocols optimisation and standardisation have been put in place along with increased awareness and management of the patient risk.

Radiation dose to obese patients in projection radiography: where we are

S.J.M. Alqahtani[1], K.M. Knapp[1], R. Welbourn[2], J.R. Meakin[1], R. Palfrey[1], K. Thomson[2], S.J. Rimes[2]; [1]*Exeter/UK*, [2]*Taunton/UK (sa512@exeter.ac.uk)*

Purpose: The increasing prevalence of obesity in the UK has brought new challenges in imaging this group of patients. This study aimed to investigate the dose delivered to obese patients and its relation to patient's size.
Methods and Materials: Data from 1964 patients from a bariatric clinic were reviewed with relevant approval. Patients' dose data were collected for all projection radiography and gastrointestinal fluoroscopy procedures. Multiple exams in one day including only one dose area product (DAP) reading and exams with missing DAP and exposure factors were excluded. Correlations were calculated and data analysed to yield the third quartile for each examination using STATA 14.
Results: A total of 630 patients matched the inclusion criteria. The national diagnostic reference level (NDRL) was used as a comparison. The 3rd quartile of DAP is used here. The lumbar spine (30.3 Gy.cm^2, 34 patients), abdomen (17.6 Gy.cm^2, 50 patients), pelvis (5.69 Gy.cm^2, 27 patients), cervical spine (0.9 Gy.cm^2, 16 patients) and chest (0.32 Gy.cm^2, 183 patients) all exceeded the NDRL. Weak to moderate correlations were found between DAP in abdominal x-ray and BMI (r= 0.42), height (r= 0.38) and weight (r= 0.52) with p <0.005, DAP in chest x-ray and BMI (r= 0.20), weight (r= 0.25) with p <0.005 and height (r= 0.15) with p <0.05.
Conclusion: Obese patients receive a significantly greater doses compared to the NDRL. Due to the weak to moderate correlations between DAP and patient's size, further research is needed to explore the variation of the doses delivered to obese patients.

B-0490 10:38

Do post-processing algorithms influence radiographic exposure factors?

M. Hardy[1], B. Snaith[2], A. Martin[3], C. Quinn[2]; [1]*Bradford/UK*, [2]*Wakefield/UK*, [3]*Bolton/UK (M.L.Hardy1@bradford.ac.uk)*

Purpose: The move from film-screen to digital imaging technologies was rapid in dissemination and implementation. Radiographers previously used image appearance to subjectively determine under/over exposure and adequacy of exposure factors adopted. With digital systems, image appearance is determined by computer algorithms and is not overtly visibly responsive to the exposure factors adopted. A number of studies have considered the limited impact of exposure factors on digital image appearance. This study examines whether radiographers have embraced digital measures of receptor dose adequacy or whether subjective assessment of image appearance persists.
Methods and Materials: 200 neonatal mobile chest images were randomly selected from 2 geographically distinct hospital Trusts in the North of England (100 at each site). Each site used different computed radiography image capture systems and mobile equipment. The routine exposure factors listed were identical across sites. Trends in exposure factors were determined from recorded patient and examination data. Study was registered as a service evaluation/audit in each Trust.
Results: A significant difference in proportion of Exposure Index measures that fell within, above and below locally determined thresholds was noted between sites (Chi2 = 48.996; P<0.001). Controlling for other factors, radiographer exposure factor selection appeared to be influenced by image appearance.
Conclusion: Image capture technologies have altered dramatically over last 20 years but radiographer technology interaction and its influence on decision making have been slower to evolve. A consequence of this may be the production of image of sub-optimal quality which is partially masked by the post-processing algorithms adopted.

Factors influencing the effective dose and dose reduction for abdominal radiography

J. Jang, Y. Cho, J.-H. Park; *Seoul/KR (jsjang@amc.seoul.kr)*

Purpose: To identify the independent factors associated with increased radiation dose and to evaluate the effect of a patient's position on the effective dose for abdominal digital radiography.
Methods and Materials: We retrospectively evaluated the effective dose for abdominal digital radiography in 222 patients in both the supine and standing positions. The patients were divided into two groups with a cutoff value of 0.311 mSv which is the upper third quartile of the dose distribution. Using logistic regression analysis, the independent factors associated with the increased effective dose were identified. The effect of a patient's position on the effective dose was also evaluated using the paired t-test.
Results: Multivariate logistic regression analysis revealed that a high BMI (odds ratio [OR], 25.201; 95% confidence interval [CI], 8.576-74.051; P<0.001) and ascites (OR, 25.132; 95% CI, 5.381-117.376; P<0.001) were significantly associated with an increased effective dose. The effective dose was significantly decreased (22.6%) with a patient in the supine position compared with that in the standing position (P<0.001). Among them, patients with a high BMI or ascites and who were placed in the supine position received a lower 22.5% or 15.3% effective dose, respectively, compared to those in the standing position.
Conclusion: High BMI and ascites were the independent factors associated with an increased effective dose in abdominal digital radiography. The significant dose reduction in patients with these factors may be achieved by the patient being placed in the supine position during abdominal digital radiography.

B-0492 10:54

The anode heel effect: a dose reducing approach in digital thoracic spine radiography?

F. Glynn; *Dublin/IE (mae.94@hotmail.com)*

Purpose: Use of the anode heel effect to optimise image quality has been widely reported but has little, if any importance in digital radiography. No studies investigating dose optimisation by utilising the anode heel effect in thoracic spine radiography could be identified. This study set out to measure the dose to critical organs when the anode-cathode alignment and kVp and mAs exposure factors were varied for thoracic spine projections.
Methods and Materials: A Rando phantom and thermoluminescent dosimeters (TLD 100H) were used to measure the absorbed radiation dose at various sites corresponding to critical organs (thyroid, superior lung, breast,

stomach, and transverse colon). Each antero-posterior (AP) projection was recorded in two phantom orientations, first with the phantom head placed towards the cathode-end of the x-ray tube, and then in the reverse direction, while exposed at a range of 70-90kVp in intervals of 5kVp.
Results: The differences in dose to all organs between the two anode-cathode alignments were statistically significant (p-values <0.05). The greatest dose savings occurred above 80kVp. At 80kVp and 20mAs, with the anode-end of the x-ray tube towards the phantom head, the breast, superior lung and thyroid received an average dose of 35%, 33% and 163% lower, respectively in the AP projection, than those obtained in the reverse orientation. The pattern of dose distribution at the two tube orientations applies to each exposure factor combination investigated.
Conclusion: Patients should be positioned with the head placed towards the tube's anode for thoracic spine radiographs to achieve significant dose reductions.

B-0493 11:02

An evaluation of the size-specific dose estimates (SSDE) in fast kVp switching dual-energy imaging

K. Yagami[1], T. Miyoshi[1], S. Shigeyama[1], H. Okada[1], S. Suzuki[2]; [1]*Gifu/JP*, [2]*Toyoake/JP (yagami@gifu-u.ac.jp)*

Purpose: The aim of this study was to evaluate the SSDE in fast kVp switching (gemstone spectral imaging [GSI]) dual-energy CT (DECT) imaging by comparing with the measured absorbed dose.
Methods and Materials: The 64 detector row CT system was used for dose measurement. A human equivalent phantom with thermo-luminescent dosimeters inside and on the surface was used to measure the SSDE and the absorbed dose. The tube current was 360mA and the tube voltage was GSI. The scanning conditions were the same as those used in clinical practice, and the scanning range was set from the thyroid gland to the symphysis pubis. The conversion factor and the SSDE were calculated based on AAPM report 204.
Results: The indicated CTDIvol. was 10.34mGy. The conversion factor in each slice of the human equivalent phantom was minimum at 1.35 and maximum at 1.80. The SSDE was lowest at 14mGy and highest at 19mGy. The measured absorbed dose was lowest at 14mGy and highest at 25mGy. The differences between the measured absorbed dose and the SSDE were within 10% in the thoracic and pelvic regions, while the measured absorbed dose was approximately 35% higher than SSDE in the abdominal region. The SSDE was lower than the measured absorbed dose in thoracic, abdominal, and pelvic regions.
Conclusion: This phantom study suggested that the SSDE may be lower than the measured absorbed dose in GSI imaging.

B-0494 11:10

An investigation into knowledge of radiation dose as an influential factor in collimation practice

J. Doyle, K. Matthews; *Dublin/IE (jenniferannedoyle@gmail.com)*

Purpose: To investigate influences on current collimation practices in Irish radiography departments, and establish whether knowledge of actual radiation dose differences could be used to compel improved collimation practice.
Methods and Materials: The study was conducted as an online image-based survey in which four radiographs were rated on a Likert scale of acceptability for six clinical situations. Stratified sampling was applied to the population of Irish radiographers and 57 responses were obtained. Non-parametric analysis of variance (Wilcoxon signed-ranks test) was performed to establish whether acceptability of the images changed significantly depending on the situation. Images were presented first without information, and secondly alongside associated organ doses. Variance between mean Likert scores with and without dose information was analysed using Wilcoxon signed-ranks test. Dose information was measured in an x-ray laboratory using TLD100Hs. Participants also rated influences on their practice when collimating the primary beam and post-processing images.
Results: Radiographer tolerance of poor collimation varied significantly based on clinical situation ($p<0.003$), with poor collimation least acceptable in co-operative patients and most acceptable in difficult patients. When presented alongside organ doses poor collimation was considered less acceptable, with significant differences when breast and thyroid doses were presented ($p<0.05$), but no significant difference with colon or peripheral lung dose.
Conclusion: A variety of factors influence radiographers' collimation practice. Radiographers have different acceptability levels depending on the clinical situation. Radiographers could be encouraged to collimate more accurately by education on organ doses associated with poor collimation and radiation sensitivity weighting factors of radiosensitive organs.

B-0495 11:18

Impact of the anode heel effect on image quality and effective dose for AP pelvis: a pilot study

C. Buissink[1], M. Bowdler[2], A. Mohammed[2], S. Al-Murshedy[2], T.K. Urdahl[3], S.C. Soares[4], Y.R. Rey[5], J. Jorge[5], L. Peters[1]; [1]*Groningen/NL*, [2]*Manchester/UK*, [3]*Oslo/NO*, [4]*Lisbon/PT*, [5]*Lausanne/CH*

Purpose: This study proposes a method together with pilot data to determine whether the anode heel effect has an impact on image quality and effective dose (E) for AP pelvis.
Methods and Materials: An adult CIRS ATOM dosimetry phantom with high sensitivity TLDs and an adult anthropomorphic pelvis phantom were positioned with feet towards anode and feet towards cathode. For each anthropomorphic phantom orientation exposures were made using 75, 80 and 85kVp and 18, 22 and 27mAs at 110cm SID. Twelve images were taken of the anthropomorphic phantom in each orientation and then assessed for physical and visual quality by signal-to-noise ratio (SNR) and two-alternative-forced-choice (2AFC). Six exposures were then made of the ATOM phantom in each orientation using 75, 80 and 85kVp and 18, 22 and 27mAs at 110cm SID; E was calculated from organ dose data.
Results: For 2AFC data, no significant difference ($p=0.811$) was found in image quality between orientations; SNR achieved significance between the two orientations ($p<0.05$). E showed no significant difference ($p=0.207$) between the two orientations.
Conclusion: No significant difference in visual image quality, or E was observed. Whilst significance was achieved for SNR this is not likely to have any clinical impact as image interpretation is a visual task. The method proved fit for purpose however the findings should be treated with caution. Further work is proposed, to increase the number of images to be evaluated and doses to be compared for the two orientations along with a lesión detection performance study.

B-0497 11:26

Steps to an optimisation process

J. Santos[1], C. Almeida[2], G. Paulo[1]; [1]*Coimbra/PT*, [2]*Lisabon/PT (joanasantos@estescoimbra.pt)*

Purpose: Analyse the exposure parameters and dose levels of three most common procedures per image modality in order to audit and implement optimisation measures.
Methods and Materials: Exposure parameters and dose values of plain radiography (in terms of dose area product- DAP), computed tomography (CT) (in terms of CTDI and DLP) and interventional neuroradiology (in terms of DAP) procedures were directly collected on the equipment's with daily quality control. During this prospective study, patient data as examination identification (ID), gender, weight and height was also collected before the examination.
Results: Standard patients were selected from the 300 patients analysed data and diagnostic reference levels were calculated for chest, abdomen and pelvis radiographs (11, 280 and 372 mGy.cm); head, abdomen and abdomen-pelvic CT in terms of CTDI and DLP (1000, 300, 500 mGy.cm); diagnostic cerebral angiography, cerebral aneurism embolisation and stroke emergency treatment (320, 242, 280 mGy.cm).
Conclusion: Considering the obtained results, optimisation measures were implemented and data is being collected in order to analyse and compare the impact on dose levels. The examination ID will be also used to compare image quality pre- and post-optimisation.

B-0498 11:34

Universal dose electronic ID (UdoseeID): a step into the future without barriers

L.P.V. Ribeiro, A. Abrantes, L. Guerra, R.P. Almeida, F. Ramos, S. Rodrigues, J. Guerreiro, A. Ribeiro; *Faro/PT (luispedroribeiro@hotmail.com)*

Purpose: The European Directive 2013/59/Euratom was unanimously adopted by the Council of the European Union and it was expected to have a relevant and positive impact on European radiology. It put on paper the need for justification of medical exposure introduces requirements concerning patient information and strengthens those for recording and reporting doses from radiological procedures.The main objective of this project was to create, apply and develop a universal application on site for registration and monitoring of radiation doses to which patients are exposed in radiological exams in all of health facilities that use ionizing radiations for clinical purposes.
Methods and Materials: We have developed a multi-profiled site, based on user authentication permissions, where the radiographers (including nuclear medicine radiotherapy professionals) can registry the dose exposure and in cases when in which its institutions are not registered on the site patients provide credentials that allows to do it. The patient with the dose electronic ID has the ability to consult and provide information from clinical exposures through a simple internet login.

Results: According to the directive, the professionals involved in medical exposure are fundamental to ensure adequate protection of patients undergoing medical radiodiagnostic and radiotherapeutic procedures. With the provided tool and the patient collaboration the universal dose electronic ID, could be the answer for acomplishing the European Directive 2013/59/Euratom.
Conclusion: This tool is universal and gives the possibility to the patient to have long-life registry of all doses that is subjected in medical imaging and radiotherapy procedures.

B-0488 11:42

Evidence of dose optimisation with a single UK radiology department
A. England[1], L. Harding[2], R. Penney[2], R. Wilde[3], F. Dunn[3], A. Manning-Stanley[1], P. Evans[2]; [1]*Manchester/UK*, [2]*Warrington/UK*, [3]*Liverpool/UK (A.England@salford.ac.uk)*

Purpose: Optimisation is a fundamental requirement of radiographic practice. The degree in which this is routinely undertaken is likely to vary and is difficult to quantify. The aim of this study was to assess levels of dose optimisation within common radiographic projections.
Methods and Materials: Within a large state hospital DICOM information was extracted from three digital radiography rooms over a two-month period. Radiographic examinations assessed included chest, abdomen, shoulder and knee. Data extraction was by bespoke software and included demographics and all available procedure/dose-related parameters. Study data were then compared with default protocols to identify evidence of optimisation. Patients under the age of 16 were excluded and all projections were subject to visual scrutiny.
Results: Data from a total of 1250 examinations were collected. With paediatric patients removed data analysis was undertaken on 1245 (99.6%) examinations (724 women; mean (SD) age 57 (18) years). Examinations were equally split between the four anatomical areas. In terms of kVp, for chest radiography, parameters were adjusted from the default in six (2.4%) cases. For abdominal radiography parameters were adjusted in a greater number of cases (29/247; 11.7%). For shoulder and knee radiography kVp settings were adjusted in 3.2% of cases. For mAs (non-AEC examinations) 6 out of 581 (1.0%) projections (knee/shoulder) had adjustments from the baseline protocol.
Conclusion: Based on this initial assessment of DICOM header data exposure factors appear to be infrequently adjusted and this raises questions regarding levels of dose optimisation within clinical practice.

B-0496 11:50

Radiation dose from pelvic radiography: a comparison of three digital radiography (DR) systems
A. England[1], P. Evans[2], F. Dunn[3], A. Manning-Stanley[1], L. Harding[2], E.M. Taylor[2]; [1]*Manchester/UK*, [2]*Warrington/UK*, [3]*Liverpool/UK (A.England@salford.ac.uk)*

Purpose: To compare the radiation dose and image quality between the three digital radiography (DR) systems when undertaking examinations of the pelvis.
Methods and Materials: Using a Carestream Directview, Siemens Ysio and a Samsung XGEO, a series of antero-posterior (AP) pelvic images were obtained using a phantom. Images were obtained using 75 kVp, outer AEC chambers and the source to image distance (SID) was varied from 115 to 140cm, 5cm intervals. The phantom was also imaged across two orientations, outer AEC chambers nearest the head and then the feet. Field size, centring point, grid usage and focal spot were fixed throughout the study. For each examination tube potential, mAs and source to skin distance were recorded. Entrance surface dose including scatter (ESD) and effective dose (ED) were calculated using the PCXMC software. The resultant images were independently assessed for image quality by two blinded observers using a previously established scoring system.
Results: The lowest ED (0.105 mSv) was achieved at 125 cm, outer AEC nearest the feet and when using Siemens DR. The highest dose (0.161 mSv) was at 105 cm, outer AEC chambers nearest the head and when using Samsung DR. When compared with a reference image (current parameters) the image obtained with the lowest ED was graded as having the same image quality.
Conclusion: Based on the equipment and acquisition factors investigated there are differences in ED between systems. Such differences should be factored into dose optimisation strategies or attempts should be made to normalise doses between systems.

An experimental study on use of 7T MRI for evaluation of myocardial infarction in SD rats
Y. Zhang[1], L. Yang[1], F. Gao[2]; [1]*Guizhou/CN*, [2]*Sichuan/CN (102651873@qq.com)*

Purpose: This study aims to build the myocardial infarction model in SD rats transfected with pcDNA 3.1(+)/VEGF$_{121}$ plasmid and study the effect of the transfection using 7T MRI.
Methods and Materials: Twenty-four male SD rats were randomly divided into 2 groups, plasmid transfection group (with improved coronary perfusion delivery) and myocardial infarction model group. Cardiac cine magnetic resonance imaging (Cine-MRI), T2-mapping and late gadolinium enhancement (LGE) cardiac imaging were performed at 24h, 48h, 72h and 7d after myocardial infarction, respectively. The signal intensity, area at risk (AAR), myocardium infarction core (MIC) and salvageable myocardial zone (SMZ) were compared. The hearts were harvested for anatomic characterisation, which was correlated to pathological examination (TTC staining, HE staining, Masson staining and immunohistochemical staining).
Results: The Cine-MRI results showed that plasmid transfection group had higher end-diastolic volume (EDV) with a reduction in MIC and SMZ, as compared with the myocardial infarction model group. MIC, SMZ and AAR of the plasmid transfection declined over time. At 7d, the two groups did not differ significantly in AAR and T2 value. According to Western Blotting, VEGF was up-regulated, while CaSR and caspase-3 were downregulated in the plasmid transfection group, as compared with the model group.
Conclusion: 7T CMR provide a non-invasive quantification of the treatment efficacy. The myocardial protection of the plasmid transfection group may be related to the inhibition of myocardial apoptosis, vascular endothelial cell (VEC) proliferation and collagen proliferation. The CaSR signaling pathway may contribute to reversing the apoptosis.

Prospect CMR study: prognostic stratification in patients with stelevation myocardial infaction over transthoracic echocardiography by CMR
G. Pontone[1], D. Andreini[1], G. Ferro[2], A. Guaricci[3], M. Guglielmo[1], S. Mushtaq[1], A. Baggiano[1], P. Carità[2], M. Pepi[1]; [1]*Milan/IT*, [2]*Palermo/IT*, [3]*Bari/IT (gianluca.pontone@ccfm.it)*

Purpose: We sought to evaluate additional value of a multiparametric cardiac magnetic resonance (CMR)score in comparison with traditional TIMI (Thromolysis in Myocardial Infarction) score and transthoracic echocardiography (TTE) score in prognostic stratification of ST-elevation myocardial infarction (STEMI) reperfused by primary percutaneous coronary intervention (PCI).
Methods and Materials: 209 STEMI patients reperfused by primary PCI underwent TTE and CMR 3 days after the index event. We measured: TIMI score, left ventricle ejection fraction (EFTTE), left ventricle end-systolic volume (LVESVTTE) and number of myocardial segment with wall motion abnormalities (WMITTE) measured by TTE, left ventricle ejection fraction (EFCMR), left ventricle end-systolic volume (LVESVCMR) and number of myocardial segment with wall motion abnormalities (WMICMR) measured by CMR, myocardial salvage index (MSI) and presence of microvascular obstruction(MVO). The primary clinical endpoint of study was the occurrence of major adverse cardiac events (MACE) defined as combined endpoint of hospitalisation, acute coronary syndrome, implantable defibrillator and cardiac death.
Results: Patients experiencing MACE showed higher TIMI score, LVESVTTE, WMITTE,LVESVCMR,WMICMR,prevalence of MVO and lower EFTTE, EFCMR and MSI.Two different models based on a binary score were created: a) Model 1 based on clinical parameters andTTE: TIMI <3=0 or >3=1; LVESVTTE<25ml/m2=0 or >25ml/m2=1; EFTTE>50%=0 or <50%=1;

WMITTE<7=0 or >7=1; b)Model 2 based on CMR:LVESVCMR<55ml/m2=0 or >50ml/m2=1; EFCMR>50%=0 or <50%=1; WMICMR<7=0 or >7=1;MSI>0.47:0 or <0.47:1; MVO: absence=0 or presence=1. Clustering the study population for both model with a score threshold of 2,model 2 provide a better prognostic stratification as compared to model 1 with a significant incremental prognostic value on the top of traditional outcome model.
Conclusion: A multiparamteric approach with CMR including markers of myocardial damage provide incremental prognostic information.

B-0501 10:55

T1 and T2 Mapping cardiovascular magnetic resonance to differentiate acute from chronic myocardial infarction

E. Tahir, M. Sinn, K. Muellerleile, S. Bohnen, M. Avanesov, J. Starekova, C. Stehning, G. Adam, G. Lund; *Hamburg/DE (e.tahir@uke.de)*

Purpose: Novel T1 and T2 mapping CMR techniques could provide incremental information to differentiate acute from chronic myocardial infarction (MI). We compared these techniques to standard T2-weighted CMR.
Methods and Materials: 67 patients with first-time AMI were enrolled. CMR were obtained at 8 ±5 days after infarction (baseline) and 6 ±1.4 months. All acquisitions were performed on end-diastolic LV short-axes. T2 relaxation times were quantified using a free-breathing, navigator-gated multiecho sequence. T1 relaxation times were measured using the modified Look-Locker inversion recovery sequence. Parametric maps were generated using a plug-in for OsiriX software (Pixmeo, Switzerland). Two experienced observers independently placed ROIs in the infarcted areas using LGE as a reference standard. A T2w-ratio was also generated: T2w-ratio = Mean SIinfarct/Mean SIremote.
Results: Native T1 had an almost perfect discriminative performance between acute and the chronic MI (AUC of 0.984), which was significantly superior to the T2w-ratio with an AUC of 0.906 (P<0.05) and to T2 with an AUC of 0.903 (P<0.05). ECV had a poor discriminative performance with an AUC of 0.655, which was significantly inferior to the other techniques (P<0.001). The cut-off of ≥1138 ms for native T1 provided a sensitivity and specificity of 96% and 100%, respectively. The other cut-offs were as follows: ≥3.3 for T2w-ratio, ≥69ms for T2 and ≥39% for ECV.
Conclusion: Native T1 is the best discriminator between acute and chronic MI and should preferably be used as an objective truly quantitative parameter to differentiate between the acute and chronic stage of MI.

Feature tracking assessment using cardiovascular MRI for the prediction of adverse left ventricular remodelling after STEMI

J. Lee, S. Kim, J. Kim, M.-R. Kwon, M. Seong, S. Yang, Y. Choe; *Seoul/KR (sig.jhl@gmail.com)*

Purpose: To investigate the feasibility of feature-tracking assessment using cardiac MRI (CMR) for the prediction of adverse LV remodelling after ST-elevation myocardial infarction (STEMI).
Methods and Materials: We retrospectively searched our institution's database between July 2010 and September 2015 for patients with a history of STEMI, who underwent reperfusion therapy, post-reperfusion CMR, and follow-up CMR. A total of 83 patients were included in the analysis. CMR included cine imaging and late gadolinium enhancement imaging. Feature-tracking assessment for myocardial strain was performed using steady-state free-precession cine imaging. Volumetric analysis and evaluation for presence of intramural haemorrhage, microvascular obstruction, and oedema were also performed.
Results: Patients were divided into two groups, ac0cording to the presence of adverse LV remodelling; STEMI without adverse remodelling (n=64) and STEMI with adverse remodelling (n=19). Significant differences in global longitudinal strain (GLS) using 2D analysis (-13.3±3.5 vs - 10.9±3.6, p = 0.01), GLS using 3D analysis (-13.4±2.8 vs -11.4±2.4, p < 0.01), and global circumferential strain using 3D analysis (-14.2±3.1 vs - 12.6±2.9, p = 0.048) were observed. Univariate logistic regression models using GLS showed significance with an AUC of 0.687 and 0.702, in 2D and 3D analyses, respectively.
Conclusion: Global longitudinal strain in both 2D and 3D analyses were significantly different between groups with and without adverse LV remodeling. CMR strain analysis, early after reperfusion for STEMI, may aid in the prediction of adverse LV remodelling.

B-0503 11:11

Depiction of adverse remodelling after ST segment elevation myocardial infarction by T1 mapping and ECV on 3 Tesla MRI

Ö. Ates[1], K. Ercan[1], A. Ertem[1], F. Eyüpkoca[1], F. Arslan[2], C. Şabanoğlu[1], T. Çimen[1], Z. Güven[1], E. Kızıltunç[1]; [1]*Ankara/TR*, [2]*Utrecht/NL (omfarat@hotmail.com)*

Purpose: To demonstrate adverse remodelling in the remote myocardium of post myocardial infarction patients as well as comparison of native-T1 values and ECV values between post-MI patients and normal controls.We also evaluate the prognostic value of T1-relaxation and ECV scores post-MI patients.
Methods and Materials: Patients with history of ST elevated MI(first-MI) and healthy controls were included the study.Patients with diseases that may affect myocardial remodelling other than current MI, and patients having suboptimal imaging quality were excluded.Follow-up were scheduled at two weeks and sixth month post-MI;prognostic indicators including EF, end-diastolic volume, MI volume and extent, transmurality and microvascular obstruction were assessed using cardiac magnetic resonance imaging.Remote myocardium were used to perform T1 mapping and ECV calculation.Native-T1 values and ECV scores were compared between patients with MI and adverse remodelling, patients with MI without adverse remodelling and control group.Association of prognostic indicators, T1 values and ECV scores were also evaluated.
Results: 31 patients (11 adverse remodelling, 7 MVO) and 22 healthy control were included to study.There was no difference in native-T1 value between MI and control group, but ECV scores were significantly higher in MI group (ECV scores in MI group vs.control group p<0.001). In MI group, MI ratio and MI extent, transmurality, MVO, native-T1 values and ECV scores of remote myocardium had significant correlation with adverse remodelling. Moreover, ECV scores alone had significant correlation with MI extent, 2. weeks LVEDV, 6. months LVEDV and MI area ratio.
Conclusion: ECV and Native-T1 may be used to demonstrate adverse remodelling in post-MI remote myocardium and ECV scores may also be correlated with poor prognostic factors.

B-0504 11:19

Towards quantitative cardiac CT imaging: texture analysis of myocardial infarction

R.M.M. Hinzpeter, M.W. Wagner, M.C. Wurnig, R. Manka, H. Alkadhi; *Zurich/CH (Ricarda.Hinzpeter@usz.ch)*

Purpose: To investigate the ability of texture analysis (TA) for CT imaging to distinguish through quantitative image information between healthy subjects and patients with acute myocardial infarction (MI).
Methods and Materials: Twenty patients (8 females; mean age 42±15.2 years) with no cardiac abnormalities (hereafter termed controls) and twenty patients (5 females; mean age 56±10.3 years) with proven acute MI underwent cardiac CT. Short axis reformations of the left ventricle (LV) were reconstructed at slice thicknesses of 1mm, 2mm, and 5mm. Two independent, blinded readers segmented the LV myocardium in controls and patients. TA was performed yielding first-level features (based on the histogram), second-level features based on the grey-level co-occurrence matrix (GLCM), and third-level features based on the grey-level run-length matrix (GLRLM).
Results: Inter- and intrareader agreement was good to excellent for all first and second-level features (ICC:0.661-0.988), and was variable for the third-level features (ICC:-0.115-0.991). Multivariate logistic regression analysis showed the single best feature from each level to be an independent predictor of acute MI (kurtosis, OR 0.86, P=0.019; correlation, OR 0.97, P=0.22; short run high grey-level emphasis, OR 1856, P=0.79). The AUC showed best results when combining the features kurtosis and short run high grey-level emphasis (AUC:0.985) and when using the 5mm short axis reformations.
Conclusion: TA can be used in cardiac CT for distinguishing healthy from acutely infarcted myocardium with most reproducible and accurate results at a short axis slice thickness of 5mm.

B-0505 11:27

Reproducibility and agreement of early synthetic PSIR imaging as compared to the conventional LGE approach for myocardial infarct areas

R. van Dijk, D. Kuijpers, T. Kaandorp, P. van Dijkman, R. Vliegenthart, P. van der Harst, M. Oudkerk; *Groningen/NL (r.van.dijk02@umcg.nl)*

Purpose: Synthetically reconstructed enhancement images in adenosine magnetic resonance perfusion imaging show potential for the assessment of myocardial viability. We compared Early Synthetic Phase-Sensitive-Inversion-Recovery (PSIR) images from post-contrast T1-mapping to the conventional PSIR late Gadolinium enhancement (LGE) approach and assessed reproducibility and agreement of quantification of myocardial infarct areas.
Methods and Materials: Presence of LGE was assessed in 214 consecutive patients suspected of myocardial ischemia. The volume of myocardial infarct

areas was quantified on a per-segment basis in both synthetic (2-3 min post-Gadolinium) and conventional (9 min post-Gadolinium) PSIR images by two independent observers twice using semi-automatic LGE volume quantification software (MASS analytical software, Medis, Leiden). Pearson correlation and Bland-Altman analysis were performed to assess inter- and intra-observer correlation (R^2) and agreement (mean difference) of LGE quantification between synthetic and conventional PSIR images.
Results: There were 37 infarct-related LGE areas [RV1] in 21 patients with a median volume of LGE of 1.9 [0.4;7.3] mL in the synthetic images and 2.1 [0.4;7.2] mL in the conventional images (p-value: 0.386). Correlation and agreement between synthetic and conventional images were excellent with R^2 = 0.995 and mean difference of -0,028±0,289). Inter-observer R^2 was 0.998 for both synthetic (mean difference, -0,056±0,079) and conventional (mean difference, -0,057±0,087) images. Intra-observer R^2 between synthetic and conventional images were 0.995 (mean difference -0,028±0,156), and 0.994 (mean difference -0,029±0,157) for observer 1 and observer 2, respectively.
Conclusion: Synthetic images calculated from T1 mapping early post-contrast show high reproducibility and agreement for myocardial LGE areas compared with conventional LGE images.

B-0506 11:35

Assessment of cardiac dynamics in a mouse model of myocardial infarction by optoacoustic imaging
F. Lohöfer[1], H.-C. Lin[2], X. Déan-Ben[2], M. Kimm[1], H. Haas[1], D. Razansky[2], M. Wildgruber[3]; [1]*Munich/DE*, [2]*Neuherberg/DE*, [3]*Münster/DE*
(fabian.lohoefer@tum.de)

Purpose: The aim of this study is the evaluation of contrast-enhanced three-dimensional optoacoustic (OA) imaging without cardiac gating in a mouse model of myocardial infarction.
Methods and Materials: Contrast-enhanced three-dimensional optoacoustic (OA) imaging at high volumetric frame rate was used. Real-time volumetric cardiac perfusion parameters were measured using indocyanine green (ICG) as optical contrast agent. A murine myocardial infarction model optimised for acquisition of artefact-free optoacoustic imaging was used. Functional parameters, including pulmonary transit time and non-linearity of the heartbeat, were compared between infarcted and healthy mice. MRI was used as a reference for assessment of cardiac function.
Results: Optoacoustic imaging was able to extract key cardiac parameters, such as pulmonary transit time and heart rate, on a beat-by-beat basis. Infarcted hearts (N=9) could be differentiated from healthy controls (N=3) with a significantly higher pulmonary transit time (2.35s (2.07s-2.4s) versus 1.25s (1.20s-1.32s), p=0.0195). Non-linear heartbeat dynamics was stronger in the healthy hearts, as evinced by the second and third harmonic components in the heartbeat spectra. MRI revealed that the pulmonary transit time increases with the size of infarction and increases with reduced ejection fraction.
Conclusion: Optoacoustic imaging can depict cardiac anatomy, function and molecular signatures, both with high spatial and temporal resolution. Beat-by-beat volumetric optoacoustic characterization of cardiac dynamics can provide new insights into the pathophysiological mechanisms of myocardial ischaemia.

B-0507 11:43

VINTAGE study: diagnostic Value of QT evaluation In aNterior STsegment elevAtion myocardial infarction for predictionof myocardial salvaGE index, as compared to CMR
A. Guaricci[1], G. Pontone[2], P. Carità[3], D. Andreini[2], M. Guglielmo[2], S. Mushtaq[2], A. Baggiano[1], M. Verdecchia[4], M. Pepi[2]; [1]*Bari/IT*, [2]*Milan/IT*, [3]*Palermo/IT*, [4]*Chieti/IT*

Purpose: Myocardial salvage index (MSI) measured by cardiac magnetic resonance (CMR) allows to evaluate the myocardial damage in ST elevation myocardial infarction (STEMI). QT interval corrected for heart rate at ECG (QTc) prolongs in all patients with early transmural ischaemia. We sought to evaluate the correlation between QTC time change after STEMI and MSI as detected by CMR in STEMI patients underwent primary percutenous intervention (PCI).
Methods and Materials: Fifty anterior STEMI patients reperfused by primary PCI underwent quantitative ECG repolarization analysis and CMR. The difference (ΔQTc) between QTc of ischaemic myocardium (maximum QTc in anterior leads) versus remote myocardium (minimum QTc in inferior leads) over the first week, left ventricle end-diastolic (LVESVCMR) and end-systolic volume (LVESVCMR), numbers of myocardial segments with wall motion abnormalities (WMA index), ventricle ejection fraction (EFCMR) and myocardial salvage index (MSI) were measured.The endpoint was defined as MSI>0.6.
Results: The QTc in anterior leads was longer than QTc in inferior leads (p<0.0001) over the first week.There was a significant correlation between ΔQTc at 6th day and percentage of LGE (r:0,49, p 0.0007) and MSI (r:0.48; p:0.0012). At univariate analysis peak myocardial enzymes, LVEDVCMR, LVESVCMR, AWM index and ΔQTC at 6th day were independent predictor of high MSI (>0.6),while at multivariate analysis only WMA index (p:0.05) and ΔQTC at 6th day (p:0.02) still remained as predictors of endpoint.The receiver operative curve of ΔQTC at 6th day showed a AUC of 0.78 to predict a MSI>0.6.
Conclusion: ΔQTC is inversely correlated with MSI and it could represent an easy tool to evaluate the myocardial damage after PCI in STEMI patient

B-0508 11:51

Effect of inversion time on the precision of myocardial late gadolinium enhancement quantification evaluated with synthetic inversion recovery MR imaging
A. Varga-Szemes[1], R.J. van der Geest[2], B. Spottiswoode[3], C.N. De Cecco[1], G. Muscogiuri[1], J.L. Wichmann[1], R. Vliegenthart[4], P. Suranyi[1], U.J. Schoepf[1]; [1]*Charleston, SC/US*, [2]*Leiden/NL*, [3]*Chicago, IL/US*, [4]*Groningen/NL*
(vargaasz@musc.edu)

Purpose: To simulate the influence of inversion time (TI) on the precision of myocardial late gadolinium enhancement (LGE) quantification using synthetic inversion-recovery (IR) imaging in patients with myocardial infarction (MI).
Methods and Materials: Fifty-three patients with suspected prior MI underwent 1.5T cardiac magnetic resonance imaging (MAGNETOM Avanto, Siemens, Germany) with conventional magnitude IR (MagIR) and phase-sensitive IR (PSIR) LGE imaging and post-contrast myocardial T1-mapping. T1-based synthetic MagIR and PSIR images were calculated with a TI ranging at 5ms intervals from -100 to +150ms relative to the optimal TI (TI_0). LGE was quantified using a 5 standard deviation threshold (5SD) and full-width at half-maximum (FWHM). Differences in LGE size at various TIs were compared using one-way analysis of variance.
Results: The $MagIR_{sy}$ technique provided precise assessment of LGE area at TIs ≥TI_0, while precision was decreased below TI_0. The LGE area showed significant differences at <25ms than TI_0 using 5SD (P<0.001), and <-65ms using the FWHM approach (P<0.001). LGE measurements did not show significant difference over the analyzed TI-range in the $PSIR_{sy}$ images using either of the quantification methods. The conventional and synthetic IR techniques yielded similar areas of infarct using the 5SD (4.38 and 5.68cm^2, P=NS) and FWHM (3.21 and 4.09cm^2, P=NS) thresholds.
Conclusion: T1-map-based $PSIR_{sy}$ images provide precise quantification of MI independent of TI at the investigated time-point post-contrast. $MagIR_{sy}$-based MI quantification is precise at TI_0 and at longer TIs while showing decreased precision at TI values below TI_0.

Advanced virtual monoenergetic reconstruction of dual-energy abdominal CT angiography of children: comparison with conventional monoenergetic reconstruction
H. Choi, Y. Choi, J.-E. Cheon, W. Kim, I.-O. Kim; *Seoul/KR*

Purpose: To determine the most effective advanced virtual monoenergetic imaging (VMI) energy level for maximising the abdominal arterial image quality in dual-energy contrast-enhanced liver CT of children, and to assess the improvement compared with conventional monoenergetic reconstruction, and linearly-blended images.
Methods and Materials: From January 2014 to October 2015, 19 consecutive liver CT scans (7boys and 12girls; mean age 6.7years) acquired in dual-energy CT scanner were retrospectively reconstructed at 7VMI energy levels from 40 to 100keV in 10-keV increments using both conventional (Mono) and advanced (Mono+) monoenergetic reconstruction techniques. Mean attenuation, image noise, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) in the common hepatic artery (CHA), superior mesenteric artery (SMA), splenic artery (SA), and left renal artery (LRA) were analysed. VMI series with the best SNR

or CNR were selected from each monoenergetic reconstruction technique, and were compared with linearly-blended images (M_0.5; 50% of 80kV, 50% of 140kV).
Results: The noise was lowest at 80keV (Mono+), and 70keV (Mono). The maximal SNRs in all arteries were observed at 50keV (Mono+), and 70keV (Mono), and maximal CNRs were observed at 40keV (Mono+), and 60keV (Mono). The SNRs, and CNRs of Mono+ was higher than those of Mono in all investigated arteries at all energy level except for the SNRs at 70keV in CHA, and LRA. The optimal VMI energy level was 50keV for Mono+ and 60keV for Mono. The SNR, and CNR of Mono+ 50keV was higher than 60keV Mono and linearly-blended (M_0.5) images.
Conclusion: The Mono+ reconstruction of dual-energy CT angiography of the abdomen at 50keV (optimal energy level) maximises image quality compared with Mono or linearly-blended(M_0.5) images.

B-0510 10:47

Advanced virtual monochromatic reconstruction of dual-energy abdominal CT in children: optimisation of kiloelectron volt settings to improve image contrast
T. Kim, Y. Choi, J.-E. Cheon, W. Kim, I.-O. Kim; *Seoul/KR (kjambong@gmail.com)*

Purpose: To compare quantitative image quality parameters in paediatric abdominal dual-energy CT using advanced (Mono+), conventional (Mono) monochromatic reconstructed images at different kiloelectron volt (keV) levels and standard linearly blended M_0.5 images (50% 80kV, 50% 140kV).
Methods and Materials: Thirty-seven consecutive abdominal dual-energy CT scans (27 boys and 10 girls; mean age 9.65 ± 5.33 years) were retrospectively included. Mono+ and Mono images were reconstructed at seven energy levels from 40 to 100keV at 10keV intervals and as standard linearly blended M_0.5 images. The contrast-to-noise ratio (CNR) and signal-to-noise ratio (SNR) of the liver, pancreas and aorta were objectively measured and compared.
Results: The maximal CNR values for all investigated organs were observed at 40keV and 60-70keV in Mono+ and Mono reconstructions, respectively. Mono+ images showed a significantly higher CNR at 40, 50 and 60keV compared to M_0.5 images for all measured organs except liver at 60keV. Mono images showed no significant superiority in CNR for all energy levels compared to M_0.5 images. The CNR of Mono+ at 40keV increased by 134% and 133% on average among all measured organs compared to the best CNR of Mono and M_0.5 images respectively. SNRs of Mono+ and Mono images showed no improvement compared to linearly blended images.
Conclusion: Mono+ showed superior CNRs at low keV levels of abdominal dual-energy CT compared to Mono and linearly blended images. The CNR in Mono+ peaked at 40keV and showed significant improvement compared to the best CNR of Mono and M_0.5 images.

B-0511 10:55

Plicae palmatae on MRI in paediatric population
M. Kitami; *Sendai/JP (rad.med3@gmail.com)*

Purpose: The ridges of plicae palmatae (RPP) are ridge of uterine cervical folds, previously considered as the remnant of fusion of Mullerian duct. Earlier studies have shown RPP could be seen on MRI in adult population, but there has been no reports regarding paediatric population. Besides, clinical significance could be different in neonate. RPP is usually important because RPP mimic uterine septum, potentially leading to unnecessary invasive procedure. In neonate, RPP could have tumourous appearance on sonography, but there is no report on MRI. Thus, the purpose of this study is to examine the depiction rate of RPP on MRI, and its appearance in paediatric population.
Methods and Materials: We retrospectively examined consecutive 117 pelvic MRI studies with patients aged from 0 to 15 years. Depiction rate in each age group (every one-year-old) was analysed, and the appearance was recorded whether tumourous or not.
Results: Depiction rate (from 0 to 15 years-old, every one-year-old) was following; 3/6 (50%); 3/8 (37.5%); 5/6 (82.5%); 0/5 (0%); 0/2 (0%); 2/6 (33%); 0/3 (0%); 3/7 (43%); 1/3 (33%); 2/6 (33%); 2/9 (22%); 4/7 (57%); 8/13 (62%); 9/12 (75%); 11/14 (79%); and 1/2 (50%). There was no case with tumourous appearance on MRI in every age group.
Conclusion: Depiction rate of RPP varied according to age groups on MRI, although RPP are relatively common feature also in paediatric population. There was no case showing tumour-mimicking appearance on MRI.

B-0512 11:03

MRI and transient elastography for the assessment of hepatic steatosis and elasticity in non-alcoholic fatty liver disease of children
J. Shin, H. Shin, H. Yoon, M.-J. Kim, M.-J. Lee, H. Koh; *Seoul/KR (drshinjs@yuhs.ac)*

Purpose: To evaluate MRI and transient elastography (TE) for assessing hepatic steatosis and elasticity in children with non-alcoholic fatty liver disease (NAFLD).
Methods and Materials: We retrospectively reviewed the records of children with clinically NAFLD who underwent hepatic MR elastography (MRE) and TE from January 2015 to August 2016. Hepatic fat fraction on MRI and hepatic steatosis by the Controlled Attenuation Parameter (CAP, dB/m) on TE was measured. Liver elasticity was also estimated on both MRE and TE. The patients were divided into normal and obese groups using the cut-off of 95 percentile body mass index (BMI). The results were analysed using Pearson's correlation.
Results: Total 76 children (M:F=53:23) were included with the mean age of 13.3±3.0 years. The mean BMI was 26.4±4.5kg/m^2 with 49 patients in the obese group. Hepatic elasticity on MRE (2.6±0.8 kPa) showed positive correlation with that on TE (6.4±2.5 kPa) (ρ=0.608, p<0.001). Hepatic fat fraction on MRI (21.7±12.1%) was significantly correlated with CAP (311.9±45.7 dB/m) (ρ=0.508, p<0.001). Both groups showed positive correlation between MRE and TE (ρ=0.646, p<0.001 in normal; ρ=0.575, p<0.001 in obese), as well as liver fat quantification on MRI and CAP (ρ=0.655, p<0.001 in normal; ρ=0.361, p=0.013 in obese).
Conclusion: In children with NAFLD, hepatic elasticity can be estimated non-invasively by MRE as well as TE. Hepatic fat quantification using CAP was also correlated with MR fat fraction. However, the obese group shows less correlation between CAP and MR fat fraction than the normal group.

B-0513 11:11

The significance of radiographic and ultrasonographic findings in the management of necrotising enterocolitis - results from a survey
M. Ahle[1], E. Rubesova[2], H. Ringertz[2]; [1]*Linköping/SE*, [2]*Stanford, CA/US (margaretaahle@gmail.com)*

Purpose: To investigate the perceived significance of various radiographic and ultrasonographic findings in necrotising enterocolitis (NEC) as reported by involved specialists.
Methods and Materials: 70 neonatologists, 58 paediatric surgeons and 74 radiologists from various countries answered a web-based questionnaire on their use of imaging in NEC. The results were descriptively analysed, using proportions with 95% confidence interval to evaluate differences between subgroups.
Results: In abdominal radiography (AR), pneumoperitoneum (PP) was stated to be of great importance by 97%, pneumatosis intestinalis by 96%, portal venous gas (PVG) by 89%, and "fixed loop" on sequential radiographs by 69%. On ultrasound, the most frequently evaluated signs were focal fluid collections, PVG, echoic fluid, and thickening of the intestinal wall, all used by over 90% of those stating that ultrasound is used for NEC in their hospital (58% of all). Among indications for surgery, PP on AR was considered possible by 99% and definite by 88%. PP on US was regarded a definite indication by 50%, significantly less than for AR. PVG in AR was considered a possible indication for surgery by 65% and PVG on US by 50%. Turbid or localised fluid on US was more often regarded an indication for surgery where US was used for NEC than where it was not.
Conclusion: There is greater consensus on possible signs of NEC, as well as the significance of these findings, on AR than on US. The perceptions are partly influenced by the respondents' experience of US in NEC.

B-0514 11:19

Analysis of clinical and ultrasound determinants of adnexal torsion in children and adolescents
R. Jourjon, B. Morel, S. Irtan, E. Audureau, H. Ducou le Pointe, E. Blondiaux; *Paris/FR (eleonore.blondiaux@aphp.fr)*

Purpose: To assess the performance of transabdominal ultrasonography (US) for diagnosis of adnexal torsion (AT) in children and adolescents and evaluate its clinical and US determinants.
Methods and Materials: We retrospectively (2004 to 2014) studied data for children referred for acute or sub-acute pelvic pain who underwent US and included children 3 months to 18 years old who underwent surgical exploration and/or clinical and radiological follow-up for at least 3 months. The evaluation of US diagnostic performance was based on the proposed diagnosis after US: AT or no AT (NAT) with or without mass. Clinical and US predictors of AT were identified by regression analysis.
Results: Among 65 girls included (mean age 11.75±4.49 years), 33 (50.8%) had AT. The sensitivity, specificity, positive predictive value, negative predictive value and accuracy of US for AT were 90.9%, 68.7%, 75%, 88% and

80%, respectively. Overall, 20/33 (60.6%) AT patients had a mass, including 33% with mature teratomas. Patients with AT versus NAT more frequently showed vomiting (64% vs 28%, p=0.008), ovarian edematous stroma with a peripheral distribution of follicles (45.5% vs 9.4%, p=0.002) and a mass of pluritissular aspect (40% vs 0%, p<0.0001). The quantitative US predictors of AT were total area ratio (ovary and mass) / area of the contralateral ovary ≥4.9 (p=0.0002) and surface area ≥18.5 cm2 (p=0.0003).
Conclusion: US has high sensitivity but low specificity for the diagnosis of AT in children. The predictive criteria are vomiting, presence of a pluritissular mass, ≥4.9 area ratio or surface area ≥18.5 cm2.

B-0515 11:27

Value of sonographic pseudogestation sac sign in diagnosing Meckel diverticulum in children presenting with bleeding per rectum: a decade's experience

V.N. Zefov, S.M. El-Maadawy, N.A. Abdelrahman, D. Abdul Rahman, A.R. Mustafawi; *Dubai/AE (samarmaadawy@gmail.com)*

Purpose: Meckel diverticulum is the most common congenital anomaly of the gastrointestinal tract. Gastrointestinal bleeding is the most frequent complication of Meckel diverticulum in the paediatric population. The purpose of our prospective study is to assess the value of using the ultrasound pseudogestation sac sign in diagnosing Meckel diverticulum in children presenting with bleeding per rectum.
Methods and Materials: 59 children were included in our study. All cases were referred with a clinical suspicion of Meckel diverticulum due to bleeding per rectum. Data were collected from 2005 to 2016. All children were examined by a paediatric radiologist using a high resolution linear or curvilinear probe with colour Doppler imaging. The results were correlated with nuclear studies, operative and histopathology findings.
Results: The ratio of boys to girls in our study population was 4:1. The age ranged from 1 month to 12 years with a median of 2 years. 42 cases were operated and 17 cases were treated conservatively and followed by ultrasound. The pseudogestation sac sign was identified in 32 cases. 2 cases were operated despite negative nuclear studies and proved later to be Meckel by histopathology. Using the ultrasound pseudogestation sac sign, the sensitivity, specificity, positive and negative predictive values for Meckel diverticulum were 87.1%, 82.1%, 84.4%and 85.2% respectively.
Conclusion: We believe that the sonographic pseudogestation sac sign is a reliable diagnostic tool for diagnosing Meckel diverticulum in children presenting with bleeding per rectum. The sonographic diagnosis of Meckel diverticulum complies with the international efforts of "Image Gently".

B-0516 11:35

Anorectal malformations: diagnostic value and reliability of MRI distal pressure colostogram in comparison with the fluoroscopic examination

D. Maslava, Z. Holubová, M. Kynčl, L. Poš, R. Škába; *Prague/CZ (darya.maslava@fnmotol.cz)*

Purpose: Application of gadolinium into the colostomy during MRI study (MRI-DPCG) of patients with anorectal malformations (ARM) facilitates demonstration of the presence and precise localization of fistula. This anatomical information and identification of other malformations by MRI guides the surgical approach. The aim of our study was to compare the diagnostic accuracy of fluoroscopic distal pressure colostogram (DPC) and MRI-DPCG in the pre-operative work-up of patients with ARM.
Methods and Materials: A retrospective study of patients with ARM admitted to the surgical department between the years 2011-2015 was conducted. DPC and MRI-DPCG were analysed and the results of these examinations were compared with intra-operative findings. The presence and location of the rectal fistula and length of the common channel in cloacal malformations in girls were evaluated.
Results: 16 colostomized patients with ARM were included in our cohort (13 boys, 3 girls). Median age at the time of MRI was 12.5 weeks. MRI revealed rectovesical fistula in 2 patients, rectourethral prostatic fistula in 2, rectourethral bulbar fistula in 5, without fistula in 4. There were 3 cloacal malformations - 2 low type cloacas and 1 high cloaca. There was full agreement between MRI-DPCG and intra-operative findings. DPC was identical in 15 patients in comparison with the intra-operative findings and didn't show bulbar fistula in 1 patient.
Conclusion: As shown in our study, MRI-DPCG provides accurate evaluation of ARM and should be considered a serious alternative to fluoroscopic imaging during preoperative work-up.

B-0517 11:43

Utility of dynamic sequence in defeco-MRI for the evaluation of patients with ano-rectal malformation

C. Tudisca, S. Salerno, C. Geraci, G. La Tona, A. Lo Casto, M. Midiri; *Palermo/IT (chiaratudisca@gmail.com)*

Purpose: Patients operated for correction of anorectal malformation (MAR) could have variables post-surgery complications, such as constipation and/or incontinence. Aim of the study was to evaluate morphologically and functionally the organs and muscle-sphincter pelvic structures involved in defecation in patients treated for MAR with post-surgery complications, by using MR-defecography technique.
Methods and Materials: 10 adolescents (17.2 ± 2.4 years), operated in childhood for MAR with defecatory difficulties were analysed by MR-defecography static and dynamic sequences. The static MRI exam assessment included evaluation of: -position the neo rectum, -perineal muscles, -expansion of the superior rectus, -abnormalities of the spinal cord and sacrum. In dynamic sequences were evaluated: -erniation of muscle and/or peritoneal fat, -position of the perineum plane, -rectal emptying.
Results: In 6 (60%) cases there was an asymmetry of the levator ani, in particular 3 patients had an hypotrophy of the right levator ani and contralateral compensatory hypertrophy. In dynamic sequences in maximum evacuative phase 8 (80%) patients presented an incomplete emptying of the rectum and minimum variation of the anorectal angle between the static phase and the phase of incomplete emptying, as from obstructed defecation syndrome. In 7 (70%) cases it was detected abnormality of the coccyx tract.
Conclusion: MR-defecography can be an important diagnostic tool in the evaluation of the postoperative regional anatomy and of perianal functionality with dynamic sequences that allow you to identify the causes of defecatory obstruction and/or incontinence.

B-0518 11:51

Modified-Seldinger technique for paediatric percutaneous nephrostomy

K. Rangarajan, D. Kandasamy, M. Jana, L. Singh, V. Ramalingam; *New Delhi/IN (krithikarangarajan86@gmail.com)*

Purpose: To describe a new technique for paediatric Percutaneous Nephrostomy (PCN). Compare the technique with the conventional Seldinger technique in terms of success rate, number of attempts and procedure time.
Methods and Materials: PCN was performed in 18 children under 4 years of age with hydronephrosis in whom renal function was expected to improve after percutaneous drainage. 8 children underwent PCN with the new technique using 14 G puncture needle. Ten children underwent PCN with Seldinger technique. Procedure time, number of attempts and success of procedure were noted for each patient.
Results: In the conventional technique it was seen that though the puncture needle entered the pelvicalyceal system, the dilators and catheter tended to push the renal parenchyma, rather than piercing it, leading to deployment of the catheter within the parenchyma or in the perinephric space. This problem was encountered in 3 patients out of 10, of which in 2 patients the procedure was abandoned as the system got decompressed. In 1 patient the catheter was deployed in the second attempt. Procedure time was 10 to 15 minutes. Fluoroscopy was used in 5 patients to confirm position of guide-wire. Using the new technique, catheter could be deployed in the first attempt in all 8 patients, without using fluoroscopy. Procedure time was under 8 minutes from local anesthesia to sutures.
Conclusion: This technique is useful for paediatric PCN to overcome the elasticity of tissues and aids successful deployment of catheter. It reduces procedure time, improves success rate and eliminates radiation exposure.

Texture-based analysis of dual-energy CT and monochromatic imaging for quantification of steatosis hepatitis: correlation with pathology

B. Hoppel[1], K. Goatman[2], P. Rogalla[3]; [1]*Vernon Hills, IL/US*, [2]*Edinburgh/UK*, [3]*Toronto, ON/CA (bhoppel@tmriusa.com)*

Purpose: To analyse texture-based parameters with dual-energy and monochromatic CT imaging in patients with suspected fatty liver disease and compare to simultaneously acquired histo-pathology.
Methods and Materials: Following REB approval, patients (n=44) with clinically indicated non-focal liver biopsy for assessment of fatty liver disease underwent biopsy within the CT area. After biopsy needle placement, a dual-energy non-contrast CT volume (16 cm, 320 slices) was acquired over the liver with the needle in-situ, which is apparent in the CT image. Single energy (80KVP/135KVP) and monochromatic images in 5 KEV increments were reconstructed from the dual-energy data. Both local and volumetric liver segmentation was performed. Data analysis used over 2000 statistical and filter methods including Grey level co-occurrence matrices (GLCM), Run Level Emphasis (RLE), Law's texture filters and first order statistical measures and were correlated to pathology.
Results: DECT images of 80kVp and 60KEV showed the highest correlations with fat and fibrosis quantification from biopsy. Overall in non-contrast images, fat had a strong correlation but fibrosis had a weak correlation. The Pearson correlation (Fat/Fibrosis) for GLCM; Autocorrelation (-0.701/-0.398), ClusterProminence (-0.692/-0.407), ClusterShade (-0.737/ -0.409), ClusterTendency (-0.744/-0.398) RLE parameters also correlated well with fat; High Gray Level Run Emphasis (-0.745/ -0.404), Short Run High Gray Level Emphasis (-0.735/-0.422), Long Run High Gray Level Emphasis (-0.673/-0.402), Mean_Long Run High Gray Level Emphasis (-0.710/ -0.415), Mean_High Gray Level Run Emphasis (-0.800 /-0.33). Law's filters were less correlated but show promise; Iso-edge-wave-Mean (0.457/0.256), Iso-edge-wave-standard Deviation (0.4212/0.228), Iso-spot-Mean (0.440/0.228), Iso-spot-wave-mean (0.460/ 0.223).
Conclusion: Histopathological measures of fat correlated well with several of DECT texture analysis parameters, which may allow for non-invasive stratification of hepatic steatosis in patients with diffuse disease. In the future, a combination of these parameters may improve prediction.

Early diagnosis of bronchiolitis obliterans syndrome after lung transplantation using functional respiratory imaging

E.J.M. Barbosa Jr.[1], F. Ferreira[2], W. Vos[2], C.V. Holsbeke[2], L. Nuyttens[3], W. De Backer[4], J. De Backer[4], J.C. Lee[1]; [1]*Philadelphia, PA/US*, [2]*Kontich/BE*, [3]*North Brunswick, NJ/US*, [4]*Antwerp/BE (eduardo.mortani@gmail.com)*

Purpose: Chronic lung allograft dysfunction after lung transplantation (LTx) manifests as a sustained decline in FEV1, heralding the onset of bronchiolitis obliterans syndrome (BOS). Identifying regional disease in the lungs could lead to earlier diagnosis of BOS and potentially improved outcomes. Functional Respiratory Imaging (FRI) using quantitative CT image processing may predict the onset of BOS.
Methods and Materials: Paired inspiratory-expiratory CT scans of 41 LTx patients were analyzed retrospectively. The BOS cohort experienced a reduction in FEV1>10% compared to baseline (BOS 0-p). FRI yielded regional parameters: lung volumes (iVlobe), airway volumes (iVaw) and airway resistance (iRaw). Differences between the two groups were analyzed via multivariate regression modelling to determine the FRI parameters most predictive of FEV1 decline.
Results: A significant increase in transplanted iVlobe at FRC was demonstrated in the BOS cohort, with no statistically significant difference in FEV1 between the two groups. In the BOS cohort, distal iVaw at FRC, transplanted iVlobe at FRC and TLC were identified as predictors of FEV1 decline, while in the non-BOS cohort FEV1 decline is driven by central iVaw at FRC and TLC of the non-transplanted lung.
Conclusion: FRI could differentiate early BOS from non-BOS in LTx patients, whereas FEV1 could not. FEV1 decline in the BOS cohort appears to be particularly associated with changes in the transplanted lung, while in the non-BOS cohort, metrics from the non-transplanted lung are more associated with FEV1 changes. These results illustrate the potential of FRI as a diagnostic tool for early diagnosis of BOS.

B-0521 10:46

Role of 320-row CT with semi-automatic 3D analysis software for evaluating the response to systemic theraphy of multicentric HCC according to the mRECIST criteria

M. Moschetta, M. Telegrafo, G. Dilorenzo, G. Di Giovanni, I. Cornacchia, A. Stabile Ianora, G. Angelelli; *Bari/IT (marco.moschetta@gmail.com)*

Purpose: To evaluate the role of 320-row CT with 3D analysis software in the follow-up of multicentric hepatocellular carcinoma (HCC) treated with systemic therapy according to the mRECIST criteria.
Methods and Materials: In the period between December 2013 and June 2016 38 patients with multicentric HCC undergoing systemic therapy were assessed twice a year by MDCT before and after injection of contrast medium with three-phasic technique. Two blinded radiologists evaluated multi-planar images (MPR) classifying the response to therapy in PR (partial response), PD (progressive disease), SD (stable disease) and CR (complete response) by using the mRECIST criteria. 30 days later, the same two blinded radiologists evaluated the same target lesions applying the 3D semi-automatic analysis software. The differences between the two evaluating systems were assessed using the analysis of variance (ANOVA test). The inter-observer agreement for both the evaluating systems was calculated using Cohen's kappa statistics.
Results: In 10/38 cases (26%) PR was found; in 6/38 (16%) PD; in 22/38 (58%) SD. The analysis of variance did not detect statistically significant differences between the two systems of measurement ($p>0.05$). The inter-observer agreement (k) was 0.62 for the measurements in MPR and 0.86 for the measurements performed by using the 3D analysis software, with a significantly higher value for the proposed semi-automatic software ($p<0.05$).
Conclusion: The semi-automatic 3D analysis software represents a reliable method for evaluating the HCC response to therapy according to the mRECIST criteria and could be proposed in the clinical practice.

B-0522 10:54

Fully automated method for lung emphysema quantification from multidetector CT images

I. Mayorga-Ruiz, D. García-Juan, A. Alberich-Bayarri, F. García-Castro, P. Calvillo, L. Martí-Bonmatí; *Valencia/ES*

Purpose: Lung emphysema is considered one of the main changes in chronic obstructive pulmonary disease (COPD) disease. Our aim was to develop an automated algorithm for segmentation of lungs, vessels, airways and emphysema areas.
Methods and Materials: New methodology for automated lung emphysema quantification was developed and tested in 28 standard-of-care thorax MDCT scans. Lungs, main airways and blood vessels were segmented using thresholding, clustering and region growing techniques, applying as initial seed a previously computed trachea centroid. The emphysema detection was performed using either fixed or adaptative thresholding (algorithm patented by QUIBIM, Valencia, Spain). A value of -950 HU was applied in the first algorithm while the second implemented the computation of a slice-wise air adaptive threshold. Lung parenchyma HU levels were also analysed to provide meaningful information about parenchyma status. Finally, the percentage of emphysema and the total lung parenchyma volume were calculated.
Results: The complete automated algorithm execution took 25 minutes on average. Emphysema ratio, blood vessels, lung parenchyma and emphysema volumes were computed from the 28 CT studies with an initial execution efficiency of 86%. The algorithm could not analyse the rest due to lung hyperinflation. Adaptative thresholding outperformed fixed threshold emphysema segmentation due to image-specific air threshold.
Conclusion: Automated lung emphysema quantification can be used for the diagnosis and follow-up of COPD, helping radiologist to integrate a quantitative evaluation when reporting these patients. Adaptive thresholding is capable to provide a better characterization of lung emphysema due to the image-specific thresholding.

B-0523 11:02

Cerebral white matter, grey matter and cerebrospinal fluid segmentation in CT using VCAST: a volumetric cluster annotation and segmentation tool

S. van de Leemput, F.J.A. Meijer, M. Prokop, R. Manniesing; *Nijmegen/NL (silvandeleemput@gmail.com)*

Purpose: Segmentation of cerebral white matter (WM), grey matter (GM) and cerebrospinal fluid (CSF) in head CT is important for subsequent quantitative analysis and automated detection of cerebral pathology. We introduce VCAST, a new volumetric annotation tool aimed at delineating soft tissue in non-contrast CT (NCCT) and CT perfusion (CTP).
Methods and Materials: VCAST supports traditional 2D visualizations and annotations, and provides functionalities to facilitate 3D segmentations based on pre-calculated grids of volumetric clusters where the clusters are spatially coherently grouped based on HUs. Clicking a cluster in a 2D-plane allows for inclusion of the 3D-cluster in the output segmentation. Ten patients with suspicion of ischaemic stroke were included in this retrospective study, five NCCTs and five whole-brain CTPs (320-row detector scanner). Temporal average CTA was reconstructed from CTP and in one slice in arbitrary direction, WM, GM and CSF were annotated two times by one observer using VCAST. In NCCT, a subvolume of approximately 22 mm^3 was randomly selected in which CSF was annotated by one observer, using VCAST either with 2D (slice-based) or 2D and 3D (cluster-based) annotation support. Dice coefficients and annotation times were reported.
Results: Dice coefficients were 0.86±0.04, 0.91±0.02, 0.87±0.02 for CSF, GM and WM respectively. CSF annotation times reduced from 16±9 to 8±5 minutes with 3D cluster support (p=0.02). CSF Dice similarity was 0.81±0.03.
Conclusion: VCAST is a volumetric annotation tool which reduces the time to obtain 3D segmentations in head CT while maintaining good overlap with a slice-based approach.

Validation of a semi-automated technique to accurately measure abdominal fat distribution using CT and MRI for clinical risk stratification

M. Waduud, A. Sharaf, I. Roy, R. Lopez-Gonzalez, A. Hart, D. McGill, G. Roditi, J. Biddlestone; *Glasgow/UK (m.a.waduud@doctors.org.uk)*

Purpose: Positive correlations exist between measurements of total abdominal fat (TAF), intra-abdominal fat (IAF), extra-abdominal fat (EAF) and abdominal waist circumference (AWC) [collectively; abdominal fat distribution (AFD)] on Computer Tomography (CT) and Magnetic Resonance (MR) imaging when performed in immediate succession. This study investigated the comparability of retrospective measurements of AFD on CT and MR imaging performed solely on clinical merit without predefined research criteria and undertaken at different times.
Methods and Materials: All patients were identified retrospectively from a local database of patients planned to undergo flap-based breast reconstruction as the Canniesburn Plastic Surgery Unit. Patients with both preoperative CT and MR imaging were identified from the Patient Archiving Computer System. Image analysis was performed using the Image-J software package. Linear regression analysis was performed between values obtained from both modalities for the individual parameters of AFD. Intra-observer and inter-observer differences were assessed using Bland-Altman plots.
Results: The AFD was quantified at the level of the umbilicus on paired CT and MRI scans from 15 patients. In total 30 scans were analysed. The mean time between the imaging modalities was 68 days (77.8 days SD, range 1 to 255). Pearson's correlation demonstrated strong relationships between imaging modalities for TAF (R=0.846, p<0.001***), IAF (R=0.858, p<0.001***), EAF (R=0.844, p<0.001***), and AWC (R=0.617, p<0.05*). Interchangeable mathematical models were subsequently developed.
Conclusion: A strong interchangeable relationship exists between calculations of AFD on retrospective CT and MR imaging performed out with strict research criteria. Results are comparable to previously published prospective studies.

3D CT texture analysis of neuroendocrine pancreatic neoplasms

M. D'Onofrio, V. Ciaravino, N. Cardobi, R. De Robertis, R. Pozzi-Mucelli; *Verona/IT (valentinaciaravino@gmail.com)*

Purpose: To evaluate the added value of CT texture analysis in the study of neuroendocrine pancreatic neoplasms.
Methods and Materials: 24 patients with PNETS were included in this study. All tumours were pathologically diagnosed after resection or with biopsy. Histological grade of these neoplasms was available in all cases. There were 7 G1, 7 G2, and 10 G3 neoplasms with presence of metastases in 21/24 (87%) cases. 3D CT texture analysis of primary tumour was performed comparing results with tumour grading. CT texture analysis results (Mean Value, Variance, Skewness, Kurtosis) were compared by using Wilcoxon correlation test.
Results: Included PNETS were located in the head of the pancreas in 7/24 (29%) cases; in the body-tail in 17/24 (71%) cases. G1 neoplasms show mean dimension of 41 mm (range: 9 - 112 mm). G2 neoplasms show mean dimension of 42 mm (range: 21 - 73 mm). G3 neoplasms show mean dimension of 50 mm (range:16 - 111 mm). CT texture analysis was finalised in all cases. There was no statistical significant difference regarding all the parameters of CT texture analysis among G1, G2, and G3 neoplasms. Higher value of kurtosis was found in G3 (Kurtosis median= 2,1499000) in respect to G1 (Kurtosis median = 0,1128400) and G2 (Kurtosis median = 1,3848000) neoplasms. Grouping together G1 and G2 neoplasms, statistical significant difference (p< 0,05) was found regarding the only kurtosis CT texture analysis parameter.
Conclusion: This preliminary results show that CT texture analysis parameters can be complementary data for PNETS grade prediction.

Quantitative CT metrics from the transplanted lung may predict FEV1 after lung transplantation

E.J.M. Barbosa Jr.[1], H. Shou[1], S. Simpson[1], N. Tustison[2], J. Gee[1], J. Lee[1]; [1]*Philadelphia, PA/US*, [2]*Charlottesville, VA/US (eduardo.mortani@gmail.com)*

Purpose: Chronic lung allograft dysfunction after lung transplantation (LTx) manifests as a sustained decline in FEV1, indicative of bronchiolitis obliterans syndrome (BOS). Our hypotheses are that quantitative CT (QCT) metrics may predict FEV1 better than semi-quantitative scores (SQS), and that the transplanted lung behaves differently from the native lung in unilateral LTx.
Methods and Materials: Paired inspiratory-expiratory CT scans and PFTs of 178 LTx patients were analyzed retrospectively, and separated into unilateral left (43), unilateral right (40) and bilateral (95) LTx. SQS were graded from 0-3 (absent, mild, moderate, severe) for features including mosaic attenuation, tree in bud nodules and bronchiectasis. QCT included lung volumes and air trapping volumes, by lobe, in inspiration and expiration. Multivariate Pearson correlation analysis was performed to measure the strength of association between QCT metrics and FEV1.
Results: QCT metrics demonstrated stronger correlation (r) with FEV1 than SQS. In bilateral LTx, whole lung volume difference (WLVD) (r=0.69), left lung volume difference (LLVD) (r=0.69) and right lung volume difference (RLVD) (r=0.65) were better than the sum of SQS (r=-0.54). Interestingly, in left LTx we obtained r=0.81, r=0.86, r=0.25 and r=-0.39, respectively. In right LTx we obtained r=0.69, r=0.49, r=0.68 and r=-0.31, respectively.
Conclusion: QCT metrics demonstrate much stronger correlations with FEV1 and therefore are better predictors of pulmonary function than SQS. SQS performs moderately well in bilateral LTx, but poorly on unilateral LTx. In unilateral LTx, QCT metrics from the transplanted lung are better predictors of FEV1 than QCT metrics from the non-transplanted lung.

B-0527 11:34

A new integrated biomarker for IVIM/diffusion MRI: clinical feasibility study

D. Le Bihan; *Gif-Sur-Yvette/FR (denis.lebihan@gmail.com)*

Purpose: IVIM/diffusion MRI results are often expressed as model parameters (ADC, Kurtosis) which are cumbersome to estimate, resulting in variable results across centers. A new integrated diffusion biomarker (Signature Index, S) which directly provides a diagnosis statement without requiring any model computation is introduced, as well as its extension to obtain angiograms and tissue shear stiffness without using contrast agents or mechanical vibrations.
Methods and Materials: The feasibility of this approach was evaluated in 30 patients (breast, head and neck, liver tumours and fibrosis). "Key b values" which provide highest sensitivity to changes in IVIM, Gaussian and non-Gaussian diffusion were first identified for the organs under evaluation. The S Index was calculated on a voxel-by-voxel basis from the "distance" between lesions MRI signals acquired at those key b values and those of typical tissues (eg, malignant/benign) to produce color-encoded diagnostic maps, which were also used for texture analysis (such as stratified conspicuity). The S Index was also tailored to identify specific tissue features, such as vessels, to generate angiograms, or converted into tissue shear stiffness to generate quantitative elastograms.
Results: The performance of the S index to identify malignant and benign lesions was excellent (AUC=0.89) with specificity and sensitivity close to 90%. The correlation between shear stiffness obtained from IVIM virtual MRE and standard MRE in liver patients was very high (R^2=0.89, p=1.02 10^{-7}), allowing accurate fibrosis staging (F0-4).
Conclusion: This integrated S index provides tissue features recognition with high accuracy without the need to estimate diffusion model parameters.

Automatic visual-like classification of lung tumour heterogeneity in DCE-CT sequences

S. Baiocco[1], D. Barone[2], A. Bevilacqua[1], G. Gavelli[1]; [1]*Bologna/IT*, [2]*Meldola/IT (s.baiocco@unibo.it)*

Purpose: Tumour heterogeneity is an important prognostic factor, as high intra-tumour heterogeneity showed to be associated with higher tumour grades. However, its assessment is still mostly accomplished subjectively through visual procedure. This work presents an automatic approach to classify the heterogeneity levels in lung tumour as performed through visual analysis.
Methods and Materials: 40 datasets referring to 13 patients (age range 36-81 years) with NSCLC, who underwent axial DCE-CT, were considered. Two 25-year experienced Readers chose the most representative slices in the DCE-CT sequences, outlined each lesion and its most significant regions. Then, each slice was assigned a class, according to a proper taxonomy for heterogeneity levels previously defined: homogeneous, macro-inhomogeneous (i.e., different homogeneities together), and micro-inhomogeneous. A statistical voxel-based index was devised to quantify the heterogeneity, then represented in colorimetric maps. The values were grouped into regions subsequently compared with those drawn by radiologists.
Results: Results for the three classes were computed in terms of specificity (SP) and sensitivity (SE). Our approach proved to be extremely specific, mostly for homogeneous (SE=77%, SP=93%) and macro-inhomogeneous (SE=75%, SP=90%) tissues. On the other hand, the most indefinite micro-inhomogeneous tissue also shows a high specificity (SE=86%, SP=87%).
Conclusion: The approach developed allows an automatic classification of heterogeneities, with a reduction of both intra- and inter-observer variability. This represents a novel approach acting as a second radiologist in the heterogeneity assessment, which could yield a great benefit for patient stratification and constitutes a valid tool to assist radiologists in daily clinical activities.

Design and implementation of a parallel filter for real-time fluoroscopy imaging

A. Brusan, F.A. Durmaz, I.B. Erguder, A. Yaman, C. Ozturk; *Istanbul/TR (altay_bn@yahoo.com)*

Purpose: Design and implementation of a parallel filter for real-time fluoroscopy imaging.
Methods and Materials: A digital filter was designed to exploit a 3D spatio-temporal averaging kernel over a queue of images captured by a digital fluoroscopy camera. The filter was implemented on both CUDA and OpenCV platforms to use their parallelization foundations. As a benchmark, a step phantom was used to figure out image noise characteristics and its dependency on contrast level. The filtering operation was performed with different spatio-temporal kernel sizes, image bit-depths, camera gain and exposure parameters to model the performance of the filter with regards to both Signal to Noise Ratio (SNR) and execution speed. Subsequently, this model is used to find optimum tune parameters of the filter.
Results: The speed was correlated with image bit-depth and spatio-temporal kernel size. Increasing bit-depth or kernel size consequently reduced the speed proportionally. However, in contrast to non-parallel algorithms, the parallel implementation brought up to twelve times speed-up. The SNR level was dependent on the contrast. At high-contrast regions the filtered image quality was (SNR: 18.37%, STD: 6.48) in contrast to (SNR: 13.97%, STD: 12.37) of non-filtered images and at the low-contrast regions the quality factors were (SNR: 13.64%, STD 11.53) in compare to respective (SNR: 12.04%, STD: 16.53) of non-filtered images.
Conclusion: CUDA and OpenCV based parallelization has been applied in machine learning and Image processing for a while. This study put these platforms under the limelight for utilizing them in real-time fluoroscopy image processing.

Pancreatic lipid deposition is determined by environmental rather than genetic factors: a classical twin study

A. Panajotu, M. Kolossváry, S. Papp, Á.L. Jermendy, D.L. Tárnoki, J. Karády, F.I. Suhai, B. Merkely, P. Maurovich-Horvat; *Budapest/HU (panajotualexisz@gmail.com)*

Purpose: Intrapancreatic fat can be assessed by non-contrast-enhanced computed tomography (CT) and is associated with beta-cell dysfunction. The role of genetic and environmental factors in pancreatic lipid accumulation is unclear. Therefore, we sought to evaluate the contribution of genetics and environmental factors on pancreatic lipid content within a cohort of adult twins.
Methods and Materials: We investigated 77 twin pairs (47 monozygotic [MZ] and 30 dizygotic [DZ] same gender pairs) with a 256-slice CT-scanner. Using non-enhanced CT images we measured the average value of pancreatic attenuation (Hounsfield units [HU]) in three regions of interest. Blood samples were collected before the CT scan. Intra-pair correlations were calculated and structural equation model was used for evaluating additive genetic (A), dominant genetic (D) and unique environmental (E) components.
Results: Main clinical and laboratory findings of the twins were: age 56.1±9.4 years, BMI 27.7±5.3kg/m^2, fasting glucose 97.5±25.7mg/dL, HbA1c 5.5±1.0% (mean±SD). Average pancreatic attenuation was 47.2±11.3 HU in MZ and 47.6±11.8 HU in DZ twins. The intra-pair correlation between HU values were stronger in MZ as compared to DZ twins (rMZ=0.498, p<0.001; rDZ=0.080, p=0.674). Using the structural equation model, a predominant environmental influence (E: 59%) and a moderate additive genetic dependence (A: 41%) was found. Dominant genetic influence was not identified (D: 0%).
Conclusion: We found a moderate genetic and a much stronger environmental dependence of pancreatic lipid accumulation in our twin cohort indicating that environmental factors and lifestyle characteristics are predominantly involved in the development of fat accumulation in the pancreas.

Differences in pancreatic proton-density fat fraction by MRI in subjects with prediabetes, diabetes, and controls from the general population

S.D. Heber[1], H. Hetterich[2], R. Lorbeer[2], C. Bayerl[2], J. Machann[1], S. Auweter[2], C. Schlett[3], A. Peters[4], F. Bamberg[1]; [1]*Tübingen/DE*, [2]*Munich/DE*, [3]*Heidelberg/DE*, [4]*Neuherberg/DE (sophia.heber@uni-tuebingen.de)*

Purpose: To determine differences in pancreatic adipose tissue between subjects with prediabetes, diabetes, and normal controls as measured by magnetic resonance imaging (MRI) and its association with other adipose tissue compartments.
Methods and Materials: Subjects without history of cardiovascular disease with established diabetes or prediabetes as well as normal controls were included from a population-based cohort study and underwent whole-body 3T MRI. The imaging protocol included a 3D multi-echo Dixon sequence for derivation of proton-density fat fraction of the pancreas ($PDFF_{panc}$) and liver ($PDFF_{hepatic}$) as well as a two-point Dixon to determine subcutaneous and visceral adipose tissue (SAT and VAT, respectively). Univariate and multivariate analyses were employed to determine associations.
Results: A total of 385 subjects were included (median age: 57 years, 58.2% males) and the prevalence of diabetes and prediabetes was moderate (13.8% and 24.7%, respectively). The median $PDFF_{panc}$ was 5.2% [IQR 3.3; 9.4], and significantly higher in subjects with prediabetes and diabetes as compared to controls (6.2% [3.5; 12] vs. 8.6% [4.3; 17.5] vs. 4.9% [3.1; 7.4], respectively; p_{Trend}<0.001). After adjusting for age, gender and BMI, the association was attenuated. In addition, while in univariate analysis BMI, $PDFF_{hepatic}$, SAT and VAT were associated with $PDFF_{panc}$ (all p<0.05), only VAT predicted $PDFF_{panc}$ independently (Beta: 0.02; p<0.001).
Conclusion: While there is a significant difference in $PDFF_{panc}$ between subjects with prediabetes, diabetes and controls, this association is largely confounded by the amount of VAT. Thus, VAT may play a prominent role in the pathophysiology of the development of hyperglycaemic states.

Optimising quality and diagnostic performance of the MDCT by using low tube voltage in patients with suspected pancreatic adenocarcinoma

E. Kondratyev, V.J. Aznaurow, I.A. Blokhin, P. Davydenko, G.G. Karmazanovsky; *Moscow/RU (evgenykondratiev@gmail.com)*

Purpose: Attenuation characteristics of the pancreatic adenocarcinoma(PA) and contrast material uptake vary depending on histologic grade, pancreatic parenchyma condition and scanning parameters. The purpose of this study was to evaluate the impact of low-tube voltage multiphase contrast-enhanced MDCT on tumour conspicuity and overall diagnostic performance.
Methods and Materials: 42 consecutive patients with clinically suspected PA and indications for MDCT were enrolled in the study and randomized into two groups based on the tube voltage (group 1 - 120 kV and group 2 - 100 kV). We compared mean tumour and parenchyma attenuation, noise, effective dose as well as qualitative score between groups. Relative tumour enhancement ratio (RTE) was calculated for each contrast enhancement (CE) phase.
Results: The mean BMI was 25.5±3.56kg/m^2 and 26.3±3.14kg/m^2, respectively (p=0.552). 34 PA and 8 chronic pancreatitis were identified by CT. Parenchyma attenuation was significantly higher during arterial and venous phase in 100kV group - 106±17 HU and 95±18 HU vs 91±14 and 89±9 HU in 120kV group, respectively (p<0,0001). Arterial RTE in 100kV group was -0.73±0.13 (-0,88±0,05 in 120kV group, p<0.001), venous RTE was -0.33±0.23 (-0,45±0,25 in 120kV group, p>0.05), delayed RTE was 0.59±0.27 (0,21±0,53 in 120kV group, p>0.05). Qualitative analysis showed better lesion conspicuity in 100kV group, especially on arterial and delayed phases. Diagnostic accuracy of the MDCT was higher in 100kV group (sensitivity 97,3 vs 91,3%, specificity 84,1 vs 80%).
Conclusion: Low-tube-voltage scanning protocol may be used for improving diagnostic quality and performance of the multiphase contrast-enhanced MDCT during pancreatic adenocarcinoma diagnostic workflow.

B-0533 14:24

Timing-specific contrast media protocol enhances image quality at reduced contrast volume and radiation dose during computed tomography of the pancreas

C. Saade, J. Chokr, L. Naffa, W. Faraj, A. Shamseddine, D. Mukherji, S. El Sageyh, R. Assi, A. Haydar; *Beirut/LB (charbel.saade@aub.edu.lb)*

Purpose: To investigate the opacification of the pancreatic vasculature and parenchyma during CT utilizing a patient-specific contrast formula.
Methods and Materials: This hybrid prospective and retrospective study was institutional review board approved. In 220 consecutive patients, pancreatic CT was performed with one of two protocols: protocol A, 100mL of contrast material injected via timed bolus triggering technique; or protocol B, employing a patient-specific contrast media protocol specifically timed at the gastroduodenal artery. Measured attenuation of pancreatic parenchymal, arterial and venous vasculature. Effective dose was calculated. Data were compared with the independent two-sample t-test. Receiver operating characteristic (ROC), visual grading characteristic (VGC) and Cohens' kappa analyses were performed.
Results: Pancreatic measurements in each of the segments during the arterial and venous phase were significantly higher in Protocol B (mean±standard deviation, art: 96.59HU±27.37; venous: 91.28HU±20.88) compared to A (art:77.86HU±21.14; venous: 73.99HU± 14.75) (p<0.0001). Arterial opacification was significantly higher in protocol B compared to A (p<0.036). In the venous circulation, the inferior vena cava, superior mesenteric, portal and splenic veins demonstrated reduction in vascular opacification protocol B compared to A(p<0.001). The contrast media volume in protocol B (57.60±12.25 mL) was significantly lower than in protocol A (100±1 mL) (p<0.001). Effective dose was significantly reduced in protocol B (2.75±0.63mSv) compared to A (4.015±0.89mSv) (p<0.001). ROC and VGC analysis demonstrated significantly higher area under the curve for protocol B (p<0.0001)(p<0.034) respectively, with inter-reader agreement increasing from good to excellent in pancreatic lesion detection.
Conclusion: Timing-specific contrast media protocol enhances image quality at reduced contrast volume and radiation dose during CT of the pancreas.
Author Disclosures:
C. Saade: Grant Recipient; GE Healthcare.

CT features of non-hypervascular endocrine tumours of the pancreas: a comparison with pancreatic adenocarcinoma

G. Zamboni, M. Chincarini, M.C. Ambrosetti, F. Lombardo, R. Negrelli, E. Boninsegna, R. Pozzi-Mucelli; *Verona/IT (marco.chincarini@gmail.com)*

Purpose: To review the CT features of non-hypervascular endocrine tumours of the pancreas (nonH-NETs) and compare them with those of pancreatic adenocarcinomas.
Methods and Materials: We reviewed the multiphasic MDCTs performed on 38 nonH-NETs. These were compared with 38 pancreatic adenocarcinomas matched by size. All patients underwent multiphasic MDCT after administration of a weight-based amount of high-concentration contrast agent. One reader evaluated tumour size, margins, homogeneity, enhancement pattern (subjectively increasing enhancement from arterial to venous phase vs other patterns) and presence of vascular invasion. All diagnoses were confirmed at pathology. Data were analysed with Fisher's test.
Results: Mean tumour diameter was 46 mm for nonH-NETs and 45.5 mm for adenocarcinomas (p=ns). 41/57 nonH-NETs had well-defined margins, in contrast to 15/57 adenocarcinomas (p<0,0001). Calcifications were seen in 5/57 nonH-NETs and none of the adenocarcinomas (specificity 100%). No difference in tumour homogeneity was observed between the two groups (p=ns). 33/57 nonH-NETs were hypodense in the arterial phase and 22/57 were isodense, 54/57 adenocarcinomas were hypodense and 3/57 isodense (p<0,0001). 15/57 nonH-NETs and 11/57 adenocarcinomas showed increasing enhancement from the arterial to the venous phase (p=ns). The MPD upstream to the tumour had significantly larger calibre in adenocarcinomas (5.8 vs 2.2 mm; p<0,0001). No difference was observed for arterial or venous invasion between the two groups (p=ns).
Conclusion: Non-hypervascular endocrine tumours have well-defined margins, cause less MPD dilatation, and are more commonly isodense than adenocarcinoma. The presence of tumoural calcifications is specific for nonH-NETs.

B-0535 14:40

Insulinoma detection with cross-sectional imaging: comparison of biphasic-enhanced CT, volume perfusion CT and 3T multiparametric MR

L. Zhu, H.-D. Xue, Z.-Y. Sun, P. Li, Z.-Y. Jin; *Beijing/CN (zhuliang_pumc@163.com)*

Purpose: To evaluate the diagnostic performance of biphasic contrast-enhanced CT (CECT), volume perfusion CT(VPCT) and multiparametric MR (mp-MR) at 3T, in patients with clinically suspected insulinomas.
Methods and Materials: Sixty-four patients with clinically suspected insulinomas were prospectively enrolled. All patients underwent biphasic CECT, VPCT and 3T mp-MR with identical protocols. Two radiologists independently determined the presence/absence of tumour using a 5-scale confidence level. Conspicuity of the lesion and clarity of tumour-to-pancreatic duct distance were graded. CECT, VPCT and mp-MR were evaluated in random order, with time interval of at least 7 days. Receiver operating characteristic (ROC) analysis was performed to compare the radiologists' diagnostic confidence.
Results: Forty-seven patients were tumour positive, with a total of 51 tumours. The Az values for tumour detection were as follows: 0.715 (CECT), 0.903 (VPCT) and 0.955 (mp-MR) for reader 1, and 0.738 (CECT), 0.895 (VPCT) and 0.956 (mp-MR) for reader 2. VPCT and mp-MR were significantly more accurate than CECT for insulinoma detection (p=0.02 and 0.01 for reader 1, and p=0.03 and 0.01 for reader 2). Lesion conspicuity was better on mp-MR and VPCT compared to CECT (both p<0.01). Tumour-to-pancreatic duct distance was better appreciated on MR, compared to CECT and VPCT (both p<0.01). The weighted k values indicate good to excellent agreement between observers for determining tumour presence/absence (k=0.64 for CECT, 0.80 for VPCT and 0.84 for mpMR).
Conclusion: VPCT and mp-MR were significantly more accurate than CECT for insulinoma detection, and mp-MR demonstrate better tumour conspicuity and clearer tumour-to-duct distance.

B-0536 14:48

Correlation between appearance of the retroportal fat plane at preoperative CT and pathology findings in resected adenocarcinoma of the pancreatic head

F. Lombardo[1], G.A. Zamboni[2], M.C. Ambrosetti[2], M. Chincarini[2], M. Bonatti[1], G. Malleo[2], G. Marchegiani[2], R. Pozzi-Mucelli[2]; [1]*Bolzano/IT*, [2]*Verona/IT (fabio.lombardo@me.com)*

Purpose: To correlate the CT and pathology findings in resected adenocarcinomas of the pancreatic head (PDAC).
Methods and Materials: We included 48 patients with resected PDAC of the pancreatic head (24M, 24F, mean age 65 years). All patients underwent multiphasic preoperative MDCT less than 30 days before surgery. All cases

were re-evaluated at pathology for the state of the retroportal lamina, lymphatic and perineural invasion. CT images were reviewed in consensus by two radiologists for assessment of the fat plane between the pancreatic head and the mesenteric vessels: this was graded in two categories (clear, effaced/infiltrated). Fisher's test was used to assess the correlation between CT and pathology findings.
Results: A clear fat plane between the pancreatic head and the mesenteric vessels was significantly associated with a negative retroportal lamina at pathology (p=0.0037). No different results were observed between effaced and clearly infiltrated fat. No association was observed between the appearance of the fat planes at CT and the presence of lymphatic or perineural invasion (p=ns).
Conclusion: A clear fat plane between the pancreatic head and the mesenteric vessels is significantly associated with negative retroportal lamina at pathology. CT is not accurate in predicting lymphatic or perineural invasion.

B-0537 14:56

Body composition parameters, pancreatic volume and texture as radiological predictors of pancreatic fistula after Whipple procedure

I. Shrainer, V. Voropaev, E.A. Mershina, Z.A. Kovalenko, V.K. Lyadov, V.E. Sinitsyn; *Moscow/RU (shrainer@gmail.com)*

Purpose: Patients after Whipple procedure (pancreatoduodenectomy) experience postoperative complications in up to 50-60% of cases. Many surgical and radiological reports describe pancreatic fistula (PF) as the most frequent complication (10-24%). Aim was to find out the radiological predictors of PF in patients after Whipple procedure.
Methods and Materials: We retrospectively analysed 32 patients who underwent Whipple procedure and had a preoperative CT scan as staging in our centre. CT images were processed to obtain measures of pancreatic texture (density in nonenhanced scan), whole pancreatic volume, volume of pancreatic remnant and body composition parameters including whole body fat-free mass index (FFMI), whole body fat mass index (FMI), L3 skeletal muscle index (SMI).
Results: PF occurred in 15 patients who were included in the first group, the other 17 patients did not have PF and were included to the second group. There were significant differences ($p \leq 0.05$) between the two groups in the whole pancreatic volume (32.1+/-3.4cm^3 vs 21.4+/-3.0cm^3), texture of the pancreas (38.5+/-3.6HU vs 21.7+/-3.0HU) and volume of pancreatic remnant (18.4+/-2.1cm^3 vs 12.1+/-1.4cm^3). The significant difference of SMI (44.3 ± 8.3cm^2/m^2 vs 40.5 ± 8.8cm^2/m^2), FFMI (15.4 ± 2.4kg/m^2 vs 14.3 ± 2.5kg/m^2), FMI (8.8±2.5kg/m^2 vs 9.5±2.5kg/m^2) was not determined.
Conclusion: Pancreatic texture, preoperative whole pancreatic volume and volume of pancreatic remnant are independent predictors of pancreatic fistula. Body composition parameters (FFMI, FMI, SMI) do not affect the development of pancreatic fistula.

B-0538 15:04

Evaluation of perfusion in pancreas graft using 640-slice computed tomography

M.S. Khubutia, S.K. Ternovoy, R.S. Muslimov, Y.A. Anisimov, A.V. Pinchuk, N.S. Serova; *Moscow/RU (transfer498@yahoo.com)*

Purpose: To define feasibility of the 640-slice dynamic volume computed tomography in diagnostics of vascular complications and assessment of pancreas graft's (PG) perfusion.
Methods and Materials: 23 patients after pancreas transplantation were investigated using Toshiba 640-slice computer tomography. The contrast was injected through the central venous 16G-catheter. Data acquisitions were done without breath holding. Arterial blood flow parameters (AF, ml/min/100ml) were measured at the level of graft head, body, tail areas, and the time of maximum PG's tissue peak (TTP, sec.) contrasting was determined. The obtained results were analysed and compared with those of others authors dealing with perfusion of native pancreas.
Results: 12 cases showed adequate PG's blood flow at both arteries with normal organ function. The TTP-19[17;21], AF-117[97;123], 113[98;125], 104[89;126]. 9 cases revealed blood flow absence in a PG's superior mesenteric artery (PG blood flow was going separately through splenic artery's system). There were neither clinical nor laboratory signs PG dysfunction. AF-137[117;160], 126[120;132], 125[105;137], TTP-18[17;19] and statistically didn't differ from first patients group and a native pancreas perfusion. Also there were in 2 patients expressed depression of PG's blood supply in both arteries which resulted in depressed perfusion: AF - 44[20;66], 52[18;85], 57[21;92], TTP - 11[9;13]. Clinical and laboratory signs of PG's dysfunction were also found in this patients.
Conclusion: 640-slice dynamic volume perfused computed tomography allows to visualise whole-PG's vascular structure and anatomy. It also helps objectively estimate the adequacy of PG's blood supply and clinical importance of vascular complications.

B-0539 15:12

Diagnostic role of new generation multidetector-CT scanner in detection and characterisation of incidental pancreatic cystic lesions: comparison with MRCP

D. Ippolito, A. Nasatti, C. Talei Franzesi, A. De Vito, E. Orsini, S. Lombardi, S. Sironi; *Monza/IT (davide.atena@tiscalinet.it)*

Purpose: To compare the diagnostic accuracy of MDCT to MRI with MRCP sequences, in detecting pancreatic cystic lesion and those features useful for their characterization.
Methods and Materials: We evaluated 50 patients with no history of pancreatitis, neoplasm and prior surgical procedures in pancreas, who underwent both MDCT and MRI with MRCP (time interval lower 90 days),for pancreatic cysts characterization. The reviewer recorded number of lesions detected in each patients and the main morphologic features of defined target lesion: location (head,uncinate process,neck,body,tail), number, size, communication with main pancreatic duct (MPD), maximum MPD diameter, presence of septa, mural enhancing nodules. Data were analysed to compare diagnostic performance of MDCT and MRI.
Results: A greatest number of pancreatic cysts was identified on MRI than CT examinations (227 vs 128); however ICC value of 0.76 suggested a good agreement.Very good agreement (ICC 0.98) was found regarding the diameter of target lesions(21.4 mm on CT vs 21.8 mm on MRI),location of target lesion (κ=0.90), and detection of MPD dilatation (κ=1.00) and septa (κ=0.86). Fair agreement about the evaluation of MPD communication (κ=0.33) and calcifications (κ=0.22) was found.
Conclusion: MDCT can be consider almost equivalent to MRI with MRCP in the evaluation of pancreatic cystic lesion, offering detailed morphologic features helpful for their characterisation and those correlated with a high risk of malignancy.

B-0540 15:20

MDCT vs endoscopic USG in evaluation of pancreatic masses

S. Gupta; *Delhi/IN (surabhig27@gmail.com)*

Purpose: Compare the diagnostic accuracy of 256 multislice CT and endoscopic ultrasound (EUS) in characterization and assessment of resectability of pancreatic masses. - Comparison of 256 slice MDCT and EUS findings with histopathological/operative findings.
Methods and Materials: Total of 36 patients with pancreatic masses were included. Clinical and laboratory findings were recorded followed by dual phase examination using pancreatic protocol. EUS was performed using transducer of 5-13 MHz. FNAC was done wherever feasible. Parameters regarding tumour size, location, imaging morphology and vessel involvement were recorded. Findings were compared with histopathological /operative diagnosis/clinical follow up.
Results: Out of 36 patients, MDCT and EUS established diagnosis consistent with tissue diagnosis in 30 (83%) and 22 (61%) patients respectively. However, best results were obtained with combined use of MDCT and EUS ie 34 (95%) patients. The number of patients categorized as inconclusive by MDCT were lower compared to EUS (2/36 cases on MDCT vs 10/36 cases on EUS) -MDCT showed specificity and PPV of 100% in assessment of resectability of pancreatic adenocarcinoma compared to EUS which had specificity and PPV of 75% and 92.3% respectively. The sensitivity and NPV was 100% for both modalities.
Conclusion: MDCT is first line imaging modality in detection, characterization of pancreatic masses and assessment of resectability in malignant solid neoplasms. The specificity and PPV of MDCT was higher than EUS in determining resectability of pancreatic adenocarcinoma. -EUS is beneficial in detection of masses <2 cm in size causing only mild pancreatic contour deformity on CT, and for guiding FNAC.

Reduced scan range abdominopelvic CT in patients with suspected acute appendicitis: impact on diagnostic accuracy and effective radiation dose

D. Zinsser, M. Maurer, P.-L. Do, J. Weiß, M. Notohamiprodjo, K. Nikolaou, F. Bamberg, A. Othman; *Tübingen/DE*

Purpose: To compare a reduced-range CT in patients with suspected acute appendicitis to a standard abdominal CT regarding diagnostic performance and effective radiation dose.
Methods and Materials: We retrospectively included 90 patients (43 female, mean age 56.7±17 years) with suspected acute appendicitis who underwent an abdominopelvic CT. From those, we reconstructed images with a reduced scan range from L1 to the top of the pubic symphysis. Two radiologists assessed full-range and reduced-range datasets for coverage of the appendix, presence/absence of appendicitis and presence of differential diagnoses. Effective radiation doses as well as organ doses were calculated using a commercially available dose management platform.
Results: The appendix was covered by the reduced-range CT in all cases. In 66 patients CT confirmed the presence of appendicitis. In 17 patients, other relevant differential diagnoses were identified by CT. No relevant findings were detected in 7 patients. Both readers identified all patients with appendicitis on both full- and reduced-range CT. For reduced-range CT, total effective dose was 40 % lower than for full-range CT (4.99±1.76 vs. 8.34±2.95 mSv; p≤0.001). Notably, a remarkable reduction of organ doses in the female breast by 96 % (0.18±0.1 vs. 4.12±3.79 mSv; p=0.003) and in the testicles in males by 66 % (6.61±7.61 vs. 19.7±10.32 mSv; p≤0.001) was observed for reduced-range CT compared to full-range CT.
Conclusion: In patients with suspected acute appendicitis, reduced-range abdominopelvic CT results in a comparable diagnostic performance with a remarkable reduction of total effective radiation dose and organ doses as compared to full-range CT.

B-0542 14:08

Impact of low-dose abdominal CT on diagnostic accuracy and image quality in patients with suspected appendicitis

C. Storz[1], M. Kolb[1], J. Weiß[1], J. Kim[2], F. Bamberg[1], A. Othman[1]; [1]*Tübingen/DE*, [2]*Seoul/KR (corinna.storz@med.uni-tuebingen.de)*

Purpose: To determine the impact of radiation dose reduction on diagnostic image quality and accuracy of abdominal CT for detection of acute appendicitis.
Methods and Materials: Consecutive patients with suspected appendicitis who underwent contrast-enhanced abdominal CT (120kV, CARE dose reference 160-200mAs) following inconclusive ultrasound were retrospectively analyzed. Realistic reduced-dose simulation was used to generate low-dose datasets with 75%, 50% and 25% of the original-dose level. Two independent readers determined objective (signal-to-noise ratio [SNR]), subjective image quality (5-point Likert scale) and presence of appendicitis and complications, including abcess formation or perforation.
Results: Among 50 patients (mean age: 47±17 years, 68% female), 200 data sets were generated and 48% had surgically confirmed appendicitis. SNR and subjective image quality of all low-dose CTs was significantly lower compared to original datasets (all p<0.005). Appendicitis was correctly identified in all original and low-dose datasets (sensitivity: 100%, NPV: 100%). The presence of complications was correctly detected in original, 75% and 50% datasets, whereas on 25% datasets the diagnostic accuracy was significantly lower (sensitivity: 75%). Similarly, diagnostic confidence was high for original and low-dose datasets down to 50% but significantly decreased for 25% datasets (p<.001). Inter-observer-agreements was high for original, 75% and 50% datasets but moderate for 25% datasets (κ=1 and κ=0.66, respectively).
Conclusion: Abdominal CT acquisitions with 50% reduced radiation exposition provide high diagnostic image quality and accuracy for the detection of appendicitis, while further reduction of exposition is associated with decreased diagnostic performance.

B-0543 14:16

The impact of CT findings in resolving appendicitis

K. Ozturk, E. Soylu Ozturk, G. Savci; *Bursa/TR (keremov54@hotmail.com)*

Purpose: To establish the outcome of patients with radiological diagnosis of acute appendicitis and to predict the significance of resolving appendicitis.
Methods and Materials: 114 patients having positive CT criteria for acute appendicitis in an emergency setting were evaluated. 26 patients with mild clinical presentation were treated conservatively. CT findings such as appendix wall thickening and enhancement, maximum appendix diameter, presence of an appendicolith, local lymphadenopathy, infiltration around peri-appendiceal fat, fluid collections and focal cecal thickening obtained from images. An univariate analysis was conducted to identify statistically significance of CT findings. Logistic regression analysis was performed in order to find the factors related to the discrimination of resolving appendicitis.
Results: Mean diameter of appendix was over 6 mm in all patients. However, mean diameter of the appendix was significantly lower in patients with resolving appendicitis compared to the non-resolving appendix, 10.9 ± 2.2 mm vs 13.4 ± 2.3 mm, respectively, (P < 0.05). In addition, the degree of infiltration of peri-appendiceal fat was milder in patients with resolving appendicitis (P < 0.05). Patients with appendix diameter over 12 mm (odds ratio [OR] 5.6) and presence of infiltration around appendiceal fat (OR 5.5) seem to have more severe and non-resolving course. The other parameters did not reached to a statistically significant level.
Conclusion: Our results indicate that CT findings using regression model can accurately predict the resolving appendicitis. It seems that it is logical to correlate the radiological findings with clinical findings to prevent unnecessary surgery.

MDCT experience of male anterior peritoneal reflection: investigate and measurement in patients with appendicitis

J. Xu; *Shanghai/CN (drxujun@yahoo.com)*

Purpose: To investigate the MDCT experience of anterior peritoneal reflection in male patients with appendicitis and see if pelvic fluid can influence the measured distance from the anal verge to the anterior peritoneal reflection.
Methods and Materials: 80 valid MDCT studies of 121 male appendicitis patients between July 2014 and June 2015 were retrospectively analysed with a Reformat application (GE Advanced Workstation version 4.5). The visualisation of anterior peritoneal reflection, the exist of pelvic fluid of each patient were investigated and the measured distances from anterior peritoneal reflection to the anal verge were recorded.
Results: In male appendicitis patients, anterior peritoneal reflection is a V-shaped line with high density along superior bladder margins and seminal vesicle and then inserting onto rectum. The mean distance from the anal verge to the anterior peritoneal reflection was 9.6±1.3 cm. Pelvic fluids were found in 29 patients, and the mean distance of patients with and without pelvic fluid were 9.2±1.3cm and 10.1±1.2cm, respectively, with statistically significant differences (P=0.0027<0.05, F=0.627).
Conclusion: Pelvic fluid may influence the distance from the anal verge to the anterior peritoneal reflection, thus, using perioperative CT or MRI to determine the location of rectal cancer with respect to the peritoneal reflection may unreliable.

B-0545 14:32

CT findings of terminal ileum wall thickening in differential diagnosis of right lower quadrant pain

M.M. Baris, O. Hatem, O. Topalak, O. Sagol, M. Secil; *Izmir/TR (mustafa.secil@deu.edu.tr)*

Purpose: The aim of this study was to investigate the direct and accompanying CT findings in terminal ileum wall (TIW) thickening in patients with right lower quadrant (RLQ) pain.
Methods and Materials: A retrospective evaluation of PACS was performed for patients presenting with RLQ pain and TIW thickening. The investigated CT parameters included the length, thickness and symmetricity of thickened segment, the presence of mural enhancement, target sign, mesenteric fat stranding, fluid or abscess in the abdominal cavity. The presence, number and the greatest diameter of lymph nodes (LN) were recorded. The final diagnoses were obtained from hospital records. Histopathological findings obtained by

operation or colonoscopy and/or long term follow-up findings were considered as the reference standards.
Results: The investigation detected 84 patients (51 male, 33 female) that met the inclusion criteria. Clinical/pathological diagnoses of these patients were acute appendicitis in 25 (29.8%), non-specific ileitis (NSI) in 32 (38.1%) and Crohn's disease (CD) in 27 (32.1%). The measurement of TIW thickening, the number and diameter of LN were shown to have statistically significant difference between appendicitis, CD and NSI (p= 0.026, p=0.003, p=0.021). There was also statistically significant difference between three groups for mural enhancement, target sign, mesenteric fat stranding, and presence of abscess.
Conclusion: The parameters of TIW thickness measurement, the number and diameter of involved LN may be used as practical parameters in differential diagnosis of terminal ileum findings in patients presenting with RLQ pain.

B-0546 14:40

Systematic evaluation of the effect of low-dose CT on diagnostic performance in patients with suspected acute diverticulitis
S. Walter[1], M. Maurer[1], J. Weiss[1], F. Bamberg[1], J. Kim[2], K. Nikolaou[1], A. Othman[1]; [1]*Tübingen/DE*, [2]*Seoul/KR (sven.walter@uni-tuebingen.de)*

Purpose: To examine the effects of radiation dose reduction on image quality and diagnostic accuracy in low-dose computed tomography in patients with acute diverticulitis and its complications.
Methods and Materials: Consecutive patients presenting with symptoms of acute diverticulitis who underwent routine abdominal CT with rectal and intravenous contrast injection (120 kVp, CareDosexxx, CTDI) were included. Low-Dose-CT datasets (25%, 50% and 75% of the original dose) were generated using a realistic low-dose simulation technique based on sinogram synthesis and quantum noise modeling. Image analysis included assessment of objective (Signal-to-noise-ratio, SNR) and subjective image quality (5-point Likert scale) and the presence of acute diverticulitis and associated complications (abscess, fistula formation or perforation) by two independent readers.
Results: Among 31 subjects of whom none was older than 40 years (mean age: 32.1 years, 12.9% female), the prevalence of the clinical diagnosis of acute diverticulitis was high (64.5%). Subjective image quality and SNR for all datasets were highest for 100% and lowest for 25% exams (both p<0.001). Similarly, diagnostic confidence was highest for 100%, 75%, and 50%, while 25% had significantly lower certainty (p<0.001). The diagnostic accuracy was excellent for all low-dose and original datasets (sensitivity: 100%, NPV: 100%) whereas associated complications (prevalence: 45%) could be detected in 25% datasets with decreased sensitivity (77.8%, NPV: 91.3%; sensitivity: 100% and NPV: 100% for all >25% low-dose exams).
Conclusion: Low-Dose CT acquisition with 50% of the standard radiation exposure permits high diagnostic confidence and accuracy for the diagnosis of acute diverticulitis and its complications.

B-0547 14:48

To use CT for management decision in small intestinal obstruction: surgery or conservative treatment?
J.-D. Chen, C.-M. Tiu, Y.-H. Chou; *Taipei/TW (jdchenjdchen2013@gmail.com)*

Purpose: To verify whether CT can differentiate the patients with small bowel obstruction (SBO) who need surgery from those who need not.
Methods and Materials: We retrospectively reviewed consecutive cases with SBO in one-year period. The patients who needed surgery for SBO constituted the study group, and those who recovered from conservative treatment, the control group. CT were evaluated for the followings: largest bowel diameter (BD) proximal to and smallest BD distal to transition zones, maximal proximal-to-distal BD ratio, proximal bowel content, small bowel faeces sign, bowel wall thickening, shape and enhancing patterns of transition zones, presence of closed loop, mesenteric fat stranding, mesenteric vascular engorgement, interloop/mesenteric fluid and ascites. All CT features were compared between two groups with Student t test or Chi-square test accordingly for statistical analysis.
Results: 128 cases with SBO were included in this study, including 84 males and 44 females with mean age 72 years. 64 cases received surgery for SBO and 64 recovered after conservative treatment. The maximal proximal-to-distal BD ratio was significantly larger in study group (mean 8.36 ± 3.05 vs 7.03 ± 2.81, *p*=0.01). The following CT features were more significantly present in study group: mesenteric fat stranding (71.9% vs 29.7%, *p*<0.001), closed loop pattern (21.9% vs 6.3%, *p*=0.02), and interloop/mesenteric fluid (70.3% vs 35.9%, *p*<0.001).
Conclusion: CT helps to facilitate management decision in SBO. When presence of larger maximal proximal-to-distal BD ratio, mesenteric fat stranding, closed loop pattern, and associated interloop/mesenteric fluid on CT, surgery should be appropriate for these patients with SBO.

B-0548 14:56

Can the characteristics of bowel wall and signs on CT differentiate the aetiology of bowel obstruction?
E. Güler, N. Elmas, M. Harman, S. Türk, T. Köse; *Izmir/TR (gulerezgi@yahoo.com)*

Purpose: To evaluate performance of bowel wall characteristics and findings on CT images in determining the aetiology of bowel obstruction accompanied with bowel wall thickening.
Methods and Materials: CT scans of 63 patients with bowel obstruction accompanied with thickened bowel wall, who were admitted to our institution between January 2015 and September 2016 were retrospectively reviewed. Bowel wall thickness, length of involvement, bowel wall attenuation in arterial and portal venous phase contrast-enhanced images were measured. Patient age, presence of small-bowel faeces sign, ascites, lymphadenopathy, liver metastasis, comb sign, mesenteric oedema, omental thickening, thrombosis of mesenteric vessels were noted. Causes of bowel obstruction were divided into 4 main groups: malignancy (n=14), adhesions (n=12), ischaemia (n=11), inflammatory bowel disease (IBD) (n=9). Comparisons between groups were evaluated using Mann-Whitney U or post-hoc tests. Pearson's chi-square test was applied to assess associations between variables and aetiology.
Results: Comparisons of adhesion-IBD, malignancy-adhesion, malignancy-IBD, malignancy-ischaemia groups were statistically significant for bowel wall thickening. Length of involved bowel wall thickening was significant in comparison of IBH-ischaemia. Differences of age were significant in comparisons of IBH-adhesion, IBH-malignancy groups. Presence of faeces sign, comb sign, thrombosis of vessels were significantly associated with comparisons of groups. There was a statistically significant difference between ischaemia and other groups in terms of bowel wall enhancement calculated using a ratio between two phases of contrast-enhanced images (p<0.05).
Conclusion: Differences of bowel wall thickening can be helpful in differentiating malignancy from other causes of bowel obstruction. A ratio of bowel wall attenuation can be useful in distinguishing ischaemia.

B-0549 15:04

Mesenteric panniculitis: is malignancy associated with higher grade of CT changes?
T. Grubesic, Z. Matana Kastelan, D. Miletic; *Rijeka/HR (tianagrubesic@yahoo.com)*

Purpose: Mesenteric panniculitis (MP) is a disorder of mesenteric adipose tissue, a subgroup of sclerosing mesenteritis, presented by inflammation and fat necrosis. Both aetiology and association with various disorders remain unclear. Our objective was to assess if there exits a difference in severity of MP in "neoplastic" and "non-neoplastic" patients.
Methods and Materials: In period between June 1, 2015 and October 1, 2016, 54 patients, 32 male and 22 female, mean age 69.13±3.33, who underwent abdominal CT were diagnosed with MP. Based on their clinical data, patients were classified as "neoplastic" (n=35 or 64.81%) or "non-neoplastic" (n=19 or 35.19%). Two radiologists independently reviewed CT examinations evaluating 5 parameters: inhomogenous higher attenuation of mesenteric fat tissue, presence of lymph nodes, hypoattenuated fatty halo around vessels, mass effect on neighbouring structures and presence of pseudocapsule. Each sign was assigned with four possible grades: absent (0), discrete (1), moderate (2) or marked (3), with overall grade of MP as minimal (≤5), moderate (6-9) or marked (10-15).
Results: In "neoplastic" group, MP was classified as minimal in 3 patients (8.57%), moderate in 22 patients (62.86%) and marked in 10 patients (28.57%), with mean score of 8.09. MP in "non-neoplastic" group was graded as minimal in 3 patients (15.79%), moderate in 10 patients (52.63%) and marked in 6 patients (31.58%). Mean score was 7.89.
Conclusion: CT grade of MP does not significantly differ in neoplastic patients in comparison to non-neoplastic in our series, so its predictive value in course of the disease is not relevant.

B-0550 15:12

Evaluation of dynamic ultrasound scanning in the diagnosis of equivocal abdominal hernias with surgical comparison
P.R. Jayaram, J. Barrett; *Bury St Edmunds/UK (premruben@yahoo.com)*

Purpose: Ultrasound has become the modality of choice for diagnosing equivocal hernias in many centres worldwide. However, there is no quantification of its effectiveness when compared to surgery. This study aims to compare dynamic abdominal sonography for hernias (DASH) with surgical findings and establish its accuracy in equivocal cases.
Methods and Materials: A retrospective review of all patients who underwent an abdominal ultrasound scan between June 2011 and June 2015 was performed. The word 'hernia' in the referral information was the sole inclusion criterion. Patients who were under 18 years of age, found to have an unrelated hernia or had a known hernia were excluded. No distinction was made

between the types of abdominal hernias. These patients were followed up for at least 6 months and operation notes, if any, were also analysed.
Results: 348 scans were included this study (F=198, M=150, F:M ratio=1.32:1). The mean age was 53.4 years (range 18-97 years). 101 scans were positive for hernias (29.0%), 189 were negative (54.3%), and 58 had other findings (e.g. seroma, lipoma, etc.; 16.7%). 54 patients were taken to surgery (15.5%), including 5 who were found to be negative on ultrasound. Of these patients, 45 were true positives, 4 true negatives, 4 false negatives, and 1 false positive, giving a sensitivity of 91.8%, specificity of 80.0% and positive predictive value of 97.8%.
Conclusion: This study provides evidence that DASH has high sensitivity, specificity and positive predictive value, and confirms the effectiveness of DASH when investigating for equivocal abdominal hernias.

B-0551 15:20

Noise insertion in abdominal computed tomography for suspected body packing: where is the limit of extensive dose reduction?
J. Aissa, L. Sawicki, P. Heusch, E. Appel, P. Kröpil, C. Thomas, G. Antoch, J. Boos; *Düsseldorf/DE (joel.aissa@med.uni-duesseldorf.de)*

Purpose: To evaluate abdominal CT at different dose levels in patients suspected of body packing in regards to image quality and capability to detect foreign body packets.
Methods and Materials: We retrospectively included 27 subjects (20 male, 7 female; 378±11years) who underwent abdominal CT (80kV, automated tube current modulation, eff. dose 2.1±1.3mSv) in clinical routine. Images were reconstructed with simulated radiation dose levels of 50%, 10%, 5% and 1% of the initial dose using a validated noise-insertion software. The initial reconstruction at 100% dose served as the reference standard. Three independent readers blinded to the dose level and findings reviewed all images in a random order and assessed: 1. the presence and composition of foreign bodies, 2. the overall image quality using a 5-point scale, and 3. the presence of incidental findings.
Results: Image quality was comparable between 100% and 50% dose simulated images (p>0.05). Further dose reduction produced significantly worse image quality compared to the 100% images (p<0.0001). The threshold for correct identification of all incidental findings was 10% of the original dose (eff. dose 0.21±0.13mSv). The threshold for correct identification of all 8 body packets by all three readers was 5% (eff. dose 0.1mSv) (p<0.008). A dose reduction to only 1% led to 3 false positive cases suspected of solid cocaine packets.
Conclusion: An effective dose of 0.1 mSv seems sufficient to detect body packets in abdominal CT. However, overall image quality is reduced and a dose of 0.21mSv is necessary to reliably detect incidental findings.

Prospective randomised MIRA trial: microwave vs radiofrequency ablation of hepatocellular carcinoma - first results
T.J. Vogl, L.-M. Klohmann, T. Gruber-Rouh, R. Hammerstingl, N.-E. Nour Eldin; *Frankfurt a. Main/DE (t.vogl@em.uni-frankfurt.de)*

Purpose: To prospectively determine and compare therapy response and safety of microwave (MWA) and radiofrequency ablation (RFA) of hepatocellular carcinoma (HCC) in a randomised trial.
Methods and Materials: In this prospective study 36 patients (31 men, 5 women; mean: 65 years; range 42-82) with 36 HCC lesions (mean: 2.4cm; range 0.9-5cm; MWA 2.5cm, RFA 2.2cm) underwent CT-guided thermal ablation. Location of HCC and changes in size, volume, necrotic area, diffusion and ADC value were evaluated using MRI. First MRI was performed before ablation. Follow-up MRI was performed 24h after ablation and then in 3-month intervals for 12 months.
Results: Mean volume 24h after ablation was 47.3cm^3 (62cm^3 for MWA, 32.7cm^3 for RFA). Complete ablation was observed in 83.3% (30/36), 66.7% (12/18) in MWA and 100% (18/18) in RFA. Local recurrence rate within one year for both groups was 16.7% (6/36). Local recurrences were only documented in the MWA-group. New malignant formations in another location than the ablated lesion were documented in 19.4% (7/36) and only in the RFA-group. 16.7% (6/36) of patients underwent thermal ablation before participating in this trial, 19.4% (7/36) received again thermal ablation in other segments of the liver while being part of this trial. The mortality rate for this trial was 0% with no major complications.
Conclusion: First data of the MIRA trial show no significant differences in mortality or complication rates between RFA and MWA. MWA generates greater ablation volumes and 1-year follow-up of the MWA-group shows a higher rate of local recurrences vs RFA.

B-0553 14:08

MWA of liver tumours with thermosphere technology: prospective analysis of ablation zone predictability in vivo with different liver conditions and operative approaches
P. Marra, M. Colombo, F. Ratti, F. Cipriani, C. Sallemi, M. Venturini, L. Aldrighetti, A. Del Maschio, F. De Cobelli; *Milan/IT (marra.paolo@hsr.it)*

Purpose: The high power/frequency MW-system with Thermosphere-technology allows ablation of liver tumours in short time. Ablation-zone (AZ) volume prediction relies on ex vivo animal studies on normal livers, with concerns about reproducibility and safety in humans. We aimed to investigate if MW effects produced in vivo on human livers reflect the ex vivo model and vary with liver conditions (normal/cirrhotic/chemotherapy-treated) and approaches (percutaneous/intraoperative).
Methods and Materials: From October-2014, 54 patients prospectively underwent MWA for the treatment of 74 liver nodules (HCC=30;mets=44), percutaneously (P=28), during laparotomy (LT=28) or laparoscopy (LP=18) in normal (N=19), cirrhotic (C=30) and chemotherapy-treated (ChT=25) livers, with a 2450MHz/100W MW-generator (EmprintTM-Medtronic). Contrast-enhanced-CT was performed 1 month after the procedure to verify complete-ablation (CA) and to quantify AZ volume and sphericity.
Results: AZ volumes were linearly correlated with ablation times (R=0.67; p<0.01) with no differences between in vivo results and the ex vivo model at regression analysis. The time/volume linear correlation was confirmed for each subgroup with no differences related to operative approach or liver condition. We observed a higher time/volume linear correlation in cirrhotic (R=0.81; p<0.01) versus non-cirrhotic (R=0.73; p<0.01) and chemotherapy-treated (R=0.59; p<0.01) livers. Mean AZ roundness-index was 0.77±0.07. MWA efficacy in terms of CA at 1 month was slightly better in intraoperative procedures (LT=100%vs LP=100%vs P=93%; p=ns). No complications occurred.
Conclusion: The extent of AZ reflected animal models in all liver conditions and operative approaches. Our results confirm that Thermosphere technology produces highly predictable AZ and is effective and safe for the treatment of liver tumours.

B-0554 14:16

Percutaneous microwave ablation of exophytic tumours in hepatocellular carcinoma patients: safe or not?
X. Jing, J. Ding, Y. Zhou, Y. Wang; *Tianjin/CN (dr.jingxiang@aliyun.com)*

Purpose: To compare the long-term therapeutic outcomes and safety of microwave ablation (MWA) of exophytic tumours with those of non-exophytic subcapsular tumours in hepatocellular carcinoma (HCC) patients.
Methods and Materials: From July 2010 to July 2014, 856 consecutive patients with HCC underwent ultrasound-guided MWA ablation. Among them, 132 patients were enrolled in this retrospective study. Those patients were divided into exophytic group (n=71) and non-exophytic group (n=61) according to the location of their tumour(s). The local tumour progression (LTP), progress free survival (PFS) and overall survival (OS) were analyzed using Kaplan-Meier and Log-rank tests.
Results: The follow up periods ranged from 6 to 62 months, with a median of 31 months in exophytic group, and ranged from 5 to 61 months, with a median of 27 months in non-exophytic group. Local progression rate was 11.3% (8/71) in exophytic group and 11.5% (7/61) in non-exophytic group (P=0.733). The 1-, 2-, 3-, 4- and 5 year PFS rate were 84.5%,53.7%,31.2%,25.6% and 21.3% in exophytic group and 82.0%,53.5%,38.6%,30.4% and 24.3% in non-exophytic group, respectively(P=0.489). The 1-, 2-, 3-, 4- and 5 year OS rate were 100.0%,87.4%,75.7%,65.5% and 52.9% in exophytic group and 95.0%,83.0%,73.8%,69.2% and 61.5% in non-exophytic group, respectively (P=0.980).There were no procedure-related mortality and major complications in both exophytic and non-exophytic group.
Conclusion: MWA is a safe and effective treatment for exophytic tumours in HCC patients. Treated by MWA, the patients with exophytic tumours can get the similar local response and long-term outcome with those with non-exophytic subcapsular tumours.

Comparison of multi-modality and mono-modality fusion imaging using ultrasound in the intraoperative immediate evaluation of the therapeutic response of liver thermal ablation

E. Xu, Y. Long, K. Li, Z. Su, S. Lv, Q. Zeng, R. Zheng; *Guangzhou/CN (xuerjiao@126.com)*

Purpose: Purpose of the study is to investigate the value of multi-modality fusion imaging combined computed tomography or magnetic resonance imaging with ultrasound (CT/MRI-US fusion imaging) and mono-modality fusion imaging using ultrasound (US-US fusion imaging) in the intraoperative immediate evaluation of therapeutic response of liver thermal ablation.
Methods and Materials: From Aug. 2015 to Dec. 2015, 157 liver cancers in 115 patients which were undergone US-guided thermal ablation were enrolled. Both US-US fusion imaging and CT/MRI-US fusion imaging were performed to immediately evaluate the therapeutic response intraoperatively. The CT/MRI results after one month were taken as references. The applicable rates, success rates of registration and complete ablation rates were compared between two types of fusion imaging by Chi-square test.
Results: The applicable rate of US-US fusion imaging was only 61.8%(95/157) because of the ill-defined lesions in US. It was lower than that of CT/MRI-US fusion imaging (99.7%(155/157)) (P<0.05). However, the success rate of registration in US-US fusion imaging (91.7%(89/95)) was superior to that of CT/MRI-US fusion imaging (81.3%(126/155)) (P<0.05). The complete ablation rates (98.7%(81/82) vs 99.2%(118/119)) were no statistical difference between two types of fusion imaging (P>0.05).
Conclusion: Both US-US fusion imaging and CT/MRI-US fusion imaging are useful means to evaluate the therapeutic response of liver thermal ablation. US-US fusion imaging could be the priority in the assessment. When the lesions are ill-defined in US, CT/MRI-US fusion imaging could be selected preferentially instead.

Cone-beam CT for percutaneous drainage of abdominal and pelvic collections: technical considerations, success rates, complications and dose compared to CT-fluoroscopic guidance

J. Das, D. Lohan, I. Davidson, D. Sheppard, R. McLoughlin, G. O'Sullivan; *Galway/IE (jjeeban@hotmail.com)*

Purpose: Cone-beam Computed Tomography (CBCT) utilises a flat panel detector and C-arm system in the Interventional Radiology suite allowing 3D reconstruction of the imaged volume of tissue. This study compares performace of CBCT with conventional CT guidance in draining abdominopelvic collections.
Methods and Materials: 111 CT drainages of abdomino-pelvic collections were performed in 108 patients between December 2010 and July 2016. 55 patients underwent drainage with CBCT (Dyna CT™, Siemens, Erlangen, Germany), 53 patients had conventional CT fluoroscopic drainage (Siemens Sensation™ 64-slice, Forchheim, Germany) Patient demographics, collection size and depth, technical success, microbiology, incidence of complications and dose were recorded.
Results: Successful collection drainage was achieved in 51/57 (89.5%) in the CBCT group and 49/54 (90%) of the CT fluoroscopy group (p=0.4). The average abdominopelvic collection size was 10.6cm vs 8.8cm in the CBCT and CT-fluroscopy guided groups respectively (p=0.6). The average depth of collection was 7.5cm in CBCT vs 7.9cm in CT fluoroscopy (p=0.07) A 12 F (or smaller) drain was placed in 41 patients in the CBCT group vs 43 in the conventional CT guided cohort. The mean duration of procedure in the CBCT group was 36 minutes, in the conventional CT group the mean time was 48 minutes (p=0.35) The average dose was lower in CBCT group vs CT-fluoroscopy (11mSv vs 17.4mSv, p=0.05). No immediate complications were recorded in either group.
Conclusion: CBCT is comparable to CT-Fluoroscopic guidance for abdominopelvic collection draininge in terms of success with the advantage of reduced dose and shortened procedure time.

B-0557 14:40

Microwave ablation of pulmonary neoplasms with enabled constant spatial energy control to achieve a predictable spherical ablation zone: retrospective evaluation

T.J. Vogl, H. Ackermann, N.-E. Nour Eldin, N.N.N. Naguib, L. Basten; *Frankfurt a. Main/DE (t.vogl@em.uni-frankfurt.de)*

Purpose: To evaluate performance of microwave ablation (MWA) with enabled constant spatial energy control (Thermosphere™) for treatment of lung malignancies in formation of a spherical ablation zone.
Methods and Materials: In this retrospective study 45 patients (23 men, 22 women; mean 58.6 years; range 27-75) were treated in 45 sessions between 05/2014 and 11/2015, after giving written informed consent, using MWA with Thermosphere™. To provide three-dimensional evaluation for each ablation zone section in each transverse and longitudinal CT slice two perpendicular diameters were measured and their ratios computed. Calculating average of all ratios per single ablation zone resulted in a final sphericity value for each ablation zone. This final value is stated as deviation from 1.0, corresponding to an ideal sphere. Same parameters were retrospectively evaluated of 45 sessions using conventional low-frequency (LF) MWA. Results of both groups were compared using Wilcoxon-Mann-Whitney test.
Results: Thermosphere interventions succeeded in 97.8%, LF-MWA in 100%. Overall complication rate was 22.2% with Thermosphere and 31.1% with LF-MWA, minor 17.8% and 20.0%, major 4.4% and 11.1% (p=0.474). Mean duration was 7.98 min (median:8.0 min) for Thermosphere and 9.59 min (median:10.0 min) for LF-MWA with a significant difference (p=0.005). Deviation from ideal sphericity was median 0.194 (range: 0.078-0.500, 25th-percentile: 0.158, 75th-percentile: 0.291) for Thermosphere interventions and 0.384 (range: 0.218-0.610, 25th-percentile: 0.312, 75th-percentile: 0.450) for LF-MWA with a significant difference (p<0.0001).
Conclusion: MWA of lung malignancies using Thermosphere™ achieves a distinctly more spherical ablation zone to facilitate complete ablation in significantly shorter duration heading towards fewer complications.

B-0558 14:48

Respiratory phase tracking with visual patient feedback facilitating consistent level of breath-hold during image-guided interventions: an exploratory study

W.J. Heerink, M.D. Dorrius, H.J. Groen, R. Vliegenthart, M. Oudkerk; *Groningen/NL (w.j.heerink@umcg.nl)*

Purpose: To validate a novel respiratory phase feedback system that facilitates consistent level of breath-hold during image-guided interventions.
Methods and Materials: A commercially available depth camera (KinectV1, Microsoft) is used to determine the mean distance to thorax and abdomen in real-time. The camera is mounted to the CT table and aimed into the gantry. After breathing instruction and breath-hold, the system is set to this specific depth-of-breath. Subsequently, visual feedback for patient and radiologist can be provided on a screen with a ball moving up and down with respiration and a stationary circle corresponding to target level of breath-hold. For eight healthy volunteers, a conversion factor from mean thoracic depth to depth-of-breath (mL) was determined in supine and prone position using spirometry. After breathing instruction and initial breath-hold, the volunteers were asked to return to the same level of breath-hold 10 times, with and without visual feedback, in both positions. Without feedback, the volunteers did receive regular breathing instructions. Mean error from initial breath-hold and standard deviation were determined for both positions, with and without feedback and compared using independent samples t tests.
Results: Without feedback, the volunteers returned to within 169±153 mL and 234±194 mL of initial breath-hold in supine and prone position, respectively. With feedback, this was reduced for all volunteers, with a mean of 42±36 mL (p<0.001) and 30±25 mL (p<0.001), respectively.
Conclusion: The system provides accurate feedback enabling healthy volunteers to return to a consistent level of breath-hold, thereby elimination potential targeting errors in image-guided interventions caused by respiratory movement.

B-0559 14:56

Performance of a robotic assistance device in computed tomography-guided percutaneous diagnostic and therapeutic procedures

A. Smakic, N. Rathmann, M. Kostrzewa, S.O. Schönberg, C. Weiß, S. Diehl; *Mannheim/DE (arman.smakic@medma.uni-heidelberg.de)*

Purpose: To evaluate a novel commercially available robotic assistance device for computed tomography-guided diagnostic and therapeutic interventions compared to standard manually performed CT-scan-guided interventions in terms of precision, exposure to radiation and intervention time.
Methods and Materials: 55 patients were treated using robotic assistance (group A) and compared to a control group of 101 patients treated with a standard CT-scan-guided, manually performed, approach (group B). Evaluated

parameters were precision, radiation exposure and time of intervention. Evaluations were performed with regard to complexity and type of anesthesia (general vs local anesthesia).
Results: Precision parameters were in general significantly better in the robotic assistance group (p<0.01) with a mean deviation of 1.2mm(±1.6 mm) compared to 2.6mm(±1.1 mm) in the comparison group. Regarding the sub-groups differences in deviation in both groups were smaller in procedures performed under general anesthesia compared to local anesthesia (Group A: 0.5mm (±0.9mm) vs 2.1mm (±1,9mm) group B: 1.9mm (±1.3 mm) vs 3.4mm (±1.1 mm) (both p<0.001). Mean number of needle replacements that there were necessary to reach the target was 0.3 (±0,4) in the robotic assistance group compared 1.8 (±0.7) in the comparison group (p<0.001).
Conclusion: Compared to manual placement the use of a robotic assistance device in out of plane CT-guided interventions under general anesthesia allows probe placement with high precision, reduces intervention time with no increase of exposure to radiation to the patient and zero radiation for the physician. These characteristics render it a useful tool, especially in complex interventions like irreversible electroporation or microwave ablation.

Ablation zone geometry in microwave ablation of the liver - comparison of two systems using a semi-automatic segmentation software
V.D. Vo Chieu[1], F. Wacker[1], C. Rieder[2], C. Schumann[2], H. Ballhausen[2], K.I. Ringe[1]; [1]*Hannover/DE*, [2]*Bremen/DE (vochieu.vandai@mh-hannover.de)*

Purpose: To evaluate ablation zone geometry in CT-guided microwave ablation (MWA) of the liver using two different ablation systems by means of a semi-automatic segmentation software.
Methods and Materials: 27 patients referred for CT-guided MWA with a total of 40 lesions (HCC n=17, CCC n=3, metastases n=20) were analysed. Two different systems were used: System 1 (2.45 GHz) or system 2 (915 MHz) with each 20 ablated lesions. Semi-automatic ablation zone segmentation and ellipticity index calculation was performed using SAFIR (Software Assistant for Interventional Radiology). For validation of semi-automatic software calculations, results were compared with those of manual analysis (Pearson's correlation, Mann-Whitney U test).
Results: Manually measured mean maximum ablation zone diameters were 32mm (system 1) and 27mm (system 2). Correlations between manual and semi-automatic measurements were very good for maximum axial and transversal diameter (both r=0.83, p<0.0001) and moderate for minimum transversal diameter (r=0.46, p=0.003). Ablation zones created with system 1 had a significantly lower ellipticity index compared to system 2 (1.17 vs 1.86, p<0.0001) in non-automatic analysis, whereby an ellipticity index of 1 indicated a perfect spherical ablation zone, correlating well with software measurements (r=0.79, p<0.0001).
Conclusion: The 2.45 GHz microwave ablation system generated a significantly more spherical ablation zone compared to the 915 MHz system. Semi-automatic assessment of ablation zone geometry using SAFIR seems feasible and significantly correlates with manual measurements, while at the same time providing further information. Software evaluation of ablation zones can prove beneficial while and before performing complex ablation procedures.

Hybrid dynaCT-guided hookwire localisation of pulmonary lesions prior to surgical resection in the same hybrid operating theatre
C. Chu, E. Dai, C. Ng, R. Lau, R. Wong, S. Yu; *Shatin/HK*

Purpose: Hybrid DynaCT-guided hookwire localisation of pulmonary lesions immediately prior to surgical resection by radiologist in same hybrid operating theatre is a new one-stop technique, which our centre is the world's first in performing such procedure. We aim to compare safety and efficacy of this new technique with conventional MSCT-guided hookwire procedure.
Methods and Materials: Retrospective case-control study performed in a university-based hospital from Feb 2014 to Jan 2016. 18 patients with lung lesion who underwent Hybrid DynaCT-guided hookwire localisation utilizing Siemens Artis Zeego system compared against 10 age- and sex-matched controls who underwent conventional MSCT guided hookwire localisation. All cases performed under local anaesthesia.
Results: Mean lesion size was significantly smaller in DynaCT group compared with MSCT (5.96±1.92min vs 8.42±3.30mm, p=0.02). All interventions met primary endpoint of satisfactory hookwire positioning. There was no hookwire dislodgement in both groups. DynaCT associated with significantly shorter transfer times (38.28±16.95min vs 98.7±35.24min, p<0.001) and a trend towards lower pneumothorax rate (22% vs 50%, p=0.13). Effective dose of DynaCT was not significantly different from MSCT (16.41±14.99mSv vs 8.26±3.88mSv, p=0.11). DynaCT had longer procedure time (55.39±19.01min vs 23.30±9.99min, p<0.001) than MSCT. Lesion size inversely correlated with procedural time (r=-0.50, p=0.01). This may suggest that smaller target lesion size may contribute towards longer procedure time in DynaCT group.
Conclusion: Hybrid DynaCT-guided hookwire localisation of pulmonary lesions immediately prior to surgical resection in same hybrid operative theatre is a pioneer one-stop technique; which is associated with shorter interdepartmental transfer time and lower post-procedure pneumothorax rate when compared with conventional MSCT procedure.

B-0562 15:20

Clinical significance of postinterventional contrast medium injection after CT-guided drainage
H. Goessmann, M. Haimerl, W. Uller, L. Bayer, V. Teusch, F. Poschenrieder, L.-M. Dendl, A. Schreyer; *Regensburg/DE (holger.goessmann@ukr.de)*

Purpose: The aim of this study was to evaluate the added clinical value of an additional postinterventional control-scan after CT-guided drainage placement with contrast medium (CM) via the newly placed drain.
Methods and Materials: All CT-guided drainages of fluid collections between January 2014 and September 2016 in a maximal care hospital were included in this study. The patients were divided into 2 subgroups, patients that underwent surgery before developing the fluid collection and patients that did not. Drainages that were additionally flushed with CM were evaluated to which extend the additional scan was helpful for either detecting the source of the fluid collection (e.g. anastomosis insufficiency) or additional cofactors (e.g. intestinal fistulas in pancreatitis) and whether or not these information led to an immediate change of therapy.
Results: A total of 499 drainages in 352 patients (123 female, mean age 60 years, range 11-87 years) were detected, 197 thereof were postinterventionally flushed with CM. 51 (26%) of those showed a clinically significant additional finding. An immediate change of therapy was found in 19 cases (9%). The group that underwent surgery (120 CM-drainages; 32 (27%) additional findings; 13 (11%) immediate change of therapy) showed no statistically significant difference to the group that did not (77 CM-drainages; 19 (25%) additional findings; 5 (6%) immediate change of therapy).
Conclusion: An additional scan with CM injection via the newly placed drain revealed clinically significant additional information in almost 26% in this study. In 9% of the cases this information led to an immediate change of therapy.

Are patients' age, height, weight and heart rate relevant in pulmonary CTA?
J. Sagasta Urrutia, S. Santos Ochoa de Eribe, L. Alonso Irigaray, E. De las Heras Diez, R. Cobos Campos, J. Etxano; *Vitoria-Gasteiz/ES (jone.sagastaurrutia@osakidetza.net)*

Purpose: To analyze the influence of patients´ characteristics in pulmonary CT angiography (CTA).
Methods and Materials: From June 2016 to October 2016, 127 patients with intermediate-high suspicion of pulmonary embolism according to Well´s criteria were prospectively recruited. All of them underwent a CTA with same technical paramethers, contrast injection dose and rate (300mg/ml, 70 ml, 4ml/s). Patients´ age, weight, height and heart rate before the acquisition of the CTA were obtained. Mean value (UH) at the main pulmonary artery was calculated drawing a region of interest. All the examinations were classified in two groups according to the enhancement of the pulmonary artery: good (>250UH) and poor (<250UH). Multivariate analysis was performed to evaluate the influence of each variable in the enhancement of the pulmonary artery. Differences between studies with poor and good enhancement were analyzed using Mann Whitney´s U test. A p<0.05 was considered significant.
Results: Out of 127 studies, 12 (9.4%) were classified as poor and 115 (90.6%) as good. Multivariate analysis showed significant association between UH and age (p=0.01), weight (p=0.01), height (p=0.025) and heart rate (p=0.037). Differences in weight (median=86kg p25-75=74-90kg vs median=70kg p25-75=60-82kg p=0.021), age (median=61years p25-75=44-76years vs median=75years p25-75=64-83years p=0.046), height (median=170cm p25-75=161-181cm vs median=162cm p25-75=156-170cm p=0.01) and heart rate (median=85beats/min p25-75=74-98beats/min vs median=76beats/min p25-75=68-90beats/min p=0.062) were found between poor and good studies.

Conclusion: The knowledge of patients' age, height, weight and heart rate are relevant in pulmonary CTA. Patients with poor enhancement in pulmonary CTA studies are younger, have higher weight, height and heart rate than patients with good enhancement studies.

B-0564 14:08

CT pulmonary angiography during pregnancy: radiation dose of commonly used protocols and the effect of z-axis optimisation

B.M.F. Hendriks[1], R.S. Schnerr[1], G. Milanese[2], C.R.L.P. Jeukens[1], S. Niesen[1], J.E. Wildberger[1], M. Das[1]; [1]*Maastricht/NL*, [2]*Parma/IT*
(babs.hendriks@mumc.nl)

Purpose: Evaluating radiation dose and the simulated effect of an optimised z-axis for pregnant women undergoing commonly used CTPA scan-protocols.
Methods and Materials: 120 CTPA datasets, acquired using 4 scan protocols (n=30 per protocol), were mapped to Cristy phantoms; simulating 120 non-pregnant women (NP) and 120 women in the first (FT), second (ST) and third trimester (TT) of pregnancy, including fetal dose in second and third trimester. Scan protocols: single-source 64-slice helical scan at 120kV (protocol A), high pitch dual-source acquisition at 100kV (protocol B), dual-energy acquisition at 80/140kV (protocol C) and automated-kV-selection high pitch scan at $100kV_{ref}$ (protocol D). Effective radiation dose (in mSv) for woman and fetus was calculated for all scan protocols and repeated after z-axis optimisation: lung apex - top of lower diaphragm.
Results: Mean effective dose per protocol: A; NP 7.6±1.5mSv, FT 10.2±3.0mSv, ST 10.5±3.1mSv, TT 10.6±3.1mSv. B: respectively 4.5±0.8mSv, 5.2±1.2mSv, 5.4±1.3mSv and 5.5±1.3mSv. C: 7.7±0.8mSv, 9.1±1.0mSv, 9.4±1.2mSv and 9.7±1.1mSv. D: 2.0±0.6mSv, 2.6±1.1mSv, 2.7±1.1mSv and 2.7±1.1mSv. Mean effective dose increase during pregnancy (NP to TT) was highest for protocol A; 3mSv or 39%. Fetal dose was highest in third trimester: 1.53±0.6mSv, 0.54±0.2mSv, 0.96±0.4mSv and 0.2±0.1mSv for the respective protocols. Z-axis optimisation showed largest benefit in 3rd trimester, reducing fetal dose by 84% for protocol A, 78% for B, 78% for C, 80% for D.
Conclusion: Careful scan protocol selection and subsequent z-axis optimisation for CTPA during pregnancy can result in significant radiation dose reduction for expecting mother and the fetus in particular.

Influence of 90-kVp low-tube-voltage pulmonary CT-angiography on radiation dose, image quality and diagnostic accuracy for the detection of pulmonary embolism using ADMIRE

L. Lenga, M. Beeres, D. Leithner, J.L. Wichmann, S. Martin, M. Albrecht, T.J. Vogl, J.-E. Scholtz; *Frankfurt a. Main/DE (l.lenga@gmx.de)*

Purpose: To compare low-tube-voltage 90-kVp acquisition using advanced modelled iterative reconstruction algorithm (ADMIRE) and standard linearly blended dual-energy images for pulmonary CT angiography (CTPA) regarding radiation exposure, image quality, diagnostic accuracy and suitability for depiction of pulmonary embolism (PE).
Methods and Materials: 40 patients suspected of PE were included (21 male, 19 female; mean age: 56 years) . Intraindividual comparison of 90-kVp and linear blended M_0.6 images was performed. Signal attenuation and image noise of the pulmonary trunk were measured, signal-to-noise (SNR) and contrast-to-noise ratios (CNR) were calculated. Presence of and suitability for central and segmental PE and overall visualisation of pulmonary arteries were evaluated by three radiologists. Interobserver agreement was calculated using intraclass correlation coefficient (ICC). Radiation exposure was measured as dose-length-product (DLP).
Results: Attenuation and noise of the pulmonary trunk were significantly increased in 90-kVp images compared to linear blended images. CNR in 90-kVp images was significantly increased (15.4±6.3 vs. 11.3±4.6, P<0.001). Interobserver agreement (mean ICC 0.83) and detection of PE were excellent in both image series with no significant difference. Overall suitability for the evaluation of PE was rated excellent for both image series with slightly but significantly lower ratings for 90-kVp. The calculated average DLP was reduced by 37.2% with 90-kVp acquisition compared to dual-energy CTPA (77.5±44 vs. 123.4±51.1 mGy•cm, P<0.001).
Conclusion: 90-kVp CTPA using ADMIRE provides increased CNR with excellent diagnostic accuracy for the evaluation of PE. Radiation exposure is significantly reduced while maintaining excellent suitability for the assessment of central and segmental pulmonary arteries.

B-0566 14:24

ECG-gated pulmonary CT angiography for the prediction of right ventricular dysfunction in patients suspected of acute pulmonary embolism

N.A. Nikitin, S.M. Minin, M.E. Amelin; *Novosibirsk/RU (n_nikitin@outlook.com)*

Purpose: Right ventricular dysfunction (RVD) is an important prognostic factor of 30-day mortality in patients with acute pulmonary embolism (PE). The purpose of this study was to investigate and compare prognostic role of ECG-gated computed tomography (CT) signs, including 3-dimensional ventricular volume measurements and the left ventricular (LV) and right ventricle (RV) functions for predicting RVD in patients with acute PE.
Methods and Materials: We evaluated 10 patients with acute PE for the following CT signs of RVD obtained on retrospectively ECG-gated pulmonary CT angiography: abnormal position of the interventricular septum, inferior vena cava contrast reflux, RV diameter to LV diameter ratio on axial sections (RV/LV_{axial}), and 4-chamber views ($RV/LV_{4\text{-}ch}$), 3-dimensional RV volume to LV volume ratio (RV/LV_{volume}), RV and LV end-diastolic volumes (EDV), end-systolic volumes (ESV) and ejection fractions (EF). The results were compared with echocardiographic data. Echocardiographic examination for cardiac function analysis was performed on the same day.
Results: The RV/LV_{axial}, $RV/LV_{4\text{-}ch}$, RV/LV_{volume}, EDV_{RV} were significantly increase in patients with acute pulmonary embolism. There were strong correlations between RV/LV_{volume} ratio and EDV_{RV} r=0,872, also between echocardiography-derived pulmonary arterial systolic pressure and RV/LV_{volume}, r=0,914.
Conclusion: ECG-gated pulmonary CT angiography can accurately quantify RV and LV function. The RV function is impaired in patients with acute PE.

B-0567 14:32

Value of low-dose ECG cardiac gating for the assessment of right ventricular dysfunction in patients with suspected pulmonary embolism

J.C. Schaefer, H. Haubenreisser, M. Meyer, S.O. Schönberg, T. Henzler; *Mannheim/DE (JulCaSch@t-online.de)*

Purpose: Right ventricular dysfunction (RVD) is the main predictor of short-term mortality in patients with acute pulmonary embolism. However, the role of ECG-gating for the assessment of RVD using computed tomography pulmonary angiography (CTPA) is still unclear. The aim of this prospective study was to investigate the differences between systolic and diastolic measurements using a novel low-dose ECG-gated CTPA protocol.
Methods and Materials: Sixty patients (32 female, age 64.6+/-17.5 years) underwent a high pitch CTPA examination with 80cc of iodinated contrast material. 5s after the end of the CTPA a retrospectively ECG-gated cardiac CT examination with a 80% reduced tube current was started. Ejection fraction of both ventricles (RVEF, LVEF), endsystolic (RV/LV 4ch sys) and enddiastolic 4-chamber view ratio (RV/LV 4ch diast), endsystolic (RV/LV EDV) and enddiastolic volume ratio (RV/LV ESV) were assessed. In the CTPA, RV/LV ratio was measured in the axial plane and 4-chamber view. Correlation between RV/LV ratios and RVEF and statistical difference between corresponding systolic and diastolic RV/LV ratios were calculated.
Results: Systolic RV/LV ratios showed higher values than the corresponding diastolic RV/LV ratios (RV/LV 4ch sys = 1.30+/-0.40, RV/LV 4ch diast = 1.01+/-0,21, RV/LV ESV = 2.18+/-1.23, RV/LV EDV = 1.33+/-0.40) with a significant difference between endsystolic and enddiastolic 4ch ratios (p=<.0001) and volume ratios (p=<.0001). RV/LV EDV had the strongest correlation of all RV/LV ratios with RVEF (r = -0.543).
Conclusion: RV/LV EDV correlates best with RVEF. Further studies have to evaluate the proposed CTPA protocol regarding its additional value for risk stratification.

B-0568 14:40

Small left atrium: a sign of pulmonary embolism

A.E. Mahfouz, F. Al-Khafaji, H. Sherif; *Doha/QA (falkhafaji@hamad.qa)*

Purpose: To assess the small size of the left atrium as a diagnostic sign and a follow-up parameter for pulmonary embolism patients.
Methods and Materials: Contrast-enhanced CT examinations of the chest of 50 patients with clinical and CT evidence of pulmonary embolism and 50 control patients were retrospectively evaluated. The initial and follow-up CT of the pulmonary embolism patients have been evaluated. In all cases; the ratio between the pulmonary artery diameter and the anteroposterior dimension of the left atrium (PA/LA ratio) has been calculated. Statistical analysis has been done by the student's t-tests.
Results: The PA/LA ratio has been 0.97±0.26 for pulmonary embolism patients and 0.73±0.12 for control (p ≤0.0001). At the cut-off value of ≥ 0.81;

the PA/LA ratio has sensitivity, specificity, positive predictive value, negative predictive value and accuracy of 68%, 72%, 70.8%, 69.2% and 70% respectively for the diagnosis of pulmonary embolism. On follow up, 31 of the pulmonary embolism patients showed improvement while 19 showed CT evidence of either recurrence or persistence of the emboli. In the first group, the PA/LA ratio has changed from 0.95 ± 0.24 to 0.78 ± 0.22 (p ≤0.0001). In the second group, the PA/LA ratio showed no statistically significant change.
Conclusion: The PA/LA ratio on contrast-enhanced CT has been significantly higher in patient with pulmonary embolism compared to control. The ratio has significantly decreased on CT follow up of patients with improvement of their pulmonary embolism and remained unchanged in patients with no improvement.

B-0569 14:48

Diagnostic value of CT measurements as a predictor of pulmonary hypertension in TAVI patients

M. Eberhard, J. Pavicevic, M. Mastalerz, T. Frauenfelder, F. Tanner, T. Nguyen-Kim; *Zurich/CH (matthias.eberhard@usz.ch)*

Purpose: To assess the diagnostic value of computed tomography (CT) measurements for detection of pulmonary hypertension (PH) in a cohort of patients undergoing transcatheter aortic valve implantation (TAVI) with known severe left heart disease.
Methods and Materials: 257 consecutive patients (median age 83.0±6.1 ys,134 f) with symptomatic severe aortic valve stenosis undergoing TAVI at the University Hospital Zurich(Switzerland) from 03/2008 to 12/2014 were retrospectively analysed. Patients underwent right heart catheterisation (RHC) and CT within 3 consecutive days. Previously described CT measurements for assessment of PH were examined. Measurements were compared between PH and no PH patients using Mann-Whitney-U- and Chi-Square-test. P-value <0.05 was considered statistically significant.
Results: 161 patients had PH (83.0±6.4y, 90f). Diameters of pulmonary artery trunk (PA) (p<0.001), right (p=0.037) and left pulmonary artery (p=0.044), anterior pericardial recess (PR) (p=0.003) as well as ratios of PA/ascending aorta (AA) (p<0.001) and PA/descending aorta (DA) (p=0.003) were significantly higher in PH patients. Pleural fluid (p<0.001) and positive segmental artery-bronchus ratio (ABR) in patients with PA diameter ≥29mm (p=0.021) were significantly more common in patients with PH. Sensitivity, specificity, NPV and PPV for presence of pleural fluid (42.0%, 90,5%, 47.7%, 88.3%), positive ABR score (28.9%, 84.0%, 43.4%, 73.7%), PA diameter ≥31mm (38.9%, 77.9%, 42.8%, 75.0%) and PR ≥10mm (37.3%, 81.7%, 43.4%, 77.6%) were computed. ROC analysis for PA, PR, PA/AA ratio and PA/DA ratio showed AUC of 0.63; 0.61; 0.62 and 0.62, respectively.
Conclusion: In our study CT showed limited diagnostic value for detection of PH in TAVI patients.

B-0570 14:56

Non-invasive estimation of mean pulmonary arterial pressure in suspected pulmonary hypertension based on automated 3D volumetry of pulmonary CT angiography

C. Melzig[1], S. Wörz[1], B. Egenlauf[1], S. Partovi[2], K. Rohr[1], E. Grünig[1], H.-U. Kauczor[1], C.P. Heussel[1], F. Rengier[1]; [1]*Heidelberg/DE*, [2]*Cleveland, OH/US (claudius1.melzig@med.uni-heidelberg.de)*

Purpose: To non-invasively estimate mean pulmonary arterial pressure (mPAP) in patients being evaluated for pulmonary hypertension (PH) by using automated 3D volumetry of central pulmonary arteries based on CT pulmonary angiography (CTPA).
Methods and Materials: 73 consecutive patients (mean age 66.3 years, 50 female) undergoing CTPA, right heart catheterisation (RHC) and echocardiographic pulmonary arterial systolic pressure measurement (PASP) for suspected PH in our institution were retrospectively reviewed. Patients with chronic thromboembolic PH were excluded. Patients were randomised to a derivation (n=36, mean age 66.4 years) and a validation cohort (n=37, mean age 66.1 years). Automated segmentation of CTPA data was performed using in-house developed software. Volumes of the main as well as right and left pulmonary artery were calculated and corrected for vessel length and body surface area (MPA-volume and RLPA-volume). A linear regression model was established in the derivation cohort to estimate mPAP and diagnostic accuracy compared to gold standard RHC assessed in the validation cohort.
Results: Mean mPAP was 29.2 mmHg in the derivation cohort and 28.9 mmHg in the validation cohort. Regression analysis yielded the following formula: estimated mPAP = -2.353 + (11.04 x MPA-volume) + (13.82 x RLPA-volume) + (0.489 x PASP) (r=0.92). When applied to the validation cohort sensitivity and specificity for prediction of PH (mPAP >= 25 mmHg) were 86% and 100%, respectively.
Conclusion: Non-invasive estimation of mPAP using automated 3D volumetry of central pulmonary arteries based on CTPA can predict the presence of PH as confirmed by RHC with high sensitivity and specificity.

B-0571 15:04

Low-kilovoltage chest CT angiography at the recirculation phase: a new option to optimise the image quality?

A. Hutt, S. Gicquel, J.-B. Faivre, M. Remy-Jardin, J. Remy; *Lille/FR (martine.remy@chru-lille.fr)*

Purpose: To reduce beam-hardening artifacts on single-energy chest CT angiograms (CTA).
Methods and Materials: The study population comprised 100 patients who underwent a chest CTA with a fixed scan delay (60s), using 90-110mL of a 35% contrast agent and a low kVp (80, 90, 100 or 110 kVp depending on the b.w.) (Group 1). The image quality was compared to that of standard chest CT examinations (Group 2; n=25) obtained with a similar injection protocol at the exception of the use of a bolus tracking technique and a kilovoltage set at 100 or 120 kVp.
Results: Homogeneous enhancement of systemic veins was significantly more frequent in Group 1 than in Group 2 (superior vena cava [95% vs 8%]; inominate vein ipsilateral [89% vs 28%] and controlateral [92% vs 4%] to the side of injection; p<0.0001). The severity scores of artifacts significantly differed between the two groups with no artifacts at the level of 2R (95%), 2L (96%), 4R (98%), 4L (100%), 7 (100%) nodal stations in Group 1 (Group 2: 2R [16%]; 2L [76%], 4R [16%], 4L [52%],7 [76%]) (p<0.0001). In Group 1, the mean level of attenuation was 219±44.38 HU in the pulmonary trunk with arteries analysable down to the subsegmental level in 80% of cases; an 209.7±44.73 HU in the descending aorta.
Conclusion: CT scanning at a recirculation phase and low kVp allows suppression of most beam-hardening artifacts while providing a diagnostic level of vascular enhancement in all vascular compartments.

B-0572 15:12

Intra-individual comparison of direct subtraction vs dual-energy for imaging of pulmonary perfusion: a feasibility study

D.J.M. Grob[1], E.J. Smit[2], M. Prokop[1], L.J. Oostveen[1], M.M. Snoeren[1], C.M. Schaefer-Prokop[2], I. Sechopoulos[1], M. Brink[1]; [1]*Nijmegen/NL*, [2]*Amersfoort/NL (Dagmar.Grob@radboudumc.nl)*

Purpose: Iodine mapping as surrogate of lung perfusion can be achieved using dual-energy acquisition (DE) or direct subtraction (s-CT), requiring image registration. Purpose of the study was to compare image quality and detection of perfusion inhomogeneities (PI) in patients suspected for acute pulmonary embolism (PE).
Methods and Materials: Prospectively included 55 consecutively patients with suspected PE underwent CTPA in addition to an unenhanced scan (100kV), allowing for intra-individual comparison of both techniques. Five blinded radiologists independently evaluated the image quality of both types of iodine maps overlaid on CTA using visual grading analysis on a 5-point scale (1=excellent, 5=non-diagnostic) and assessed the presence and underlying causes of PI. McNemar tests were used to compare proportions.
Results: Median DLPs were 172mGy-cm for DE and 162mGy-cm for subtraction. The mean proportion of iodine maps rated as showing excellent or good overall image quality was 36% (range: 5-69%) for DE and 67% (31-80%) for subtraction (p< 0.05 for 4 radiologists), mainly because of fewer artefacts. Mean proportion of PI positive scans was 46% (31-98%) for DE and 51% (29-98%) for subtraction, mostly related to airways pathology. Of 6 patients with PE, readers detected on average 90% of PE-related PIs with DE compared to 70% with subtraction.
Conclusion: Pulmonary iodine mapping of the lung in CTA is feasible with subtraction at the same radiation dose as DE, but with superior image quality. In the small group of patients with PE, DE detected more PE-associated perfusion inhomogeneities.

Ventilation/perfusion ratio map by dual-energy CT after xenon inhalation and intravenous contrast media

N. Honda[1], H. Osada[1], W. Watanabe[1], K. Aoki[1], K. Izumi[1], M. Nakayama[1], T. Itoh[2], K. Otani[2]; [1]*Kawagoe/JP*, [2]*Tokyo/JP (honda.nyasie@gmail.com)*

Purpose: Ventilation/perfusion (V/Q) ratio represents efficiency of pulmonary blood oxygenation. The purpose of the study was to report a method to create V/Q ratio map from dual-energy CT.
Methods and Materials: Twenty-six patients of lung caner treated with lobectomy were included. The study was approved by IRB and informed consent was obtained. The first CT of the chest after a vital-capacity inhalation of xenon-oxygen mixture in 35/65% ratio, and the second CT at individualised pulmonary artery phase were acquired consecutively both in dual-energy mode. Ventilation and perfusion CT was generated through material decomposition applied to each CT data. V/Q ratio map was created by pixel-by-pixel division between the ventilation and perfusion CT images. Mean V/Q ratio, SD, mode, median and fractal dimension (FD) was calculated. Paired *t*-test was applied.
Results: Mean age, SD, range and male/female ratio were 67, 1.9, 51 to 86 years and 12:16. Mean, SD, mode, median and FD of the V/Q ratios were 0.877, 0.392, 0.797, 0.703, and 2.511 before and were 0.912, 0.346, 0.842, 0.768, and 2.522 after the lobectomy, respectively. The difference was non-significant in all. All of the patients maintained activities of daily living after the lobectomy.
Conclusion: V/Q map was generated from CT using xenon CT and perfusion CT. No changes in the mean, SD, median, mode and FD of V/Q ratios after the lobectomy may indicate that enough compensation to restore V/Q ratio was present as all of the patient regained activities of daily living after the operation.

Prostate volume assessed by TRUS and its correlation with post-void residue

A. Mereu, E. Scapin, L. Saba; *Monserrato/IT*

Purpose: To analyse whether there is a correlation between prostate volume measured by transrectal ultrasonography (TRUS), post-void residual urine volume and post-void/pre-void urine volume ratio.
Methods and Materials: 493 TRUSs (age range 28-88 years) were retrospectively analysed. Prostate volume, post-void residual urine volume and post-void/pre-void urine volume ratio were assessed. Included patients were categorised into three groups: subjects who did not have transurethral resection of the prostate (TURP) (473 cases, 96%), subjects who had TURP (20 cases, 4%) and all the subjects. Statistical analysis was performed using the two-tailed unpaired Student's t test and the Pearson's r.
Results: Weak correlations between prostate volume and post-void residual urine volume (r value: 0.133 in non-TURP, -0.093 in TURP, 0.132 in all) and between prostate volume and post-void/pre-void urine volume ratio (r value: 0.243 in non-TURP, -0.272 in TURP, 0.239 in all) were found using the Pearson's r. No statistically significant difference was observed between prostate volume, post-void residual urine volume, post-void/pre-void urine volume ratio of non-TURP and TURP patients, determined using the two-tailed unpaired Student's t test (p value=0.146 of prostate volume, p value=0.084 of post-void residual urine volume, p value=0.055 of post-void/pre-void urine volume ratio).
Conclusion: Our study results showed that prostate volume does not have a statistically significant correlation neither with post-void residual urine volume nor with post-void/pre-void urine volume ratio. Furthermore, these measurements do not differ significantly statistically between non-TURP and TURP patients. Therefore, evaluation of all these parameters should be considered.

B-0575 14:08

Role of multiparametric MRI in the follow-up of patients with a clinical suspicion of prostate cancer

G. Cappello, S. Mazzetti, V. Giannini, L. Vassallo, F. Russo, D. Regge; *Candiolo/IT (giovanni.cappello@ircc.it)*

Purpose: To investigate patients in follow-up (FU) with a clinical suspicion of prostate cancer (PCa) after a negative mp-MR of the prostate or previous negative prostate biopsy.
Methods and Materials: The dataset comprised 368 subjects with suspicion of PCa who underwent diagnostic mp-MRI. Of these, 97 patients (26%) showed at least one suspicious lesion at mp-MRI, while 271 (73.6%) had a negative mp-MR and were monitored with clinical FU. Among the 97 subjects with a positive mp-MR, 21 had a negative biopsy and they also underwent clinical FU. The final dataset was composed of 292 patients.
Results: Among the 292 patients, 13/292 (4.4%) had a PSA doubling time (PSA-DT) less than 3 years: 5/13 (38.4%) had a positive mp-MR and, therefore, they underwent prostate biopsy resulting in 3/5 (60%) patients with pathologically confirmed PCa. 8/292 (2.7%) patients repeated mp-MR after a positive digital rectal examination: all of them resulted negative at the repeated mp-MR. Overall, 3/292 (1.02%) patients had a positive biopsy during FU, resulting in a negative predictive value (NPV) of 99%.
Conclusion: The results suggest that mp-MR of the prostate has high NPV in predicting PCa reducing the number of useless biopsy and the risk to overdiagnose and overtreat low-risk cases, with limitation in patient's quality of life.

B-0576 14:16

Sub-differentiating equivocal PI-RADS 3 lesions in multiparametric MRI of the prostate

N.L. Hansen[1], B. Koo[2], A. Warren[2], C. Kastner[2], T. Barrett[2]; [1]*Cologne/DE*, [2]*Cambridge/UK (nienke.hansen@uk-koeln.de)*

Purpose: To evaluate if equivocal PI-RADS 3 lesions on multiparametric magnetic resonance imaging (mpMRI) of the prostate can be further differentiated using pre-defined T2- and diffusion-weighted imaging criteria in order to aid in the biopsy decision process.
Methods and Materials: 143 patients with an index PI-RADS 3 lesion on mpMRI underwent transperineal MR/US fusion biopsy from 2013 to 2016. Two radiologists with 2 years and 7 years of experience performed a blinded retrospective second-read of each lesion and gave a recommendation whether or not to biopsy. Inter-reader agreement, Gleason score (GS), positive (PPV) predictive values (+-95% confidence intervals) were calculated and compared by exact Fisher test.
Results: 43% (61/143) patients had any cancer and 21% (30/143) GS 7-10 cancer in the biopsy. Using shape, border, homogeneity, and diffusion restriction as objective imaging criteria had a significant effect on PPV. When asked to make a subjective biopsy recommendation, agreement between the two readers was observed in 62% of cases (89/143). PPV for finding any cancer decreased from 0.43 (±0.08) for all PI-RADS 3 to 0.21 (±0.10) with "defer biopsy" and increased to 0.61 (±0.11) with "biopsy recommended"; p=0.0001. PPV for GS 7-10 cancer decreased from 0.21 (±0.07) for all PI-RADS 3 to 0.08 (±0.07) with "defer biopsy" and increased to 0.32 (±0.10) with "biopsy recommended"; p=0.0003.
Conclusion: Identification of certain imaging criteria, as well as a subjective biopsy recommendation can help to increase the PPV of PI-RADS 3 prostate lesions and aid the decision to biopsy, even without using contrast enhancement.

Clinically significant prostate cancer: evaluation of PI-RADS v2 score 3 lesions on prebiopsy MRI

J. Kim, C. Kim, M.-R. Kwon, R. Kim, J. Yim; *Seoul/KR (ssakpo.kim@samsung.com)*

Purpose: To evaluate the value of score 3 lesions on Prostate Imaging Reporting and Data System (PI-RADS) v2 at prebiopsy magnetic resonance imaging (MRI) in predicting clinically significant cancer (CSC).
Methods and Materials: 103 consecutive patients underwent prebiopsy 3-T multiparametric MRI, followed by radical prostatectomy. Two independent readers performed PI-RADS v2 scoring. Based on the histopathological

findings, the CSC was defined when a tumour had Gleason score 7 or greater, tumour volume ≥ 0.5 cm^3, or extraprostatic extension. Statistical analysis was performed using receiver operating characteristics (ROC) curve analysis and κ statistics.
Results: Of 103 patients, 81 (78.6%) had 107 lesions of CSCs on surgical specimen. In patient-based analysis, the CSCs of each PI-RADS assessment category in both readers were 60.0% (9/15) and 56.3% (9/16) for score 1-2, 68.4% (13/19) and 70.6% (12/17) for score 3, 75.8% (25/33) and 77.5% (31/40) for score 4, and 94.4% (34/36) and 96.7% (29/30) for score 5. The PI-RADS score 3 lesions rated from both readers were 68 and 66 on MRI, respectively and of these, 22 (32.3%) and 21 (31.8%) lesions had CSCs. For predicting CSCs, the area under the ROC curve for both readers was 0.71 and 0.72. The inter-reader agreement for PI-RADS scoring was good (κ = 0.65).
Conclusion: PI-RADS v2 score 3 lesions on prebiopsy MRI might harbor substantial CSCs in patients with prostate cancer. Thus, a targeted biopsy needs a lesion with PI-RADS v2 score 3 or greater.

B-0578 14:32

Multiparametric MRI of the prostate: prospective evaluation of PIRADSv2 in detection of prostate cancer using ISUP grading system for validation

S. Bednarova[1], S. Mehralivand[2], J.H. Shih[3], F.V. Mertan[4], S. Gaur[4], R. Girometti[1], M.J. Merino[4], B.J. Wood[4], P.A. Pinto[4], P.L. Choyke[4], B. Turkbeyi[4]; [1]*Udine/IT*, [2]*Mainz/DE*, [3]*Rockville, MD/US*, [4]*Bethesda, MD/US (sandra.bednarova@gmail.com)*

Purpose: To prospectively assess prostate cancer detection rate (CDR) of PIRADSv2 using the new ISUP grading system.
Methods and Materials: 339 consecutive treatment naïve patients (mean age=64years, mean PSA=8.3 ng/mL) prospectively underwent mpMRI scored with PI-RADSv2, 12 core systematic and TRUS/MRI guided biopsy (Fbx) between May 2015-May 2016. The highest Gleason score for each PCa lesion was assigned an ISUP score, ISUP≥2 represented clinically significant (CS) PCa. CDRs for all and CS PCa were determined for each PIRADS score for the entire prostate, peripheral and transition zone. CDRs of each PIRADS score was compared.
Results: Overall, 737 lesions detected at mpMRI underwent Fbx. 346 lesions were positive for PCa, 237/346 lesions were CS PCa, resulting in CDR of 47% and 32% for all and CS PCa, respectively. CDRs for PIRADS scores 1, 2, 3, 4 and 5 for all PCa were 25%, 20.2%, 24.8%, 39.1% and 86.9%, respectively, while for CS PCa CDRs were 0%, 9.6%, 12%, 22.1% and 72.4%, respectively. For all and CS PCa, differences in CDRs between PIRADS4 and 5 scores, as well as between PIRADS3 and 4 scores were statistically significant ($p<0.05$). Overall PIRADS score 4 had unexpectedly high false positive results; whereas corresponding T2W PIRADS score 4 had higher CDR compared to overall PIRADS score 4 (39% vs 51%, p<0.001).
Conclusion: CDR increases with higher PIRADS scores for all and CS PCa lesions. PIRADS4 score had a high false positive rate, but the additional use of T2W scores can improve the CDR of PIRADS4 lesions.

B-0579 14:40

Updating prostate image reporting and data system version 2 (PI-RADS v2) for the detection of clinically significant prostate cancer in patients with elevated PSA level

C.-C. Wang, J.-S. Huang; *Kaohsiung City/TW (chunchiehwang1221@gmail.com)*

Purpose: To determine the predictive value of prostate image reporting and data system (PI-RADS v2) for the assessment of clinically significant prostate cancer by multiparametric MRI (mp-MRI) patients with elevated PSA level.
Methods and Materials: A retrospective and prospective study was performed in 221 patients with elevated prostate-specific antigen (PSA) level by 1.5T or 3T mp-MRI. MRI studies containing T2 weighted, diffusion weighted, and dynamic contrast enhancement images. Two experienced abdominal radiologists reviewed images and reported all the studies according to recent PI-RADS v2 scoring system. All suspected lesions were recorded due to multifocal prostate cancer, and then we focused on index lesions (defined by PI-RADS v2) in each patient. Patients who had PI-RADS 3, 4, 5 received either targeted core biopsies and systemic core biopsies. Clinically significant prostate cancer was defined by PI-RADS v2 (Gleason score (GS) ≥ 3+4 or tumour volume ≥ 0.5 ml). ROC curve for clinically significant prostate cancer using PI-RADS v2 category was analyzed.
Results: 205 patients diagnosed as prostate cancer, 183 patients tumour volume ≥0.5 ml (any Gleason score) , 22 tumours <0.5 ml (18 with GS =3+3, 4 with GS≥3+4). Area under ROC curve for clinically significant prostate cancer using PI-RADS was 0.981. For the threshold of PI-RADS scores of 3 or greater, sensitivity was 91.89%, positive predictive value (PPV) was 90.91%. Interobserver agreement for PI-RADS scoring system was good (k=0.80).
Conclusion: PI-RADS v2 can be a simple and valuable diagnostic tool for the detection of clinically significant prostate cancer before biopsy.

B-0580 14:48

Quantitative analysis of dynamic contrast-enhanced MRI for prostate cancer detection: is there an added value compared to PI-RADS v.2 classification?

G. Cristel, A. Esposito, S. Antunes, G. Brembilla, L. Brunetti, A. Briganti, F. Montorsi, A. Del Maschio, F. De Cobelli; *Milan/IT (cristel.giulia@hsr.it)*

Purpose: To assess whether there is a significant difference in pharmacokinetic dynamic contrast-enhanced MRI (DCE-MRI) parameters between benign and malignant prostatic lesions, in order to improve multiparametric MRI (mpMRI) diagnostic performance.
Methods and Materials: Among a total of 339 patients who underwent prostatic mpMRI (1.5T) from February to September 2016, we selected all the lesions, with available corresponding histological specimen (n=61) obtained through target biopsies. The imaging protocol consisted of multiplanar T2W, diffusion-weighted imaging and DCE-MRI. For each lesion the following pharmacokinetic parameters were assessed: transfer constant (Ktrans), rate constant (Kep), extravascular extracellular volume fraction (Ve), fractional plasma volume (Vp) and area under the curve (AUC). The association between the analysed parameters and the histological result was then evaluated basing on Gleason score ≥7 (GS).
Results: Malignant lesions showed higher Ktrans, Kep and AUC compared to the benign ones, all p<0.01. Moreover a significant difference among the Gleason score groups was observed, with more aggressive tumours showing higher values, all p<0.01. ROC curve analysis was used to identify a Ktrans cut-off value of $180x10^{-3}$/min (AUC 0.81) which in turn predicted the presence of GS≥7 with sensitivity, specificity, NPV, PPV and accuracy respectively of: 95%, 65%, 96%, 59% and 75%. The corresponding values basing on PI-RADSv.2 were as follows: 100%, 38%, 100%, 46%, 59%. The application of Ktrans cut-off on PI-RADS≥3 cases shifted 13 false positives to true negatives with the loss of 1 true positive.
Conclusion: DCE-MRI pharmacokinetic analysis may improve PI-RADSv.2 capability of prostate lesions' characterisation.

B-0581 14:56

Monocentric experience in the detection of prostate cancer comparing PI-RADS Version 1 and Version 2: the role of dynamic contrast enhancement (DCE)

G. Michelini, L. Panebianco, A. Mancini, A. Pace, C. Gianneramo, C. Marsecano, I. Capretti, R. Manetta, C. Masciocchi; *L'Aquila/IT (giuliamichelini.gm@gmail.com)*

Purpose: To compare two system of PIRADS score, Version 1 (PiradsV1) and 2 (PiradsV2), and analyse the effectiveness of DCE to detect prostate lesions.
Methods and Materials: Two dedicated MRI-prostate radiologists (A and B) retrospectively and independently evaluated 90 multiparametric 3T MRI (mpMRI) (mr750w GE, with pelvic phased-array 32 channel coil + endorectal coil) performed between February 2015 and February 2016, with both PiradsV1 and PiradsV2. From PiradsV1 the score (1-5) of only DCE was considered, from PiradsV2 the score (1-5) of ESUR 2015 guidelines. Patients Median age:62,6 years. Exclusion Criteria: contraindications to mpMRI, previous prostatectomy, radiotherapy or ormonotherapy. Contrast media: Gadobutrol (1mmol/ml/Kg). For each patient the histological report was obtained, and a histological score was assigned to it (PI): normal=1; prostatitis=2; Atypical Small Acinar Proliferation (ASAP)=3; prostatic intraepithelial neoplasia (PIN)=4; Prostate cancer (CaP) (GS≥6)=5. The PI was subtracted from the two Pirads Scores (PiradsV1-PI and PiradsV2-PI) to obtain an absolute value that is truer the more it nears to 0 (maximum correlation between PR and PI). The statistical analysis was performed with Student t test.
Results: All values are expression of an average. Concordance between PiradsV1 and PiradsV2 from A and B: A-PiradsV1=2,37, B-PiradsV1=2,71 (p=0,5); A-PiradsV2=2,96, B-PiradsV2=2,92 (p=0,16). Statistically significant differences between PiradsV1-PI e PiradsV2-PI: A-PiradsV1-PI=1,66, A-PiradsV2-PI=0,58 (p<0.05); B-PiradsV1-PI=1,75, B-PiradsV2-PI=0,66 (p<0.05).
Conclusion: The study confirms the usefulness of PIRADS systems for structured and concordant report. Introduction of PiradsV2, which subtracts importance to DCE, in our experience has resulted in higher correlation with histological report.

B-0582 15:04

Multiparametric MRI of prostate cancer for the prediction of lymph node metastasis

G. Brembilla, A. Esposito, G. Cristel, F. Giganti, L. Brunetti, P. Dell'Oglio, A. Briganti, F. Montorsi, F. De Cobelli; *Milan/IT (brembilla.giorgio@hsr.it)*

Purpose: To investigate the role of pre-operative mp-MRI of prostate cancer (PCa) in predicting lymph node involvement (LNI).
Methods and Materials: 87 PCa patients treated with radical prostatectomy (RP) and extended pelvic lymph node dissection at a single tertiary care referral center were included in our study. All patients underwent pre-operative

MRI. For each patient PSA dosage, pre-operative biopsy Gleason score and MRI-related parameters (PI-RADS score, tumour ADC, tumour volume, MRI stage) were assessed. Logistic regression analyses and ROC curves were performed in order to identify the predictors of LNI.
Results: Overall, 18 (20,7%) had LNI at final pathology. At univariate analysis all the MR parameters were predictors of LNI (all p <0.05). At multivariate analysis tumour ADC, tumour volume and extracapsular extension (ECE) were significantly associated with LNI (all p <0.05). Sensitivity, specificity, PPV and NPV in predicting LNI were respectively 89%, 87%, 65% and 97% for an ADC value <0.7 x 10^{-3} mm^2/s (AUC = 0.89) and for a tumour volume > 0.9 cc (AUC = 0.93); 89%, 78%, 53% and 96% for ECE (AUC = 0.83). The presence of seminal vesicle invasion (SVI) was 98% specific with 91% PPV.
Conclusion: Pre-operative MpMRI of PCa is a promising tool in the prediction of LNI. High tumour volume (> 0.9 cc), low ADC (< 0.7 x 10-3 mm2/s), presence of ECE and SVI at MRI correlate with LNI at post-operative pathologic examination.

B-0583 15:12

Evaluation of clinical outcome for prostate cancer after radical prostatectomy using PI-RADS v2

R. Kim, C. Kim, J. Yim, J. Park; *Seoul/KR (ran1001.kim@samsung.com)*

Purpose: To determine whether the Prostate Imaging and Reporting and Data System (PI-RADS) v2 helps predict the clinical outcome for prostate cancer (PCa) after radical prostatectomy (RP).
Methods and Materials: From February 2005 to January 2007, 166 consecutive patients with localized PCa underwent multiparametric MRI (mpMRI) at 3T before RP. The PI-RADS v2 score was performed per patient. Biochemical recurrence-free survival (RFS) and progression-free survival (PFS), cancer-specific survival (CSS) and overall survival (OS) were assessed using Kaplan-Meier curves. Preoperative clinical and imaging parameters were evaluated using Cox proportion hazards regression analysis.
Results: During a median follow-up of 9.1 years, 16 patients (9.6%) died. The biochemical recurrence and disease progression were identified in 67 patients (40.4%) and 55 patients (33.1%). No clinical and imaging parameters were significantly associated with CSS and OS. On univariate analysis, prostate-specific antigen, Gleason score, number of positive cores, PI-RADS score and tumour apparent diffusion coefficient were significantly associated with RFS and PFS. On multivariate analysis, Gleason score, number of positive core and PI-RADS score were independent predictors of RFS [hazard ratio (HR)= 1.45, p= 0.006; HR= 1.20, p=0.026; HR= 1.43, p= 0.041] and PFS (HR= 1.46, p= 0.017; HR= 1.32, p= 0.001; HR= 1.62, p= 0.016]. The PI-RADS score < 3 was significantly associated with better RFS (p= 0.002) and PFS (p= 0.013). The inter-reader agreement of PI-RADS score was fair (κ= 0.353).
Conclusion: PI-RADS v2 score on mpMRI may be a useful marker for predicting RFS and PFS after RP in patients with PCa.

B-0584 15:20

Usefulness of PI-RADSv1 vs PI-RADSv2 in multiparametric MR imaging of prostate cancer recurrence after radical radiotherapy

J. Rembak-Szynkiewicz[1], A. Hebda[1], K. Kansy[1], A. Badzinski[2], B. Bobek-Billewicz[1]; [1]*Gliwice/PL*, [2]*Sosnowiec/PL (remszyn@wp.pl)*

Purpose: PI-RADS is used for prostate cancer detection. PI-RADSv1 was applied until 2014; currently PI-RADSv2 is used. Prostate assessment after radiotherapy is difficult due to intensified fibrotic and inflammatory changes, atrophy, and necrosis. To analyse the usefulness of PI-RADSv1vs PI-RADSv2 to assess focal prostate cancer recurrence after radiotherapy.
Methods and Materials: We analysed 118 patients (mean age: 71 yrs) treated with radical radiotherapy due to prostate cancer with microscopically confirmed local recurrence. Mp MR examination was done using a 3T scanner. T1-w, T2-w, DWI and DCE images were obtained.
Results: For PI-RADSv1 T2-w, DWI and DCE were assessed using a 5-point score. For PI-RADSv2 T2-w and DWI were assessed using a 5-point score, DCE +/- images were applied to assess local recurrences. Mean “index lesion” size was 17mm. In PI-RADSv1 and v2 focal recurrent size correlated with a point score (p <0.0001). PI-RADSv2 (≥4) result: “cancer is likely to be present” in 91/118 (77.1%) recurrences. PI-RADSv1 (≥9) result: “cancer is likely to be present” in 89/118 (75%) recurrences. For T2-w images 30.5% lesions had PI-RADS in both versions highly suggestive of malignancy. Diffusion restriction was confirmed in 79.7% of local recurrences. DWI ≥4for PI-RADSv1:91/118 (77.1%), for PI-RADSv2: 86/118 (72.9%). Positive DCE result in PI-RADSv2 was observed in 82.7% recurrences, but DCE influenced the final PI-RADS result in only 6%, resulting in a change from 3 (intermediate) to 4 (cancer likely to be present).
Conclusion: Usefulness of PI-RADSv1 is similar to PI-RADSv2 in the assessment of focal recurrence of prostate cancer.

Abnormal regional activity and functional connectivity in resting-state brain networks associated with aetiology confirmed unilateral pulsatile tinnitus in the early stage of disease

H. Lv, P. Zhao, Z. Liu, R. Li, L. Zhang, P. Wang, F. Yan, L. Liu, Z. Wang; *Beijing/CN (chrislvhan@126.com)*

Purpose: The abnormal neural activities revealed by the resting-state functional magnetic resonance image (rs-fMRI) are defined by the regional activity and functional connectivity (FC) of the networks in the brain. This study was designed to demonstrate the network alterations in the patients with pulsatile tinnitus (PT).
Methods and Materials: In this study, we recruited 45 patients with unilateral PT in the early stage of disease (less than 48 months of disease duration) and 45 normal controls. We used the regional homogeneity (ReHo) and seed-based FC analytic methods to reveal the resting-state brain activities associated with pulsatile tinnitus.
Results: Compared with healthy controls, PT patients showed regional abnormalities mainly in the left middle occipital gyrus (MOG), posterior cingulate gyrus (PCC), precuneus and right anterior insula (AI). When set as seeds, we demonstrated widespread modification of interaction between the auditory and non-auditory networks. The auditory network was positively connected with cognitive control network (CCN), which was associated with tinnitus related distress. Both altered regional activities and changed FC with other brain areas were found in the visual network. The modification of interaction of higher order networks were mainly found in DMN, CCN and limbic networks. Functional connectivity between left MOG and left parahippocampal gyrus could also be an index to reflect the disease duration.
Conclusion: This study helped us to have a better understanding of the characters of neural network modification in patients with pulsatile tinnitus.

B-0586 14:08

Evaluation of cochlear implants with Dyna CT previous and after surgery: what the radiologist needs to know/what the otologist wants to know

P. Largo Flores, E. Barcena Ruiz, X. Santos Sala, C. Sierra, M. Calderon Sanchez; *Madrid/ES (plargoflores@gmail.com)*

Purpose: To evaluate the anatomy of the temporal bone with a flat panel CT. To measure diameter A, B and insertion depth angle (IDA) and evaluate the interclass correlation (ICC) between two observers. To analyse the intracochlear electrodes position and possible dislocations after surgery.
Methods and Materials: Prospective study with 24 patients and different deaf causes. Two different observers evaluated the temporal bones before and after the cochlear implant with a flat panel CT. Flat diameter A (largest distance measured from the centre of the round window to the lateral wall) and diameter B (largest perpendicular cochlear measurement of “A”) were measured before the intervention to evaluate the interobserver correlation. After surgery, electrodes position, the IDA and possible dislocations were evaluated with a new CT.
Results: Preliminary results show that the mean distance A was 9.74 +/- 0.38 mm (observer 1) and 9.65 +/- 0.45 (observer 2) and ICC of 0.7. The mean distance B was 6.70 +/- 0.43 mm (observer 1) and 6.63 +/- 0.37 mm (observer 2) (95% IC) and ICC of 0.74. The mean IDA was 509.79 +/- 87.68 degrees (observer 1) and 509.38 +/- 87.57 degrees for (observer 2) with an ICC >0.95. Electrodes of the cochlear implants had no signs of dislocations.
Conclusion: Flat panel CT showed advantages on demonstrating the critical landmarks of the cochlea previous to cochlear implants and the evaluation of the position of intracochlear electrodes after surgery. A good ICC was demonstrated between both observers in the measurement of the diameter A, B and the IDA.

B-0587 14:16

MR imaging strategies in cochlear implants with novel self-aligning magnets, 1.5T vs 3T, high-bandwidth vs WARP artefact reduction: a phantom study

A. Pomschar, M.F. Reiser, B. Ertl-Wagner; *Munich/DE (Andreas.Pomschar@med.uni-muenchen.de)*

Purpose: Susceptibility artefacts caused by magnets in cochlear implants pose a significant problem for cranial MR imaging. Novel CIs are MR-compatible up to 3T without explanation of their magnet. Artefacts caused consist of a large central loss of signal and extensive surrounding distortion. Little information on reducing these artefacts is available. We aimed to optimise the cranial imaging protocol in patients with cochlear implants.
Methods and Materials: We examined a 3T compatible CI with self-aligning magnet (Synchrony, MED-EL) in a plastic phantom at 1.5 and 3T (Aera and Skyra, SIEMENS), comparing different bandwidth (low, middle, high) and WARP metal artefact reduction with VAT (view angle tilting). Penetration depth of the signal loss was measured. Distortion and visual image quality were rated on a 5-point Likert scale.
Results: For reducing penetration depth 1.5T was superior to 3T by 21.4%±7.7; WARP showed a general reduction of 12%±6.5; at 1.5T T1 generated smaller artefacts than T2 (-8.3%±3.3) but slightly larger artefacts at 3T (2.9%±3.5); low vs medium vs high bandwidth reduced the artefact from 7.5cm to 7 to 6.8. Distortion was greatly reduced using WARP by 1.8±0.5 points and by increased BW (low vs medium vs high) 4±1.1 vs 2.9±1.1 vs 2.5±1.2. Using WARP reduced sharpness at low BW but only slightly at medium and high BW.
Conclusion: From this preliminary phantom results we conclude that scanning at 1.5T with intermediate bandwidth and using WARP should yield the best results for whole brain imaging. However, specific areas of interest can be scanned at 3T as long as they have a certain distance from the implant.

Longstanding sensorineural hearing loss: impact of aetiology of hearing loss on the size of the cochlear nerve

N.N.N. Naguib, N.-E.A. Nour-Eldin, T. Gruber-Rouh, B. Kaltenbach, T.J. Vogl; *Frankfurt a. Main/DE (nagynnn@yahoo.com)*

Purpose: To test whether the size of the cochlear nerve measured in the internal auditory canal using multiplanar reconstruction (MPR) of the high-resolution MRI sequence correlates with the aetiology of hearing loss in patients with longstanding sensorineural hearing loss (SNHL).
Methods and Materials: The retrospective study was performed on 64 patients with longstanding SNHL due to different diseases of the inner ear. High-resolution MRI was performed using a T2-weighted SPACE sequence with 0.6 mm slice thickness. The cross-sectional surface area of the cochlear nerve was measured by drawing a region of interest around the circumference of the nerve. The correlation between the cochlear nerve size measured in MPR and the aetiology of hearing loss was tested using the Kruskal-Wallis test.
Results: The aetiology of SNHL was genetic disorder in 14 patients, sudden hearing loss in 10 patients, infection in adulthood in 8 patients, chronic otitis media in 4 patients, perinatal infection in 3 patients, toxic in 2 patients, due to congenital anomaly in 2 patients and idiopathic in 21 patients. The median size of the cochlear nerve in the different aetiologies was $1.2mm^2$, $1.1mm^2$, $1.25mm^2$, $1.2mm^2$, $1.3mm^2$, $1.25mm^2$, $1.17mm^2$ and $1.1mm^2$, respectively. Statistical analysis showed no statistically significant correlation between the aetiology of hearing loss and the size of the cochlear nerve ($p = 0.923$).
Conclusion: The size of the cochlear nerve in patients with longstanding SNHL does not correlate with the aetiology of hearing loss.

B-0589 14:32

The new classification system for inner ear malformations: the INCAV system

Z.H. Adıbelli, L. Isayeva, A.M. Koc, T. Catlı, H. Adıbelli, L. Olgun; *Izmir/TR (m_leyla_87@hotmail.com)*

Purpose: This study was conducted to explore a more specific, definitive classification system which was based on radiological criteria for inner ear malformations.
Methods and Materials: We found 43 patients who had inner ears malformations, magnetic resonance (MR) and computed tomography (CT) imaging together with the retrospectively evaluation of the medical records between August 2010 and February 2015. We separated the inner ear structures into 5 anatomical subgroups; internal acoustic canal (I), cochlear nerve (N), cochlea (C), vestibular aqueduct (A) and vestibule (V). Based on their malformations, these anatomical structures have been assigned grades and have been classified by using increasing numbers which were dependent to increasing order of severity of the malformation. We defined typical incomplete partition type II (IP-II) by using INCAV system as $I_0N_0C_1A_0V_2$; Mondini as $I_0N_0C_1A_1V_2$; IP-I as $I_0N_0C_4A_0V_4$; IP-III as $I_1N_0C_2A_0V_0$; Michel aplasia as $I_3N_3C_6A_0V_6$.
Results: Among these 43 patients, there were 80 inner ear malformations and 6 normal inner ears ($I_0N_0C_0A_0V_0$). All of the ears were defined successfully by the INCAV system, even 26.25% of the patients, who could not be categorised with existing classification schemes, could be defined successfully by using the INCAV system.
Conclusion: The proposed INCAV system standardises reporting of inner ear malformations; gives adequate information about the structures of inner ear; defines the ears which could not be classified before; helps in the selection of the ear as the cochlear implant candidate. Also the INCAV system is easy-to-use for radiologists, is useful to the referring otolaryngologists.

B-0590 14:40

Diagnostic accuracy of the perilymphatic signal drop on a 3D FIESTA C sequence at 3 Teslas to differentiate vestibular schwannomas from meningiomas of the internal auditory canal

A. Venkatasamy, A. Karol, A. Charpiot, C. Debry, F. Proust, N. Meyer, F. Veillon; *Strasbourg/FR (aina.v@hotmail.fr)*

Purpose: The perilymphatic signal changes on a 3D FIESTA C sequence may be a reliable diagnostic tool to differentiate obstructive vestibular schwannoma (VS) from IAC (internal auditory canal) meningioma (M), through a compartmental analysis of the signal intensity of inner ear fluids.
Methods and Materials: 203 patients with all criteria for a typical VS or IAC M, on a T1-weighted contrast-enhanced sequence, were retrospectively enrolled. 64 healthy subjects (G1), 190 typical VS and 13 typical IAC M (G5) were included. The VS were separated in non-obstructive VS (G2), CSF-border VS (G3) and obstructive VS (G4). All subjects underwent a gradient-echo 3D FIESTA C on a 3T MRI. Two radiologist analysed the signal intensity of the perilymph (vestibular cistern and cochlea) and endolymph (saccule and utricle).
Results: Obstructive VS (G4) presented with a marked perilymphatic signal drop in the vestibular cistern (RCiCSF=0,62) and cochlea. IAC M(G5) presented with a significant but more moderate drop (RCiCSF=0,81). For RCiCSF above 0.70, the tumour was more likely a meningioma, with a high Se=92%, Sp=83% and PNV=0.99. The perilymphatic signal drop was correlated to the degree of IAC's obstruction and no endolymphatic signal changes were observed.
Conclusion: The more pronounced drop of the perilymphatic signal on a 3D-FIESTA-C sequence in obstructive VS provides an additional tool to differentiate obstructive VS from IAC M, which may be useful to overcome the insufficiency of the morphological analysis itself. A cut-off value RCiCSF=0.70 enables the reader to differentiate between these two tumours with a high Se and Sp.

B-0591 14:48

Effect of the duration of hearing loss on the size of the cochlear nerve in patients with longstanding sensorineural hearing loss

N.N.N. Naguib, N.-E.A. Nour-Eldin, T. Gruber-Rouh, M. Al-Subhi, T.J. Vogl; *Frankfurt a. Main/DE (nagynnn@yahoo.com)*

Purpose: To test whether the size of the cochlear nerve measured in the internal auditory canal correlates with the duration of hearing loss in patients with longstanding sensorineural hearing loss (SNHL).
Methods and Materials: The retrospective study was performed on 98 patients who were divided into two groups. In group 1 (n = 68, test group), patients presented with bilateral longstanding SNHL and in group 2 (n = 30, control group) normal hearing patients referred for MRI of the inner ear for other diseases. High-resolution MRI was performed using a T2-weighted SPACE sequence with 0.6 mm slice thickness. The cross-sectional surface area of the cochlear nerve was measured by drawing a region of interest around the circumference of the nerve in the multiplanar reconstructed images.
Results: For group 1, the mean cross-sectional surface area of the cochlear nerve was $1.2mm^2$ (standard deviation: 0.35, range: 0.31-2.2). For group 2, the mean cross-sectional surface area of the cochlear nerve was $1.5mm^2$ (standard deviation:0.34, range: 1-2.5). Patients with SNHL (Group 1) had a statistically significant ($p=0.001$) smaller size of the cochlear nerve than normal hearing patients (group 2). A statistically significant ($p=0.0019$) weak negative correlation (rho= - 0.2) between the cochlear nerve size and the duration of hearing loss in patients with longstanding SNHL was noted.
Conclusion: Patients with longstanding SNHL have a significantly smaller size of the cochlear nerve compared to those with normal hearing. The cochlear nerve size correlates negatively with the duration of SNHL.

B-0592 14:56

Diagnostic performance of reformatted isotropic thin-section helical CT images in the detection of superior semicircular canal dehiscence

G. Sparacia[1], F. Agnello[1], A. Anastasi[1], A. Iaia[2], K. Traylor[2], M. Midiri[1];
[1]*Palermo/IT*, [2]*Newark, DE/US (fra.agnello@libero.it)*

Purpose: To assess the diagnostic performance of highly collimated isotropic CT reformatted images in detection of superior semicircular canal (SSC) dehiscence.
Methods and Materials: Forty-two patients, with sound- and/or pressure-induced vestibular symptoms, and forty-two control subject, underwent CT with highly collimated beam (0.5-mm). Reformatted images of the vestibular labyrinth structures were obtained from volumetric CT data in standard axial, and coronal planes (group A images). Additionally, reformatted images in a plane oriented to be parallel (plane of Pöschl) and perpendicular (plane of Stenver) to the SSC were obtained (group B images). Group A and group B images were evaluated separately by two neuroradiologists in consensus to establish whether a dehiscence of the SSC was present at the arcuate eminence.
Results: Diagnostic performance of group A images measured by the AUC was 0.929 (sensitivity 85.7%, specificity 100%, TP 36, TN 42, FP 0, FN 6) with an overall accuracy of 92.9%. Diagnostic performance of group B images measured by the AUC was 0.988 (sensitivity 97.6%, specificity 100%, TP 41, TN 42, FP 0, FN 1) with an overall accuracy of 98.8. Although differences between two AUCs were not statistically significant, group B images alone showed an improved diagnostic performance over the group A images alone.
Conclusion: Thin-section isotropic voxel CT with reformatted images oriented in the plane parallel (plane of Pöschl) and perpendicular (plane of Stenver) to SSC improves diagnostic accuracy in assessing for SSC dehiscence in comparison to CT images with reconstructions limited to traditional axial and coronal planes.

B-0593 15:04

MRI findings in infants with auditory neuropathy spectrum disorder due to thiamine deficiency

P.A. Caruso; *Boston, MA/US (pcaruso@partners.org)*

Purpose: A group of 11 Israeli children who developed encephalopathy due to nutritional thiamine deficiency has previously been reported. These children later developed moderate to severe hearing loss with features of auditory neuropathy spectrum disorder. Our purpose is to describe the MRI findings in this unique cohort.
Methods and Materials: The clinical records were reviewed for demographics, age at presentation, duration of nutritional thiamine deficiency, findings confirmatory of ANSD, outcome of the hearing loss following treatment with thiamine supplementation, and for neurologic sequelae. The MRIs were reviewed for abnormal findings along the auditory pathway from the external auditory canal to the cerebral cortex. All MRIs included T1- and T2-weighted images. Post-gadolinium T1-weighted images were available in six patients and DWI in five patients. Four children underwent additional MR imaging following thiamine supplementation.
Results: The study group included 7 infants: five female and two male aged 3-10 months. Along the auditory pathway, abnormal signal on the T2-weighted images was seen in the cochlear nuclei in six patients, in the trapezoid body in four patients, in the lateral lemnisci in four patients, in the inferior colliculi in five patients. Abnormal diminished diffusion was seen in the tectum, brainstem, posterior thalami, and the basal ganglia.
Conclusion: Our report describes for the first time the MR findings along the auditory pathway in infants with auditory neuropathy spectrum disorder due to nutritional thiamine deficiency.

B-0594 15:12

Detection and measurement accuracy of cholesteatomas: a comparison between non-EPI RESOLVE DWI and 3T MRI vs EPI DWI PROPELLER on 1.5T MRI

P.G. Chan, M. Thong, W. Maclaurin, S. Kerr, H. Kavnoudias, V. Cousins;
Melbourne/AU (pchan713@gmail.com)

Purpose: PROPELLER non-EPI DWI is highly sensitive and specific for the diagnosis of cholesteatoma, with a 98% clinical and radiological concordance rate. The aim of this study is to determine if 3T RESOLVE EPI DWI is equivalent in cholesteatoma detectability and accuracy compared to 1.5T PROPELLER non-EPI DWI.
Methods and Materials: All consecutive patients aged 18 or above who had undergone MRI for investigation for cholesteatoma, and received both PROPELLER and RESOLVE DWI imaging, were reviewed from June 2014 and September 2016. The images were independently reviewed by two head and neck consultant radiologists. Detection of cholesteatoma was the primary endpoint for each sequence. Lesions were measured along maximal dimensions and compared for concordance as the secondary endpoint.
Results: There were 28 patients who underwent 32 examinations. 14 lesions (PROPELLER) and 4 lesions (RESOLVE) were identified by both radiologists in total. Radiologist A detected 11 lesions and Radiologist B detected 13 lesions on PROPELLER; three lesions were identified on RESOLVE by each radiologist. All lesions (100%) that were detected by RESOLVE were detectible by PROPELLER. Concordance rates between the sequences were 27.27% (Radiologist A) and 23.08% (Radiologist B). The interobserver concordance rate for PROPELLER was 71.43% and 50% for RESOLVE. Six measurements were obtained in only four lesions. The mean percentage size concordance between the sequences was 78.8% (range 45.45% - 110.20%).
Conclusion: 3T RESOLVE EPI DWI has been shown to be inferior in both cholesteatoma detection and lesion size equivalence when compared to 1.5T PROPELLER non-EPI DWI.

B-0595 15:20

Comparison between a flat-panel angiography system and a 64-slices multisection computed tomography scanner in the cross-sectional imaging of the temporal bone

G. Conte, E. Scola, C. Sina, S. Calloni, R. Brambilla, L. Lombardi, F. Triulzi;
Milan/IT (giorgioconte.unimed@gmail.com)

Purpose: To compare the image quality and radiation dose between a flat-panel angiography (FPA) system and a 64-slices multisection computed tomography (MSCT) scanner in the cross-sectional imaging of the temporal bone.
Methods and Materials: We retrospectively collected 29 FPA and 29 MSCT of normal whole-head temporal bones. Image quality was assessed by two neuroradiologists who rated the visualisation of 30 anatomic structures with a three-point ordinal scale. Radiation dose was assessed using an anthropomorphic Rando Alderson Phantom in which thermoluminescent dosimeters were inserted in sites corresponding to organs and tissues.
Results: FPA showed better image quality than MSCT in depicting anterior and posterior crura of the stape, footplate of the stape, stapedius muscle, anterior ligament of the malleus ($p<0.05$). On the contrary CT showed better image quality than FPA in assessing tympanic membrane, bone marrow of the malleus and incus, tendon of tensor tympani, interscala septum and modiulus of the cochlea ($p<0.05$). No statistical difference, in terms of image quality, was found for the remaining anatomic structures. FPA had a significantly higher overall image quality rate than FPA ($p = 0.035$). A reduction of the effective dose of about 40% was proved for FPA compared to MSCT, with a reduction of 76% of dose for the lenses of the eye and 40% for the thyroid.
Conclusion: FPA is a convincing technique for cross-sectional imaging of the temporal bone. It provides better image quality in depicting the normal anatomy at lower radiation exposure compared to 64-slices MSCT.

Digital breast tomosynthesis: rate of recalls and screen-detected breast cancer in a population-based screening program by previous screening acquisition

S. Hofvind[1], T. Hovda[2], Å.S. Holen[1], J.L. Albertsen[3], H. Bjørndal[2], S.H.B. Brandal[1], L. Romundstad[2], E. Vigeland[3], P. Skaane[1]; [1]*Oslo/NO*, [2]*Drammen/NO*, [3]*Tønsberg/NO (solveig.hofvind@kreftregisteret.no)*

Purpose: To compare the recall rate and rate of screen-detected breast cancer using synthetic images and digital breast tomosynthesis (DBT) by previous screening acquisition in the Norwegian Breast Cancer Screening Program (NBCSP).
Methods and Materials: The study population included women screened with DBT at the NBCSPs screening unit in Oslo, 2014 and 2015, who also attended screening two years earlier, 2012 and 2013 respectively (n=23 154). The women were stratified by screening technique used at their previous screening examination, DBT (n=9947) or DM (n= 13 207). Data on women with a previous DBT were retrieved from the Oslo Tomosynthesis Screening Trial, 2012. Z-test was used to test for statistical significance ($p<0.05$) between the groups.
Results: Women with a previous DM had a higher recall rate compared to women with a previous DBT (2.4% and 1.9% ($p=0.02$), respectively). The rate of screen-detected breast cancer did not differ statistically significantly for

women with a previous DBT (8.6/1000 screened) compared to a previous DM (10.1/1000 screened) (p=0.27).
Conclusion: The results imply that fewer women are recalled when screened with DBT for two consecutive screening rounds. However, it does not affect the rate of screen-detected breast cancer.

B-0597 14:08

Interpretation time for digital breast tomosynthesis vs digital mammography in a population-based screening program

H.S. Aase[1], C.W. Frøland[1], Å.S. Holen[2], T.K. Neraas[1], K. Obst-Gleditsch[1], C.K. Sandvik[1], K.T. Søvik[1], I.M.O. Ulvik[1], S. Hofvind[2]; [1]*Bergen/NO*, [2]*Oslo/NO (solveig.hofvind@kreftregisteret.no)*

Purpose: To compare interpretation time for initial and consensus reading using digital breast tomosynthesis (DBT) versus digital mammography (DM) in the Norwegian Breast Cancer Screening Program.
Methods and Materials: As part of a randomized controlled trial performed in Bergen, interpretation time was registered at initial reading and consensus for DM (n=3694 and 242, respectively) and DBT (n=3765 and 227, respectively), January-June 2016. Mean time was calculated, while t-test with a 95% confidence interval (CI) was used to test for statistical significance between the two means.
Results: Mean initial interpretation time was 38 seconds (95% CI: 37-39) for DM and 01:12 minutes (95% CI: 01:11-01:13) for DBT, p<0.01. Mean interpretation time at consensus was 02:03 minutes (95% CI: 01:54-02.13) for DM and 03:24 (95% CI: 03:07-03:41) for DBT, p<0.01. For DM, mean time for initial reading decreased from 51 seconds in January to 27 seconds in June (p<0.01), while it decreased from 01:56 minutes to 58 seconds (p<0.01) for DBT. For consensus, the time decreased from 03:05 to 01:42 minutes (p<0.01) for DM and from 05:44 to 03.34 (p<0.01) for DBT during the study period.
Conclusion: The mean interpretation time at initial reading at DBT was double that of DM and a longer interpretation time should be expected when reading DBT images, also at consensus. The decreasing interpretation time might be related to the start-up of the randomized trial, indicating that the readers became more familiar with the protocol and reading DBT after six months.

Syntetic 2D + tomosynthesis for population breast cancer screening: first year of a pilot study

F. Caumo[1], G. Romanucci[1], S. Brunelli[1], P. Bricolo[1], L. Cugola[1], C. Fedato[2], M. Zorzi[3], S. Montemezzi[1]; [1]*Verona/IT*, [2]*Dorsoduro (VE)/IT*, [3]*Padova/IT (francescacaumo@gmail.com)*

Purpose: To assess advantages and limitations of Synthetic 2D + tomosynthesis (C-view + 3D) for population breast cancer screening.
Methods and Materials: From 1st April 2015 to 1st April 2016, 16755 women (aged 50-69 years) underwent screening C-view + 3D examinations at our institute and satellite centres. Participants were asymptomatic women at standard risk (population) for breast cancer. All examinations was interpreted on double-reading whereby recall was decided based on recall by either radiologist. Outcome measures were: incremental of storage, reading time, number of detected cancer, the number of detected cancer per 1000 screens, recall rate and pTN category. We also compared data with conventional 2D-mammography screening performed on previous screening round (14510 women screened from 1st April 2014 to 31th March 2015).
Results: Among C-view + 3D screening participants, 157 breast cancer were detected (vs 80 detected at 2D screening). Recall rates were 4,9% (vs 5,5% in 2D screening), cancer detection rate were 10,1% (vs 6,5% in 2D screening), T2+ were 16% (vs 26,4%), conservative treatment 88,5% (vs 79% in 2D screening). The incremental of storage increased from 532.862 MB to 5076.176 MB. The mean number of studies interpreted in hour was 38,5 +/- 0.55 (standard deviation) for C-view + 3D and 60 +/- 0.55 (standard deviation) for 2D alone.
Conclusion: Despite a consequential increase of reading time, C-view + 3D significantly increased cancer detection rates and conservative treatment and lowered T2+ cancer in breast screening population.

B-0599 14:24

The accuracy of digital breast tomosynthesis (DBT) and spot compression views for the diagnosis of different soft tissue breast lesions in a screening programme

J.J. James[1], E.J. Cornford[1], Y. Chen[2], A.E. Turnbull[3]; [1]*Nottingham/UK*, [2]*Loughborough/UK*, [3]*Derby/UK (jonathan.james@nuh.nhs.uk)*

Purpose: To compare the accuracy of DBT and spot compression views in the diagnosis of masses, asymmetric densities (AD) and parenchymal deformities (PD) in women recalled for further investigation following screening mammography.
Methods and Materials: The women recruited received both spot compression views and two-view DBT. The radiologists working up the case first prospectively recorded their suspicion of malignancy on a five-point scale when reading standard two-view digital mammograms (DM) together with spot compression views. They then prospectively recorded scores for DM read in conjunction with two-view DBT. Pathology data were obtained.
Results: 334 lesions were assessed. The breast lesions were masses (51%), AD (15.5%) and PD (33.5%). There were 107 malignant and 227 benign/normal cases. The overall performance of DBT (as determined by ROC analysis) was equivalent to spot compression views for the assessment of each type of breast lesion (AUC was 0.94996 and 0.91055, respectively, for masses; 0.98913 and 0.95897 for AD; 0.86943 and 0.8679 for PD - all non-significant). DBT demonstrated significantly higher absolute sensitivity for malignancy manifesting as an AD (p=0.039). There was no significant difference in specificity or negative and positive predictive values for each technique.
Conclusion: DBT can be used to assess all types of soft tissue breast lesions with overall accuracy at least equivalent to spot compression views. For a malignant lesion presenting as an AD, a significant improvement in sensitivity was demonstrated when DBT was used to characterise the lesion.

Added value of one-view digital breast tomosynthesis combined with digital mammography according to readers concordance: changing in BIRADS rate and follow-up management

F. Galati, F. Marzocca, E. Bassetti, M. Luciani, F. Pediconi, C. Catalano; *Rome/IT (flaminia.marzocca@gmail.com)*

Purpose: To evaluate the added value of Digital Breast Tomosynthesis (DBT) when combined with Digital Mammography (DM): changing in BIRADS assessment and follow-up management.
Methods and Materials: From February 2014 to April 2015, 214 patients underwent one-view DBT and two-view DM. Two readers, with 15 and 10 years experience in breast imaging, independently reviewed all exams in two steps: DM and DM+DBT, according to BIRADS classification. Patients with BIRADS 0, 3, 4 and 5 were recalled for work-up. Inter-reader concordance of BIRADS rate and work-up rate were evaluated using Cohen's Kappa.
Results: K value for BIRADS classification was 0.58 for DM and 0.8 for DM+DBT. DM+DBT increased BIRADS 1 and 2 (Reader 1: DM 29.44%, DM+DBT 60.28% - Reader 2: DM 21.96%, DM+DBT 63.55%; p<0.01) and BIRADS 4 and 5 (Reader 1: DM 18.22%, DM+DBT 31.78% - Reader 2: DM 16.83%, DM+DBT 28.51%; p<0.01). While reduced BIRADS 0 and 3 compared to DM alone (Reader 1: DM 52.34%, DM+DBT 7.94% - Reader 2: DM 61.21%, DM+DBT 7.94%; p<0.01). K value for work-up rate was poor for DM and substantial (0.7) for DM+DBT. DM+DBT reduced work-up rate for both Reader 1 (DM 85.98% vs DM+DBT 52.8%, p<0.01) and Reader 2 (DM 97.2 % vs DM+DBT 55.14%, p<0.01).
Conclusion: The combination of DM and DBT increased the concordance between the readers for BIRADS classification and work-up rate. DBT+DM also increased the number of BIRADS 1-2 and BIRADS 4-5, while reduced the number of BIRADS 0 and 3 (uncertain cases) for both readers.

B-0601 14:40

One-view digital breast tomosynthesis as a standalone modality for breast cancer detection: do we need more?

A. Rodríguez-Ruiz, A. Gubern-Mérida, M. Imhof-Tas, S. Lardenoije, N. Karssemeijer, R. Mann, I. Sechopoulos; *Nijmegen/NL (alejandrorzrz@gmail.com)*

Purpose: To compare the performance of three different implementations of digital breast tomosynthesis (DBT) as a replacement or an adjunct to digital mammography (DM) for breast cancer detection.
Methods and Materials: Two radiologists retrospectively reviewed 181 unilateral DBT and DM cases (79 malignant, 49 benign, and 53 normal). All non-malignant cases had >1 year of negative imaging follow-up. A sequential study with three steps per case was used, displaying different protocols. Step 1: only medio-lateral oblique (MLO) DBT. Step 2: MLO-DBT plus cranio-caudal (CC) DM. Step 3: CC and MLO from both modalities. Lesions were annotated and scored following BI-RADS (for diagnostic performance analysis) and level of suspiciousness (for jackknife alternative free-response receiver operating characteristic (JAFROC) analysis). Inter-reader variability was assessed using Cohen's kappa.
Results: Inter-reader agreement was moderate for all steps (k>0.46). Averaged across readers, sensitivity increased significantly from step 1 to step 2 (71% vs 77%; p<0.01) but step 3 had no added value (78%). Specificity decreased in step 2 (75% vs 72%; p=0.04), but was similar between steps 1 and 3 (step 3: 76%). The JAFROC figure of merit was comparable between steps 1 and 2 (p=0.66), but significantly greater for step 3 (p<0.05). Sub-analysis by lesion type and breast density showed that additional views improved performance only for detection of microcalcifications and in dense breasts.

Conclusion: One-view DBT has similar diagnostic performance whether or not the CC-DM is added, but the performance increases slightly when scoring the full breast exam. Studies with additional readers are ongoing.

Galactography in tomosynthesis technic - renaissance of a method?
R. Schulz-Wendtland[1], P. Fasching[1], C. Löhberg[1], M. Lux[1], M.W. Beckmann[1], M. Uder[1], M. Müller-Schimpfle[2]; [1]*Erlangen/DE*, [2]*Frankfurt a. Main/DE*
(ruediger.schulz-wendtland@uk-erlangen.de)

Purpose: The conventional galactography was used as the only imaging method in case of pathological nipple discharge for decades. Aim of our study was the comparison of the ductal oriented sonography with the contrast-enhanced galactography in tomosynthesis technique and of this generated reconstructed synthetic 2D-full-field digital mammographies.
Methods and Materials: From 01.10.2014 bis 31.03.2016 we investigated a total of 100 patients with a ductal oriented sonography as well as a contrast-enhanced galactography in tomosynthesis technique and of this generated reconstructed synthetic 2D-full-field digital mammographies. The mean age of the patients was 54.2 yrs (minimum 21 yrs, maximum 83 yrs). The evaluation of the three methods was made and correlated with the final histology.
Results: About all three investigators the results were: ductal oriented sonography with a sensitivity of 79.7%, a specificity of 58.3%, a ppV of 77.3% and a npV of 61.8%; for synthetic 2D-full-field digital mammography resp. 80.0%, 60.0%, 78.8% and 61.8% and the 3D-digital tomosynthesis resp. 90.9%, 73.9%, 92.1% and 73.9%. The accuracy, separated for the three methods: the ductal oriented sonography 0.72, synthetic 2D-full-field digital mammography 0.73 and the 3D-digital tomosynthesis 0.87.
Conclusion: First application of tomosynthesis in the galactography with significant better results in comparison to the ductal oriented sonography. This might become a renaissance of this method and an expansion of the spectrum of tomosynthesis in the complementary breast diagnostic. The generated reconstructed synthetic 2D-full-field digital mammographies are comparable with these of the ductal oriented sonography in high resolution.

To compare total radiation dose of FFDM alone and FFDM+DBT when additional views were considered
C.S. Lo, L.H.Y. Sinn, K.W.M. Wong, T.P.W. Lam, W.W.M. Lam; *Hong Kong/HK*
(chrissy.lo@gmail.com)

Purpose: To compare total radiation dose of FFDM alone and FFDM+DBT when additional views were considered.
Methods and Materials: Retrospective analysis of women attending annual surveillance mammography to assess number of additional views before (FFDM only: 1/10/2012-31/03/2013) and after implementation of combined FFDM+DBT (01/04/2015-31/03/2016) utilising same mammography unit. Average glandular dose (AGD) estimates obtained from DICOM images. Total radiation for each examination and additional views compared with Fisher exact test for periods A and B. Statistical significance considered when $p<0.05$.
Results: 2181 and 2701 women were included in period A (FFDM) and Period B (FFDM+DBT) respectively. Additional views dropped from 242 (11.1%) to 50 (1.9%). Mean AGD per view of FFDM in Period A and B shows no significant difference (1.51mGy to 1.53mGy). Mean AGD measures 3.09mGy in period B when combined with DBT. Significant increase in mean AGD per view (1.11mGy to 2.56mGy, $p<0.01$) and total radiation dose from additional views (1.86mGy to 4.23mGy, $p<0.01$) in period B. Average total radiation dose per patient including additional views increased from 5.27mGy to 11.4mGy, $p<0.01$.
Conclusion: Significant reduction in recall rate for additional views after implementation of combined FFDM and DBT. Radiation dose per additional view was considerably higher in period B, possibly attributed by decreased compression force and increased compression thickness. No significant difference in radiation dose when initial FFDM dose compared with stand-alone DBT, implying potential significant reduction in radiation dose when synthesised mammography used in lieu of FFDM in clinical practice.

B-0604 15:04

Comparison of detectability and characterisation of micro calcifications with digital mammography (DM), synthesised 2D mammography (SM) and digital breast tomosynthesis (DBT)
L.H.Y. Sinn, W. Wong, T.P.W. Lam, S.H.Y. Lam, V.W.H. Lau, J.J.K. Ip, G. Ho, H. Leung, W.W.M. Lam; *Pokfulam/HK (lorriesinn@gmail.com)*

Purpose: Comparison of the ability of detection and characterisation of benign and malignant microcalcifications in DM, SM and DBT.
Methods and Materials: Women attending surveliiance mammography since October 2014 were recruited with informed consent. Combined DM and DBT performed at same time for all cases with reconstruction of SM from DBT data. 9 radiologists reviewed the images without access to prior examinations / clinical history. Characterisation of the lesions and calcifications are documented.
Results: Interim analysis of 1067 study sets showed there were 475 sets demonstrated presence of benign microcalcifications in all three modalities. 61.9% sets showed increase in benign microcalcifications on SM, while only 13.1% showed increase benign microcalcifications when interpreting SM with DBT. When comparing BIRADS assignment of benign microcalcifications with DM, 14 and 19 cases were changed from BIRADS 0 to 1/2 in SM and DBT respectively. None of the cases were being upgraded from category 1/2 to 4/5 or downgraded vice versa in both SM and DBT groups. 15,15 and 16 cases with suspicious microcalcifications (BIRADS 4/5) were found in the DM, SM and DBT groups with respective sensitivity of 33%, 33% and 37.5%.
Conclusion: Increase benign microcalcifications were found when interpreting SM compared to DM, but most “overcalled” could be eliminated when interpreting together with DBT. None of the cases were upgraded from normal/benign findings in DM to BIRADS 4 or 5 or downgraded vice versa in both SM and DBT. Diagnostic performance of suspicious microcalcifications of DM and SM group was comparable.

B-0605 15:12

Is digital breast tomosynthesis (DBT) favourable for the evaluation of breast microcalcifications and for pre-procedural study of stereotactic biopsy?
G. Choi[1], O. Woo[1], H. Shin[1], K. Cho[1], B. Seo[2]; [1]*Seoul/KR*, [2]*Ansan/KR*
(cgyjulie@gmail.com)

Purpose: To investigate the diagnostic power of digital breast tomosynthesis (DBT) in evaluation of breast microcalcifications and usefulness as a pre-procedural study for stereotactic biopsy in comparison with full-field digital mammogram (FFDM) and FFDM plus magnification images (FFDM+MAG).
Methods and Materials: An IRB approved retrospective observer performance study on DBT, FFDM, and FFDM+MAG was done. Image quality was rated in 5-point scoring system for lesion clarity (1, very indistinct; 2, indistinct; 3, fair; 4, clear; 5, very clear) and compared by Wilcoxon test. Diagnostic power was compared by diagnostic values and AUC with 95% confidence interval. Additionally, procedural report of biopsy was analysed for patient positioning and adequacy of instruments.
Results: DBT showed higher lesion clarity (median 5, interquartile range 4-5) than FFDM (3, 2-4, p-value<0.0001), and no statistically significant difference to FFDM+MAG (4, 4-5, p-value=0.3345). Diagnostic sensitivity and specificity of DBT were 86.4% and 92.5%; FFDM 70.4% and 66.7%; FFDM+MAG 93.8% and 89.6%. The AUCs of DBT (0.88) and FFDM+MAG (0.89) were larger than FFDM (0.59, p-values<0.0001) but there was no statistically significant difference between DBT and FFDM+MAG (p-value=0.878). In 2 cases with DBT, petit needle could be appropriately prepared; and other 3 without DBT, patient repositioning was needed.
Conclusion: DBT showed better image quality and diagnostic values than FFDM and equivalent to FFDM+MAG in evaluation of breast microcalcifications. Evaluation with DBT as a pre-procedural study for breast stereotactic biopsy can lead to more accurate localisation and successful biopsy and also waive the need for additional magnification images.

B-0606 15:20

To what extent is the detectability of breast microcalcifications and spiculated lesions dependent on display luminance level?
C. Ferranti, A. Primolevo, F. Cartia, C. Cavatorta, M. Lualdi, E. Pignoli, M. Plebani, P. Verderio, G. Scaperrotta; *Milan/IT*
(claudio.ferranti@istitutotumori.mi.it)

Purpose: Evaluation of the influence of the calibrated luminance level of medical displays in the detectability of microcalcifications and spiculated lesions in Digital Breast Tomosynthesis (DBT) images.
Methods and Materials: Four models of medical displays with calibrated maximum and minimum luminance respectively ranging from 500 to 1000cd/m^2 and from 0.5 to 1.0cd/m^2 were investigated. Forty-eight studies were selected by a senior radiologist: 16 with microcalcifications, 16 with spiculated lesions and 16 without lesions. All images were anonymised and blindly evaluated by

one senior and two junior radiologists. For each study, lesion presence/absence and localisation statements, interpretative difficulty level and overall quality were reported. Cohen Kappa statistic was computed between monitors and within/between radiologists to estimate the reproducibility in correctly identifying lesions; for multi-reader-multi-case (MRMC) analysis, weighted Jackknife Alternative Free-response Receiver Operating Characteristic (wJAFROC) statistical tools were applied.
Results: Intra-radiologist reproducibility ranged from 0.75 to 1.00. Inter-reader as well as reader-truth agreement values were >0.80 and higher with the two 1000cd/m^2 luminance displays than with the lower luminance displays for each radiologist. Performances in the detectability of breast lesions were significantly greater with the 1000cd/m^2 luminance displays when compared to the display with lowest luminance value (p<0.001).
Conclusion: Our findings highlight the role of display luminance level on the accuracy in detecting breast lesions.

Tumour vascular pattern on MRI: a new and promising potential biomarker of glioblastoma survival
A. Gimeno[1], G. Blasco[1], P. Daunis-i-Estadella[1], C. Biarnés[1], J. Sanchez-Gonzalez[2], A. Alberich-Bayarri[3], M. Puigdemont[1], S. Pedraza[1], J. Puig[1]; [1]*Girona/ES*, [2]*Madrid/ES*, [3]*Valencia/ES (fredigimeno1989@gmail.com)*

Purpose: Vascularity correlates with shortened survival. We aimed to determine whether the tumoural vascular pattern on MRI (TVP-MRI) of newly diagnosed glioblastomas is useful in predicting survival, and to correlate TVP-MRI with dynamic susceptibility contrast (DSC) perfusion and diffusion parameters for contrast-enhancing lesion (CEL) and surrounding non-CEL.
Methods and Materials: Ninety-seven patients (59 men; mean age, 61 years) with histologically proven glioblastoma underwent 1.5T-MRI including anatomical sequences, first-pass DSC images and post-contrast T1-weighted SE images after gadobutrol (Gadovist; Bayer Schering Pharma, Berlin, Germany) at 0.1 mmol/kg) with a 1 mm isometric voxel. Volumes of interest for CEL, non-CEL, and contralateral tissue were obtained for relative cerebral blood volume (rCBV), relative cerebral blood flow (rCBF), delay time (DT), mean temporal maximal intensity projection (tMIP), and apparent diffusion coefficient (ADC) using Olea Sphere V.3.0 software (Olea Medical, La Ciotat, France). Tumours over 5 vessels were classified as hypervascular (hyper-TVP-MRI) on post-contrast 1 mm-T1SE images. Prognostic factors were evaluated by Kaplan-Meier survival and Cox proportional hazards analysis.
Results: Fifty-five (56.7%) glioblastomas were hyper-TVP-MRI. Patients with hyper-TVP-MRI, mean age, volume-CEL, ADC-CEL, DT-CEL, rCBV-CEL, rCBV-nonCEL and tMIP-CEL were higher and DT-nonCEL lower. Mean survival for hypo- and hyper-TVP-MRI glioblastomas treated with surgery and with radiotherapy plus chemotherapy was 12.9±7.7 and 8.3±6.9 months, respectively. TVP-MRI was the best survival predictor for glioblastoma at 1 year (AUC 0.84, 88.5% sensitivity, 77.9% specificity, 82.3% positive predictive value, 87.8% negative predictive value).
Conclusion: TVP-MRI might be a new and promising potential biomarker for predicting survival in newly diagnosed glioblastoma.

B-0608 14:08

Medulloblastoma in adults: identifying imaging biomarkers of genetic status in a prospective multi-centre study
V.C. Keil[1], M. Warmutz-Metz[2], C. Reh[1], J. Enkirch[1], H.H. Schild[1], T. Pietsch[1], E. Hattingen[1], P. Hau[3]; [1]*Bonn/DE*, [2]*Würzburg/DE*, [3]*Regensburg/DE (vera.keil@ukb.uni-bonn.de)*

Purpose: Medulloblastomas are rare in adults. Histopathological and molecular profiles are known to influence the course of disease. This study is a first radiogenomic approach to identify MR imaging biomarkers of molecular subtypes in adults with medulloblastomas, which may facilitate pre-operative tumour assessment and elucidate differences between adult and paediatric tumours. This is a subanalysis of the multi-center NOA-07 study.
Methods and Materials: Between 2008 and 2014, 18 neuro-oncological centers recruited 28 patients above 21 years with confirmed and molecularly sub-grouped medulloblastomas and full pre-operative MRI datasets (T1w, T2w, FLAIR and contrast-enhanced T1w sequences). Morphological characteristics (predefined as: enhancement pattern, T1 and T2 signal, hemorrhage) and further tumour and edema volumes, location, Chang criteria and hydrocephalus were evaluated by 3 experienced neuroradiologists. These MR findings were matched to histological and molecular subtypes (Fischer and ANOVA testing). Results were compared to findings from the only radiogenomic medulloblastoma study in children (S Perreault et al., AJNR 2014).
Results: Relation to the 4th ventricle and lower rhombic limb, edema volume, CNS metastases, non-enhancing tumour volume (Chang larger 2) and hydrocephalus differed significantly between molecular subtypes (P=0.01 to 0.04 respectively). None of these criteria matched with corresponding findings in paediatric medulloblastomas. Perifocal edema was larger in the desmoplastic subtype (P=0.01). Except for hemorrhage, none of the predefined MR-morphological characteristics could differentiate between the molecular or histopathological subtypes.
Conclusion: There are indicators that prognostically different molecular subtypes of adult medulloblastoma can be preoperatively identified based on MRI imaging. These seem distinct from findings in children.

B-0609 14:16

Apparent diffusion coefficient and permeability parameters from dynamic contrast-enhanced perfusion MR imaging: preliminary correlation study with glioma genetic profiles
J. Zhao, J.-P. Chu, Y.-L. Wang, X.-B. Li, J.-Y. Wang, Y.-K. Song; *Guangzhou/CN (zhaojing_sysu@126.com)*

Purpose: Preliminary evaluation of the efficacy of diffusion and DCE-MR imaging in predicting major genetic alterations in glioma.
Methods and Materials: 30 gliomas (male: 19, female: 11; mean age: 37.3 y) were retrospectively included and they all underwent DWI and DCE-MRI. ADC and permeability parameters (K^{trans}, Ve, Kep and iAUC) maps were generated. 5~10 ROIs were placed on tumour parenchyma. The max, min, mean value of ADC and the median, mean value of permeability parameters were recorded. Four major glioma genetic alterations (IDH-1; n=27), (MGMT; n=26), (ATRX; n=27) and Ki-67 (n=29) were included and their associations with ADC and permeability parameters were analysed.
Results: The max and mean value of ADC and mean value of Ve and iAUC in IDH-1 mutated group were significantly higher than those of the IDH-1 negative group (P<0.040) and the max value of ADC showed the highest diagnostic value; The mean value of ADC and Ve demonstrated the highest sensitivity (96.8%) and specificity (94.8%), respectively. Compared with ATRX-negative group, the max and mean value of ADC also significantly higher (P<0.001) and it demonstrated the highest diagnostic value. Further, in the analysis of MGMT-positive group, the mean/median value of K^{trans}, Kep, ADC and the max/mean value of ADC were significantly higher; in addition, we found that only Kep and ADC values were negatively correlated with Ki-67 (P<0.022).
Conclusion: Tumours with mutated IDH-1, ATRX and MGMT prone to have a higher permeability and ADC value. Thus, DWI and DCE-MRI, especially DWI, might be helpful in predicting genetic alterations.

B-0610 14:24

Hybrid methionine PET/MRI and MR spectroscopy in the diagnostic workup of primary brain tumour
C. Deuschl, S. Göricke, T. Pöppel, H. Quick, M. Forsting, L. Umutlu, M. Schlamann; *Essen/DE (cornelius.deuschl@uk-essen.de)*

Purpose: The objective of this study was to assess the diagnostic value of integrated 11C-methionine positron emission tomography/magnetic resonance imaging (methionine PET/MRI) and MRI with magnetic resonance spectroscopy (MRS) for suspected primary brain tumour.
Methods and Materials: Thirty-four consecutive patients with suspected primary brain tumour were prospectively enrolled for an integrated 11C-methionine PET-MRI with MRS. 5 Spectra were non diagnostic (25.6%); therefore, 29 spectroscopic data sets were available for definitive evaluation (85.3%). Reference standard was the histopathological report in 21 patients, whereas in the remaining 8 patients follow-up imaging was used. Two radiologists evaluated the integrated PET/MRI data sets and the MRI datasets with MRS regarding the most likely diagnosis and diagnostic confidence on a 5-point Likert-scale.
Results: In 29 patients 30 lesions were detected and classified by the reference standard. Twenty-seven lesions were primary brain tumour: 15 low-grade glioma (LGG), 12 high-grade glioma (HGG). Three lesions were classified as non-oncologic lesions. MRI with MRS correctly identified 27 of the 30 lesions (90%), whereas integrated PET/MRI was correct in 26 of the 30 lesions (Fig 1). Diagnostic confidence was better for MRI with MRS vs. integrated PET/MRI (4.3±0.8 vs. 4.1±1.1), but did not reach significance (p < 0.17).
Conclusion: This is the first study comparing the clinical impact of integrated PET/MRI and MRI with MRS. MRI with MRS was more sensitive and reached a higher diagnostic confidence than integrated PET/MRI, even though it was not significant.

B-0611 14:32

Micro-fractionated brain cancer high-dose radiosurgery observed using 3D x-ray phase contrast CT

G.E. Barbone[1], P. Romanelli[2], G. Battaglia[3], A. Mittone[4], M.F. Reiser[5], S. Auweter[5], T. Gaaß[5], A. Bravin[4], P. Coan[5]; [1]*Garching/DE*, [2]*Milan/IT*, [3]*Pozzilli/IT*, [4]*Grenoble/FR*, [5]*Munich/DE*
(Giacomo.Barbone@physik.uni-muenchen.de)

Purpose: Current limitations in brain imaging, especially the lack of tissue discrimination at the cellular level, lead to the inability to detect microscopic spread of cancerous tissue and to verify the survival of cancer cells following surgical resection, chemo- or radio-therapy. We used high sensitivity of x-rays Phase Contrast micro-computed tomography (PCI-CT) to non-invasively study the effects of a novel spatially fractionated single-stage high-dose radiotherapy technique, Microbeam Radiation Therapy (MRT), administered in-vivo to both healthy and cancerous rat brains.
Methods and Materials: 9 Fisher rats implanted with 9L gliosarcoma were treated with MRT (75 microns-thick micro-beams reaching up to 600Gy peak doses) and then imaged by PCI-CT (with 32 keV x-rays and an imaging CCD camera with voxel size of 8^3 micron³).
Results: PCI-CT allows recognition and differentiation of brain anatomical details down to cellular level, and identification of single cancerous cells, microscopic cancerous cell-clusters far from the main lesion, tissue necrosis, neuronal degeneration, tumour oedema, high-density calcifications as well as micrometric MRT-transections. Furthermore, the technique permits the segmentation of full brain vessel networks down to blood micro-capillaries.
Conclusion: The ability of PCI-CT to replicate the accuracy of histology and to provide far more anatomical detail than MRI opens a fascinating novel avenue for brain imaging. This technique appears to be well suited for post-mortem studies of brain cancer dissemination and radiotherapy effects. In the future, PCI-CT may provide image-guidance during radiotherapy, e.g. by directing focused x-ray irradiation in the ablation of inlets of cancerous cells.

Assessment of intracranial meningioma-associated calcifications using susceptibility-weighted magnetic resonance imaging

L.C. Adams, S.M. Böker, Y.Y. Bender, E. Fallenberg, M. Wagner, R. Buchert, B. Hamm, M. Makowski; *Berlin/DE (lisa.adams@charite.de)*

Purpose: To determine the diagnostic performance of susceptibility-weighted magnetic resonance imaging (SW-MRI) for the detection of intracranial meningioma-associated calcifications compared to standard MR sequences, using computed tomography (CT) as a standard of reference.
Methods and Materials: MRI scans of 354 patients, who received a clinical brain MR with SW-MRI sequences between January 2014 and July 2016, were retrospectively evaluated and 316 patients were included. 50 patients had positive findings for intracranial meningioma-associated calcifications on CT scans. Calcification diameter was used to assess correlation between imaging modalities. Sensitivity and specificity as well as intra- and interobserver reliability were calculated for SW-MRI and standard MRI sequences.
Results: SW-MRI reached a sensitivity of 94% (95% CI: 83-99%) and a specificity of 95% (95% CI: 92-98%) for the detection of meningioma-associated calcifications, while standard MR yielded a sensitivity of 64% (95% CI: 49-77%) and a specificity of 94% (95% CI: 90-96%). Diameter measurements between SW-MRI and CT showed a close correlation (R^2= 0.993, p<0.001) with a slight overestimation of size, which, however, did not reach significance level (SW-MRI: 8.2 mm ± 7.2; CT: 6.8 mm ± 6.4, p>0.05). Interobserver-agreement for size measurements of calcifications was high on SW-MRI (κ = 0.85, p < 0.0001) and fair on standard MRI (κ = 0.29, p < 0.001).
Conclusion: The combination of SW magnitude and phase images enables an accurate detection of intracranial meningioma-associated calcifications, using CT as standard of reference, and offers a higher sensitivity and specificity than standard MRI sequences.

The role of diffusion-weighted imaging for radiological identification of molecular subgroups of medulloblastoma in children

L. Filograna, A. Mastronuzzi, E. Miele, C. Carducci, A. Cacchione, A. Napolitano, A. Carai, E. Ferretti, G.S. Colafati; *Rome/IT (chi.carducci@gmail.com)*

Purpose: Recent studies on genomic characterisation of medulloblastoma (MB) prompted the development of new classification combining histopathological and molecular approach.The identified subgroups have shown potential for improved risk stratification. The aim is to verify if DWI and ADC maps are able to predict new subgroups of MB.
Methods and Materials: Twenty-six patients with diagnosis of MB, with pretreatment MR imaging, histologic, genomic characterisation after surgery, were retrospectively selected. ADC maps were coregistered with T1w post-contrast and FLAIR images. ROIs were double-blindly selected (ADC): restricted, intermediate, not restricted areas and (post-contrast) absent, inhomogeneous, homogeneous areas. Standard t test was performed to evaluate differences among paired MB subgroups.
Results: No statistical significance was detected. A trend in differences was found for both restricted ADC values between WNT and group 3 (0.61+/- 0.36 vs 1.29+/- 0.10) and ADC values in areas of homogeneous contrast enhancement (0.44 +/- 0.26 vs 1.13 +/- 0.15). Mean values along with standard deviations: for areas of restricted ADC (WNT: 0.67+/- 0.03; SHH: 0.72 +/- 0.06; group 3: 0.81+/- 0.14; group 4: 0.74 +/- 0.11).
Conclusion: The study shows no statistically significant correlation between ADC values and T1 post-contrast between and within different MB subgroups. However, a trend was identified in restricted ADC value and ADC in areas of homogeneous contrast enhancement between WNT and group 3. The study demonstrates that it is not possible to predict the type of medulloblastoma based on ADC/contrast enhancement characteristics. A larger cohort of patients is needed to clarify their real potential to discriminate molecular MB subgroup before surgery as suggested by observed trend.

B-0614 14:56

Residual tumour identification with intra-operative CEUS during glioblastoma resection

F. Prada[1], M. Del Bene[1], A. Martegani[2], L. Aiani[2], L.M. Sconfienza[3], G. Mauri[3], L. Solbiati[4], B. Pollo[1], F. DiMeco[1]; [1]*Milan/IT*, [2]*Como/IT*, [3]*San Donato/IT*, [4]*Rozzano/IT (io@lucasconfienza.it)*

Purpose: Our purpose was to assess contrast-enhanced ultrasound (CEUS) capability to identify residual tumour mass during glioblastoma (GBM) surgery, in order to increase the extent of resection.
Methods and Materials: We prospectively evaluated 10 patients who underwent surgery for GBM removal with navigated ultrasound guidance. Navigated B-mode and CEUS were performed prior to resection, during resection and after complete tumour resection. Areas suspected for residual tumours on B-mode and CEUS were localised within the surgical field with navigated ultrasound and sent separately for histopathological analysis to confirm tumour presence.
Results: In all cases tumour remnants were visualised as hyperechoic areas on B-mode, highlighted as CEUS positive areas and confirmed as tumoural areas on hystopathological analysis. In 1 case only CEUS partially failed to demonstrate residual tumour because the residual hyperehoic area was devascularised prior to ultrasound contrast agent injection. In all cases CEUS enhanced B-mode findings.
Conclusion: As already shown in other neoplastic lesions in other organs CEUS is extremely specific in the identification of residual tumour. CEUS distinction between tumour and artefacts/normal brain on B-mode is based on its capability to show the vascularisation degree and not the echogenicity of the tissues. Therefore, CEUS can play a decisive role in the process of maximising GBM surgical resection.

B-0615 15:04

Texture analysis on diffusion-tensor imaging: discriminating glioblastomas from single brain metastasis

K. Skogen[1], A. Schulz[1], E. Helseth[1], J.B. Dormagen[1], B. Ganeshan[2], A. Server[1]; [1]*Oslo/NO*, [2]*London/UK (kaskog@ous-hf.no)*

Purpose: Texture analysis has been used to stage, differentiate and predict prognosis in many oncologic tumours. It has been used on CT, MRI and PET. The purpose of this study was to determine the diagnostic accuracy of discriminating glioblastoma (GBM) from single brain metastasis (MET) by assessing the heterogeneity of both the solid tumour and the peritumoural oedema with MRI texture analysis (MRTA).
Methods and Materials: Preoperative MRI examinations done on a 3T scanner of 44 patients were included, 23 GBM and 21 MET. MRTA was performed on the DTI in a representative ROI. The MRTA was assessed using a commercially available research software program (TexRAD) which applies a

filtration histogram technique for characterising tumour and peritumoural heterogeneity. The filtration step selectively filters and extracts texture features at different anatomical scales varying from 2mm (fine) to 6mm (coarse). Heterogeneity quantification was obtained by the statistical parameter entropy. A threshold value to differentiate GBM from MET with sensitivity and specificity was calculated by receiver operating characteristics (ROC) analysis.
Results: Quantifying the heterogeneity of the solid part of the tumour showed no significant difference between GBM and MET. However the heterogeneity of the GBMs peritumoural oedema was significantly higher than the oedema surrounding MET, differentiating them with a sensitivity of 90% and specificity of 80%.
Conclusion: Assessing the peritumoural heterogeneity can increase the radiological diagnostic accuracy when discriminating GBM and MET. This will facilitate the medical staging and optimise the planning for surgical resection of the tumour and postoperative management.

Progressive disease in glioblastoma: benefits and limitations of semi-automated volumetry

T. Huber, G. Alber, S. Bette, J. Kaesmacher, J. Gempt, B. Meyer, C. Zimmer, B. Wiestler, J.S. Kirschke; *Munich/DE (thomas.huber@med.uni-muenchen.de)*

Purpose: Definite detection of glioblastoma (GB) progression in follow-up MRIs is essential, both for clinical trials and everyday clinical routine. 3D-volumetry provides quantification of tumour extent, and might therefore facilitate unbiased disease assessment. Aim of the present study was to evaluate the utility of absolute changes in volume (delta) or regional, segmentation-based subtractions for detecting disease progression in longitudinal MRI follow-ups.
Methods and Materials: 165 high-resolution, 3-Tesla MRIs of 30 GB patients (23m, mean age 60y) were retrospectively included. Contrast enhancement (CV) and tumour-associated signal alterations in FLAIR images (FV) were semi-automatically segmented. Delta volumes (dCV, dFV) as well as regional subtractions (sCV, sFV) were assessed. For every follow-up, disease progression was classified according to the histopathologic results of resected specimen, decisions of the local multidisciplinary CNS tumour board and a consensus rating of the radiologic report.
Results: A generalized logistic mixed model for disease progression (yes/no) and the input variables dCV, dFV, sCV and sFV showed that only dCV was significantly associated with prediction of disease progression (P = .005). Delta volumes had a better accuracy than regional, segmentation-based subtractions (79 % versus 72 %) and a higher area under the curve in ROC analysis (.83 vs .75).
Conclusion: Absolute volume changes of the contrast enhancing tumour part were the most accurate volumetric determinant to detect progressive disease in GB follow-ups and outweighed FLAIR changes as well as regional image subtractions. This volumetric parameter might be valuable in upcoming objective response criteria for glioblastoma

Quantitative analysis of brain tumours perfusion with contrast-enhanced ultrasound

F. Prada[1], C. Richetta[1], M. Del Bene[1], L.M. Sconfienza[2], G. Mauri[2], L. Solbiati[3], F. DiMeco[1]; [1]*Milan/IT*, [2]*San Donato/IT*, [3]*Rozzano/IT (io@lucasconfienza.it)*

Purpose: Neuroimaging plays an essential role in brain tumours resection which is a major prognostic factor in order to increase the survival rate. Contrast enhanced ultrasound (CEUS) using intravascular contrast media enhances image quality and allows visualization of tumour's perfusion. Perfusion quantification is one of the newest application of CEUS and it may give a clue about tumour's biological features and vascularisation. Even though this technique is already well established in other fields, it has never been applied to Neurosurgery before. The aim of the study is to evaluate quantitatively different histological types of brain tumours in order to detect specific perfusion patterns which may correlate with molecular parameters and with antiangiogenetic treatment response.
Methods and Materials: We evaluated 102 DICOM clips recorded during brain tumour excision with the perfusion quantification software Vuebox©.
Results: Only 27 video clips were amenable for quantitative analysis. However we found that some parameters, particularly PE, mTTI and FT, seem to be related with tumour's grade and histology.
Conclusion: The use of Vuebox© underlined some conditions which may increase data variability or make the images inadequate for the quantitative evaluation. This allowed us to define a precise protocol for video clip acquisition which should make data loss less likely. Thanks to quantitative analysis we detected some differences in perfusion patterns between tumours with different histology.

Radiomics reveals prognostic information from baseline MRI in patients with glioblastoma

M. Ingrisch[1], M.J. Schneider[1], D. Nörenberg[1], G. Negrao de Figueiredo[1], K. Maier-Hein[2], B. Suchorska[1], M.F. Reiser[1], J.C. Tonn[1], B. Ertl-Wagner[1]; [1]*Munich/DE*, [2]*Heidelberg/DE (dominik.noerenberg@med.lmu.de)*

Purpose: Radiomics has recently gained much attention as a tool that promises to extract the maximal amount of information from standard-of-care images. The present study investigates whether a radiomics analysis can predict overall survival from T1-weighted contrast-enhanced baseline MR images in a uniformly treated cohort of glioblastoma patients.
Methods and Materials: This retrospective study was approved by the institutional review board and informed consent was waived. MR images from 66 patients with newly diagnosed GBM from a previous prospective study were analyzed. Tumour segmentation was performed manually on contrast-enhanced 3D T1-weighted images. Using these segmentations, n=100 quantitative image features characterizing tumour shape, signal intensity and texture were calculated by automated high-throughput analysis and prognostic models based on random survival forests were trained on the data. For each patient, mortality was predicted using leave-one-out cross validation and average prediction error was recorded. Association of predicted mortalities with overall survival was assessed using Kaplan-Meier analysis and univariate proportional hazard models.
Results: The final prognostic model predicted a median mortality of 32.3% (range 7.1% - 61%) with a prediction error of 34.5%. Kaplan-Mayer analysis clearly distinguished two patient groups with high and low predicted mortalities (p=8.0e-4). Low predicted mortality was found to be a favorable prognostic factor for overall survival in a univariate Cox proportional hazard model (p=1.7e-04).
Conclusion: Baseline MR imaging in GBM patients contains strong prognostic information, which become accessible by radiomics analysis using random survival forests.

Cerebrovascular events in glioblastome multiforme patients

T. Auer, M. Renovanz, F. Marini, M.A. Brockmann, Y. Tanyildizi; *Mainz/DE (y.tanyildizi@gmx.net)*

Purpose: Bevacizumab (BVZ) is a monoclonal antibody directed against vascular endothelial growth factor (VEGF) and has been suspected to increase the incident of ischemic stroke (IS) and intracranial hemorrhage (ICH) in GBM patients.
Methods and Materials: In this study 364 MRI of 82 GBM patients were eligible for analyses. All patients were treated with basic treatment. Out of the 82 patients, 40 were treated with BVZ in addition to basic treatment. (BVZ-group) The cohorts matched in age and gender. Vascular risk factors were analyzed retrospectively. The KPS was captured at the beginning and end of

the observation, and before and after the event. Chi-square test was used to evaluate the level of significance.
Results: In seven (8 % / 7/82) out of 82 patients a vascular pathology was detected with MRI. 4 (4.8 % / 4/82) of them revealed an IS, while ICH was detected in 3 (3.6 % / 3/82). 4 of them had been treated with BVZ- with a total of 3 IS (7.5% 3/40), and 1 ICH (2.5% / 1/40). Three of them were part of the control-group, with a total of 1 IS (2.3% / 1/42) and 2 ICH (4.7% / 2/42).
Conclusion: The incidence of vascular events did not differ significantly between patients receiving BVZ and the control group. Thus, BVZ treatment does not seem to be associated with an elevated risk for vascular events in GBM patients.

B-0620 14:16

1H magnetic resonance spectroscopy of supratentorial WHO grade II gliomas

A. Hebda, B. Bobek-Billewicz, G. Stasik-Pres, P. Wawrzyniak; *Gliwice/PL (ahebda@io.gliwice.pl)*

Purpose: Comparison of supratentorial WHO grade II gliomas spectroscopic image.
Methods and Materials: Group of 45 patients with supratentorial WHO grade II gliomas: 26/45 (58%) Astrocytoma fibrillare, 10/45 (22%) Astrocytoma fibrillare partim gemistocyticum, 9/45 (20%) Oligodendroglioma. All patient had their 1HMRS study in Cancer Center Gliwice before surgery. Studies were performed on 1.5 T or 3T scanners. Single voxel PRESS method was used with long (135 ms), and also in 43 patients short (30 ms) echo time (TE). Reference spectra were obtained from healthy tissue of contralateral hemisphere (ref). Spectra were analyzed with LCModel. Following metabolite ratios were calculated for TE135ms: Cho/Cr, NAA/Cr, Cho/NAA, Gly/Cr in lesion and reference and Cho lesion/ Cho ref, NAA lesion/NAA ref and Gly lesion/Gly ref. In TE30ms: mI/Cr, Glx/Cr in lesion and reference and mI lesion/mI ref, Glx lesion/Glx ref. Metabolite integrals between lesion and healthy tissues were compared with statistical methods using STATISTICA 10 software.
Results: Maximal and minimal values in groups: Astrocytoma fibrillare: Cho/Cr 1.17-3.96, NAA/Cr 0.31-2.19, Cho/NAA 0.69-6.21, Gly/Cr 0.04-0.72, mI/Cr 0.19-1.36, Glx/Cr 0.03-5.13, mIlesion/ mIref 0.55-3.09, Glxlesion/Glxref 0.01-2.00, Cholesion /Choref 0,27-3,60, NAAlesion/NAAref 0,06-0,69. Astrocytoma fibrillare partim gemistocyticum: Cho/Cr 1.09-6.40, NAA/Cr 0.50-1.33, Cho/NAA 1.40-5.07, Gly/Cr 0.21-0.98, mI/Cr 0.37-0.92, Glx/Cr 0.29-4.16, mIlesion/mIref 0.70-1.95, Glxlesion/Glxref 0.27-2.00, Cholesion/Choref 0.87-2.80, NAAlesion/NAAref 0.01-0.40.
Oligodendroglioma: Cho/Cr 1.01-7.23, NAA/Cr 0.50-1.54, Cho/NAA 0.68-4.07, Gly/Cr 0.50-1.11, mI/Cr 0.35-0.74, Glx/Cr 0.81-3.35, mIlesion/mIref 0.88-2.34, Glxlesion/Glxref 0.29-1.10, Cholesion /Choref 0.93-5.08, NAAlesion /NAAref 0.30-0.68.
Conclusion: No significant differences in 1HMRS were found between groups: Astrocytoma fibrillare, Astrocytoma fibrillare partim gemistocyticum and Oligodendroglioma.

B-0621 14:24

Multiparametric MRI assessment of glioblastoma for predicting patient survival

A. Gimeno[1], G. Blasco[1], P. Daunis-i-Estadella[1], C. Biarnés[1], J. Sanchez-Gonzalez[2], A. Alberich-Bayarri[3], M. Puigdemont[1], S. Pedraza[1], J. Puig[1]; [1]*Girona/ES*, [2]*Madrid/ES*, [3]*Valencia/ES (fredigimeno1989@gmail.com)*

Purpose: MRI biomarkers role in prognosis of newly diagnosed glioblastoma remains unclear. We retrospectively determined the usefulness of dynamic susceptibility contrast (DSC), permeability maps, diffusion parameters, extensive battery of qualitative findings for contrast-enhancing lesion (CEL) and surrounding non-CEL in predicting survival.
Methods and Materials: Before treatment, 72 consecutive patients (45 men; mean age, 64 years) with histologically proven glioblastoma underwent 1.5T MRI (anatomical, first-pass DSC, DWI and post-contrast T1-weighted sequences). Perfusion maps were computed with the Bayesian approach. Volumes of interest for cerebral blood (CB) volume ratio, CB flow ratio, mean transit time (MTT), time-to-peak, delay time (DT), permeability constant (k_2), and apparent diffusion coefficient (ADC) in CEL, non-CEL, and contralateral tissue using Olea Sphere V.3.0 software (Olea Medical, La Ciotat, France) we determined. We evaluated 26 VASARI descriptors. Patients were classified by survival:<1year and >1year. Surgery, radiotherapy and chemotherapy was considered complete treatment.
Results: Forty-nine patients (68%) survived<1year. Thirty-nine (54.16%) underwent complete treatment. Survival groups differed in age (62.21±12.53 vs 50.63±15.1years;P<0.001), ADC-CEL (0.98±0.97 vs 0.78±0.05mm^2/s;P=0.032), delay-CEL (-0.41±0.82 vs 0.07±0.54sec; P=0.043), DT-nonCEL (-0.26±0.58 vs 0.18±0.47sec;P=0.01) and treatment (P<0.001), for <1 and >1year survival, respectively. In univariate analysis, complete treatment best predicted survival at 1 year (AUC=0.774, 60.6% sensitivity, 94.3% specificity, 95.6% positive predictive value, 54.1% negative predictive value). However, DT-CEL and age yielded the best combined prediction of survival (AUC=0.859, 86.7% sensitivity, 73.3% specificity, 86.7% positive predictive value, 73.3% negative predictive value).
Conclusion: Beyond well-known survival factors, our data suggests perfusion parameter DT might help predict survival in newly diagnosed glioblastoma.

B-0622 14:32

Evaluation of deep brain large metastasis after hypofractioning stereotactic radiotherapy

A.V. Smirnova, O. Lukina, N. Plakhotina, P. Ivanov, A. Kuzmin, I. Zubatkina; *St. Petersburg/RU (smirnova_alina@bk.ru)*

Purpose: To asses by MRI the dynamic changes of deep brain large metastases after hypofractionation stereotactic radiation therapy.
Methods and Materials: In retrospective analysis, 146 patients (mean age 55 y.o.) with 215 brain metastases, treated by hypofractioning radiotherapy were included (dose 8-10 Gy, mean metastasis volume 1.5 cm^3). 1.5 and 3.0T scanners were used with T13D sequences 1mm before and after contrast enhancing, T2 WI tra 2mm, flair tra 1-3mm, T2 WI cor 2mm, DWI. In 21 patients SWI was added. Tumour volume control was performed by GammaPlan 10.1 station. Patients were assessed before treatment, after 1 month, then, every 3 months.
Results: We have detected 6 radiologic patterns: tumour dimensions changes (68%), structural necrosis (28%), metastasis contrasting decreasing (64%), contour changes (83%), perifocal swelling area reduction (97%), intratumour haemorrhage (14%). The most variable were dimensions and volume changes: volume reduction or stabilisation, volume increasing by necrosis or disease progression, volume increasing on 1st control, then decreasing on 2nd control (necrosis), then increasing by haemorrhage.
Conclusion: Brain metastases reaction after radiotherapy characterised by heterogeneity. Imaging results (volume and contour changes, haemorrhage) are non-specific and may be signs of local disease progression or postradiation reactions. To clarify these findings, well-designed prospective multi-centre clinical trials are needed in future.

B-0623 14:40

Image-based response evaluation of intracranial lesions after cyberknife robotic radiosurgery: a radiological review

S. Kadri, N. Ahmed, K. Saeed, T. Mahmood; *Karachi/PK (shaziaum_wk@yahoo.com)*

Purpose: To study the radiological response of Cyber Knife Robotic Radiosurgery for treating intracranial tumours by tailored MRI sequences in providing maximum details.
Methods and Materials: 653 patients from Dec. 2012 to 2015 were selected with tumour less than 6 cm size, post-operative residual/recurrent tumour and surgically unresectable tumour. Follow-up MRI with 3D T1 contrast done every three monthly with added sequences according to need.
Results: Out of 653 patients, 35% of benign tumours showed reduction in size and 63% remain stable and 2% were resolved radiologically with clinical improvement in 80% whereas 47% of malignant tumours were reduced, 31% remain stable and 22% showed progression but 70% of patients showed clinical improvement. Considering meningiomas, 33% reduced, 65% stable and 2% resolved. In AVM, 82% reduced,13% remained stable and 5% were resolved. In gliomas, 64% low-grade gliomas and 58% high-grade gliomas were reduced with clinical improvement of 86% and 73%, respectively. Acoustic neuromas were 20% reduced and 80% stable. Metastasis were 83% reduced with 85% clinical improvement. Pituitary adenomas, 52% were reduced and 76% clinically improved and craniopharyngioma 53% were reduced and 88% were clinically improved.
Conclusion: Cyberknife is highly effective in controlling benign tumours and a good palliative modality for recurrent malignant and metastatic brain tumours. T1 3D contrast is the sequence of choice for most of the intra-cranial lesions after treatment follow-up, while in some cases, we utilized BTFE for cranial nerve definition. Longer follow-up is mandatory.

B-0624 14:48

Brain gliomas recurrence imaging after chemoradiation therapy

A.V. Smirnova[1], O. Lukina[1], N. Plakhotina[1], I. Lobanov[2], A. Kuzmin[1], A. Tkachev[3]; [1]*St. Petersburg/RU*, [2]*Nizhny Novgorod/RU*, [3]*Volgograd/RU (smirnova_alina@bk.ru)*

Purpose: To assess gliomas reaction after different types of radiation therapy.
Methods and Materials: In prospective trial 101 patients with brain gliomas were included. Patients were stratified into 2 groups: group A with grade I-II (n=58), group B with grade III-IV (n=43). 1.5 and 3.0T scanners were used with T13D sequences before and after contrast enhancing, T2 WI tra 2mm, flair tra 1-3mm, T2 WI cor 2mm, DWI. Tumour volume control was performed by GammaPlan 10.1 station. First assessment was before treatment, then after 1 month, next - every 3 months. For disease progression evaluation, stereotactic brain biopsy, PET-CT and CT-perfusion were used.

Results: We have detected 4 postradiation patterns: tumour dimension changes (reduction in 23% in group A and 9% in group B, stabilisation in 46 and 18%, respectively, increasing and then decreasing due to necrosis or haemorrhage - 15 and 7%, respectively, disease progression - 16 and 66%, respectively), contrasting decreasing (17% in group A and 8% in group B), contour changes (54 and 82%, respectively), intratumour haemorrhage (5% in group A and 12% in group B).
Conclusion: Postradiation reaction in patients after gliomas radiotherapy characterised by heterogeneity. Grade III-IV is the serious prognostic risk factor for disease recurrence. MRI-based only disease assessment potentially may be nonspecific and the complex diagnostic tools (included PET-CT and brain biopsy) should be used.

B-0625 14:56

MRI evaluation of sacral chordoma treated with carbon ion hadron therapy

D. Stoppa, S. Camisa, L. Preda, G. Viselner, G. Fontana, M. Fiore, P. Fossati, E. Ciurlia, R. Orecchia; *Pavia/IT (dvdstoppa@gmail.com)*

Purpose: To compare Response Evaluation Criteria in Solid Tumours (RECIST 1.1) to volume modifications, in order to evaluate the response in patients with sacral chordoma, not suitable for surgery, treated with carbon ions radiotherapy (CIRT) alone. Secondarily, to detect if baseline ADC values could predict response to treatment.
Methods and Materials: 39 patients were retrospectively studied, considering baseline (03/2013 - 04/2016) and follow-up multiparametric MR exams (mean follow-up 18 months, range 3-37), for a total of 195 examinations. The exams were performed with a 3T MR scanner (Siemens Magnetom Verio). For each exam, lesion maximum diameter and volume were obtained from T2w axial images. Lesion segmentations were consequently aligned to the ADC maps calculated from DWI sequences. The baseline ADC values within the lesion volume were analyzed.
Results: Considering maximum diameter changes between baseline MRIs and the last available follow-ups, according to RECIST 1.1, patients were classified: Partial Response (PR) 0%, Stable Disease (SD) 89.7% and Progressive Disease (PD) 10.3%. Considering lesion volume changes, applying the same response criteria, PR were 53.8%, SD 35.9% and PD 10.3%. The assessment of baseline examinations ADC maps, using Wilcoxon test, demonstrated significantly higher median ADC values of PD vs both PR and SD (p=0.0306 and p=0.0143 respectively).
Conclusion: Our study demonstrates that lesion volume measurement may be more accurate than maximum diameter to better stratify the response of sacral chordoma treated with CIRT. Preliminary results suggest that baseline ADC values could be predictive of response to CIRT, particularly to detect potential non responders.

Does elevated glucose metabolism correlate with higher cell density in neurofibroma?

D. Berzaczy, T. Traub-Weidinger, M. Mayerhoefer; *Vienna/AT (dominik.berzaczy@meduniwien.ac.at)*

Purpose: To investigate wether elevated glucose metabolism in neurofibroma determined by [18F]-FDG-PET is correlated with cell density in MRI as expressed through the apparent diffusion coefficient.
Methods and Materials: Maximum and mean standardised uptake values (SUVmax, SUVmean) on [18F]-FDG-PET/CT and [18F]-FDG-PET/MR were compared, and correlated with minimum and mean apparent diffusion coefficients (ADCmin, ADCmean).
Results: 12 (6 male/6 female, mean age was 16,2 ± 5,2 years) patients were prospectively included and analysed on a per-lesion (n=39) basis. The SUVmean of examined neurofibroma loci showed a moderate negative correlation of the ADC mean (r:-.441) and ADCmin (r:-.477), which both proved to be statistically significant (p=.005 and p=.002); the SUVmax of respective lesions however, showed a weaker negative correlation for ADCmean (r: -.311) and ADCmin (r: -.300) and did not reach statistical significance (p=.054 and p=.057).
Conclusion: Our data suggest that the ADCmean and min could possibly supersede the SUVmean as a potential determinant of malignant transformation in neurofibromatosis 1.

B-0627 15:12

3D texture analysis distinguishes low-grade chondrosarcoma from enchondroma

C.S. Lisson[1], C.G. Lisson[1], R. Mayer-Steinacker[1], T.F.E. Barth[1], A. von Baer[1], M. Schultheiss[1], M. Baumhauer[2], M. Beer[1], S.A. Schmidt[1]; [1]*Ulm/DE*, [2]*Heidelberg/DE (catharinavonend@gmail.com)*

Purpose: Differentiation of low-grade chondrosarcoma from enchondroma is both a radiologic and histologic challenge. Benign lesions do not require surgery, whereas curative surgical resection is mandatory in treatment for chondrosarcoma. Texture analysis is a promising tool in oncologic imaging. This study evaluates the performance and accuracy of MRI-based 3D texture analysis for the discrimination of G1-chondrosarcoma from enchondroma.
Methods and Materials: 22 patients were retrospectively evaluated: 11 patients with chondrosarcoma confirmed by histopathological diagnosis; 11 patients with enchondroma confirmed by histopathology or with a follow-up greater 5 years without changes in radiological features. Texture analysis was performed using the commercially available software mint Lesion by Mint Medical, a spinoff from the German Cancer Research Center (DKFZ). It allows 2D-and volumetric measurements and multiparametric texture analysis. Mann-Whitney U test and ROC-analysis were performed to identify the most discriminative texture features (kurtosis, entropy, skewness, MPP, uniformity), and by Youden's index optimal cut-off-values were selected.
Results: Significant differences were found in 6 out of 20 texture parameters ($p<0.05$). The area-under-the-ROC-curve for this 6 parameters to discriminate chondrosarcoma from enchondroma were 0.876 and 0.826 for kurtosis and skewness in ceT1-fs, respectively; in non-contrast T1 the values were 0.851, 0.793 and 0.822 for entropy, MPP and uniformity, respectively; in STIR it was 0.802 for MPP. Highest discriminatory power had kurtosis in ceT1-fs with an optimal cut-off ≥3.15 (82% sensitivity, 91% specificity, accuracy 86%).
Conclusion: MRI-based 3D texture analysis has the potential to distinguish low-grade chondrosarcoma from enchondroma by kurtosis in ceT1-fs having the highest power of discrimination.

Ewing's sarcoma: comparative diagnostic merits of different MRI pulse sequences

M.M. Saleh, T.A. Raafat, Y.M. Said, M.K.A. Asran, N.M. Abdel Wahab; *Cairo/EG (Mahmoud.m.ali@interns.kasralainy.edu.eg)*

Purpose: The aim of the study is to investigate the role of MRI using conventional and DWI sequences in initial evaluation and follow-up of pathologically proven cases of Ewing's sarcoma family of tumours.
Methods and Materials: Our study included 35 patients with pathologically proven Ewing's sarcoma family of tumours. We recorded the conventional and diffusion-weighted MR features of the examined lesions at initial presentation and after neo-adjuvant treatment including tumour location, size, signal characteristics, enhancement and breaking down. The diffusion images with ADC of the minimum and mean values were obtained.
Results: This study included (35) patients, their ages ranges from 2 to 41 years (mean age 17.2 years). Intermediate signal intensity on T1WI was noted in 77.1% of Ewing's sarcoma cases while high signal intensity on T2WI was noted in 62.9%. Our cases showed homogeneous contrast pattern and avid intensity contrast uptake in 45.7% and 74.3% respectively. Intra-tumoural breaking down was noted in 25.7% of the patients at initial assessment as compared to 65.7 % in patient post neo-adjuvant therapy with statistically significant P=0.005. The initial mean ADC of the Ewing's sarcoma family of tumours ($0.68x10^{-3}$ mm²/sec) was significantly different from that after neo-adjuvant treatment ($1.60x10^{-3}$ mm²/sec) with mean difference (-0.9125) and P<0.001.
Conclusion: MR imaging is the method of choice in the initial evaluation and follow-up of Ewing's sarcoma family of tumours. Diffusion-weighted MR imaging has the potential of being an additional non-invasive tool offering means for a more detailed analysis of these lesions and assessment of their therapeutic response.

A survey by the European Society of Breast Imaging on the utilisation of breast MRI: technical notes

P.A.T. Baltzer[1], P. Clauser[1], R. Mann[2], A. Athanasiou[3], K. Pinker[1], T.H. Helbich[1], F. Sardanelli[4], G. Forrai[5], H. Prosch[1]; [1]*Vienna/AT*, [2]*Nijmegen/NL*, [3]*Athens/GR*, [4]*Milan/IT*, [5]*Budapest/HU (patbaltzer@gmail.com)*

Purpose: While breast MRI is recognised as a powerful diagnostic tool in breast cancer diagnosis, standardisation in acquisition and interpretation still remain a matter of debate. The European Society of Breast Imaging (EUSOBI) launched a survey to gather data on MRI acquisition and interpretation in clinical practice.
Methods and Materials: A survey reviewed by the board and committees of the EUSOBI was distributed to the members online using a dedicated platform (SurveyMonkey). Data were extracted and summarised. Statistical analysis was performed using SPSS.
Results: 27.4% of the EUSOBI members answered the survey. The majority were radiologists (90.5%) based in a university hospital (51.9%). The majority of responders used exclusively 1.5T (57.3%) magnets. 22.6% used exclusively 3T and 19.5% both. Other field strengths were seldom used (0.6%). The majority of participants employed a dedicated breast coil with at least 7 channels, and an automatic injector for contrast medium (78.4% and 82.3%, respectively). 3D gradient echo (GE) imaging for dynamic contrast-enhanced sequences was used by 73.2%, 2D GE by 21.1% and both alternatively by 5.7%. Fat saturation (FS) was favoured over non-fat saturated (NFS) sequences for both T1 and T2 weightings (77% used FS-T1w alone and 71.4% used FS-T2w alone or along with non-FS sequences). 40% of the responders did not acquire DWI regularly.
Conclusion: Dedicated equipment (coils, injector), 1.5T and 3D dynamic GE sequences were used by majority of the survey participants. Of note, the majority prefers FS protocols and only a large minority uses new techniques such as DWI.

B-0630 14:08

A survey by the European Society of Breast Imaging on the utilisation of breast MRI: clinical indications

P. Clauser[1], H. Prosch[1], R. Mann[2], A. Athanasiou[3], K. Pinker[1], T.H. Helbich[1], F. Sardanelli[4], G. Forrai[5], P.A.T. Baltzer[1]; [1]*Vienna/AT*, [2]*Nijmegen/NL*, [3]*Athens/GR*, [4]*Milan/IT*, [5]*Budapest/HU (clauser.p@hotmail.it)*

Purpose: Breast MRI as a highly sensitive breast imaging modality is applied to a variety of clinical indications. Although consensus recommendations have been published, institutional and national variations in the use of breast MRI are a matter of debate. The European Society of Breast Imaging (EUSOBI) launched a survey to gather data on MRI application in clinical practice.
Methods and Materials: A survey reviewed by the executive board and the committees of the EUSOBI was distributed to the members online using a dedicated software platform (SurveyMonkey). Data were extracted and summarised. Statistical analysis was performed using SPSS.
Results: 27.4% of the EUSOBI-members answered the survey. The majority were radiologists (90.5%) based in university hospitals (51.9%). The majority of responders used MRI in the preoperative setting (85.7%). Differences in subgroups that receive MRI were found: in southern countries MRI was commonly performed in all cancer patients, while in northern countries it was performed according to recommendations (P<0.003). Other common indications were: carcinoma of unknown primary (89.6%), neoadjuvant chemotherapy (NAC) (84.2%), high-risk screening and nipple discharge (83.9%). MRI was performed as problem-solving by 83.0% of the responders. Evaluation of nipple discharge was more common in southern countries (P<0.001). In eastern countries, HR screening and evaluation of response during NAC were less frequent (P<0.036). MR-guided interventions were performed by only a minority of participants (35.4%).
Conclusion: Recommendations were generally followed. MRI was frequently used for preoperative staging and problem-solving but substantial international variations were noted. The availability of MRI-guided interventions could seemingly be improved.

B-0631 14:16

Kinetic breast MRI parameters of normal parenchyma in healthy individuals and invasive ductal carcinoma patients

M. Nadrljanski, Z. Jokovic, Z. Milosevic; *Belgrade/RS (dr.m.nadrljanski@gmail.com)*

Purpose: Dynamic contrast-enhanced MRI (DCE-MRI) kinetic parameters: wash-in (WI), washout (WO), and positive enhancement integral value (PEI) - the semiquantitative kinetic parameters were obtained from normal breast parenchyma of healthy individuals and patients with invasive ductal carcinoma (IDC).
Methods and Materials: Initial DCE-MRI exams of 30 patients with confirmed IDC (n1=30) were compared to those of the paired 30 healthy individuals (n2=30). The exams were realized on 1.5T MRI system with the full diagnostic protocol (T2W-STIR, T2W-TSE, T1W-TSE, 3D T1W C+ five series) with the generated parametric maps for the semiquantitative kinetic parameters: WI, WO and PEI. The region of interest was defined in the normal breast parenchyma for both groups.
Results: The average WI and WO values for the normal parenchyma in patients with IDC were significantly different compared to those of the healthy individuals (WI: 39.43 +/- 7.89 vs 29.42 +/- 2.71, p less than 0.01 and WO: 35.10 +/- 7.58 vs 25.23 +/- 3.35, p less than 0.01). The same applies to the PEI values, where the value for the normal parenchyma in IDC patients was 101.7+/-18.72, compared to 72.02+/-9.85 in healthy individuals (p less than 0.01) - considered statistically significant.
Conclusion: DCE-MRI kinetic parameters (WI, WO and PEI) in normal breast parenchyma, may be considered associated with IDC, therefore should the results of the large studies confirm the data, these parameters may serve as the potential cancer risk markers, together with morpho-dynamic and functional imaging parameters.

B-0632 14:24

Occult nipple-areola complex (NAC) involvement in breast cancer patients: can we predict it with preoperative MRI before nipple sparing (NSM) or skin sparing (SSM) mastectomy?

C. Berzovini, F. Esposito, M. Durando, G. Mariscotti, M. Brunetti, L. Bergamasco, P. Fonio, G. Gandini; *Turin/IT (claudioberzovini@yahoo.it)*

Purpose: To identify clinically occult NAC involvement using preoperative MRI, to properly select patients with newly diagnosed breast cancer eligible for NSM; to compare MRI findings with histopathological features and intraoperative evaluation of retroareolar tissue.
Methods and Materials: Retrospective monocentric analysis of 180 patients, who underwent preoperative breast MRI between January 2010 and June 2016 before NSM/SSM. Tumour features at MRI [mass-non mass lesion, diameter, lesion-NAC distance (LND)] and pathology (diameter, histopathological type, receptor status) were recorded, as well as type of surgery (NSM/SSM) and presence (NAC+) or absence (NAC-) of tumour at intraoperative evaluation of retroareolar tissue. Mann-Whitney test, multivariate and ROC curve analysis were applied.
Results: Over the study period, 109 patients were NAC- and 71 NAC+ (61 NSM and 119 SSM performed). Among the examined imaging and histological features, only MRI LND was associated with NAC+, being LND statistically different between NAC+ and NAC- patients (p<0.001). MRI LND proved to be a good discriminant between the two groups (area under the ROC-curve 0.8): the best cutoff was determined at 12mm, with sensibility 73%, specificity 82%, odds ratio=13 (vs 86%, 48% and 5, respectively, for 20mm distance cutoff). The analysis of this subgroup showed no further features statistically associated with NAC+.
Conclusion: MRI is able to identify most NAC+ patients. LND≤12mm is associated with increased risk of NAC+; this cutoff has higher specificity than 20mm LND cutoff (p<0.0001), allowing a larger proportion of patients to be selected for NSM, even though intraoperative retroareolar tissue examination remains mandatory.

B-0633 14:32

MRI to predict nipple-areola complex (NAC) involvement: an automatic method to compute the 3D distance between the NAC and tumour

V. Giannini, S. Mazzetti, V. Doronzio, E. Tabone, F. Arabia, S. Pedalino, D. Regge, L. Martincich; *Candiolo/IT (valentina.giannini@ircc.it)*

Purpose: To describe and test an innovative and automatic method able to compute the 3D tumour-NAC distance and to assess its role in predicting NAC involvement.
Methods and Materials: 99 patients scheduled to NAC sparing mastectomy underwent MR examination at 1.5T. The method developed consists of different steps. First, the NAC and the lesion were automatically segmented on the T2w sagittal and the maximum intensity projection over time images, respectively. Then, the 3D distance was computed between the base of the NAC and the nearest margin of the lesion. 3D distance was compared with

manual 2D measurements. NAC involvement was defined by the presence of invasive ductal/lobular carcinoma and/or ductal carcinoma in situ/ductal intraepithelial neoplasia.
Results: The tumour-NAC distance was computed on a dataset of 95/99 patients (25 having NAC involvement), since 3 patients were discarded because their lesions were not segmented and one was removed because the NAC was not detected by the system. Area under the ROC curve was equal to 0.830 (95%CI: 0.749-0.911), 0.676 (95%CI: 0.557-0.796), 0.664 (95%CI: 0.542-0.786), 0.664 (95%CI: 0.542-0.783) for the automatic, manual axial, manual sagittal, minimum manual distances, respectively. The best performances were obtained by the automatic distance (cutoff=21mm) with sensitivity, specificity, positive predictive value and negative predictive value of 72%, 80%, 56% and 89%, respectively.
Conclusion: The proposed automatic method outperformed the manual 2D measurements in assessing the NAC involvement and it could provide reliable information for surgical planning and intraoperative management of candidate patients to the NAC sparing mastectomy.

B-0634 14:40

MRI evaluation of post-mastectomy irradiated breast implants: prevalence and analysis of complications

M. Telegrafo, L. Rella, A. Cirilli, V. Ranieri, A. Stabile Ianora, G. Angelelli, M. Moschetta; *Bari/IT (mikitele@hotmail.it)*

Purpose: To evaluate the effect of post-mastectomy radiation therapy (RT) on breast implants as detected by magnetic resonance imaging (MRI) searching for short-term complications.
Methods and Materials: 140 patients (total of 144 implants) were evaluated by MRI; 80 (group 1) had undergone RT, whereas the remaining 60 patients (group 2) underwent mastectomy with implant reconstruction without RT. Two radiologists evaluated MRI images searching for implant rupture signs, sub-capsular seromas, capsular contracture, soft-tissue oedema, peri-implant fluid collections. Implant ruptures were classified as severe complications; seromas and capsular contractures as moderate complications; oedema and fluid collections as mild complications. The prevalence of MRI findings in two groups was calculated and compared by unpaired t-test. Cohen's kappa statistics was used to assess interobserver agreement.
Results: 69/144 (48%) implants presented pathological findings at MRI with complication rates of 47.5 and 48.4 for groups 1 and 2, respectively. Two (5%) severe complications, 10 (26%) moderate complications, and 26 (69%) mild complications occurred in group 1 and surgical treatment was performed in 10 cases. Two (6%) severe, seven (23%) moderate and 22 (71%) mild complications occurred in group 2 and surgical treatment was performed in eight cases. No significant difference between the two groups was found ($p>0.1$). Almost perfect agreement between the two radiologists was found ($k=0.86$).
Conclusion: RT does not seem to cause a significant effect on breast implants in terms of complication rate in patients undergoing implant-based breast reconstruction. One-stage immediate implant-based breast reconstruction performed at the same time as mastectomy could be proposed.

B-0635 14:48

Multi-parametric MRI in differentiation of benign and malignant breast lesions: imaging interpretation and radiology-pathology correlation

Y.G.S.E. Shokry, R.M.K.E. Kamal, M.R.L. Louis, S.A.M.S. Salem; *Cairo/EG (youstina_youanna@yahoo.com)*

Purpose: The additive role of functional MRI (diffusion-weighted MRI and MR-spectroscopy) to dynamic contrast-enhanced MRI in characterization of breast lesions.
Methods and Materials: 35 female patients with 47 breast lesions were examined using 1.5 T MRI. Morphology and dynamic curves of the lesions were assessed. Analysis of DWI was done at b values 0, 500 and 850 s/mm² followed by quantitative analysis of ADC values. SV-MRS was done using (PRESS) technique for Choline peak measurement. Agreement between the results of each MRI modality and histopathological results was done.
Results: 47 breast lesions (pathologically proven 32/47 malignant and 15/47 benign) were analysed. The sensitivity and specificity were 87.5% and 93.3% respectively using morphology, 96.9% and 73.3% using dynamic curve pattern, 96.9% and 66.7% using DWI and 74.2% and 71.4% using MRS. The suggested ADC cut-off value was 1.063×10^{-3}mm²/s. The suggested cut-off value of Choline was 0.36 mmol/l. Combining dynamic curve with morphology increased the sensitivity and specificity to become 100% and 93.3%. Sensitivity and specificity were also increased after combining DWI with morphology to become 100% and 93.3%. Combining MRS with morphology increased the sensitivity to 90.3%, but the specificity was slightly reduced to 92.9%.
Conclusion: Post-processing and addition of DWI to dynamic contrast-enhanced MRI have improved the diagnostic performance of MRI. Addition of MRS has increased the sensitivity but slightly decreased the specificity of MRI. DWI and MRS are not recommended as standalone diagnostic modalities for breast lesions but should be interpreted in combination with morphological features and dynamic curves.

B-0636 14:56

Breast cancer radiomics in the semantic feature space: association with therapeutically relevant subtypes

P. Clauser[1], P. Kapetas[1], R. Woitek[1], M. Bernathova[1], F. Leone[2], K. Pinker[1], T.H. Helbich[1], P.A.T. Baltzer[1]; [1]*Vienna/AT*, [2]*Monza/IT (clauser.p@hotmail.it)*

Purpose: To identify semantic lesion features on breast MRI associated with therapeutically relevant breast cancer subtypes.
Methods and Materials: Prospectively collected consecutive patients with a diagnosis of invasive breast cancer undergoing multiparametric (high temporal resolution DCE, T2w, DWI) breast MRI at 3T were included in this IRB-approved observational study. Two experienced breast radiologists evaluated semantic lesion features: T2w signal intensity; size; number and type of lesions (mass, non-mass, both); presence of blooming sign; perifocal oedema; feeding vessels; most suspicious curve type (I-III). Oestrogen receptor (ER) status, HER-2neu status and MIB-1/Ki67 were assessed according to international recommendations. A multivariate, 10-fold cross-validated data mining approach was run on the semantic feature space to predict dichotomised ER, HER-2neu and MIB-1/Ki67 status.
Results: 77 patients (mean age: 56 years, range 29-85) with 77 index lesions (55 mass and 22 mass with non-mass) were included. Signal intensity on T2w TSE sequences was high in 90.9% of the lesions with a high MIB-1/Ki67 ($P=0.001$). 97.4% of lesions not presenting with perifocal oedema were ER positive ($P<0.001$). Absence of non-mass components was highly specific (92.7%) for HER-2neu negativity ($P=0.005$). The remaining semantic features did not provide incremental information to further distinguish these subtypes.
Conclusion: Semantic lesion features such as intensity on T2w sequences, perifocal oedema and lesion type were found useful for characterising therapeutically relevant subtypes of invasive breast cancer by MRI.

B-0637 15:04

The spatial relationship of malignant and benign breast lesions to the fat-gland interface in three-dimensional magnetic resonance imaging

S. Shin[1], W. Kim[2], W. Moon[1]; [1]*Seoul/KR*, [2]*Daegu/KR (dominica84@naver.com)*

Purpose: To investigate the location of malignant and benign breast lesions based on the spatial relationship of the fat-gland interface using MR imaging in women under 50 years old.
Methods and Materials: A total of 881 women (≤50 years) with 792 malignant and 165 benign lesions were included. The location of 957 lesions based on the spatial relationship of the fat-gland interface was reviewed using MR imaging with five categories (within gland; near interface, gland side; interface; near interface, fat side; and within fat). The shortest distance between lesion center and fat-gland interface was measured for quantitative analyses. We calculated percentages of breast lesions and breast volumes within 2mm and 1cm from the fat-gland interface.
Results: Most breast lesions were located in or near the interface in qualitative (89.7%) and quantitative (90.0%, 1cm within the interface) analyses. Malignant lesions were located in or near the interface in significantly higher proportions in qualitative (94.3% vs 67.3%, $P<.0001$) and quantitative (49.7% vs 34.5%, $P=.0004$, 2mm within the interface) analyses than benign lesions. The calculated percentages of breast volumes within 2mm and 1cm from the interface were 12.3% and 55.7%, respectively.
Conclusion: Most breast lesions were located in or near the fat-gland interface, with a higher proportion in malignant lesions being found in this region than benign lesions in women under 50 years old. This phenomenon may reflect a biological importance of the fat-gland interface in breast cancer development and progression.

B-0638 15:12

MRI for the assessment of malignancy in mammographic microcalcifications

B. Bennani-Baiti[1], M. Dietzel[2], P.A.T. Baltzer[1]; [1]*Vienna/AT*, [2]*Erlangen/DE (barbara.bennani-baiti@meduniwien.ac.at)*

Purpose: Assess the performance of breast MRI to diagnose breast cancer in BI-RADS 4 microcalcifications detected by mammography.
Methods and Materials: This retrospective, IRB-approved study included 248 consecutive contrast-enhanced breast MRI (1.5T, protocol in accordance with EUSOBI recommendations) performed to further diagnose BI-RADS 4 microcalcifications detected at mammography during a 3-year period. Standard of reference had to be established by histopathology. Routine consensus reading results by two radiologists were dichotomised as positive or negative

and compared with the reference standard (benign vs malignant) to calculate diagnostic parameters.
Results: There were 107 malignant and 141 benign microcalcifications. Malignancy rates were 18.3% (23/126 BI-RADS 4a), 41.7% (25/60 BI-RADS 4b) and 95% (59/62 BI-RADS 4c). There were 103 true-positive, 116 true-negative, 25 false-positive, and 4 false-negative (one invasive cancer, three DCIS; 2 BI-RADS 4c, 1 BI-RADS 4b on mammography) breast MRI findings, effecting a sensitivity, specificity, PPV, and NPV of 96.3% (95%-CI 90.7-99.0%), 82.3% (95%-CI 75.0-88.2%), 80.5% (95%-CI 72.5-87.0%) and 96.7% (95%-CI 91.7-99.1%), respectively.
Conclusion: MRI is an accurate tool to further diagnose BI-RADS 4 microcalcifications. MRI may be particularly helpful to exclude invasive cancer before surgery and may allow to obviate unnecessary biopsies in microcalcifications not highly suspicious for malignancy.

B-0639 15:20

Correlation of the radiological findings with the Baker score of capsular contracture: does it have added value?
G. Bar On, H. Maresky, V. Kent, G. Landau, I. Wiser, P. Gottlieb, S. Tal;
Zrefin/IL (galiam2004@gmail.com)

Purpose: The purpose of our research was to determine and whether there is a correlation between the clinical and the radiological findings of capsular contracture and if the MRI has added value.
Methods and Materials: Our retrospective study included 29 patients (with an age range of 39 - 55.75, average 48) who had undergone cosmetic breast augmentation or breast reconstruction surgery with silicone implants, 58 breast with clinical features of capsular contracture. The reports were performed by two breast imaging specialists and correlated with the Baker score. These assessments were made by two plastic surgeons using palpation.
Results: The clinical examination proved the following distribution of the Baker score: Baker grade I - II 39 (69.6%), Baker grade III - IV 17 (30.4%). Our findings include a change in the shape of the implant 14 (25.0%), a thickening of the fibrous capsule 0.19 (0.15-0.22) cm, enhancement of the capsule and the presence of implants rupture 30 (53.6%). The thickening of capsule was not associated with Baker grade (p=0.613). 21.4% (3/14) of patients with no enhancement, 29% (7/24) of mild to moderate enhancement, 16.7% (2/12) with severe enhancement had Baker of III-IV (p=0.741). There are no difference between enhancement and thickening of the capsule mean (SE) thickness: no enhancement 0.25 (0.017), mild to moderate enhancement 0.26 (0.022), with severe enhancement 0.26 (0.026), p=0.941.
Conclusion: There is no association between the Baker score and radiological findings. This emphasises the need of MRI imaging. It is an important objective measurement which can add value for physical examinations.

Meniscus T2 relaxation time and knee joint degeneration
R. Kijowski, B. Beduhn, F. Liu; *Madison, WI/US (rkijowski@uwhealth.org)*

Purpose: To investigate changes in meniscus T2 relaxation time at various stages of knee joint degeneration.
Methods and Materials: T2 mapping was performed on the knees of 121 patients with meniscus tears who underwent subsequent knee arthroscopy. T2 of the torn and untorn portions of the meniscus with a tear and the T2 of the contralateral untorn meniscus were measured. The severity of radiographic osteoarthritis was assessed using the Kellgren-Lawrence (KL) grading scale. The severity of cartilage loss within the knee joint at arthroscopy was numerically scored. Kruskal-Wallis tests were used to compare meniscus T2 between KL0, KL1, and KL2 subjects, while Spearman correlation coefficients were used to correlate T2 of the meniscus and severity of cartilage loss in the same compartment of the knee joint.
Results: There was a significant difference (p<0.001) in meniscus T2 between KL0, KL1, and KL2 subjects in both the torn and untorn portions of the meniscus with a tear and within the untorn contralateral meniscus with KL2 subjects having highest T2 and KL0 subjects having lowest T2. There was a significant direct moderate correlation (rho=0.535, p<0.001) between meniscus T2 and severity of adjacent cartilage loss.
Conclusion: Meniscus T2 was progressively higher in individuals with worsening radiographic knee joint degeneration indicating that joint degeneration leads to changes in the composition and microstructure of both torn and untorn meniscus. The direct correlation between meniscus T2 and the severity of adjacent cartilage loss indicates the important inter-relationship between changes in meniscus and cartilage during joint degeneration.

B-0641 14:17

Assessment of meniscal and cartilage damage of the knee with ultrahigh field imaging at 7Tesla: a comparison to 3Tesla imaging with arthroscopic correlation
B. Friebe, M. Richter, S. Penzlin, C. Staerke, F. Godenschweger, J. Ricke, S. Kropf, F. Fischbach, O. Speck; *Magdeburg/DE (bjoern.friebe@med.ovgu.de)*

Purpose: To determine the diagnostic accuracy of ultrahigh-field MRI at 7Tesla (7T-MRI) in meniscal tears and cartilage damage compared to clinical routine MRI at 3Tesla (3T-MRI).
Methods and Materials: 41 patients with suspected meniscal damage or mild osteoarthritis (Kellgren-Lawrence 0-2) received 7T-MRI as well as clinical routine 3T-MRI consecutively. The imaging protocol in both field strengths consisted of a PD-weighted fat saturated and a T1-weighted turbo spin echo (TSE) sequence with a higher resolution at 7T-MRI. Images were read blinded regarding field strength and patient characteristics by three readers with different experience in musculoskeletal MRI (3 years, 6 years and 10 years) according to a modified whole-organ magnetic resonance imaging score of the knee in osteoarthritis (WORMS). Arthroscopic reports as a gold standard were available for twelve patients.
Results: A multifactorial mixed model analysis was performed. The mean cumulated diagnostic score in 7T-MRI was significantly closer to the gold standard compared to 3T-MRI in patients where gold standard was available (p<0.001). In all 41 patients 7T-MRI detected significantly more severe damages in cartilage (p<0.001) and in meniscus (p<0.001). No difference in interreader variability between 3T and 7T was observed. Imaging acquisition time was similar.
Conclusion: Morphologic imaging of cartilage and meniscal damage of the knee in ultrahigh-field MRI at 7T with T1- and PD-weighted TSE-sequences has a significantly higher diagnostic accuracy than compared to 3T-MRI and can be performed with equal acquisition times exploiting higher resolution of 7T-MRI. 7T-MRI detected significantly more severe damages in cartilage as well as in meniscus.

B-0642 14:25

Weight loss regimens in obese and overweight individuals impact cartilage degeneration: 96-month data from the Osteoarthritis Initiative
G.C. Feuerriegel[1], A.S. Gersing[1], B.J. Schwaiger[1], J. Zarnowski[1], P.M. Jungmann[1], C.E. McCulloch[2], M.C. Nevitt[2], E.J. Rummeny[1], T.M. Link[2];
[1]*Munich/DE*, [2]*San Francisco, CA/US (g.feuerriegel@gmail.com)*

Purpose: To investigate MR-based cartilage biochemical degeneration and morphologic joint abnormalities over 96 months in overweight and obese subjects with stable weight and weight-loss and to assess how these changes are affected by different weight loss regimens.
Methods and Materials: Subjects with a BMI>25kg/m^2 from the Osteoarthritis Initiative (n=760; age 62.6±9.0y; 465 females) with risk factors for or radiographic mild to moderate osteoarthritis were included. Subjects losing weight (>5% of baseline BMI; N=380) were frequency matched to controls with stable weight (N=380) and categorised into groups regarding the weight-loss method (diet and exercise, diet only, exercise only). 3T MRI of the right knee was performed at baseline, 48-and 96-months. T2 changes of cartilage composition, including laminar and texture analysis as well as morphological knee abnormalities, assessed with Whole-Organ-Magnetic-Resonance-Imaging-Scores (WORMS) were analysed using mixed random effects models to calculate associations between weight-loss degree and regimen.
Results: Progression of cartilage WORMS was significantly lower in the weight-loss group compared to controls (P<0.001) over 96 months. Subjects with weight-loss showed significantly less T2-value increase in the bone layer of all compartments (P<0.03, for each). Rates of increase in cartilage T2 averaged over all compartments were lowest in the diet and diet and exercise groups compared to the stable weight group (P=0.042 and P=0.003, respectively). Weight-loss through exercise alone was not beneficial.
Conclusion: Results suggest that cartilage degeneration is slowed through weight-loss in obese and overweight subjects over 96-months. This protective effect was strongest in subjects losing weight through combined exercise and diet programs.

B-0643 14:33

Risk factors for biochemical cartilage alterations in young asymptomatic individuals

A.F. Tschischka, B. Bittersohl, N. Heinzler, J. Boos, A. Joel, F. Fichter, G. Antoch, C. Schleich; *Düsseldorf/DE (Alexander.Tschischka@med.uni-duesseldorf.de)*

Purpose: To assess the glycosaminoglycan (GAG) content of lumbar intervertebral discs (IVD) in healthy volunteers with facet tropism (FT) and sagittal facet joint (FJ) orientation using glycosaminoglycan chemical exchange saturation transfer imaging (gagCEST).
Methods and Materials: Seventy-five lumbar IVDs of twenty-five young, healthy volunteers without any history of lumbar spine pathologies (13 female; 12 male; mean age: 28.0 ± 4.4 years; range: 21 - 35 years) were examined with a 3T MRI scanner. Orientation of FT and FJ were assessed for L3/4, L4/5 and L5/S1 using standard T2 weighted images. Biochemical gagCEST imaging was used to determine the GAG content of each nucleus pulposus (NP) and annulus fibrosus (AF).
Results: Significantly higher gagCEST values of NP were found in volunteers without FT and normal FJ orientation compared to volunteers with FT and sagittal FJ orientation > 45° ($p < 0.0001$). GagCEST values were significantly higher in volunteers without FT compared to volunteers with moderate or severe FT (moderate FT: $p < 0.0001$; severe FT: $p = 0.0033$). Volunteers with normal FJ orientation showed significantly higher gagCEST values compared to those with sagittal FJ orientation > 45° ($p < 0.001$). We found a significant, negative correlation between gagCEST values and higher angels in sagittal FJ orientation ($rho=-0.459$; $p < 0.0001$).
Conclusion: GagCEST analysis indicated lower GAG values of NP in young volunteers with FT and sagittal orientated FJ, indicating that FT and sagittal orientation of the FJ represent risk factors for the development of early biochemical alterations of lumbar IVDs.

Simultaneously measured T2 and dGEMRIC indices do not correlate in an experimental, ovine FAI model

F. Schmaranzer[1], L. Arendt[2], N. Wolfer[2], T. Lerch[1], S. Steppacher[1], K. Nuss[2], P. Kircher[2], B. von Rechenberg[2], M. Tannast[1]; [1]*Berne/CH*, [2]*Zurich/CH (schmaflo@gmail.com)*

Purpose: dGEMRIC and T2 mapping estimate glycosaminglycan respectively water content and collagen fiber network organisation. These techniques are increasingly used in prearthritic conditions such as femoroacetabular impingement (FAI). However their correlation is yet to be established. Hence we aimed to correlate T2 and dGEMRIC indices in a validated, experimental ovine FAI model.
Methods and Materials: This experimental, controlled, prospective study on 5 sheep (10 hips) was conducted after IRB approval. Five sheep underwent unilateral surgical induction of FAI by varus intertrochanteric osteotomy, which rotates the naturally aspherical ovine femoral head into the acetabulum, inducing typical focal chondrolabral damage as seen in humans. Correction of the deformity was performed after 70 days. No surgery was performed in the 5 contralateral hip. Sheep were sacrificed after further 70 days. One hour before sacrifice sheep received i.v gadolinium-DTPA and roamed free. Hip were dissected to fit into the coil. dGEMRIC and T2 maps (inversion recovery technique) were obtained at 3T. dGEMRIC and T2 times were fitted and merged with radial PD-w morphologic slices using a specifically developed software (GT1*map, Gyro Tools) to enable simultaneous dGEMRIC and T2 measurements in the same region of interest. Peripheral and central regions of interest measured at the 12 acetabular and femoral clock-face positions were correlated using linear regression analysis ($p<0.05$).
Results: No correlation between acetabular/femoral dGMERIC and T2 indices could be found.
Conclusion: No correlation between dGEMRIC and T2 indices was observed which suggests that both techniques show complementary effects in cartilage.

Can the offset correction in experimentally induced ovine, cam FAI stop the process of biochemical and histologic cartilage degeneration: a pilot study

F. Schmaranzer[1], L. Arendt[2], N. Wolfer[2], C. Zurmühle[1], S. Steppacher[1], K. Nuss[2], P. Kircher[2], B. von Rechenberg[2], M. Tannast[1]; [1]*Berne/CH*, [2]*Zurich/CH (schmaflo@gmail.com)*

Purpose: The potential of hip preservation surgery for correction of femoroacetabular impingement (FAI) to prevent osteoarthritis progression is unclear. We asked whether offset creation in an ovine, cam FAI model can stop cartilage degeneration assessed with dGEMRIC and histologic Mankin scores.
Methods and Materials: This experimental, prospective study on 5 sheep (10 hips) was conducted after IRB approval. Five sheep underwent surgical FAI induction by varus intertrochanteric osteotomy unilaterally, which rotates the naturally aspherical ovine femoral head into the acetabulum, inducing typical focal chondrolabral damage as seen in humans. Offset was corrected after 70 days `FAI`. No surgery was performed in the 5 contralateral hips `No FAI`. Sheep were sacrificed after further 70 days. One hour before sacrifice sheep received i.v. gadolinium-DTPA and roamed free. Hips were dissected to fit into the coil. dGEMRIC maps (inversion recovery) were obtained at 3 T. Acetabular and femoral cartilage dGMERIC indices were measured radially at the 12 clock-face positions. Cartilage samples were stained with toluidine blue and degeneration was graded with the Mankin score. Unpaired T-tests were used for comparison ($p<0.05$).
Results: Acetabular and femoral dGEMRIC indices decrease after FAI induction and correction (411 ± 151ms vs 371 ± 110ms; $p<0.04$ respectively 391 ± 141ms vs 351 ± 91ms; $p<0.017$) while only femoral Mankin scores [0-15 points] increased (4 ± 3 vs 7 ± 3; $p<0.001$).
Conclusion: Despite a uniform dGEMRIC decrease no general histologic osteoarthritis progression was observed which underlines the potential of joint preservation hip surgery to stop the degenerative process.

Follow up after matrix based autologous chondrocyte transplantation of the hip vs microfracture: a comparative 3T-MRI-study

J. Haubold, J.M. Theysohn, C. Geis, K. Körsmeier, S. Landgraeber, O. Kraff, A. Lazik-Palm; *Essen/DE (johannes.haubold@uk-essen.de)*

Purpose: To evaluate the regeneration of acetabular cartilage repair tissue after matrix based autologous chrondrocyte transplantation (ACT) vs. microfracture (MF) using proton density weighted (PDw) high resolution 3T-MRI.
Methods and Materials: The hips of patients with acetabular focal cartilage defects resulting from CAM-impingement were examined 6 and 12 months after ACT (n = 20) and MF (n = 16) using 3T high-resolution PDw sequences. The cartilage repair tissue was evaluated using an adapted MOCART score rating the integrity, surface and signal-intensity of the repair tissue as well as surrounding pathologies to a maximum of 85 points. MOCART scores were compared between the groups using Student's t-test and one-way Anova with Bonferroni correction.
Results: Six and 12 months after MF the characteristics of the repair tissue were nearly stable with a mean MOCART score of 51 and 49 points respectively. After ACT the MOCART score increased from a mean of 58 points after 6 months to a mean of 66 points after 12 months mainly because of a proceeding defect filling (35% of the points increase). The absolute scores after 12 months ($p < 0.01$; one-way Anova with Bonferroni correction) as well as the individual differences between the 6- and 12-month follow up ($p < 0.001$; Student's t-test) were significantly higher after ACT compared to MF.
Conclusion: With PDw 3T MRI significant better cartilage regeneration could be shown in the follow up after ACT vs. MF. After ACT MOCART scores were significantly higher compared to MF in a one-year follow-up.

B-0647 15:05

Cartilage repair tissue composition assessed with 3T MRI correlates with trabecular bone remodeling in patients with spongiosa augmented matrix-associated chondrocyte implantation

A.S. Gersing, G. Feuerriegel, C. Holwein, A. Suchowierski, D.C. Karampinos, T. Baum, B.J. Schwaiger, E.J. Rummeny, P.M. Jungmann; *Munich/DE (alexandra.gersing@tum.de)*

Purpose: To investigate whether maturation of cartilage repair tissue is associated with maturation of the subchondral bone in patients after spongiosa augmented matrix-associated autologous chondrocyte implantation (MACI).
Methods and Materials: Both knees of patients (n=25, 25.5±7.8y; 10 female) were examined 2 years after unilateral spongiosa augmented MACI at one femoral condyle or patella using 3T MRI. Cartilage composition was assessed in all knee compartments using MRI T2 relaxation time mapping. Three dimensional phase-cycled balanced steady state free-precision (bSSFP) sequences were used in order to quantify the subchondral trabecular bone structure. Cartilage T2 values in the compartment treated with MACI (patella, medial or lateral femur condyle) that were higher than those of the corresponding compartment of the contralateral knee were considered as elevated. Values were compared using t-tests.
Results: Cartilage T2 values were significantly higher in compartments undergoing cartilage repair compared to the corresponding compartment of the contralateral knee (mean±standard error, 41.1±1.2ms vs. 38.8±1.6ms, P=0.035). Apparent trabecular thickness and bone fraction were also significantly higher in the compartment undergoing cartilage repair compared to the contralateral side (each comparison, P<0.001). Apparent trabecular thickness in the compartment undergoing cartilage repair was significantly

higher in patients with elevated cartilage T2 in the cartilage repair compartment (n=17; 0.37±0.05mm) compared to those without elevated cartilage T2 (n=8; 0.27±0.05mm; *P*=0.042).
Conclusion: After spongiosa augmented MACI, patients with elevated cartilage T2 values of the cartilage repair tissue showed thickened subchondral trabecular bone structure. The observed findings suggest a synergetic maturation of cartilage and subchondral bone after osteochondral transplantation.

Standing CT imaging to enable earlier and more accurate detection, diagnosis, and longitudinal monitoring of knee osteoarthritis features
N. Segal[1], A. Guermazi[2]; [1]*Kansas City, KS/US*, [2]*Boston, MA/US (segal-research@kumc.edu)*

Purpose: Radiographs are insensitive, requiring years to detect signs of knee osteoarthritis (OA). The optimal knee flexion angle and x-ray beam tilt to visualize the joint surface is person-specific and difficult to reproduce, further complicating radiographic detection of OA features before joint damage is advanced. This line of research was initiated to accelerate detection of knee OA through improving sensitivity and reliability of knee OA imaging.
Methods and Materials: Advances in cone beam CT have enabled lower limb imaging while standing (SCT). SCT has the same Relative Radiation Level as x-ray, while enabling weight-bearing 3D imaging that places physiological stress on the cartilage and menisci. Knees of older adults were imaged with fixed-flexion radiographs, MRI and pulsed SCT (isotropic resolution of 0.37 mm; FOV of 20x35cm; SCT footprint 121x147 cm) were read for OA features. Diagnostic performance as well as test-retest reliability statistics were compared between modalities.
Results: In comparison with fixed-flexion radiography, SCT demonstrated (1) higher sensitivity (93%, 100%) and accuracy (95%, 99%) for detection of osteophytes and subchondral cysts respectively, (2) high reliability for joint space width (JSW) measurements (ICC=0.94-0.97), and (3) significantly better correlation with central medial tibia cartilage morphology by MRI (SCT, r_s=0.84; radiographs, r_s=-0.66); and better differentiation between cartilage and subchondral bone compared with MRI.
Conclusion: SCT imaging offers greater diagnostic performance for tibiofemoral and patellofemoral OA features than radiographs, without increasing radiation dose. SCT is unique in offering 3D weight-bearing imaging of the bilateral legs and holds potential for wide-spread implementation.

MRI scoring of osteoarthritis of the ankle
S.M. Aboelmagd, S.B.L. Low, J.G. Cahir, A.P. Toms; *Norwich/UK (sharief.aboelmagd@nnuh.nhs.uk)*

Purpose: To develop a semi-quantitative MR-based scoring system for osteoarthritis of the ankle, and to determine its inter and intra-observer reproducibility. To examine association between MR features and radiographic osteoarthritis severity.
Methods and Materials: A retrospective sample of 50 patients who underwent MRI and plain radiographs were included. Features included were bone marrow lesions, bone marrow oedema, cysts, osteophytes and cartilage integrity. Anatomical zones were based on existing published systems. MR examinations were graded using the proposed system by two consultant radiologists and two residents. Radiographs were graded using a published Kellgren-Lawrence ankle score. Inter and intra-observer reproducibility were examined using a weighted kappa statistic (kw), and association between MR and radiographic severity using Spearman's Rho.
Results: Inter-reader reproducibility was "almost perfect" for all features for total joint scores (kw 0.88-0.97) except osteophyte scoring between the residents that was "substantial" (kappa 0.64). Zonal-based assessment demonstrated "substantial agreement" between the residents (kw 0.63-0.75), and "substantial" or "almost perfect" agreement for the consultants (kw 0.73-0.92). Intra-reader reproducibility was "substantial" or "almost perfect" for total joint scores (kw 0.79-0.97) and "moderate" to "almost perfect" for the zonal approach (kw 0.51-0.89). Confidence intervals were narrow for total joint scores although variable for the zonal approach. There was strong positive correlation between all features and radiographic severity (rho 0.75-0.85) except cysts which demonstrated positive although weaker correlation (rho 0.35).
Conclusion: This new grading system demonstrated "substantial" to "almost perfect" inter and intra-observer reproducibility. This tool may be useful in clinical OA and epidemiological studies.

Initial evaluation of image performance of a novel 3D x-ray system: phantom-based comparison of 3D tomography with conventional computed tomography
R.M. Benz[1], M. Garcia[1], F. Amsler[1], J. Voigt[2], A. Fieselmann[2], A.L. Falkowski[1], B. Stieltjes[1], A. Hirschmann[1]; [1]*Basle/CH*, [2]*Erlangen/DE (robyn.benz@usb.ch)*

Purpose: Phantom-based performance assessment of a prototype 3D x-ray system and comparison with conventional computed tomography (CT).
Methods and Materials: A 3D-image quality phantom (Cone Beam Phantom/ QRM/ Moehrendorf/ Germany) was scanned with a prototype of a novel 3D x-ray system (Multitom Rax/ Siemens Healthineers/ Erlangen/ Germany) using three dedicated trajectories of 163° (table), 188° (upright) and 200° (side) scanning angles and 160 projections. Images were obtained with 60/70/81/90/100/121kV and 0.348/0.696/1.740/3.480µGy/p as well as conventional CT (Somatom Definition Flash/ Siemens Healthineers/ Erlangen/ Germany) with a clinical protocol. Spatial resolution was assessed as well as soft tissue contrast resolution. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated. Additionally, radiation dose was measured for the x-ray system as well as the CT. Descriptive and ANOVA analyses (P<0.05) were performed.
Results: Using 3D x-ray a maximum of 16lp/cm were visible and best soft tissue contrast resolution was 2mm at 30HU compared to CT with 10 lp/cm and 4mm at 20HU, respectively. Mean SNR and CNR were significantly lower in the upright trajectory (mean SNR: upright, 7.7±2.9/side, 9.7±3.8/table, 9.1±4.1/CT, 9.1±1.6 [P<0.05]). Radiation dose was significantly higher using 3D tomography than CT (P<0.05).
Conclusion: The 3D x-ray system renders an equal or higher spatial resolution and comparable soft tissue contrast to conventional CT for medium and high dose protocols in the side and upright trajectory, but with increased radiation doses.

A human cadaver study to evaluate automatic image quality assessment in chest CT
C. Franck[1], A. De Crop[2], B. De Roo[1], P. Smeets[1], E. Achten[1], T. Van Hoof[1], K. Bacher[1]; [1]*Ghent/BE*, [2]*Roeselare/BE (caro.franck@ugent.be)*

Purpose: The evaluation of clinical image quality (IQ) is important to optimise CT protocols and to keep patient doses as low as reasonably achievable. Considering the significant amount of effort needed for human observer studies, automatic IQ tools are a promising alternative. The purpose of this study was to evaluate automatic IQ assessment in chest CT using Thiel embalmed cadavers.
Methods and Materials: Chest CT's of Thiel cadavers were acquired at different exposures. Clinical IQ was determined by performing a visual grading analysis. Physical-technical IQ (noise, contrast-to-noise and contrast-detail) was assessed in a Catphan phantom. Soft and sharp reconstructions were made with filtered back projection and two strengths of iterative reconstruction. A filtering algorithm (IQs) was used for automatic IQ evaluation. Normalisation of IQs allowed comparison of soft and sharp reconstruction kernels.
Results: Correlation coefficients between IQs and physical-technical parameters varied from 0.882 to 0.990. The correlations between IQs and clinical IQ were 0.824 (soft reconstructions) and 0.930 (sharp reconstructions).
Conclusion: IQs can be used in clinical practice for the evaluation of chest CT scans. It allows to monitor the IQ of a clinical chest protocol over time, without human intervention. Different reconstruction kernels can be compared after normalisation of the IQs.

B-0652 14:16

Clinical use of digital scatter correction in bedside chest radiography to improve image quality and reduce patient dose

C. Cases[1], D. Mentrup[2], A. Ruíz[1], R. Pallerol[1], A. Gimenez[1], I. Gich[1], M. Ribas[1], A. Capdevila[1]; [1]*Barcelona/ES*, [2]*Hamburg/DE (ccasadevall@santpau.cat)*

Purpose: Accumulation of bedside chest radiographs can lead to significant patient dose in an intensive care unit (ICU). Anti-scatter grids improve image quality (IQ) at the expense of increasing patient dose and workflow complexity. Recently, digital scatter correction (DSC) which simulates grid-like image contrast has been introduced as an alternative. We evaluated the influence of DSC on IQ and dose.
Methods and Materials: 50 ICU patients received clinically indicated bedside chest radiographs on two consecutive days. First-day images were acquired using the institution's standard protocol (80kVp, 2mAs, no grid). On the second day, dose was reduced up to 40% depending on the exposure index. The visibility of six anatomical features plus a general score was evaluated by two senior radiologists using a 10-point scale (1=insufficient, 10=excellent) with and without DSC (SkyFlow, Philips Healthcare). ANOVA tests were used to evaluate the influence of DSC on IQ.
Results: Scores with DSC were significantly higher (ANOVA test, $p<0.001$) than those without DSC with a mean difference greater than 1 point for each feature. Pairwise comparison showed that dose reduction resulted in lower image scores on 4 (out of 6) features and on general judgement ($p<0.05$). However, dose-reduced images with DSC obtained significantly higher scores (mean 7.5) than standard-dose images (mean 5.7) without DSC ($p<0.001$) for all anatomical features and for the general judgement.
Conclusion: Even with a dose reduction of up to 40%, usage of DSC results in significantly higher image scores for bedside chest radiographs compared with images acquired without grid.

Towards automated clinical image quality assessment in CT: 3D model observer applied to simulated images of a virtual lung phantom

I. Hernandez-Giron[1], W.J.H. Veldkamp[1], G.J. Streekstra[2]; [1]*Leiden/NL*, [2]*Amsterdam/NL (irene.debroglie@gmail.com)*

Purpose: To develop a method for clinical image quality assessment in CT. As a proof of concept the detectability of nodules embedded in an anthropomorphic lung phantom was investigated with a 3D model observer analyzing simulated CT images.
Methods and Materials: A virtual phantom representing the distribution and sizes of lung vessels was generated using a custom algorithm in MATLAB. For nodules, 10 spheres, (3-5-8mm diameter), were digitally inserted in different locations, mimicking attenuations (-800,-630,-500,-250HU). Two levels of Gaussian white noise were added to the phantom images, which were then blurred with the PSF of a CT standard lung kernel. As proof of concept, a 3D model observer with Gabor channels was used to calculate the detectability of the nodules (d') based on test-statistics measured in samples with/without nodule, extracted from the images.
Results: For equivalent locations in the phantom d' increased with object attenuation, diameter and decreasing noise. For 3mm diameter objects (-800,-630,-500,-250HU) the average (d'±σ) were (3.8±0.3, 7.3±0.6, 9.9±0.4, 15.0±0.7) and (5.3±0.3, 10.2±0.4, 14.0±0.3, 21.2±1.0), for high and low noise simulated images, respectively. Regarding d'vsobject size, for (-800HU and 3-5-8mm), d' was (3.8±0.3, 7.9±1.0, 16.5±2.6) and (5.3±0.3, 11.1±1.9, 23.1±2.5) for each noise level.
Conclusion: A 3D model observer was successfully used to analyze the detectability of nodules in matematically generated lung structures with CT-like colored noise simulated images. The 3D model observer is a promising tool to assess clinical image quality in CT. As a next step, the 3D model performance will be compared to human observers.

Performance evaluation of a dual-layer spectral CT: initial results

P.B. Noel, S. Ehn, T. Sellerer, A. Fingerle, J. Dangelmaier, R. Braren, F. Pfeiffer, E.J. Rummeny, D. Muenzel; *Munich/DE (peter.noel@tum.de)*

Purpose: We present a performance evaluation of a recently introduced spectral computed tomography system equipped with a dual-layer detector.
Methods and Materials: A semi-anthropomorphic abdomen phantom for CT performance evaluation was imaged on a dual-layer spectral CT (IQon Spectral CT, Philips Healthcare, USA) with three different radiation dose levels. The phantom was equipped with a specific spectral insert. The insert included the following material: water, adipose tissue, muscle, liver, bone, and a variation of iodine concentrations. Additionally, the phantom was enlarged with four different extension rings to simulate obese patients. With these acquisitions we have evaluated the contrast-to-noise (CNR) ratio over the range of available virtual monoenergetic images (MonoE) and the quantitative accuracy of MonoE Hounsfield Units (HU), effective Z-maps and iodine concentrations.
Results: For all evaluated tasks the results are within the calculated theoretical range of the spectral inserts. Especially for lower contrasts at low energies, the CNR could be boosted by a factor up to 200% with respect to the conventional image. The quantitive accuracy of MonoE images, effective Z-maps and iodine concentrations are well below 10% and the quantitive difference between normal to obese patients is on average around 6%.
Conclusion: Dual-layer spectral CT offers excellent quantitative CT capabilities over the whole field of view without any compromise in radiation dose or image quality.

B-0655 14:40

Objective comparison of high- and low-contrast detectability for three clinical protocols on eight CT scanners

D. Racine[1], A. Viry[1], F. Becce[1], S. Schmidt[1], A. Ba[1], A. Schegerer[2], F.R. Verdun[1]; [1]*Lausanne/CH*, [2]*Oberschleißheim/DE (damien.racine@chuv.ch)*

Purpose: To objectively compare computed tomography (CT) scanner performances for three clinically relevant protocols using a task-based image quality assessment method in order to assess the potential for radiation dose reduction thanks to technological developments.
Methods and Materials: Eight CT scanners from 4 manufacturers released between 2003 and 2014 were compared using ideal model observers: Prewhitening (PW) model for high-contrast detectability (HCD) and channelised Hotelling (CHO) model with Laguerre-Gauss channels for low-contrast detectability (LCD). HCD was assessed using a custom-made phantom to estimate task transfer function, and noise power spectrum. LCD was assessed using an abdominal phantom providing equivalent diameters of 24, 29.6, and 34.6 cm. Three protocols were reviewed: a head (trauma) and an abdominal (urinary stones) protocol were applied to assess HCD; and another abdominal (focal liver lesion) protocol was applied for LCD. The last protocol was tested with fixed and modulated tube currents.
Results: Compared to older generations, newer CT systems did not yield major improvements for HCD; one recent system had even lower performances than its predecessor. The use of the CHO model revealed that excellent image quality for LCD could be obtained with newer scanners at a significantly lower dose level.
Conclusion: This study shows that model observers can objectively benchmark CT scanners using a task-based image quality method, thus helping to estimate the potential for further dose reductions offered by the latest technology. Such an approach may be useful for adequately comparing clinically relevant image quality between various scanners.

Properties of primary MDCT x-ray source spectra: influence on total energy deposition and spatial absorption distribution

A. Steuwe, H.-U. Kauczor, W. Stiller; *Heidelberg/DE (andrea.steuwe@med.uni-heidelberg.de)*

Purpose: X-ray spectra of different MDCT sources differ by shape and mean photon energy (E_{mean}) due to different anode geometries, materials and filtration. Nonetheless, a variety of spectra and monoenergetic x-rays are applied in Monte-Carlo simulations of CT, despite possible differences in total energy deposition and spatial absorption distribution. This study aims at assessing resulting differences and implications.
Methods and Materials: The effect of different 120kV$_p$-x-ray spectra ([a] Toshiba CXB-750D MegaCool (E_{mean}=57.7keV, reference spectrum measured in-house), "Siemens Healthcare Online tool for the simulation of x-ray Spectra"-spectra without [b] and with [c] 3.3mm aluminum-filtration matching E_{mean} of the reference spectrum) and monoenergetic x-rays ([d] 57.7keV, [e] 120.0keV) on total energy deposition and spatial distribution in a water phantom (Ø=32cm, d=16cm) was determined with Monte-Carlo simulations (Geant4). Simulations were performed using stationary x-ray sources with/without bowtie filter.

Results: Compared to reference spectrum [a], differences in total energy deposition are: +63.5% [e], -1.5% [d], -5.0% [b] and +0.5% [c]. Approximate maximum differences in spatial absorption distribution are larger: 400% for [e] and 20% for [d], with underestimation in the phantom periphery and overestimation at its center. Differences of [b] are 20%, whereas added aluminum-filtration decreases differences to 5% [c]. Ignoring bowtie filtration causes up to 250% difference in energy distribution, especially in the phantom periphery.
Conclusion: Total energy deposition and spatial distribution are comparable for different spectra, if tube potential and E_{mean} match. Monoenergetic sources are not suited for x-ray source modeling. Simulations of correct spatial absorption distributions require modeling of bowtie filtration.

Reducing mean contrast volumes in small patients and harmonising chest-abdomen CT-image quality using personalised contrast volumes
M.-S. Walgraeve[1], L. Pyfferoen[1], K. Van De Moortele[1], C. Lafay[2], F. Zanca[2], J.W. Casselman[1]; [1]*Bruges/BE*, [2]*Buc/FR (marie-sofie.walgraeve@azsintjan.be)*

Purpose: To achieve consistent contrast enhancement across different patients, patient-tailored contrast protocols should be considered. The aim of this study was to evaluate the effect of fixed contrast volumes compared to patient-tailored contrast volumes on contrast-enhanced chest-abdomen CT-images.
Methods and Materials: Data of 77 patients who underwent two contrast-enhanced chest-abdomen CT-examinations over a one-year period were collected. First exam was performed with a fixed contrast volume (95 ml), follow-up exam with a patient-tailored contrast protocol (based on patient body surface area and heart rate). Contrast volumes were compared and contrast enhancement of liver, spleen, portal vein and aorta was assessed by 2 radiologists. Wilcoxon-rank-sum test and Kruskal-Wallis test were used to assess significant differences.
Results: Reduced contrast volumes were administered in 51 (66%) patients and mean contrast volumes were significantly (p=0.002) lower (-17%) in female patients using a patient-tailored contrast protocol compared to a fixed contrast volume. There was a significant reduction in variance of enhancement of spleen and portal vein in all patients across different BMI categories (fixed protocol, p=0.001 and 0.0007, respectively; patient-tailored, p=0.18 and 0.12) and there was a significant reduction in variance of liver enhancement across different BMI categories in female patients (fixed protocol, p=0.02; patient-tailored, p=0.15).
Conclusion: A patient-tailored contrast protocol can reduce mean contrast volumes in small patients, especially females. It also improves CT-image quality by harmonising contrast enhancement of spleen, portal vein and liver across different BMI categories. This avoids administration of inappropriate high contrast volumes in small patients and inadequately low contrast enhancement in large patients.

Optimisation of abdominal CT protocols using a mathematical model observer: a multicentre study
D. Racine, N. Ryckx, A. Viry, F. Becce, F.R. Verdun, S. Schmidt; *Lausanne/CH (damien.racine@chuv.ch)*

Purpose: To highlight the spread of patient exposure and image quality performances for comparable clinical questions.
Methods and Materials: An abdominal phantom containing spheres of 5 and 8 mm at 10 and 20HU was scanned on 58 CT machines of 50 different institutions using locally clinical settings of the native phase for the detection of focal liver lesions (FLL). Objective image quality was assessed with a Channelised Hotelling Observer (CHO) with ten dense differences of Gaussian channels. The area under the ROC curve (AUC) was used the figure of merit (FOM). Because of various reconstructed slice thickness, the product of the CTDIvol and slice thickness, dose-slice thickness product (DSP) was used as radiation dose metric.
Results: No significant differences in AUC were noted between FBP and iterative reconstructions, but the DSP varied from 2.6 to 61mGy.mm and the reconstructed slice thickness varied from 2 to 5mm. For the 5mm-20HU target, 49% of the CTs gathered around an AUC range of 0.86-0.98 for a DSP range of 5-20mGy.mm. Nevertheless, 10% of the CTs were outliers because of relatively high dose levels and limited AUC scores.
Conclusion: The use of a CHO model showed that the majority of institutions performed reasonably well when searching FLL. However, the limited spread in objective image quality was associated with a large spread in the chosen dose indicator. In the future, an expected level of low-contrast detectability should be used as FOM to ensure that the optimisation process does not impair the diagnostic goal.

B-0659 15:12

Effect of acquisition geometry on image quality of a digital tomosynthesis system for general radiography
A. Maldera, M. Sutto, P. Colombo, A. Torresin; *Milan/IT (angela.maldera@gmail.com)*

Purpose: In tomosynthesis system, the optimization process is strongly related to the acquisition geometry: sweep angle(θ) and number of projections(p). We investigated the relationships between acquisition geometry and image quality (IQ) metrics as artefact spread function(ASF), blurring ripple, in-plane/in-depth resolution and signal difference to noise ratio(SDNR).
Methods and Materials: All exposures were performed on a Fujifilm FDR AcSelerate with 55kVp, 1.25mAs/projection and reconstructed with FBP, 1mm pitch. θ(20°-60°) and p(20-60) were changed with the sampling angle. Agatha phantom was used to evaluate ASF, ripple and in-depth resolution(z-PSF). Copper steps of different thickness were imaged to assess SDNR and MTF (edge method). All IQ metrics were evaluated on the reconstructed images.
Results: Sweep angle is the only parameter affecting ASF and z-PSF: they both improve with larger scan angles. FWHM of ASF ranges from 16.7mm for θ =20° to 10.6mm for θ =60°. FWHM of z-PSF ranges from 5.0mm for θ =20° to 1.5mm for θ =60°. Blurring ripple is affected by sampling angle: ripple is reduced or eliminated when the sampling angle is narrower.In plane MTF was found to be anisotropic: MTF50%=1.99±0.04 (1.21±0.12)lp/mm for the edge parallel or orthogonal to the tube-travel direction, respectively; regardless the acquisition geometry.SDNR depends only on total exposure, i.e. number of projections, no matter the sweep angle.
Conclusion: This study showed that for Fujifilm FDR AcSelerate wider sweep angles improve in-depth resolution and narrower sampling angle reduces off-focus blurring. The choice of the optimal configuration needs to take into account also SDNR and the total dose.

B-0660 15:20

Impact of detector type, dose and image processing on the quality of digital neonatal chest x-ray images
M.-H. Smet, L. Breysem, E. Mussen, H. Bosmans, N.W. Marshall, L. Cockmartin; *Leuven/BE (Marleen.Smet@uzleuven.be)*

Purpose: To study the impact of different detector types, dose levels and processing algorithms on image quality (IQ) of digital chest x-ray imaging using a neonatal chest phantom.
Methods and Materials: An absolute visual grading analysis (VGA) study was performed on 400 x-ray images of the Gammex^{R} neonatal chest phantom mimicking hyaline membrane disease, pneumothorax and additional vascular lines. Three Agfa HealthCare detectors (CR powder phosphor (PIP), CR needle crystal based phosphor (NIP) and CsI DR detector (DXD)), and a Carestream CsI DR detector (CRX) were included. For each detector, 10 images at 5 dose levels were acquired with 2 processing algorithms for each vendor. Three experienced paediatric radiologists scored the reproduction of important normal anatomical structures following European quality criteria, with additional questions on the visibility of vascular lines, noise and disease simulation. Visual grading characteristic (VGC) analysis compared the different detectors while ordinal regression was used to test the effect of dose and processing on VGA score.
Results: No significant differences were found between the NIP, DXD and CRX detectors (p>0.05) whereas the PIP detector had significantly lower VGA score (p< 0.0001). Processing did not influence the VGA scores (p=0.819) whereas increasing dose level resulted in significantly higher VGA scores (p<0.0001). VGA identified a ~2.3μGy detector air kerma as optimal working point for NIP, DXD and CRX.
Conclusion: VGA score could identify differences between detectors and dose levels but was not sensitive for image processing. VGA shows the dose values above which perception of quality does not improve.

A multicentre international study to develop and validate a reproducible assessment tool for evaluating the image quality of screening mammograms

K. Taylor[1], D. Parashar[2], A. Poulos[3], R. Gullien[4], R. Aarre[5], M. Wallis[1]; [1]*Cambridge/UK*, [2]*Warwick/UK*, [3]*Sidney/AU*, [4]*Oslo/NO*, [5]*Hvidovre/DK (kathryn.taylor@addenbrookes.nhs.uk)*

Purpose: Optimum mammography positioning technique is necessary to maximise cancer detection. Current criteria for mammography evaluation lack reliability and validity with a need to develop a more objective system. We aimed to establish current international practice in assessing image quality (IQ), of screening mammograms then develop and validate a reproducible assessment tool.
Methods and Materials: A questionnaire sent to centres in countries undertaking population screening identified practice, participants for an expert panel (EP) of radiologists/radiographers and a testing panel (TP) of radiographers. The EP developed category criteria and descriptors using a modified Delphi process to agree definitions. The EP scored 12 screening mammograms to test agreement then a main set of 178 cases. Weighted scores were derived for each descriptor enabling calculation of numerical parameters for each new category. The TP then scored the main set. Statistical analysis included ANOVA, t-tests and Kendalls coefficient.
Results: 11 centres in 8 countries responded forming an EP of 7 members and TP of 44 members. The EP showed moderate agreement when the scoring the mini test set W=0.50 p<0.001 and the main set W=0.55 p<0.001, 'posterior nipple line' being the most difficult descriptor. The weighted total scores differentiated the 4 new categories Perfect, Good, Adequate and Inadequate (p<0.001).
Conclusion: We have developed an assessment tool by Delphi consensus and weighted consensus criteria. We have successfully tabulated a range of numerical scores for each new category providing the first validated and reproducible mammography IQ scoring system.

B-0662 14:08

The impact of image blurring on lesion detection performance in full field digital mammography FFDM

A.K. Abdullah[1], J. Thompson[1], C. Mercer[1], R. Aspin[1], J. Kelly[2], P. Hogg[1]; [1]*Salford/UK*, [2]*Chester/UK (P.Hogg@salford.ac.uk)*

Purpose: Image blurring is a known phenomenon in FFDM, but no research has quantified its impact on lesion detection performance. This study investigates the detection of malignant masses and microcalcifications using FFDM with varying magnitudes of simulated blurring.
Methods and Materials: Seven observers (15±5 years' reporting experience) evaluated two image sets for three conditions; each set consisted of 124 cases (62 normal; 62 abnormal). Abnormal cases contained malignant masses and microcalcifications; these were confirmed as malignant by biopsy. Images were evaluated for 3 conditions - without blurring (0mm), and two magnitudes of simulated blurring (0.7mm and 1.5mm), introduced by mathematical simulation. A free-response observer study was conducted to compare lesion detection performance in blurred and non-blurred images. Equally weighted jackknife alternative free-response receiver operating characteristic (wJAFROC) analysis was used for statistical analysis. Test alpha was set at 0.05 to control probability of Type I error.
Results: A statistically significant difference was evident for the detection of masses (F(2,21)=6.01, P=0.0084) and microcalcifications (F(2,20)=6.12, P=0.0082). Statistical differences were found between multiple pairs (0.0mm v 0.7mm) and (0.0mm v 1.5mm) for both masses and microcalcifications. No difference was detected between 0.7mm and 1.5mm for masses or microcalcifications. The observer averaged wJAFROC figures of merit are 0.905(0.859, 0.952) [0mm], 0.869(0.814,0.924) [0.7mm] and 0.862(0.810,0.915) [1.5mm] for masses, and, 0.894(0.856,0.931) [0mm], 0.813 (0.757,0.870) [0.7mm] and 0.802(0.714,0.890) [1.5mm] for microcalcifications.
Conclusion: Simulated image blurring has a statistically significant impact on lesion detection performance (increasing false-negative and false-positive); this has implications for clinical practice.

B-0663 14:16

Radiation doses received by women attending BreastScreen NSW in 2014

M.E. Suleiman, P.C. Brennan, P. Kench, M.F. McEntee; *Lidcombe/AU (msul1801@uni.sydney.edu.au)*

Purpose: To review radiation doses received by women attending BreastScreen NSW Australia in a period of two months in 2014. To compare doses with doses from international digital mammography screening programmes.
Methods and Materials: Anonymised mammograms (52,405 mammograms for 12,034 women) across 61 mammography units taken over a period of two months, had their metadata and QA data examined. Exposure information was extracted from DICOM headers and medical physics QA reports were collected for all mammography units. Women between 20-110mm breast thickness, with no breast implants were included. Mammograms with incomplete exposure or QA information were excluded. Mean glandular dose (MGD) was calculated using methods described by Dance et al., using an in-house developed Microsoft Excel workbook.
Results: Mean breast thickness was 58mm. Median MGD for all images, CC view and MLO view were 1.39, 1.43mGy respectively. DRLs (75th percentile) suggested for a breast thickness range of 60±5mm for the whole population and for three different detector technologies were for all data, 2.06mGy; CR, 2.22mGy; DR, 2.04mGy; Photon counting, 0.79mGy.
Conclusion: Mean MGD was lower than the latest UK dose audit (1.79mGy) and higher than some international published mean MGDs. Breast thickness and detector technologies have a big impact on dose, hence DRLs have been reported separately for different breast thickness ranges and each detector technology.

B-0664 14:24

Students, teaching-staff and clinical radiographers' perspectives about difficulties and challenges in mammography education and training

C.S. Reis[1], J. Pires Jorge[2], B. Strøm[3], N. Richli Meystre[2], A. Henner[4], T. Kukkes[5], E. Metsala[6]; [1]*Perth/AU*, [2]*Lausanne/CH*, [3]*Bergen/NO*, [4]*Oulu/FI*, [5]*Tartu/EE*, [6]*Helsinki/FI (Jose.JORGE@hesav.ch)*

Purpose: To identify the main challenges and difficulties in mammography education around Europe according to three perspectives - students, teaching-staff and radiographers.
Methods and Materials: Questionnaires were developed and applied in five European countries to collect data regarding individual profile, academic background, challenges, difficulties and education needs. Before sending by email, the questionnaires were translated into national languages and tested.
Results: Students, teaching-staff and radiographers fulfilled 254 questionnaires. 76(out of 97) students from 5 European countries identified 5 topics that could promote difficulties in mammography education/training: teaching-related (45 answers), breast positioning-related (16 answers), image evaluation (10 answers), lack of resources (7 answers) and human interaction (6 answers). The transition from theory to practice and breast positioning in media-lateral oblique were highlighted as very demanding by students and radiographers. The need to providing an explanation to the patients about the role of the students inside mammography room was identified by radiographers as difficult. The challenges identified by this group were supervising students practice (22.6%) and perform exams and teach at the same time (22.6%). The majority of the students (60.8%) and radiographers (80%) reported the need of update their knowledge and skills in breast imaging areas.
Conclusion: The difficulties and challenges identified were similar for all participants. The transition from theory to practice due to the reduced time allocated to mammography education in undergraduates studies was pointed out as one of the main reasons. Regarding these findings, it could be possible to identify pedagogical strategies and develop recommendations to harmonise education and training around Europe.

B-0665 14:32

Assessing risk of pain in mammography

S. Pacifici; *Rome/IT (s_pacifici@virgilio.it)*

Purpose: According to literature, a wide percentage of women reports pain or discomfort during the procedure that may undermine compliance with periodic or follow-up mammography. Firstly, the study focuses on identifying the factors that determine the risk of pain with special attention to the woman-related factors, the procedure itself and the staff. Secondly, it sets out to define recommendations to reduce the pain experienced during mammography.
Methods and Materials: 300 women 40-70 years old were interviewed immediately before and after undergoing mammography. Pre-test interview was used to evaluate the expected pain and the risk factors. Subsequently, after an appropriate counselling and the given option over the control the pressure, mammography was performed. In post-test interview the women were questioned about the pain they experienced, the difference between their

experience and their expectations, and the most stressful part of the entire procedure.
Results: A number of women-related factors, staff-related and procedural factors were found significant in assessing the risk of pain, besides anxiety related to anticipatory representations of possible positive diagnosis. Anticipation of pain and discomfort were the dominant factor explaining a pain experience. Despite the most of assessed women expected that mammography would be painful, most of those who anticipated pain has reported that the severity experienced during current test was much lower than the anticipated severity.
Conclusion: Study results emphasise the need for a careful assessment of the emotional state of the woman and an appropriate pre-mammography counselling to address those factors which may interfere with future test compliance.

B-0666 14:40

Ergonomic analysis in mammography: strategies to improve radiographers' activity and postures

N. Cernean[1], F. Serranheira[1], P. Gonçalves[1], C.S. Reis[2]; [1]*Lisbon/PT*, [2]*Perth/AU (nicolaicernean@gmail.com)*

Purpose: To investigate the ergonomic characteristics of mammography equipment and identify strategies to improve radiographers' postures to reduce the risk of work-related musculoskeletal disorders (WRMSDs).
Methods and Materials: The study was conducted in two phases. During the first phase, the standard breast positions used in mammography exams were simulated (craniocaudal - CC and mediolateral-oblique - MLO). In the second phase interventions were performed (radiographer and/or patient stead; elevation of the patient using a step). The postures were analysed in both contexts for several anthropomorphic combinations through photo/video. Angles were measured using the kinovea0.8.15 software and classified according to European-Standards (EN1005-4:2005+A1:2008).
Results: For a radiographers taller than patient (180cmm/153cm) were identified postures that could lead to WRMSDs, mainly during the MLO positioning. The measured angles in this context were 139º for arm flection, -24º head/neck, 120º arm abduction and 72º for trunk/back, being classified as non-acceptable according to European-Standards- After the introduction of corrective actions (radiographer seated), the measured angles were 60º for arm flection, 99º arm abduction, 0º head/neck and 14º for trunk/back. The classification of angles was acceptable after corrective measures.
Conclusion: The radiographers can develop WRMSDs while they are positioning the breast to acquired CC and MLO views. The introduction of corrective measures improved the positioning procedure and demands, considering several anthropomorphic characteristics of patients and workers. These improvements have potencial to reduce the risk of WRMSDs for radiographers.

B-0667 14:48

The effect of mean glandular dose variations on effective risk from full-field digital mammography in screening

R.M.K. M.Ali, A. England, A.K. Tootall, C.E. Mercer, P. Hogg; *Manchester/UK (P.Hogg@salford.ac.uk)*

Purpose: Investigate the effect of Mean Glandular Dose (MGD) variations of 16 Full Field Digital Mammography (FFDM) machines on the risk of radiation-induced cancer from screening mammography.
Methods and Materials: Organ doses from FFDM screening exposures (craniocaudal and mediolateral oblique) were measured using a simulated approach involving average breast thickness and adult ATOM phantoms with 16 FFDM machines. Doses were measured using TLDs accommodated inside the ATOM phantom; examined breast MGD was calculated. Total effective risk during a client's lifetime was calculated for 150 screening scenarios of different screening commencement ages and frequencies. For each scenario, a set of conversion factors was graphically obtained to convert MGD values into total effective risk.
Results: The examined breast received the highest radiation dose. For the 16 FFDM machines, MGD contributes approximately 98% of total effective risk. Although total effective risk decreases as screening commencement age increases, MGD contribution remains approximately constant because the radio-sensitivity of all body tissues, including breast tissue, reduce with age. The high breast tissue dose makes variations due to other tissues very small. Three sets of conversion factors were obtained for three screening frequencies (annual, biennial, triennial). Three relationship graphs between screening commencement age and total effective as percentages of MGD were established.
Conclusion: The use of graphical representation of total risk could be an easy way to illustrate the total effective risk during a client's lifetime. Screening frequency, commencement age, and MGD are good predictors for total effective risk generating more understandable data by clients than MGD.

B-0668 14:56

Radiographers' practice in mammography departments: challenges in training and clinical performance

E. Metsälä[1], N. Richli[2], J. Jorge[2], A. Henner[3], T. Kukkes[4], C. Reis[5]; [1]*Helsinki/FI*, [2]*Lausanne/CH*, [3]*Oulu/FI*, [4]*Tartu/EE*, [5]*Lisbon/PT (eija.metsala@metropolia.fi)*

Purpose: The aim of this study was to identify European radiographers' most common challenges of clinical performance and mammography training.
Methods and Materials: An extensive search was performed to identify studies focused on clinical practice and on training in mammography published in the English language between January 2010 and December 2015. Several electronic databases were used in search engines EBSCO Host, Pro Quest, MEDLINE and the Open Access Theses and Dissertations database (OATD). The data were analysed by using deductive thematisation analysis.
Results: A total of 27 full text articles were reviewed in the first stage, 11 were excluded due to the content and 16 were used to perform the integrative review. Most common challenges of clinical performance in mammography among European radiographers involved technical performance, quality of practices and patient-centred care. The main challenges of training were related to the need of more education in mammography, the structure and organisation of education and radiographer-related challenges.
Conclusion: Introduction of harmonised guidelines across Europe may serve as an evidence-based tool to be implemented in mammography education. However, the variability in human and material resources across Europe as well as the different cultures contexts should be considered in the introduction of improvements in this field of radiographers practice.

B-0669 15:04

Importance of training the radiographer in communication technique with female patient with breast cancer

H. Mohammed; *Doha/QA (hessa-salem@hotmail.com)*

Purpose: This paper seeks to explore the benefits of radiographer training regarding communication with woman breast cancer patients. The study targets women patients undergoing breast imaging procedures. It aims to show that it is beneficial for patients to be aware of how the radiographer is relaying the patient's health condition.
Methods and Materials: The procedure involved administering multiple-choice questionnaires. The multiple questions helped to determine if patients are comfortable with being taken through the imaging process due to communication between the radiographer and the patient. Another survey was conducted to gage whether patient's knowledge of their imaging procedure experience helped radiologists avoid mistakes in diagnosis or improved the accuracy of the diagnosis. This was done by administering the questionnaire to radiologists. The aim was to discover if radiographer interaction with patients who understood the breast imaging procedure eased the diagnosis process.
Results: Two-third of patients respondents expressed interest in understanding breast imaging procedures. Half of the radiologists who responded acknowledged that patients who understand breast imaging procedures make the diagnosis process a smoother process, as those patients comprehend the importance of the procedure.
Conclusion: Radiographer communication training can ease communications with all patients who are undergoing cancer treatment. Such an arrangement improves the quality and speed of cancer diagnosis procedures.

B-0670 15:12

Radiographer's role in the conscious participation in breast screening: the importance of interpersonal aspects and communication

M. Simoncini[1], M. Biondi[1], M. Virgilio[2], L. Giuliani[2], C. Ottonello[1]; [1]*Pomezia/IT*, [2]*Rome/IT (marta.simo@hotmail.it)*

Purpose: To evaluate the role of mammographic screening dedicated radiographer in: 1) improving patient awareness; 2) promoting patient's active participation; 3) better managing the patient's emotional component.
Methods and Materials: In the last three years we have organised an information campaign based on: 1) explanatory leaflets on the screening programme; 2) research and development of more effective communication channels (verbal and non-verbal) in order to better interact with patient with more empathy. That was possible through few precise details and by paying more attention to the emotional state of women, in close collaboration with radiologist, in order to create a safe and welcoming environment and improving a better response at screening examination call.
Results: With an information programme consisting in awareness screening flyers and by searching an effective and more empathic communication channel (verbal and non-verbal) we observed a progressive increase of mammographic call response up to 37,71% from 2012 to 2015.

Conclusion: Radiographer-patient communication channel is an important element in clinical practice, as seen as the first contact with a breast unit. The whole examination procedure is therefore optimised not only because of improving imaging quality but also because of improving full and conscious patient compliance.

B-0671 15:20

Mathematical modelling of radiation-induced caner from screening mammography

R.M.K. M.Ali, A. England, A.K. Tootall, C.E. Mercer, P. Hogg; *Manchester/UK (P.Hogg@salford.ac.uk)*

Purpose: Establish a mathematical model to predict radiation risk from Full Field Digital Mammography (FFDM) screening.
Methods and Materials: Radiation risk from screening mammography was quantified using effective risk. For effective risk calculations, organ doses and examined breast mean glandular dose (MGD) were used. Screening mammography was simulated by exposing a breast phantom (cranio-caudal and medio-lateral oblique) for each breast using 16 FFDM machines. An ATOM phantom loaded with thermo-luminescent dosimeters was positioned in contact with the breast phantom to simulate the client's body. Effective risk data were analysed to establish a regression model to predict the effective risk of any screening programme. Graphs were generated to extrapolate the effective risk of all screening programmes.
Results: Screening commencement age and number of screening visits are the most important factors which influence total effective risk (correlation coefficients >0.5). The regression model shows that 87% of total effective risk variability can be predicted by commencement/end ages and number of screens. Since tissue radio-sensitivity reduces with age, the secession age does not result in noteworthy effect on total effective risk.
Conclusion: Regression modelling can be used to predict total effective risk for breast screening clients but it cannot be used for exact assessment of total effective risk (standard error of estimate=91.13case/10^6, 31.21%). Graphical representation of risk could be a better and easy way to represent risk in a manner which might be helpful to clients and clinicians, unlike MGD which is not readily understandable within certain populations.

High-risk plaque and calcification at coronary CT to predict future events after second generation drug eluting stent implantation

N. Tomizawa, K. Yamamoto, S. Inoh, T. Nojo, S. Nakamura; *Matsudo/JP (tomizawa-tky@umin.ac.jp)*

Purpose: To investigate whether high-risk plaque (HRP) and calcium detected by coronary CT could predict future events after second generation drug eluting stent (DES) implantation.
Methods and Materials: We included 317 patients from December 2012 to April 2015 who received second generation DES implantation (everolimus-eluting, zotalorimus-eluting or biolimus-eluting stent) because coronary artery disease was suspected by coronary CT and confirmed by coronary angiogram or functional tests. Patients were divided into three groups for further analysis: high-risk group (HRG) as possessing HRP (low-attenuation and positive remodelling or napkin-ring sign) with Agatston score ≥400, low-risk group (LRG) as Agatston score <400 without HRP and the remaining patients as intermediate-risk group (IRG). The primary endpoint was a composite of all-cause mortality, myocardial infarction, fatal arrhythmia or repeated revascularisation.
Results: During the median follow-up period of 26.3 months, primary endpoint was observed in 74 patients (23%). Primary endpoint occurred more frequently in the HRG (42%, p=0.0001), and the IRG (26%, p=0.02) than the LRG (12%). Cox regression model adjusting for baseline characteristics showed that HRG and IRG were significant predictors of the primary endpoint (hazard ratio, 2.7 and 1.9, 95% confidence interval 1.3−5.7 and 1.0−3.8, p=0.001 and 0.04, respectively).
Conclusion: The presence of coronary HRP and calcium detected by CT would be an independent risk factor for future cardiovascular events after second generation DES implantation.

Different anticoagulation regimes affect stenosis and plaque composition in patients with atrial fibrillation

C. Beyer, F. Plank, G. Friedrich, M. Wildauer, W. Dichtl, G. Feuchtner; *Innsbruck/AT (christoph.beyer@student.i-med.ac.at)*

Purpose: Vitamin K Antagonists (VKA) are associated with an increase of vascular calcification which may lead to a higher cardiovascular event risk. However, the mechanism has not yet been fully understood. If new anticoagulants(NOACs) have similar vascular effects is unclear. Therefore, we analysed patients with atrial fibrillation(AF) and different anticoagulation regimes regarding coronary stenosis and plaque morphology by CTA.
Methods and Materials: Three patient cohorts matched for age, gender and cardiovascular risk factors (total N=132, mean60.8years) in patients with AF and VKA, without anticoagulation and a control group without arrhythmia underwent coronary CTA.To compare results of VKA to NOACs, an additional matched patient cohort (N=45) has been analysed. Images were evaluated for plaque types (non-calcified,mixed,calcified) and stenosis (<50%;50-70%,>70%). Segment involvement score (SIS) and non-calcified SIS were calculated. High risk plaque features (HRP; napkin ring sign, low attenuation plaque, spotty calcifications, positive remodelling) were quantified.
Results: Patients under AF using VKA had equal degrees of stenosis, overall plaque burden and calcification, however, increased rates of non-calcified plaques (ncSIS 0.9vs.0.3vs.0.3,p<0.001). Especially HRP features were increased (37%vs.14%vs.16%,p<0.001). Also, low attenuation plaques had significantly lower CT-attenuation levels (40.2vs.46.0vs.49.9HU,p<0.05). Patients under AF and NOACs showed inverse results: equal non-calcified plaques and HRP, however, increased overall plaque burden (SIS 3.2vs.1.4vs.1.4,p<0.05) and calcium score (240vs.58vs.146HU,p<0.05).
Conclusion: Patients in AF using VKA had increased vulnerable and lipid-rich plaques, whereas patients under NOACS had a higher rate of calcification and overall plaque burden. Therefore, NOACs may not attenuate overall CV risk while conventional VKA may be associated with higher rates.

Calcified coronary artery disease: advanced calcium subtraction improves luminal visualisation and diagnostic confidence in dual-energy coronary CT angiography

D. De Santis, M.H. Albrecht, M. Eid, C.N. De Cecco, A. Varga Szemes, T.M. Duguay, U.J. Schoepf; *Charleston, SC/US (domenico.desantis@hotmail.it)*

Purpose: To evaluate a prototype algorithm for calcium subtraction and its impact on luminal visualisation in patients with calcified coronary artery disease (CAD) using dual-energy coronary computed tomography angiography (DE-CCTA).
Methods and Materials: Twenty-nine patients (62% male; mean age, 62 ± 9 years) who had undergone DE-CCTA were retrospectively included in this IRB-approved study. Linearly-blended M_0.6 (60% low-kV spectrum) and calcium subtracted (CS) images were reconstructed. Two independent readers assessed luminal visualisation of the coronary arteries in a segment-based analysis, as well as subjective image quality and diagnostic confidence using 5-point Likert scales. Contrast-to noise ratios (CNR) for both datasets were calculated. Wilcoxon testing and Cohen's κ were used for statistical comparisons.
Results: CS images showed higher lumen visualisation (P=0.008), with excellent inter-reader agreement (mean score, 3.3; κ=0.82), compared to standard M_0.6 series (mean score, 2.9; κ=0.77). The CS algorithm granted a higher diagnostic confidence in comparison with linearly-blended reconstructions (mean scores, 4.0 and 3.1, respectively; P<0.001). No significant differences between CS and M_0.6 datasets were found in terms of image quality (subjectively - mean scores, 4.1 and 4.2, respectively; P = 0.442, and objectively - mean CNR, 37.0 and 38.2, respectively; P = 0.733).
Conclusion: A prototype algorithm for CS substantially improves coronary lumen visualisation and diagnostic confidence in patients with calcified CAD without deteriorating image quality.

Assessing genetic and environmental influences on epicardial and abdominal fat quantities: a classical twin study

A.L. Jermendy[1], M. Kolossvary[1], Z.D. Drobni[1], A.D. Tarnoki[1], D.L. Tarnoki[1], J. Karady[1], S. Voros[2], B. Merkely[1], P. Maurovich-Horvat[1]; [1]*Budapest/HU*, [2]*Richmond, VA/US (adam.jermendy@gmail.com)*

Purpose: Increased quantity of epicardial and abdominal adipose tissue compartments are linked to elevated cardiometabolic risk. The role of genetic and environmental factors in the lipid accumulation of different fat compartments is unclear. This study aims to assess the genetic and environmental effects on epicardial and abdominal adipose tissue quantities within a cohort of adult twin pairs.
Methods and Materials: We investigated 180 twin subjects (mean age: 55.8±9.6) of whom 57 were monozygotic (MZ) pairs and 33 were dizygotic (DZ) same-gender pairs. Epicardial adipose tissue (EAT) volume as well as subcutaneous and visceral adipose tissue (SAT and VAT) compartments at the upper abdominal level were quantified by a 256-slice CT-scanner. Values of MZ and DZ twin pairs were separately analysed and compared. Intra-pair correlations and multi-trait structural equation model were used to assess genetic and environmental influences.
Results: In co-twin analysis, MZ twins had higher degree correlations (r values) than DZ twins for EAT (rMZ = 0.81, rDZ = 0.32) and also for SAT and VAT quantities (rMZ = 0.80, rDZ = 0.68 and rMZ = 0.79, rDZ = 0.48, respectively). In multi-trait model fitting analysis the overall contribution of genetic factors to EAT, SAT and VAT quantities was 80%, 78% and 70% whereas that of environmental factors was 20%, 22% and 30%, respectively.
Conclusion: In our twin cohort, genetic effects strongly predominated over environmental influences in the phenotypic appearance of EAT, SAT and VAT quantities.

PARISK (Plaque At RISK) study: the association between intraplaque haemorrhage and thrombin generation in symptomatic carotid atherosclerotic plaques

G.A.J.C. Crombag[1], H. Spronk[1], A. van der Lugt[2], J. Hendrikse[3], P.J. Nederkoorn[4], J.W. Wildberger[1], H. ten Cate[1], R.J. van Oostenbrugge[1], M.E. Kooi[1]; [1]*Maastricht/NL*, [2]*Rotterdam/NL*, [3]*Utrecht/NL*, [4]*Amsterdam/NL (g.crombag@maastrichtuniversity.nl)*

Purpose: Carotid atherosclerosis is an important cause of stroke. Intraplaque hemorrhage (IPH) on MRI increases the ischaemic stroke risk. Little is known, however, about mechanisms leading to IPH development. Thrombin is an essential enzyme in haemostasis. Recent animal studies have shown that direct thrombin inhibitors attenuate atherosclerosis. We hypothesize that thrombin generation affects IPH and plaque development and may be a suitable blood biomarker for IPH on MRI. To investigate whether thrombin generation parameters are associated with MRI plaque parameters in stroke patients.
Methods and Materials: Patients were included in the Plaque-AT-RISK study and underwent multi-sequence carotid 3.0T MRI and blood sampling. Presence and volume of IPH, lipid-rich necrotic core and fibrous cap status were assessed on MRI using dedicated software by trained observers. The thrombin generation was assessed in platelet-poor plasma, resulting in the following parameters: lag time, peak height, endogenous thrombin potential and velocity index. Binary logistic regression was used to investigate the association between MRI and thrombin generation parameters.
Results: Valid MR plaque imaging results were available in 224/244 patients; in 161 patients blood samples also were available. IPH was present in 65/161 patients. There were no significant associations between the various MRI parameters and the different thrombin generation parameters.
Conclusion: Plaque MRI parameters show no strong association with thrombin generation in stroke patients. Systemic thrombin generation does not seem to affect IPH. The identification of IPH on MRI remains the method of choice to identify this important hallmark of plaque vulnerability.

Epicardial adipose tissue and pericoronary fat tissue thickness in patients with essential hypertension environmentally exposed to cigarette smoke

P. Gac, P. Jazwiec, M. Poreba, G. Mazur, R. Poreba; *Wroclaw/PL (pawelgac@interia.pl)*

Purpose: The determination of the influence of the environmental exposure to cigarette smoke on epicardial adipose tissue and pericoronary fat tissue thickness in patients with hypertension.
Methods and Materials: The research has covered 96 people with hypertension: 48 non-smokers, declaring the environmental exposure to cigarette smoke (group A, mean age: 65.83±10.86 years) and 48 non-smokers declaring the lack of environmental exposure to cigarette smoke (group B, mean age: 64.67±10.24 years). In all patients 128-slice multidetector computed tomography of coronary vessels (coroCT) was carried out. Scans acquired in coroCT were evaluated with regard to epicardial adipose tissue thickness (EATT) and pericoronary fat tissue thickness (PFTT). EATT was measured on the right ventricular anterior free wall. PFTT was determined in 3 localisations: at the region of the right coronary artery ($PFTT_{RCA}$), left anterior descending ($PFTT_{LAD}$) and left circumflex ($PFTT_{LCX}$).
Results: In group A the average values of EATT, $PFTT_{RCA}$, $PFTT_{LAD}$, $PFTT_{LCX}$ were significantly higher than in group B (EATT [mm] - 6.18±1.94 vs 5.43±1.57; $PFTT_{RCA}$ [mm] - 14.98±3.67 vs 13.48±3.18; $PFTT_{LAD}$ [mm] - 6.15±1.96 vs 5.12±2.01; $PFTT_{LCX}$ [mm] - 12.57±3.91 vs 11.06±2.84; $p<0.05$). In regression analysis it was documented that passive smoking constitutes a risk factor for higher values of EATT, $PFTT_{RCA}$, $PFTT_{LAD}$ and $PFTT_{LCX}$.
Conclusion: In patients with hypertension the environmental exposure to cigarette smoke is connected with the thickening of epicardial adipose tissue and pericoronary fat tissue.

Iterative model reconstruction improves semiautomated plaque quantification in coronary CT angiography

I. Kocsmar, M. Karolyi, B. Szilveszter, M. Kolossvary, J. Karady, A. Jermendy, A. Bartykowszki, B. Merkely, P. Maurovich-Horvat; *Budapest/HU (ildi.kocsmar@gmail.com)*

Purpose: The performance of automated plaque quantification in coronary CT angiography (CTA) dependents on image quality. It has been demonstrated that hybrid iterative reconstruction (HIR) technique improves CTA image quality compared to standard filtered back projection (FBP) allowing more accurate plaque quantification. Our aim was to evaluate the effect of iterative model reconstruction (IMR) on automated coronary plaque assessment, as compared to HIR and FBP.
Methods and Materials: We studied 20 consecutive patients (80.0% male, mean age 66.7±8.9 years) with coronary artery disease using 256-slice multidetector-row coronary CTA. All CTA datasets were reconstructed with FBP, HIR and IMR. Total plaque volume of the three main coronaries were quantified using automated plaque quantification software. Lumen and outer vessel wall contours were manually corrected, if necessary. Fixed window settings were used for CTA reading.
Results: Overall volume was larger without manual correction, as compared to manually adjusted measurements using FBP (924±367 vs 823±333 mm^3, $p=0.013$). Using HIR, we also found significant difference between the non-adjusted and manually adjusted plaque volumes (852±331 vs 784±325 mm^3, $p=0.043$). However, no difference was found between the non-adjusted and manually corrected measurements for overall plaque volume using IMR (801±328 vs 709±297 mm^3, $p=0.078$).
Conclusion: IMR-based fully automated plaque quantification leads to similar values as the manually corrected measurements. Therefore, IMR might result in a more efficient and less observer-dependent coronary CTA plaque quantification as compared to FBP and HIR.

Contrast-enhanced MRI of inflammatory component of coronary atherosclerosis in patients with acute coronary syndrome

W.Y. Ussov, N.V. Belokopytova, T.A. Shelkovnikova, E.A. Aleksandrova, E.Y. Pushnikova, V.D. Aptekar; *Tomsk/RU (wolfussov@yandex.ru)*

Purpose: We evaluated the patterns of contrast enhancement (CE) of arterial walls of coronary arteries in CE-MRI of the heart in patients with myocardial infarction due to stenosis or in non-stenotic coronary atherosclerosis.
Methods and Materials: Of 23 patients with myocardial infarction in 11 no coronary stenosis over 40% of lumen was revealed whereas in 12 the coronary stenosis was > 50%. In everyone the CE-MRI of the heart included imaging with contrast as 0,1 mM/Kg of BW and acquisition of slices depicting the descending and circumflex branches of the left coronary artery. Volume of myocardial damage (V_{md}, cm^3) and index of enhancement (IE), were calculated.
Results: V_{md} in patients with and without coronary stenosis did not differ significantly and was 14,5 ± 2,6 cm^3 and 13,8 ± 3,5 cm^3 ($p > 0,1$). Highly intense uptake of paramagnetic was seen in patients with coronary stenosis in infarction-related CA for as long as 19 — 31 mm (in average 24 ± 4 mm), IE = 1,57 ± 0,09 for the infarction itself and IE = 1,87 ± 0,12 for the region of stenosis. In patients with "pure" coronary arteries the IE for infarction region = 1,68 ± 0,14, and the infarction-related coronary artery IE = 2,67 ± 0,21 (1,58 — 5,89), superior to values in group of persons with myocardial infarction and critical stenosis.
Conclusion: CE-MRI of coronary arteries provides imaging of coronary inflammatory response in patients with myocardial infarction both due to and without coronary critical stenosis.

Relationship between complications during pregnancy and coronary atherosclerosis later in life in African-American women assessed by coronary computed tomography

J.L. Wichmann[1], J.H. Nunez[1], R. Vliegenthart[2], K. Otani[3], S.E. Litwin[1], P.B. Morris[1], T.J. Vogl[4], N.K. Wenger[5], U.J. Schoepf[1]; [1]*Charleston, SC/US*, [2]*Groningen/NL*, [3]*Tokyo/JP*, [4]*Frankfurt a. Main/DE*, [5]*Atlanta, GA/US (docwichmann@gmail.com)*

Purpose: To compare the prevalence and degree of coronary atherosclerosis detected by coronary computed tomography angiography (CCTA) in African-American women with and without a history of complications during prior pregnancy.
Methods and Materials: We retrospectively evaluated patient characteristics and CCTA findings in groups of African-American women with a history of pregnancy complications including preterm delivery (n=154), preeclampsia (n=137), or gestational diabetes (n=148), and a matched control group of African-American women who gave birth without such complications (n=445). Univariate and multivariate analyses were performed to assess predictors of coronary atherosclerosis.
Results: Average age at delivery and CCTA, number of pregnancies, smoking history, body mass index, and prevalence of hypertension or hyperlipidaemia were similar between groups (all P>0.2). All groups with a history of pregnancy complications showed higher rates of any (=20% luminal narrowing) and obstructive (>=50% luminal narrowing) coronary atherosclerosis (preterm delivery: 29.2% and 9.1%; preeclampsia: 29.2% and 7.3%; gestational diabetes: 47.3% and 15.5%) compared to control women (23.8% and 5.4%). After accounting for confounding factors at multivariate analysis, gestational diabetes remained a strong predictor of any (OR 3.26; 95% confidence interval 2.03-5.22; P<0.001) and obstructive coronary atherosclerosis (OR 3.00; 95% confidence interval 1.55-5.80; P<0.001) on CCTA.
Conclusion: A history of pregnancy complications was associated with a higher prevalence of coronary atherosclerosis on CCTA in African-American women, but only a history of gestational diabetes represented an independent predictor of any and obstructive coronary atherosclerosis in our study.

Sensitivity and specificity of epicardial adipose tissue thickness measured with 128-slice computed tomography as a marker predicting significant lesions in coronary arteries

P. Gac, P. Jazwiec, O. Kornafel-Flak, R. Poreba; *Wroclaw/PL (pawelgac@interia.pl)*

Purpose: To determine the sensitivity and specificity of epicardial adipose tissue thickness measured by 128-slice computed tomography as a marker predicting significant lesions in coronary arteries in patients with the suspicion of coronary artery disease (CAD).
Methods and Materials: The study group included 99 patients with the suspicion of CAD who were sent for 128-slice multidetector computed tomography of coronary vessels (coroCT). Mean age in the study group was 60.53±12.65 years. Scans obtained in coroCT were evaluated in order to find significant lesions in coronary arteries and to estimate epicardial adipose tissue thickness (EATT). Significant lesion of coronary artery was defined as stenosis exceeding 50%. EATT was measured on the right ventricular anterior free wall.
Results: The presence of the significant stenosis in coronary arteries in the study group was confirmed in 15.15% of patients. Mean value of EATT was 5.42±1.82mm. On the base of ROC curve EATT value was estimated, as an optimal cut-off point of the prediction of the significant stenosis in coronary arteries in the study group, giving the result of 6.7mm. The area under the curve for EATT was 89.7%. Sensitivity, specificity and accuracy of the EATT ≥6.7mm as a predictor of the significant stenosis in coronary artery were, respectively, 0.893, 0.867 and 0.889.
Conclusion: In a study group of patients with suspicion of CAD the determination of epicardial adipose tissue thickness in computed tomography angiography of the coronary arteries may constitute a good predictive marker of the significant lesions in coronary arteries.

Downstream investigation of non-cardiac incidental findings in patients undergoing CT coronary angiography: findings from the multi-center randomised controlled SCOT-HEART trial

M.C. Williams[1], A. Hunter[1], J. Dreisbach[2], J.R. Weir-McCall[3], M. Macmillan[1], S. Mirsadraee[1], E.J.R. van Beek[1], D.E. Newby[1], G. Roditi[2]; [1]*Edinburgh/UK*, [2]*Glasgow/UK*, [3]*Dundee/UK*

Purpose: The prospective multi-centre randomized controlled Scottish COmputed Tomography of the HEART (SCOT-HEART) trial showed CT coronary angiography (CTCA) improved diagnostic certainty, changed management and reduced myocardial infarction. Here we assessed non-cardiac findings (NCF), and the impact of changes in lung nodule guidelines.
Methods and Materials: Trial radiologists reported NCF and assessed whether they were responsible for symptoms (yes, probable, unlikely, no). Significant NCF were those requiring further investigation, follow-up or treatment. Lung nodule follow-up recommendations were provided using 2005 Fleischner Guidelines. We assessed potential changes to management using the 2015 British Thoracic Society (BTS) Guidelines.
Results: NCF were reported in 677 (38%) of 1778 patients who underwent CTCA, with 173 (9.7%) defined as significant. NCF were the cause of symptoms in 22 (1.2%), and probably the cause in 33 (1.9%). Five patients (0.3%) had pulmonary emboli, 135 patients (7.6%) required further imaging for NCF and 41 (2.5%) required additional clinic consultations. Lung nodules or masses were identified on 200 scans (11%) and 81 had follow-up CT (4.6%). Malignancy was subsequently diagnosed in 7 patients (0.4%), all of whom had either lung nodule >10mm or mediastinal lymphadenopathy. Application of the BTS guidelines would mean 22 patients (27%) did not require follow-up, none of whom have developed evidence of lung malignancy.
Conclusion: Although common in outpatients undergoing CTCA, most NCF are not clinically important and only a small number are the cause of chest pain. Application of new lung nodule guidelines will reduce follow-up imaging, without the risk of missing malignancy.

Triple rule out in patients with acute chest pain: economic aspects

M. Fusaro, G. Tessarin, M. Milana, M. Tessarin, L. La Torre, G. Morana; *Treviso/IT (tessarin.giovanni@gmail.com)*

Purpose: To asses economic impact of triple rule out with second generation dual source CT in the management of patients with atypical acute chest pain.
Methods and Materials: Blinded prospective observational cohort study to conduct a cost-effectiveness analysis of TRO CT versus standard care in patients with atypical acute chest, with negative ECG and troponin test, arriving to ED from March 7, 2016 to July 7, 2016. Endpoints were costs (euro) and length of hospitalization (hours) per patient. The descriptive analysis of the data was performed with SPSSv13 and with WinPEPI v11.5. Z test (p<0.05) was used to compare all means (euro and length of hospitalization).
Results: 70 patients (53.9yo ±10.3), 44 (62.9%) males, were enrolled: 44 (62.9%) were free of CAD, 23 (32.9%) had <50% CAD and 3 (4.3%) had a >50% CAD. No pulmonary embolism or aortic dissection were observed. The mean length of hospitalization per patient was significantly lower for the TRO protocol (8.41 hours vs. 63.21 hours, p<0,05). Invasive coronary angiography (ICA) was performed in 5 patients, suggested by CT only in 2 cases. The mean costs per patient were significantly lower for the TRO protocol than the standard of care (376.64 € vs 976.28 €, p<0,05).
Conclusion: In patients with atypical acute chest pain, properly stratified, triple rule out with second generation dual source CT is more cost-effective compared to the standard of care of our institution.

B-0684 14:17

Acute chest pain CT in comparison with standard treatment: a cost-effectiveness study

J.L. Wichmann[1], K. Otani[2], C.M. Carr[1], C. Tesche[1], S.E. Litwin[1], R.R. Bayer[1], C.N. De Cecco[1], T.J. Vogl[3], U.J. Schoepf[1]; [1]*Charleston, SC/US*, [2]*Tokyo/JP*, [3]*Frankfurt a. Main/DE (docwichmann@gmail.com)*

Purpose: To evaluate the cost-effectiveness of coronary CT angiography (CCTA) in comparison with traditional management protocols in patients presenting to the emergency department (ED) with chest pain.
Methods and Materials: We performed a retrospective single-centre analysis in 2,156 patients who presented to the ED with acute chest pain. Patient cohorts matched by patient characteristics and pretest likelihood for coronary artery disease (CAD) had undergone CCTA as the primary imaging test (n=1,139) or traditional standard of care (n=1,017). Cost-relevant factors of ED visits, utilisation of downstream tests and total patient care cost were compared.
Results: No significant differences between cohorts were observed for age, gender, race, BMI, or CAD risk factors (all P>0.08). In addition, no significant differences in the diagnosis of CAD were observed (all P>0.11). Time to discharge (4.5 vs 7 hours), hospital admission rate (12.6% vs 54.2%), length of hospital stay (48 vs 72 hours) and readmission rate within 30 days (3.5% vs 14.6%) were significantly lower in CCTA patients (all P>0.001). Reduced rates of additional downstream testing (e.g. nuclear stress test) and invasive coronary angiography (4.9% vs 22.7%; P<0.001), and ultimately lower total cost per patient (11,783$ vs 18,996$, P<0.001) were observed in the CCTA cohort.
Conclusion: In this large single-center study, the use of CCTA as the initial imaging test in patients presenting to the ED with acute chest pain was associated with shorter ED and hospital stays, lower readmission rates and ultimately reduced total cost, mostly due to reduced utilisation of additional downstream tests.

B-0685 14:25

Coronary CT angiography-derived plaque quantification in patients with acute coronary syndrome

C. Tesche, D. Caruso, C.N. De Cecco, T.M. Duguay, D.C. Shuler, J.D. Rames, M.H. Albrecht, A. Varga-Szemes, U.J. Schoepf; *Charleston, SC/US (tesche.christian@gmail.com)*

Purpose: To assess the discriminatory value of quantitative atherosclerotic plaque markers derived from coronary CT angiography (cCTA) in patients with acute coronary syndrome (ACS) compared to patients with stable coronary artery disease (CAD).
Methods and Materials: 40 patients (56.9±9.3years, 55% male) admitted for ACS were retrospectively analysed and compared to Framingham risk score matched controls with stable CAD. All patients underwent cCTA followed by invasive catheter angiography (ICA). ACS-related culprit lesions were identified using ICA. Total plaque volume (TPV), calcified and non-calcified plaque volumes (CPV, NCPV), plaque burden (PB), remodeling index (RI), lesion length (LL), presence of napkin-ring sign, segment involvement score (SIS), and segment stenosis score (SSS) were derived from cCTA and compared between both groups on a per-lesion and per-patient level.
Results: Patients with ACS showed significantly more obstructive CAD, and higher values for SSS, SIS, NCPV, LL, and RI compared to the stable CAD group (all p<0.05). Culprit lesions had significantly higher values for PB, TPV, NCPV, RI, LL, and prevalence of napkin-ring sign in comparison to non-culprit lesions (all p<0.05). A ROC analysis showed that clinical risk scores and plaque markers demonstrated incremental discriminatory power in identifying ACS on a per-patient (AUC 0.92, p<0.0001) and per-lesion (AUC 0.88, p<0.0001) level.
Conclusion: cCTA-derived culprit plaque markers show discriminatory value on a per-patient and per-lesion level. A combination of markers added to the Framingham risk score yields the greatest discriminatory ability and may aid in the identification of patients at risk for ACS over clinical risk scores alone.

Global and regional left ventricular myocardial deformation in cardiac amyloid light-chain amyloidosis: assessment with cardiovascular magnetic resonance tissue tracking

R. Li, Z.-G. Yang, Y.-K. Guo; *Chengdu/CN (ddtwg_nsmc@163.com)*

Purpose: To clarify the feasibility of cardiovascular magnetic resonance (CMR) derived tissue tracking strain analysis for assessing the difference of LV myocardial deformation between normal subjects and light-chain amyloid (AL) cardiac amyloidosis (AL-CA) patients.
Methods and Materials: Thirty-two AL-CA patients, including 19 with preserved systolic function and 13 progressed to systolic dysfunction (LVEF<50%), and 26 healthy controls underwent CMR examination. LV global and regional radial, circumferential and longitudinal myocardial peak systolic strain values (PSS) and rates (PSSR), as well as peak diastolic strain rates (PDSR) were compared among three patients groups. Receiver operating characteristic analysis (ROC) was performed to determine if myocardial deformation parameters could help discriminating LV dysfunction between normal subjects and AL-CA patients with preserved LVEF.
Results: AL-CA patients, regardless of LVEF, had significantly reduced PSS and PDSR (radial, circumferential and longitudinal) compared with normal subjects (all P<0.05). Patients with AL-CA and impaired LVEF showed lower radial, circumferential and longitudinal PSS and circumferential PDSR in basal, mid and apical levels, reduced radial PSSR and PDSR in mid and apical level, and decreased longitudinal PSSR in basal and mid slices compared with AL-CA patients with preserved LVEF (all P<0.05). The ROC curve analysis revealed that global and regional circumferential and longitudinal PSS, and radial PDSR may be used as indicators for differentiating LV dysfunction between AL-CA patients with preserved LVEF and normal subjects.
Conclusion: The differences in LV myocardial deformation between normal subjects and AL-CA patients can be monitored using tissue tracking CMR.

Myocardial contractile disfunction is correlated with maximum wall thickness and myocardial lipid accumulation in Fabry's disease: a CMR study with tissue tracking technique

N. Galea, R. Ammendola, M. Francone, A. Fiorelli, F. Ciolina, A. Frustaci, C. Catalano, I. Carbone; *Rome/IT (rosamaria.ammendola@gmail.com)*

Purpose: Our purpose was to investigate the relationships between degree of left ventricular (LV) hypertrophy, function impairment and lipid accumulation in patients with Fabry Disease Cardiomyopathy (FDC) using cardiac magnetic resonance (CMR) tissue tracking technique (TTT).
Methods and Materials: 22 FDC biopsy-proven consecutive patients (9 males, age 53.4 years) underwent to CMR exam on 1.5 Tesla unit acquiring STIR-T2w, cineMR, late enhancement and Modified Look Locker inversion recovery (MOLLI) sequence before and 15 minutes after injection of 0.2mmol/Kg Gd-DOTA for extracellular volume fraction (ECV) measurement. LV volumes, maximal wall thicknesses (MWT), native T1 (nT1) and ECV were analysed. Global longitudinal strain (GLS), circumferential strain (GCS) and radial strain (GRS) were measured on cineMR images by a dedicated software (Cvi42, Circle Cardiovascular Imaging). Patients were categorised into 4 groups (pre-hypertrophic, mild, moderate and severe hypertrophy) according to MWT (<11mm,11-15mm,16-18,>18mm). Correlations between tracking parameters, glicosphingolipids accumulation (measured by nT1) and myocardial fibrosis (LGE and ECV) among four groups were investigated.
Results: nT1 was lower in patients with severe (908ms), mild (910ms) and moderate (920ms) hypertrophy than with no-hypertrophy (959ms). 14 patients showed typical LV inferolateral scar and 4 patients had areas of myocardial oedema. Mean LV ejection fraction was preserved in all groups. Significant correlations were found between all TTT features and hypertrophy degree (p<0.01 for all) and between GCS and nT1 (p<0.05). No associations were noted between tracking parameters and ECV.
Conclusion: In FDC, contractile disfunction assessed by CMR-TTT is correlated to hypertrophic degree and lipid accumulation.

B-0688 14:49

Myocardial strain analysis using feature-tracking CMR approach for the differential diagnosis of amyloidosis vs HCM: a novel approach besides conventional imaging sequences?

G. De Rubeis, F. Cilia, N. Galea, I. Carbone, M. Francone, C. Catalano; *Rome/IT (derubeis.gianluca@gmail.com)*

Purpose: To evaluate the potential role of global radial and circumferential peak myocardial strain, calculated with CMR feature-tracking technique, in the differential diagnosis between amyloidosis and HCM.
Methods and Materials: We evaluated the global radial (GRS) and circumferential myocardial (GCS) strain peak, through CMR feature-tracking technique, in 12 patients with known cardiac amyloidosis and 32 patients with

histologically proven or clinical referral for HCM. All patients presented, in at least one segment, a myocardial thickening >13 mm.
Results: Patients' median age was 55±16 years, and 64% were male; per group analysis shows significant younger age in HCM group compared with amyloidosis ones (50±16 vs 66±10 years; p<0.05). GRS was lower in amyloidosis group than HCM group (25.0±10.6% vs 34.0±7.4%; p<0.01), while GCS was higher (-13.6±4.2 vs -16.4±2.9%; p<0.05). However, with a multiple regression analysis weighted for age, the r partial coefficients were 0.31 (p = 0.07) for GRS and 0.38 (p=0.02) for GCS. Using ROC curves, the optimal cutoffs for radial and circumferential strain were, respectively, ≤24.09% and >-15.18%. The sensitivity, specificity and AUC were 58.3, 93.75 and 0.779 for GRS and 66.7, 71.87 and 0.702 for GCS. Comparing the two ROC curves no statistically significant differences were highlighted (differences between areas=0.0768; p=0.17).
Conclusion: GRS and GCS can help in the differential diagnosis between cardiac amyloidosis and HCM likely reflecting diffuse intracellular accumulation of amyloid material with subsequent disease-dependent global contraction impairment. This might help in differentiating between two forms mostly in patients with negative or non-specific LGE findings.

B-0689 14:57

Denoising effect on T2* values in magnetic resonance imaging with application in iron load of patients with thalassaemia major

M. Dodangeh, S. Gholami Bardeji, Z. Gholami Bardeji, S. Sefidbakht, R. Jalli; *Shiraz/IR (dodangeh@sums.ac.ir)*

Purpose: To investigate the effect of noise and denoising on the measurement of magnetic resonance imaging (MRI) T2* values at interventricular septum of the heart in thalassaemia major patients. A second objective is to estimate the T2* value based on the improvement of Signal to Noise Ratio (SNR).
Methods and Materials: Different levels of Rician and Gaussian noises were added to the cardiac T2* MR images of 5 thalassaemia major patients. The state-of-art denoising methods were applied to the obtained noisy images. T2* values of the interventricular septum and SNR were measured in both series of images by Segment and Matlab software, respectively.
Results: With respect to the Gaussian noisy and denoised images in different noise levels, although SNR improved, there were no significant differences between T2* values in original, noisy and denoised images. On the other hand, after denoising images with Rician noise a relation between improvement of SNR and T2* value is noticed. A predictor model is constructed based on the level of Rician noise for each method.
Conclusion: In the case of existence Gaussian noise, the results confirm that denoising is not effective on the measurement of T2* value. In the case of image distortion by Rician noise, a predictor model is proposed to estimate the original T2* value. The predictor model is used to estimate the T2* value of new patients. The predicted T2* values were in a good agreement with the corresponding original T2* values.

B-0690 15:05

The cardiac MRI sphericity index in the dilated cardiomyopathy: new diagnostic and it prognostic marker

A. Zidi, I. Ben Amara, R. Aouini, A. Ben Halima; *Tunis/TN (drzidiasma@yahoo.fr)*

Purpose: Study the diagnostic and prognostic value of left ventricular sphericity in dilated cardiomyopathy.
Methods and Materials: Retrospective study of 132 patients, 44 diagnosed with dilated cardiomyopathy (DCM+) and 88 control patients with normal ventricular function and volumes (DCM-). All patients underwent a cardiac MRI with standerdized clinical protocol : cine-acquisition in short axis, 4-chamber and long axis views and late enhancement data sets acquired 10 minutes after intra-venous administration of extracellular gadolinium contrast agent. The sphericity index (SI) = left ventricular short axis end-diastolic length / long axis end-diastolic length x 100. Statistical investigation of correlations between SI and Left ventricular ejection fraction (LVEF) and occurrence of cardiac events
Results: In our study, SI was inversely correlated with LVEF (P<0,001), and positively correlated with end-systolic LV volume (p=0,03). For patients with LVEF >50%, SI was ≤ 63,5% (sensitivity = 90,9% and specificity = 92%). In DCM+ group, the mean SI was 72,7% ± 7 and the mean LVEF was 30%. Occurrence of a cardiac event was noted in 45% of patients and it was correlated to a high SI (p<0,001).
Conclusion: Few studies have investigated the IS which proves to be according to our study a good diagnostic marker reflecting cardiac dysfunction and prognostic predictor ECM occurred.

B-0691 15:13

Stratification of arrhythmic risk in HCM patients on the basis of oedema and myocardial scar on late gadolinium enhancement-cardiac magnetic resonance (LGE-CMR): a 11-year follow-up study

S. Bertugno, L. Nocetti, F. Fiocchi, A. Barbieri, Y. Bartolacelli, P. Torricelli, G. Ligabue; *Modena/IT (serena.bertugno@libero.it)*

Purpose: To investigate the role of LGE-CMR to predict the risk of Ventricular Tachyarrhythmia (VT) in HCM patients throughout a LGE% cut-off determination associated with the presence of oedema.
Methods and Materials: LGE-CMR was performed in 150 consecutive HCM patients (mean age: 57±17 years; 73% males) using a 1.5T scanner to determine cardiac functional parameters. LGE images were obtained 15 minutes after injection of 0.2 mmol/kg of Gadolinium. LGE was quantified using 6SD method. Indexed end-diastolic left ventricular mass (IEDLVM) was determined and LGE extension was defined as percentage of IEDLVM. We assessed myocardial fibrosis and oedema according to the 17 AHA (American Heart Association) segment-model. Occurrence of VT during a follow-up of 11 years were recorded. Multivariate analysis was performed to determine independent CMR parameters with a statistically significant correlation with VT. ROC analysis was performed to determine the optimal cut-off value for the parameter already individuated.
Results: The mean IEDLVM was 89±27 g/m^2. On LGE-CMR 116 (77%) patients showed myocardial scar (mean LGE%:6.4±7.8) and 61 (41%) oedema. During the follow-up 33 (22%) VT were recorded. Multivariate analysis revealed that both LGE% and oedema were independently associated with VT (P<0.001 both). According to the ROC curve, patients with a LGE>6%, have a high risk to present VT (sensitivity:82%; specificity:77%; AUC:0.882). If we considered oedema associated with a LGE>4% both the sensitivity and the specificity increased (respectively 85% and 85%; AUC:0.858).
Conclusion: Extension of fibrosis and oedema detected with LGE-CMR predict the occurrence of VT in HCM patients.

B-0692 15:21

Age- and gender-specific differences and magnetic resonance characteristics of hypertrophic cardiomyopathy

Z. Dohy, C. Czimbalmos, I. Csécs, A. Tóth, F. Suhai, B. Horváth, E. Dinya, B. Merkely, H. Vágó; *Budapest/HU*

Purpose: The aim of our study was to investigate age- and gender-specific differences and the prognostic value of cardiac magnetic resonance imaging (CMR) in patients with HCM.
Methods and Materials: CMR examination was performed on 152 adults (89 male; 47.6±13.7 years) and 24 children (17 male; 11.8±3.0 years) with HCM. Using cine short-axis images we evaluated left ventricular ejection fraction (EF), end-diastolic (EDVi) and end-systolic volume indices (ESVi), stroke volume index (SVi), mass index (LVMi) and maximal end-diastolic wall thickness (MEDWT). The amount of fibrosis was quantified on delayed contrast enhancement images. During the clinical follow-up adverse cardiac events (ACE) were recorded.
Results: Male patients had higher ESVi (34.8±9.8 vs 29.4±7.9 ml/m2), EDVi (92.8±17.2 vs 80.9±13.2 ml/m2), SVi (59.2±10.6 vs 51.5±9.4 ml/m2) and LVMi (98.9±33.0 vs 79.3±23.0 g/m2) (p<0.001). LVMi was higher in female children than in adult women (107.7±27.2 vs 79.3±19.8 g/m2) (p<0.01). The amount of fibrosis correlated positively with LVMi and MEDWT (p<0.001), negatively with EF (p<0.05). In 16 male patients with apical HCM morphology LVMi (83.5±13.7 vs 102.2±35.0 g/m2, p<0.05) and MEDWT (17.4±2.8 vs 23.5±5.4 mm, p<0.001) were lower. Obstructive form was found in 20 male patients, who had higher EDVi (99.6±18.1 vs 90.8±16.5 ml/m2) and MEDWT (25.1±6.2 vs 21.6±5.1 mm) (p<0.05). During clinical follow-up (1216±449 days) the incidence of ACE was higher in HOCM patients (p<0.05). Age, LVMi and EDVi combined had an effect on the incidence of ACE.
Conclusion: HCM seems to be influenced by gender-specific differences and CMR may have an essential role in complex risk stratification.

Effect of PIRADSv2 instead of PIRADSv1 in the analysis of multiparametric prostate MRI at 310 prostatic lesions proven by MR-guided biopsy at 3T vs 1.5T

A. Malich, I. Papageorgiou, R. Chelaru, A. Kott; *Nordhausen/DE (ismini.e.papageorgiou@gmail.com)*

Purpose: To verify diagnostic potential of PIRADS-V2 at the exact localisation of prostate lesions being histologically proven by MR-guided biopsy; to verify the influence of field strength on PIRADS-analysis and histopathological outcome.
Methods and Materials: 2080 patients underwent mp-prostate-MRI at our hospital (2009-2016) (T2w, DWI/ADC b-values: 0, 100, 400, 800, 1000; dynamic analysis >5min, single series: 13sec). 310 lesions were, after inconclusive sonographically-guided biopsy, scored as suspicious justifying an endorectally performed MR-guided biopsy (18G gun, 2 samples/lesion; access planning using DYNACAD-software and InVIVO at 3T Philips Ingenia and 1.5T Philips Achieva, respectively).
Results: Histopathological outcome was (1.5T/3T): PCA: 32/97(33%) vs 101/213(47%); ASAP: 9/97(9%) vs 20/213(10%); prostatitis: 26/97(27%) vs 33/213(15%); BPH: 14/97(14%) vs 31/213(15%); other findings: 16/93(16%) vs 28/213(14%). Gleason6: 10/32(32%) vs35/101(35%); Gleason7: 17/32(55%) vs 49/101(49%); Gleason8: 4/32(13%) vs 7/101(7%); Gleason9: 1/32(3%) vs 8/101(8%); Gleason10: 0 vs 2/101(2%). Using PIRADS-V1 17(5.5%) lesions were scored as PIRADS3 (3xPCA; remaining benign); 156 (50.3%) as PIRADS4 (42 PCA; 16 ASAP; all other benign) and 137 (44.2%) lesions as PIRADS5 (88 PCA, 13 ASAP; all other benign). When applying PIRADS-V2 9 lesions (2.9%) were downgraded as PIRADS2 (1/9 ASAP, all other benign), 23 lesions (7.4%) as PIRADS3 (1/23 PCA, 4/23 ASAP, all other benign), 162 lesions (52.3%) as PIRADS4 (70/162 PCA; 18/162 ASAP; other benign). 93 lesions (30.0%) revealed PIRADS5 (60/93 PCA; 4/93 ASAP). Consequently, sensitivity remained stable, specificity raised by V2, confirmed by ROC-analysis to be significant. No side effects or complications occurred. Mean scan time was 30min/intervention.
Conclusion: Application of PIRADSv2 reduces significantly the number of unnecessary MR-guided biopsies on the one hand and strengthens the indication for biopsy especially by upgrading suspicious lesions from PIRADS 4 to 5 with a high PPV.

B-0694 10:38

The role of PI-RADSv2 in determining who needs active surveillance or definitive treatment according to PRIAS

B. Park, J. Park; *Seoul/KR (1436park@gmail.com)*

Purpose: To evaluate the role of Prostate Imaging Reporting and Data System version 2 (PI-RADSv2) in triaging patients with prostate cancer according to Prostate Cancer Research International: Active Surveillance (PRIAS).
Methods and Materials: This HIPPA-compliant study was approved by IRB. Between January 2012 and December 2014, 456 patients with biopsy proven cancer underwent MRI and then radical prostatectomy. Two radiologists independently reviewed MR images using PI-RADSv2. According to PRIAS, cancer suitable for AS was defined as insignificant lesion with clinical stage <T3, prostate specific antigen (PSA) ≤10ng/mL, PSA density <0.2ng/mL^2, Gleason score (GS) ≤6, and the number of positive cores ≤2. According to PI-RADSv2, an insignificant cancer was defined when an index lesion scored <4. Standard reference was prostatectomy, in which insignificant cancer was defined as a small (<0.5cm^3) organ-confined lesion with GS ≤6. Sensitivity and specificity for insignificant cancer were obtained with PRIAS, PI-RADSv2, and both. Comparison of diagnostic performances was multiplied by two according to Bonferroni method.
Results: Of 456 patients, 82 (18.0%) were histologically diagnosed as insignificant cancer. The sensitivity and specificity with PRIAS were 82.9% (68/82) and 70.9% (265/374), respectively. PI-RADSv2 by two readers decreased the sensitivity to 61% (50/82)-80.5% (66/82), but increased the specificity to 77.8% (291/374)-90.8% (340/374). Combination of PRIAS and PI-RDASv2 increased significantly the specificity to 89.6% (335/374)-92.8% (347/374) (P<0.001).
Conclusion: PRIAS can identify a greater number of insignificant cancers than PI-RADSv2. However, PI-RADSv2 helps detect many significant cancers which are misdiagnosed as insignificant cancer with PRIAS.

B-0695 10:46

Clinical outcome following a low-suspicious multiparametric MRI or benign MRI-targeted biopsies for prostate cancer detection: a 3-year follow-up study

L. Boesen, N. Nørgaard, V. Loegager, H.S. Thomsen; *Herlev/DK (lars.boesen@dadlnet.dk)*

Purpose: To asses the clinical impact and time-varying risk of being diagnosed with significant prostate cancer (sPCa) following either a low-suspicious multiparametric (mp)-MRI or benign mp-MRI targeted biopsies (mp-MRI-bx) in men with prior negative transrectal ultrasound guided biopsies (TRUS-bx).
Methods and Materials: 289 patients were included and underwent mp-MRI followed by re-TRUS-bx and mp-MRI-bx of suspicious lesions at baseline. Of these, 194 patients had either a low suspicious mp-MRI or benign mp-MRI-bx and were selected for this analysis. Men diagnosed with PCa by re-TRUS-bx were classified as mp-MRI false-negative. Men without cancer were followed for at least three years to assess how many had a diagnosis of PCa within follow-up. The negative predictive values (NPV) of mp-MRI and mp-MRI-bx for ruling out any PCa, significant grade (Gleason score≥7) PCa and clinical sPCa were calculated.
Results: PCa was detected in 38/194 (20%) patients during the entire follow-up period. The overall NVP of mp-MRI and mp-MRI-bx to rule out any PCa and significant grade PCa (GS≥7) was 80% (156/194) and 95% (185/194), respectively. In addition, the NPV of clinical sPCa was 88% (170/194) caused by 15 patients with Gleason score 6 cancer having a PSA-density >0.15 ng/ml/cc. No patients with low suspicious mp-MRI features had significant grade PCa detected.
Conclusion: A low suspicious mp-MRI in patients with previous negative TRUS-bx has a high NVP for ruling out sPCa in a longer term. Thus, immediate repeated biopsies have only diminutive clinical impact and could be avoided even in men with persistent elevated PSA-levels.

B-0696 10:54

Accuracy of multiparametric MRI with PI-RADS V2 assessment in detecting infiltrations of the neurovascular bundles prior to prostatectomy

M. Sauer, J. Weinrich, G. Salomon, G. Adam, D. Beyersdorff; *Hamburg/DE (m.sauer@uke.de)*

Purpose: To evaluate multiparametric MRI (mpMRI)-based assessments of neurovascular bundle (NVB)-infiltration and to determine the value of PI-RADS V2 scores for the prediction of NVB infiltration before prostatectomy.
Methods and Materials: Our institutional review board approved the study. 198 patients underwent standardised mpMRI at 3T prior to surgery, including high resolution T2w-TSE-imaging in 3 planes, T1-w-TSE, DWI with ADC map, PD-TSE and Gd-DCE with post-processing of images. Assessment for NVB-infiltration was made for each side of each prostate (n=396). Maximum PI-RADS-V2 scores were determined for the posterolateral areas adjacent to the NVB (n=396). MRI-findings were correlated to pathologic analysis as reference standard, where NVB-infiltration was defined as tumour invasion into the NVB or extraprostatic expansion in the posterolateral area adjacent to the NVB.
Results: Overall T-staging accuracy, sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of mpMRI were 78.3%, 64.4%, 89.2 %, 82.4% and 76.2%, respectively. In 396 cases infiltration of the NVB was predicted with 89.4%, 75.2%, 94.0%, 80.2% and 92.1% overall accuracy, sensitivity, specificity, PPV and NPV, respectively. By correlating 365 maximum PIRADS-V2 scores to the pathology of adjacent NVBs, infiltration was demonstrated in 13 NVBs despite low likelihood of cancer presence (PI-RADS 1 or 2 scores), amounting to 14% false negative predictions.
Conclusion: mpMRI-based assessment of NVB-infiltration should be acknowledged when nerve sparing surgery is considered. However, areas without tumour suspicion (PI-RADS 1 or 2) might demonstrate NVB-infiltration in pathology causing false negative predictions.

B-0697 11:02

Validation of prostate imaging reporting and data system version 2 using a MR-ultrasound fusion biopsy in prostate cancer diagnosis

Y. Nam, S. Kim, Y. Yeo; *Daegu/KR (nyk3435@gmail.com)*

Purpose: The purpose of our study was to prospectively assess PI-RADS version 2 to use a MR-ultrasound fusion biopsy for the diagnosis of clinically significant prostate cancer (csPCa).
Methods and Materials: This study included 295 consecutive patients with 478 lesions who underwent multiparametric MR imaging and subsequent MR-ultrasound fusion biopsy between December 2014 and September 2016. Lesions were assessed using an overall score of PI-RADS version 2. One radiologist assessed the presence or absence of csPCa in the whole gland,

and subgroups of peripheral zone and transition zone using cut-off values ≥4 and 3. Histologic examination of MR-ultrasound fusion biopsy specimens was used as the reference standard. Sensitivity, specificity, PPV and NPV, and accuracy were calculated to assess the ability of PI-RADS version 2 for the diagnosis of csPCa.
Results: The overall scores of the PI-RADS version 2 showed an accuracy of 82.2% (393 of 478) for the whole gland, with a cut-off value ≥4 granting sensitivity of 90.0% (90/100), specificity of 80.1% (303/378), PPV of 83.3% (90/108), and NPV of 81.8% (303/370). For the peripheral zone, the overall scores showed an accuracy of 84.7% (301/355), and an accuracy of 74.7% (92/123) in the transition zone. In applying an arbitrary overall score ≥3, overall score showed an accuracy of 68.6% (328/478), a sensitivity of 94.6% (124/131), specificity of 58.7% (204/347), PPV of 51.6% (124/240), and NPV of 85.7% (204/238).
Conclusion: PI-RADS version 2 has moderate overall performance for the diagnosis of csPCa.

B-0698 11:10

Manual adjustment in mpMRI-directed prostate biopsy significantly improves the detection rate of prostate cancer: experience in 180 patients
S. Alessi, L. Nicosia, P. Pricolo, B. Jereczek-Fossa, V. Cubadda, G. Renne, O. De Cobelli, M. Bellomi, G. Petralia; *Milan/IT (Sarah.Alessi@ieo.it)*

Purpose: To compare the results of software-guided sampling with those obtained after manual adjustment in multiparametric prostate magnetic resonance imaging directed prostate biopsy (mpMRI-PB), and evaluate the percentage of core involvement at mpMRI-PB and lesion diameter at surgery.
Methods and Materials: 180 patients with suspicious prostate cancer (PCa) and a lesion visible on multiparametric prostate magnetic resonance underwent mpMRI-PB between November 2014 and September 2016. After calibration of the biopsy device the first sample was obtained using the coordinates provided by the device software to guide the needle along a trajectory to the target lesion. The trajectory of subsequent samples was manually adjusted to improve localisation to the target lesion.
Results: Biopsy was positive for PCa in 0/14 PIRADS 2, 13/58 PI-RADS 3, 47/78 PI-RADS 4 and 26/30 PI-RADS 5 lesions. Of the 86 lesions with positive biopsy, just 47 were obtained with the first sample, whereas biopsy with manual adjustment was positive in all 86 lesions. The additional 39 positive biopsies correspond to an increase in detection rate of 83% (p<0,0001; McNemar's Test). To date, 32 of the patients have undergone radical prostatectomy; the core involvement averaged 59% (range 10-90%) and lesion diameter in the surgical specimen 10,2 mm (range 5-16mm).
Conclusion: Manual adjustment of needle trajectory significantly improves the detection rate of PCa with mpMRI-PB. The percentage of core involvement in mpMRI-PB is high relative to literature values for conventional biopsy, suggesting that the criteria for clinical decision-making in these patients should be re-examined.

B-0699 11:18

Early dynamic imaging increases the detection rate of local recurrence in prostate cancer patients with biochemical relapse referred for ^{68}Ga-PSMA-11 PET/CT
C. Uprimny, A. Kroiss, C. Decristoforo, B. Warwitz, L. Scarpa, E. von Guggenberg, J. Bektic, W. Horninger, I. Virgolini; *Innsbruck/AT (Christian.UPRIMNY@tirol-kliniken.at)*

Purpose: ^{68}Ga-PSMA-11 PET/CT has proved to establish a very accurate imaging modality in prostate cancer (PC) patients with biochemical relapse after primary therapy. Despite a high overall detection rate visualisation of local recurrence remains challenging due to high physiological tracer accumulation in the urinary bladder on whole-body ^{68}Ga-PSMA-11 PET usually performed 60 min post injection (p.i.). The purpose of this study was to evaluate whether early dynamic PET-imaging allows differentiation of PC lesions from urinary bladder activity and thereby probably increasing detection rate of local recurrence.
Methods and Materials: 64 PC patients with biochemical relapse (median PSA: 1.7ng/ml) referred for ^{68}Ga-PSMA-11 PET/CT were retrospectively analysed. In addition to whole-body imaging 60 min p.i. early dynamic acquisition of the pelvis in the first 8 min p.i. was performed.
Results: On whole-body PET 13 patients exhibited pathological lesions in the prostatic fossa consistent with local recurrence, which were also positive on early dynamic imaging. However, in 6 additional patients pathological lesions suspicious for local recurrence could only be detected on early dynamic PET. Combination of early dynamic PET and whole-body PET increased the detection rate of local recurrence compared to imaging 60 min p.i. alone (29.4% versus 20.3%).
Conclusion: Early dynamic imaging of the pelvis enhances detection rate of local recurrence in PC patients with biochemical relapse and should be integrated in the routine acquisition protocol of ^{68}Ga-PSMA-11 PET/CT.

B-0700 11:26

Detection rate of PET/CT in patients with biochemical relapse of prostate cancer using [68Ga]PSMA I&T and comparison with published data of [68Ga]PSMA HBED-CC
C. Berliner[1], M. Tienken[1], Y. Kobayashi[1], U. Kirchner[1], S. Klutmann[1], L.H. Budäus[1], H.-J. Wester[2], J. Mester[1], P. Bannas[1]; [1]*Hamburg/DE*, [2]*Munich/DE (caberliner@gmail.com)*

Purpose: To determine the detection rate of PET/CT in biochemical relapse of prostate cancer using [^{68}Ga]PSMA I&T and to compare it with published detection rates of [^{68}Ga]PSMA HBED-CC.
Methods and Materials: We performed a retrospective analysis in 83 consecutive patients with biochemical relapse after prostatectomy. All patients underwent whole-body [^{68}Ga]PSMA I&T PET/CT. PET/CT images were evaluated for presence of local recurrence, lymph node metastases, and distant metastases. Proportions of positive PET/CT results were calculated for six subgroups with increasing prostate specific antigen (PSA) levels (<0.5 ng/ml, 0.5 to <1.0 ng/ml, 1.0 to <2.0 ng/ml, 2.0 to <5.0 ng/ml, 5.0 to <10.0, >10.0 ng/ml). Detection rates of [^{68}Ga]PSMA I&T were statistically compared with published detection rates of [^{68}Ga]PSMA HBED-CC using exact Fisher's test.
Results: Median PSA was 0.81 (range: 0.01-128) ng/ml. In 58/83 patients (70%) at least one [^{68}Ga]PSMA I&T positive lesion was detected. Local recurrent cancer was present in 18 patients (22%), lymph node metastases in 29 patients (35%), and distant metastases in 15 patients (18%). The tumour detection rate was positively correlated with PSA levels, resulting in detection rates of 52% (<0.5 ng/ml), 55% (0.5 to <1.0 ng/ml), 70% (1.0 to <2.0 ng/ml), 93% (2.0 to <5.0 ng/ml), 100% (5.0 to <10.0 ng/ml), and 100% (>10.0 ng/ml). There was no significant difference between the detection rate of [^{68}Ga]PSMA I&T and published detection rates of [^{68}Ga]PSMA HBED-CC (all p>0.05).
Conclusion: In our retrospective study, [^{68}Ga]PSMA I&T PET/CT has high detection rates of recurrent prostate cancer that are comparable to [^{68}Ga]PSMA HBED-CC.

Assessing early treatment induced changes on diffusion signal of prostate cancer: comparison of two radiotherapy schemes
N. Papanikolaou[1], G. Manikis[2], I. Santiago[1], A. Gaivao[1], C. Greco[1], Z. Fuks[1], C. Matos[1]; [1]*Lisbon/PT*, [2]*Iraklion/GR (npapan@npapan.com)*

Purpose: To assess radiation therapy induced early changes in patients with prostate cancer, and compare the effects on diffusion biomarkers of two different treatment schemes.
Methods and Materials: Twelve patients with locally confined prostate cancer underwent either single dose radiotherapy (SDRT; 24Gy, n=7) or hypo-fractionated radiotherapy (HYPO; 9Gy per fraction repeated daily for 5 days, n=5). Multiple diffusion sequences were acquired beginning at 15 minutes after treatment completion up to 40min, to detect early diffusion signal changes. A bi-exponential diffusion model was applied to quantify true Diffusion coefficient (D), pseudo-diffusion coefficient (D*) and micro-perfusion fraction (f), in visible lesions. The diffusion sequence utilised comprised of 7 b values (0, 50, 100, 200, 500, 1000 and 1500 s/mm^2).
Results: A major decrease in f values along with an increase in D, as early as 15min after the end of the treatment, was noted forming a plateau configuration in both D and f , till 40min after treatment. In patients with HYPO treatment there was a major reduction of D that returned to the baseline value at 40min and a moderate reduction of f that resulted in a minor increase of the f value at 40min after the end of treatment. No clear changes were observed on D* in both types of treatment.
Conclusion: Our preliminary results indicate that diffusion related biomarkers can detect early treatment induced changes. They may therefore have the potential to be used for assessing treatment effects of different radiotherapy schemes.

IVIM of prostate cancers: assessing grade and response to treatment
R. Balaji; *Chennai/IN (ravikanthbalaji@gmail.com)*

Purpose: Investigate use of intravoxel incoherent motion (IVIM) diffusion-weighted imaging of prostatic cancers, correlation with Gleason score and assess response to treatment.
Methods and Materials: 35 patients with histologically proven prostate cancer underwent IVIM diffusion imaging on 1.5 Tesla MR scanner using 11 b values 0, 10, 20, 30, 50, 80, 100, 200, 400, 800 and 1000 s/mm^2. Biexponential fits were applied to diffusion decay curves to calculate molecular diffusion coefficient (D), perfusion-related Diffusion coefficient (D*), and perfusion fraction (f). Grading of tumours was based on correlation of ADC, D and f

values with Gleason score. Post treatment imaging was performed after 3 months to assess changes in ADC, D and f values.
Results: D values were significantly reduced within tumour foci compared to normal parenchyma. High grade tumours had lower D values 0.70 +/- 0.23 x 10^{-3} mm^2/s compared to low grade tumours which had higher D values 0.92 c 0. 27 10^{-3} mm^2/s. f values were increased in tumours at b-values below 800 s/mm^2 - 7+/- 2.6 %. When higher b-values were used f values in tumours was indistinguishable from normal prostatic glandular tissue.D values increased after treatment with radiotherapy - 1.22 +/- 0.23 x 10^{-3} mm^2/s with decrease in f values 3.4 +/- 2.4 %.
Conclusion: True diffusion (D)obtained by IVIM technique is a much superior biomarker of malignancy, grade of tumour and response to treatment. f values are also an important indicator of malignancy at b values below 800 s/mm^2 in the prostate gland.

B-0703 11:50

Multiparametric MRI of prostate cancer bone disease: correlation with bone biopsy histological and molecular features
R. Perez Lopez, D. Nava Rodrigues, J. Mateo, M. Rata, Z. Zafeiriou, D.J. Collins, D.-M. Koh, J.S. de Bono, N. Tunariu; *London/UK (Raquel.PerezLopez@icr.ac.uk)*

Purpose: To assess multiparametric MRI (MP-MRI) of metastatic and non-metastatic bone in patients with prostate cancer and correlate with histological features from bone metastases biopsies.
Methods and Materials: Patients with metastatic castration resistant prostate cancer (mCRPC), MP-MRI, bone metastases biopsies and biopsy tract visible on a subsequent CT between May 2012 and March 2016 were included. A cohort of 10 consecutive CRPC patients with MP-MRI and no bone metastases was also analysed. Associations of MRI parameters (apparent diffusion coefficient [ADC], normalised DWI [nDWI] signal and fat fraction [FF]) with bone marrow biopsy histological characteristics were evaluated using Mann Whitney test; Spearman's correlations were assessed. Univariate and multivariate analyses were performed using logistic regression models.
Results: Forty-three bone marrow biopsies from 33 patients (median age 72, range 48-84 years) were included. In the non-metastatic bone cohort, 10 patients were included (median age 69, range 53-75 years). The median ADC in bone metastases and non-metastatic bone was $993x10^{-6}mm^2/s$ (IQR 872.5-$1093.5x10^{-6}mm^2/s$) vs $601.8x10^{-6}mm^2/s$ (IQR 545-$667x10^{-6}mm^2/s$), the median nDWI signal was 4 AU (IQR 2.6-6.7 AU) vs 1.6 AU (IQR 1.4-2.7AU) and the median FF was 16% (IQR 9-45%) vs non 63% (IQR 60-76%); p<0.001 in all cases. There was a significant inverse correlation of ADC and FF and positive correlation of nDWI signal with tumour cellularity; p<0.001.
Conclusion: MP-MRI parameters correlate with histological characteristics of bone marrow biopsies in mCRPC. These data further supports clinical qualification of DWI as a prognostic and response biomarker in mCRPC.

Evaluation of different methods to optimise contrast media amount in abdominal CT of obese patients
F. Rivosecchi, D. Caruso, M. Rengo, D. Bellini, M. Zerunian, A. Laghi; *Latina/IT (flaminiarivosecchi@gmail.com)*

Purpose: To prospectively compare two different approaches for calculating the lean body weight (LBW) and the amount of intravenous contrast media (CM) for MDCT of the abdomen in obese patients.
Methods and Materials: Nineteen patients (9 men, 10 women) with a BMI greater than 35 kg/m2 were included in this prospective study and underwent MDCT of the abdomen. The amount of CM injected was computed according to the patient's LBW which was estimated using either the Boer formula (Group A) or the James formula (Group B). The following variables were compared and analysed between the two groups: patient's characteristics, CM volume and iodine dose. CNR of liver, kidney, portal vein, aorta and pancreas was also calculated.
Results: Patients in Group A has a superior BMI than Group B (38.56±6.31 vs. 37.23±5.54 kg/m2) while an inferior LBW was observed for Group A vs Group B (59.15±12.23 vs 59.79±12.68 kg). Group A provided greater CNR (liver 3.64±1.12; kidney 13.53±7.2; portal vein 10.22±6.34; aorta 11.93±3.45; pancreas 2.51±0.98) during the portal venous phase compared to CNR of Group B (liver 3.38±2.11; kidney 9.87±6.55; portal vein 7.70±3.43; aorta 8.07±2.69; pancreas 2.35±1.12). A significant difference was observed for CNR of kidney, portal vein and aorta (p<0.05) although a lower amount of CM was administered in Group A compared to Group B (115.45±13.3 ml vs 116.64±12.56, p>0.05).
Conclusion: The optimisation of contrast media volume using Boer formula significantly improves parenchymal enhancement in obese patients although a lower amount of contrast media was administered.

B-0705 10:38

Clinical robustness of accelerated and optimised abdominal DWI
J. Taron, P. Martirosian, J. Weiß, A. Stemmer, A. Othman, K. Nikolaou, M. Notohamiprodjo; *Tübingen/DE (taronjana@yahoo.com)*

Purpose: To assess the robustness of accelerated and optimised diffusion-weighted imaging (DWI) in routine abdominal MRI using the simultaneous-multislice (SMS) technique for scan time reduction and a 3D Diagonal diffusion mode to improve image quality.
Methods and Materials: A total of 152 patients (88 male, 64 female; mean age 62 years) were included in this study. All received the institutional standard abdominal MRI protocol including an optimized diffusion-weighted sequence (DWI_{OPT}: TR/TE 3100/56ms; b-values 50, 400 and 800s/mm²; diffusion mode 3D Diagonal; SMS factor 2; scan time 1:44min). A subgroup of 41 patients (mean age 62 years) additionally received standard DWI (DWI_{STD}: TR/TE 5100/60ms; b-values 50, 400 and 800s/mm²; diffusion mode 4-scan-Trace; scan time 2:35min) as reference. Image quality criteria, lesion conspicuity (rated on a 5-point Likert-scale; 5=excellent) and ADC-values (measured in a region-of-interest-analysis) in DWI_{STD} and DWI_{OPT} were compared interindividually using dedicated statistics. P-values <.05 were considered significant.
Results: Interindividually DWI_{OPT} proved superior to DWI_{STD} in comparison of overall image quality (DWI_{OPT}: 4.6 ±0.7; $DWI_{STD:}$ 4.2 ±0.8; p=.025); lesion conspicuity was comparable (p=.461); ADC-values showed no statistically significant difference (right hepatic lobe p=.107; kidney p=.098). The patients receiving DWI_{OPT} only showed very high overall image quality and lesion conspicuity (4.7±0.6 and 4.7±0.6, respectively).
Conclusion: Integrating the SMS technique- and a 3D-Diagonal diffusion mode abdominal DWI can be accelerated and optimised with superior image quality and similar ADC-values compared to standard DWI. This approach proved stable in a larger patient cohort, so that we can recommend it for clinical routine application.

Diagnostic value and radiation dose reduction of model-based iterative reconstruction compared with hybrid iterative reconstruction in routinely upper abdominal CT study
A. De Vito, D. Ippolito, C.R.G.L. Talei Franzesi, L. Riva, S. Drago, S. Sironi; *Monza/IT (a.devito@campus.unimib.it)*

Purpose: To evaluate dose reduction and image quality of upper abdominal CT images reconstructed with model-based iterative reconstruction (IMR) compared with hybrid iterative reconstruction (iDose4).
Methods and Materials: We prospectively enrolled 72 patients who underwent to upper abdominal CT scan;36 patients were examined using a low-kV setting (100kV) while the other 36 patients were investigated using standard kV setting (120kV), on the same 256-row CT. In the first group (Study Group) images were reconstructed using IMR algorithm while in the second group (Control Group) we used iDose4 technique. CTDIvol, DLP and Estimate Doses (ED) were evaluated. Region of interests were drawn in three different points in the liver and spleen; signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated. A four-point scale was used to subjectively evaluate the imageS in both groups.
Results: Mean CTDI Volume was 9,2 ± 1,2 mGy and 17,7 ± 2,5 mGy for low-kV IMR CT scans and standard dose iDose4 CT scans, respectively. Compared to iDose4-CT, low kV IMR CT showed significant lower DLP (570,5 ± 8,3 mGy x cm) and ED (6,3 ± 1,8 mSv). Low kV IMR images yielded higher attenuation values (HU) and higher SNR and CNR in the liver and spleen, compared with standard dose iDose4 images.The subjective image quality of both groups was comparable.
Conclusion: Low-kV MBIR technique allows significant reduction of radiation doses exposure maintaining high image quality (i.e. attenuation values, SNR and CNR in the liver and in the spleen) at routine abdominal CT, compared with standard-dose HIR technique.

B-0707 10:54

Contrast dose variability depending on morphometric values: a retrospective analysis on patients undergoing multi-phase abdominal CT

M. Zanardo[1], F.M. Doniselli[2], A. Esseridou[2], S. Tritella[2], G. Di Leo[2], F. Sardanelli[2]; [1]*Milan/IT*, [2]*San Donato Milanese/IT* *(moreno.zanardo90@gmail.com)*

Purpose: The dose of contrast material for multi-phase abdominal CT is usually based on patient body weight (BW). Inter-patient morphometric variables, such as muscular and adipose tissues or blood pool extent, are implicated in variations of parenchymal contrast enhancement (CE). We assessed their impact on liver CE.
Methods and Materials: We retrospectively evaluated 200 abdominal CT exams in 106 males and 94 females, intravenously injected with Iopamidol (370mg/ml). Body mass index (BMI), lean body weight (LBW) and body surface area (BSA) were estimated using validated formulas. Liver CE, defined as the absolute difference in HU between portal and basal phases, was measured. Data were reported as mean±standard deviation; bivariate correlation and multivariate regression analyses were performed.
Results: Patient age was 66±13 years, with a BW of 72±15kg and a LBW of 53±11kg. The contrast dose was 1.2±0.2 ml/kg of BW or 1.7±0.2 ml/kg of LBW; the liver CE resulted 43±9 HU. A negative correlation was found between BW and dose (r=-0.686, p<0.001). Liver CE weighted on iodine grams positively correlated with the BW (r=0.704, p<0.001), LBW (r=0.665, p<0.001) and BSA (r=0.712, p<0.001). At multivariate regression analysis, the contrast dose per kg of BW was the only independent predictor of contrast enhancement variability, with a standardised correlation coefficient of 0.268 (p=0.002).
Conclusion: We found a high variability of administered dose due to radiologist's adjustment based on patient morphometry and comorbidities. To reduce liver CE variability, further studies are needed to find out a more patient-centered way to calculate contrast dose.

Material suppressed iodine using dual-energy spectral CT: feasibility and influencing factors

H. Zhao; *Zhengzhou/CN (kindergirl@sina.cn)*

Purpose: To investigate the feasibility of material suppressed iodine (MSI) images derived from spectral CT to replace true noncontrast-enhanced (TNC) images and assess the effect of contrast agent dose and body mass index (BMI) on MSI images.
Methods and Materials: Sixty patients who underwent spectral CT were divided into two scan protocols based on BMI (n = 30 each; protocol A, 80 kVp/300 mgI/kg, 18-23.9kg/m^2; protocol B, 100 kVp/400 mgI/kg, 24-29kg/m^2). TNC images (A1 and B1) were obtained while MSI images with adaptive statistical iterative reconstruction (ASIR) were reconstructed during the arterial phase (A2 and B2) and venous phase (A3 and B3). Image noise, CT value and contrast-to-noise-ratio (CNR) of liver, aorta and portal vein were compared between MSI images and TNC images and between protocols A and B.
Results: Intra-group: image noise in A3> A2>A1 and B3>B2, in B1 was similar to those of B2 and B3. The CT values of liver in A1 were similar to A3 but higher than A2, in B1>B3>B2. The CT values of vessels in MSI images were similar to TNC images except B2> B1 in aorta and A3>A1 in portal vein.The CNR values of liver and vessels were similar except A1>A2 and A1>A3 in aorta and portal vein. Inter-group: compared with protocol B, protocol A showed higher image noise but lower CT values of vessels.
Conclusion: The image quality of MSI images might be able to replace TNC images; the increase of contrast material dose and BMI might improve the image quality of MSI images.

B-0709 11:10

Feasibility of material suppressed iodine using dual-energy spectral CT with optimised adaptive statistical iterative reconstruction (ASIR) in abdominal CT

H. Zhao; *Zhengzhou/CN (kindergirl@sina.cn)*

Purpose: To assess the image quality of material suppressed iodine (MSI) images derived from spectral CT imaging with different percentages of ASIR.
Methods and Materials: Forty-six patients underwent conventional non-contrast-enhanced (TNC) and arterial-phase (AP) and venous phase (VP) with CT spectral imaging mode. MSI images generated from spectral CT were reconstructed with different percentages of ASIR (0%, 30%,50%, 70%) during the arterial phase (B1, C1, D1, E1) and venous phase (B2, C2, D2, E2). TNC images (A) were reconstructed with 0% ASIR and compared with MSI images in image noise, CT value and contrast-to-noise ratio (CNR) of liver, aorta and portal vein. Volume CT dose index (CTDIvol) was recorded.
Results: Image noise in E1<D1<C1<B1<A, C2<D2<B2<E2<A (all *P* values <0.05). The CT values of the liver in B1<C1<D1<E1<A (all *P* values <0.05), C2<B2<D2<E2<A (all *P* values> 0.05). The CT values of the aorta and portal vein of MSI images were similar to those of TNC images, and the CT value of MSI with 70% ASIR was close to the TNC images. There were significant differences in CNR of liver: E1>B1>C1> D1>A, C2>E2>D2>B2>A. There was no significant difference between MSI images and TNC images in CNR of aorta and portal vein (all P values >0.05).The CTDIvol could be reduced by 9.92mGy (34%) without TNE scan.
Conclusion: MSI images with 70% ASIR might replace TNC images and could reduce 34% radiation dose.

Fast abdominal imaging with high parallel-imaging factors: comparative study of a 60-channel receiver coil with the standard coil setup

A. Othman, J. Weiss, J. Taron, K. Nikolaou, M. Notohamiprodjo; *Tübingen/DE (ahmed.othman@uni-tuebingen.de)*

Purpose: To assess a novel 60-channel receiver coil setup regarding signal-to-noise ratio (SNR) and image quality in fast abdominal imaging as compared to a standard 30-channel coil setup.
Methods and Materials: All imaging data were acquired on a 3T MR scanner (Magnetom Skyra, Siemens Healthineers). 3D-T1-GRE imaging with different PAT factors (CAIPIRINHA: none,2,3,2x2,3x2,2x3,3x3) was performed in a water-phantom and in 5 volunteers using a novel 60-channel (30-channel anterior+posterior) receiver coil setup and standard 30-channel (18-channel-body and 12-channel-spine coil)-setup. SNR was measured on phantom images. Image quality assessed by two radiologists (5-point Likert scale; 5=excellent quality). In a further step, standard contrast-enhanced abdominal 3D-T1-GRE imaging with PAT 2 and accelerated imaging with PAT 2x2 and 3x2 was performed in 17 patients who were assigned into two groups (60-channel, n=8; 30-channel, n=9). Image quality was compared between the two patient groups.
Results: In comparison to the 30-channel coil, SNR gain for the 60-channel setup was observed for all acquisitions except for PAT=none. Relative SNR gain for the 60-channel coil ranged between 2.21% for PAT=2 and 22.69% for PAT=3x2. Comparison of image quality in healthy participants revealed significantly higher ratings of the 60-channel setup for all acquisitions (p≤.046), except for PAT=none (p≥.180). In patients, similar results were observed with comparable image quality at lower PAT factors (PAT=2; p≥.069) and significantly superior image quality of the 60-channel setup for higher PAT factors (2x2 and 3x2; p≤.036).
Conclusion: The 60-channel coil setup improves image quality and, therefore, enables fast abdominal imaging at high PAT factors with diagnostic image quality.

B-0711 11:26

Assessment of bolus tracking for the acquisition of a single dual-energy iodine map as a quantitative imaging biomarker replacing abdominal CT perfusion

S. Skornitzke, F. Fritz, P. Mayer, M. Koell, T. Hackert, H.-U. Kauczor, W. Stiller; *Heidelberg/DE (Stephan.Skornitzke@med.uni-heidelberg.de)*

Purpose: To quantitatively evaluate dual-energy (DE) computed tomography (CT) iodine concentration maps acquired using bolus tracking with different trigger delays as a dose-reduced replacement of CT-perfusion maps for diagnosis and treatment response assessment of abdominal tumours, such as pancreatic carcinoma.
Methods and Materials: For 22 patients with pancreatic carcinoma, DECT perfusion sequences were dynamically acquired using dual-source DECT at tube potentials of 80kV$_p$ and 140kV$_p$ with tin filtration. After deformable motion-correction, perfusion maps were calculated from 80kV$_p$ image series and DECT iodine maps were calculated for each of the 34 DECT acquisitions per patient. Measurements of perfusion and iodine concentration were performed in regions of interest in healthy pancreatic tissue and carcinoma. For each patient, 34 iodine maps at different acquisition delays were evaluated with regard to correlation to perfusion and inter-group differences between healthy tissue and carcinoma, simulating acquisitions triggered by bolus tracking by using the timing of bolus tracking of prior three-phase contrast-enhanced CT as a reference (threshold 120HU in abdominal aorta).
Results: Average perfusion measured in healthy pancreatic tissue and carcinoma was 87.6±28.4ml/100ml/min and 38.6±22.2ml/100ml/min, respectively. Correlation between iodine concentrations and perfusion was statistically significant for bolus tracking with trigger delay greater than 0s (r_{max}=0.89). Differences in iodine concentrations between healthy pancreatic tissue and carcinoma were statistically significant for DECT acquisitions corresponding to trigger delay of 15-21s.

Conclusion: DECT iodine maps acquired using bolus tracking with appropriate trigger delay could serve as a quantitative imaging biomarker in the abdomen, providing a dose-efficient replacement of CT-perfusion.

B-0712 11:34

Image quality comparison of low-dose contrast-enhanced abdominal CT with different protocols: reduced tube voltage or reduced tube current?
S. Ying[1], F. Chen[1], J. Yao[1], G. Yang[1], G. Lei[1], Y. Jiang[2]; [1]*Hangzhou/CN*, [2]*Shanghai/CN (ysh0609@126.com)*

Purpose: To determine a better optimised scan protocol between reduced tube voltage and reduced tube current for low-dose-enhanced abdominal CT.
Methods and Materials: 41 patients who were randomly assigned into 2 groups underwent enhanced abdominal CT. The scan protocols were 100kV/150mAs with ATCM for group 1, and 120kV/100mAs with ATCM for group 2. Images were reconstructed with filtered back projection (FBP), hybrid iterative reconstruction (HIR) and iterative model reconstruction (IMR) algorithms, respectively. Images acquired in portal vein phase were used for analysis. CT attenuation, image noise and CNR of liver parenchyma were measured. Subjective image quality assessments were performed according to the features of structure delineation, noise, artefacts, image distortion, and diagnostic confidence.
Results: No difference was found in mean $CTDI_{vol}$ between two groups. Image noise was higher in group 1 than group 2 in FBP and HIR images; however, no difference of image noise was observed in IMR images. No difference was found in CNR between groups. FBP images in both groups failed to reach acceptable subjective image quality, although images in group 2 exhibited better scores than group 1. HIR images in both groups reached acceptable image quality with no difference between each other. IMR images in both groups reached excellent image quality with better score in group 1 than group 2.
Conclusion: Both reduced tube voltage and tube current protocols can be used in low-dose abdominal CT with HIR and IMR. Reduced tube voltage protocol tends to exhibit better image quality when using IMR.

B-0713 11:42

Spleen stiffness: an index marker of oesophageal varices in patients with liver cirrhosis
N. Balpande[1], D. Aditi[1], K. Meera[1], K. Sudhakar[1], K. Ajairamcharan[1], M. Ipsit[2]; [1]*Chennai/IN,* [2]*Kozhikode/IN (drnikb@gmail.com)*

Purpose: To correlate spleen stiffness (SS) measured by ARFI (acoustic radiation force impulse) with upper GI endoscopy for the presence of esophageal varices (EV) in patients of cirrhosis.
Methods and Materials: Our study included 78 patients of cirrhosis (66 males, 12 females). We performed 5 measurements in each and a median value was obtained. Patients were examined by endoscopy and grade of EV was noted.
Results: A cut-off value of 3.04 m/s for spleen stiffness by ARFI showed sensitivity of 78.2%, specificity of 78.3%, PPV of 89.5% and NPV of 60% for differentiating those with and without EV. SS in patients with grade 3 EV was significantly higher than those with grade 1 EV. Spleen size in patients with EV was significantly higher than those without EV. Within the group of patients with EV, those with higher grades of EV had higher values of spleen size.
Conclusion: 1) SS is significantly higher in patients of cirrhosis than in normal individuals. 2) In patients of liver cirrhosis, SS by ARFI can be used to predict the presence of EV; and endoscopy being an invasive procedure can be avoided in rest of the patients who do not have EV. 3) SS in patients with grade 3 EV was significantly higher than those with grade 1 EV. Thus it could predict the severity of EV.

B-0714 11:50

Focal splenic lesion: to remove or not to remove?
S. Jang[1], J. Kim[1], B. Hur[2], I. Joo[1], S. Ahn[1], M. Kim[2], J. Han[1]; [1]*Seoul/KR*, [2]*Gyeonggi-do/KR (junemiru@gmail.com)*

Purpose: To assess the important CT findings and clinical features for differentiating malignant from benign focal splenic lesions.
Methods and Materials: From 2003 to 2015, among 673 patients with splenectomy in two institutes, we included 114 patients with focal splenic lesion who underwent preoperative CT scans (malignant=66, benign=48). Two radiologists retrospectively accessed CT findings including size of spleen, multiplicity, nature (mainly cyst vs mainly solid), margin (well- vs ill-defined), presence of wall, calcification, and enhancement pattern. They also graded the possibility of malignancy. Clinical features including presence of underlying malignancy, fever, and leukocytosis were assessed. Multivariate logistic regression analysis was performed to identify significant predictors for malignant lesion. We used receiver operating curve analysis for diagnostic performance.
Results: Statistically common features for malignant lesions included enhanced, mainly solid nature, ill-defined margin, absence of splenomegaly, absence of wall and calcification, and presence of underlying malignancy ($p<0.05$). In multivariate analysis, mainly cystic nature (OR, 7.428, P=0.005) and presence of underlying malignancy (OR, 15.017, P=0.001) were significant predictors for malignant lesion. Diagnostic performance for differentiating malignant lesions were 0.856 and 0.893 for each reviewers with substantial interobserver agreement (κ=0.6336). Malignant lesion (3.9+3.2cm) was smaller than benign lesion (5.9+3.3cm). Using the 4.25cm as a cut-off value, sensitivity and specificity were 66.7% and 72.7%.
Conclusion: CT and clinical features were useful for prediction of malignant splenic lesion. Mainly solid nature and presence of underlying malignancy can be helpful when differentiating malignant splenic lesion.

4D-flow MRI in patients with Fontan circulation for evaluation of pulmonary artery blood distribution
A. Curta, A. Lehner, U. Walter, R. Dalla-Pozza, M. Fischer, N. Haas, H. Kramer; *Munich/DE (harald.kramer@med.lmu.de)*

Purpose: To implement 4D-phase-contrast-flow MRI (4D-flow MRI) in the workup of patients with congenital heart disease and Fontan (FO) circulation and to evaluate the feasibility to assess caval blood flow distribution towards the pulmonary arteries (PA).
Methods and Materials: 4D-flow MRI scans were acquired in 10 FO patients (12.8±4.2 years) with extracardiac tunnel. 4D-flow MRI was performed with a velocity encoding (VENC) of 100cm/s, spatial resolution of 2.2x1.8x1.8mm and 10 time-frames/heart beat (HB). Flow pattern and distribution to the PAs were visualised using colour-coded path lines. All acquired data were processed offline using vendor prototype software.
Results: Blood from the Glenn and Fontan tunnel drained predominantly to the right PA (53% vs 47%). Left PA blood supply tended to be lower but with higher flow velocity compared to the RPA (12.68 ml/HB vs 15.68 ml/HB; 62.2 cm/s vs 49.7 cm/s), consistent with anatomically smaller or distorted LPAs. Path lines revealed Fontan blood predominantly draining to the RPA within our patient cohort on the contrary to recently published data. However, within our group, Glenn and Fontan tunnels were rather placed orthogonal to each other than with a distinct offset to one or the other side as reported by others.
Conclusion: 4D-flow MRI in Fontan patients was feasible with promising results. This work can serve as pilot data for further studies with larger patient numbers to correlate different surgical methods to the resulting PA blood flow distribution and its possible impact on late complications of the Fontan operation-like protein-losing enteropathy.

Optimising image quality in CT pulmonary angiography using low contrast media volume and automated tube voltage selection
B.M.F. Hendriks, N.G. Eijsvoogel, B. Horehledova, M. Kok, B. Martens, L.F. Carati, J.E. Wildberger, M. Das; *Maastricht/NL (babs.hendriks@mumc.nl)*

Purpose: Evaluating image quality of ultra-low contrast media (CM) volume and ultra-low radiation dose computed tomographic pulmonary angiography (CTPA) using automated tube voltage selection (ATVS).
Methods and Materials: 140 consecutive patients receiving CTPA at 70, 80 and 90kV as selected by ATVS on a 3rd generation MDCT (SOMATOM Definition Force, Siemens Healthcare) were analysed. Scan protocol: 105 $mAs_{qual.ref}$, 100 kV_{ref}, pitch 1.2, 1 mm slice, 0.7 mm increment, iterative reconstruction strength 3 (ADMIRE). CM (Iopromide 300 mgI/ml, Bayer) was adapted to body weight and kV-setting via iodine delivery rate based on an 8 s injection time. Objective image quality (IQ) was assessed in the pulmonary trunk (PT; attenuation measurements [HU]), contrast-to-noise and signal-to-noise ratio (CNR/SNR). Variables are reported as mean±SD. Subjective IQ was assessed at central, lobar, segmental and subsegmental level.
Results: Mean body weight was: 70±14 kg for 70 kV (n=42), 71±13 kg for 80 kV (n=67)and 92±14 kg for 90 kV (n=31), p-value between 70/80 kV and 90

kV<0.01. Mean effective radiation dose for 70 kV: 1.2±0.2 mSv, 80 kV: 1.7±0.4 mSv and 90 kV: 2.1±0.6 mSv. Mean CM bolus was 24±3 ml, 28±3 ml and 38±3 ml, respectively. Mean PT attenuation was similar for 70, 80 and 90 kV: 397±99 HU, 396±97 HU and 378±101 HU. CNR/SNR: 14±6/14±4, 16±6/14±4 and 14.±7/13±4 for 70, 80 and 90 kV (p>0.6). Eight scans (4 at 70 kV, 3 at 80 kV and 1 at 90 kV) were rated non-diagnostic on subsegmental level; all other segments were graded as diagnostic/excellent IQ.
Conclusion: CTPA can be individually optimised using ATVS in combination with CM application adapted to body weight and kV, resulting in very low radiation and CM doses for patients.

Virtual monoenergetic imaging and iodine perfusion maps improve diagnostic accuracy of dual-energy CT pulmonary angiography with suboptimal contrast attenuation

D. Leithner, J.L. Wichmann, T.J. Vogl, J. Trommer, S.S. Martin, S. Jan-Erik, B. Bodelle, M.H. Albrecht; *Frankfurt a. Main/DE (doris.leithner@googlemail.com)*

Purpose: To evaluate the impact of virtual monoenergetic imaging (VMI+) and perfusion maps (DECT-PM) on diagnostic accuracy and reader confidence in dual-energy CT pulmonary angiography (DE-CTPA) examinations with suboptimal contrast attenuation, compared to standard linearly-blended series.
Methods and Materials: DE-CTPA examinations with suboptimal contrast attenuation of 68 patients with suspected pulmonary embolism (PE) were included in this IRB-approved retrospective study. VMI+ series at 40keV, DECT-PM and linearly blended images (M_0.6 - 60% 90 kV spectrum) were reconstructed. Contrast-to-noise (CNR) and signal-to-noise ratios (SNR) within the pulmonary trunk were calculated. Four independent radiologists assessed the presence of PE and their diagnostic confidence using three DE-CTPA reconstruction protocols: protocol 1: M_0.6 images; protocol 2: M_0.6 series and DECT-PM; protocol 3: M_0.6, DECT-PM, and VMI+ series. Receiver operating characteristic (ROC) analysis was performed.
Results: 14 patients showed central and 29 segmental PE. Higher CNR and SNR values were measured in VMI+ series at 40keV in comparison to M_0.6 images (P<0.001). Diagnostic accuracy for segmental PE detection was as follows: protocol 1: 69.1%; protocol 2: 86.8%; protocol 3: 92.6%. Protocol 3 resulted in a significantly greater area under the curve (AUC) for diagnosing segmental PE (0.991, P≤0.033), compared to protocol 1 and 2 (0.897 and 0.951, respectively), and provided the highest diagnostic confidence (P<0.001).
Conclusion: A reconstruction protocol including 40keV VMI+ series and DECT-PM improves reader confidence and diagnostic accuracy for segmental PE detection compared to standard M_0.6 images in DE-CTPA with suboptimal contrast attenuation.

B-0718 11:03

Validation and error quantification of pulmonary artery 4D-flow MRI in a digital broadband 3T-MR setup

C. Berlin, T.H. Oechtering, M. Sieren, D. Droemann, J. Barkhausen, A. Frydrychowicz; *Lübeck/DE (thekla.oechtering@uksh.de)*

Purpose: 4D-flow MRI offers a yet unmet potential diagnosing pulmonary hypertension. Until now, there has been no comprehensive validation of the sequence at a system with digital broadband technique, which promises an increased signal-to-noise ratio. Therefore, our aim was to validate 4D-flow MRI in the pulmonary arteries (PA).
Methods and Materials: The PA of 23 healthy volunteers (14f, 38±18y) were examined at 3T (Philips Ingenia) with a 4D-flow MRI sequence. Using GTFlow (GyroTools, CH), planes transecting the main, right, and left PA (MPA, RPA, LPA, respectively) were analysed. The MPA stroke volume (SV) was measured in 4D data and compared to 1) a static phantom acquisition, 2) 2D phase contrast (2DPC) acquisitions, 3) right ventricular SV (RVSV) derived from a bSSFP-sequence, and 4) a conservation of mass analysis (COM). Statistical analyses included Bland-Altman analysis and Student's t test.
Results: Using 4D flow-MRI, the MPA SV was 93.0±26.1 vs. 90.5±25.3ml/s with phantom correction, respectively, compared to 2DPC with 87.3±19.1 and 87.4±19.0ml (uncorrected p<0.05, corrected p=0.241). The average difference between 4D flow-MRI and 2DPC was 5.7±10.6ml and improved to 3.1±12.3ml after phantom correction. Compared to RVSV (92.9±15.6ml), the average difference was 5.5±17.2ml and improved to -0.1±20ml (p=n.s.) after phantom correction. The average difference to the COM analysis was 2.2±15.6ml which worsened through correction to 7.7±15.9ml (p=n.s.; p<0.05).
Conclusion: Quantitative 4D-flow MRI in the pulmonary artery is comparable to alternative MR approaches. The improvement of the already good data after phantom correction and the standard deviation may be explained by imperfectly corrected phase offsets.

B-0719 11:11

Comparison of unenhanced and contrast-enhanced MRI in the detection of pulmonary AV-malformations in patients with hereditary haemorrhagic telangiectasia

P. Jagoda, J. Stroeder, A. Massmann, A. Buecker, G. Schneider; *Homburg/DE*

Purpose: The aim of our study was to compare Gd-enhanced MR angiography with unenhanced MR imaging techniques for the detection of pulmonary AV-Malformations (PAVMs) in patients with hereditary hemorrhagic telangiectasia (HHT).
Methods and Materials: 122 patients with HHT underwent 188 MR examinations between 2011 and 2015. During each examination a non contrast enhanced SPACE (3D TSE-sequence/TR 4.733 ms/TE 101 ms/FLIP 150°) and a contrast enhanced 3D GRE MRI sequence (TR 2,87ms/TE 1,07 ms/FLIP 25°, 0.1 mmol/kg BW MultiHance) were acquired. Both examinations were read by two experienced radiologists and the number of detected AV-Malformations was reported in mutual agreement for each examination. The contrast enhanced images were always read first and after an interval of 6 weeks, the SPACE was read. In those patients that underwent interventional treatment, catheter angiography and in all other patients CE-MRA served as the gold standard. A paired t-test was utilised for statistical evaluation.
Results: 4 Examination were excluded due to respiratory artifacts in both sequences. 60 AV-malformations requiring therapy were reported in 35 patients. Using contrast enhanced images, an overall significantly higher number of AV-malformations was detected (166 vs. 96, p<0.001) but none of the AV-malformations requiring therapy were missed using the unenhanced SPACE sequence.
Conclusion: The detection of clinical relevant pulmonary AV-malformations can be safely performed in patients with contraindications for i.v. contrast medium (e.g. pregnancy) by using a SPACE sequence.

B-0720 11:19

C-arm computed tomography (CACT) in patients with chronic thromboembolic pulmonary hypertension and a positive V/Q SPECT/CT: evaluation of additive diagnostic information

J. Hinrichs, T. Werncke, M.M. Hoeper, K.M. Olsson, T. Brunkhorst, F.K. Wacker, J.M. Sohns, B.C. Meyer, C. von Falck; *Hannover/DE*

Purpose: To evaluate the potential additional diagnostic information of C-arm computed tomography (CACT) in patients suffering from chronic thromboembolic pulmonary hypertension (CTEPH) with a positive ventilation/perfusion (V/Q) SPECT/CT.
Methods and Materials: Seventeen patients (11 men, 6 women, 73±11 years) with CTEPH who had undergone SPECT/CT, followed by CACT and right heart catheterisation (RHC) were included. Two independent readers reviewed SPECT/CT and another two readers the CACT images. CTEPH-indicating findings and their location (segmental or sub-segmental) were identified (V/Q mismatch in SPECT/CT and vascular pathologies in CACT). Inter-observer agreement was calculated and consensus reading was done for calculation of inter-modality agreement (Cohen´s Kappa).
Results: Overall, 306 pulmonary artery segments were assessed in SPECT/CT and CACT. SPECT/CT identified 128/306 (41%) arterial segments without and 178/306 (59%) with CTEPH-indicating V/Q mismatch. CACT detected 57/306 (19%) segments without abnormal findings and 249/306 (81%) with CTEPH-indicating findings. Inter-observer agreement was good for both modalities (SPECT/CT κ=0.73; CACT κ=0.77, respectively). Inter-modality agreement after consensus reading was fair (κ=0.28). Discrepant findings were mostly attributed to a higher frequency of sub-segmental pulmonary arterial pathologies on CACT (79 sub-segmental CTEPH-indicating findings) rated as normal on SPECT/CT.
Conclusion: In patients with CTEPH, contrast-enhanced CACT detects additional findings as compared to V/Q SPECT/CT. CACT indicates abnormalities even in segments without V/Q abnormalities.

Model-based iterative reconstruction on low-dose CT pulmonary angiography: diagnostic image quality and radiation dose saving compared with hybrid iterative reconstruction CTPA

A. De Vito, D. Ippolito, C.R.G.L. Talei Franzesi, L. Riva, E.B. Orsini, S. Sironi; *Monza/IT (a.devito@campus.unimib.it)*

Purpose: To evaluate dose reduction and image quality of low-dose CT pulmonary angiography (CTPA) reconstructed with model-based iterative reconstruction (IMR) and compared with hybrid iterative reconstruction (iDose4).
Methods and Materials: 69 patients were prospectively enrolled and investigated for pulmonary embolism; a study group of 39 patients underwent low-kV setting (100kV;automated mAs) CTPA study, while a control group of 30 patients underwent standard CTPA protocol (120 kV;automated mAs); all patients were examined on 256 MDCT scanner (iCT elite;Philips). In the first group (Study Group) images were reconstructed using IMR technique while in the second group (Control Group) we used iDose4 technique. CTDIvol, DLP and Estimate Doses (ED) were evaluated in both groups. Region of interests were drawn in the three main pulmonary vessels; signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated. A four-point scale was used to subjectively evaluate the image quality of iDose4-CTPA and low kV IMR-CTPA.
Results: Compared to iDose4-CTPA, low kV IMR-CTPA presented lower CTDIvol (9,68 ± 3,54 vs 16,7 ± 5,34 mGy) and DLP (352,48 ± 3,59 vs 673,5 ± 36,9 mGy x cm). ED were 4,93 ± 1,8 vs 9,64 ± 3,05 mSv. Moreover IMR-CTPA showed higer values of attenuation in the three main pulmonary vessels and a significantly higher SNR (p<0,0001) and CNR (p<0,0001). The subjective image quality of low kV IMR-CTPA was also higher compared with iDose4-CTPA.
Conclusion: Low kV IMR-CTPA allows a significant dose reduction and improves attenuation values, SNR and CNR in the pulmonary vessels, as compared with standard kV iDose4-CTPA.

B-0722 11:35

Analysing pulmonary artery haemodynamics with 4D-flow MRI: comparison to 2D phase contrast MRI in patients with pulmonary hypertension and healthy volunteers

M. Sieren, C. Berlin, T. Oechtering, P. Hunold, D. Droemann, J. Barkhausen, A. Frydrychowicz; *Lübeck/DE (malte.sieren@uksh.de)*

Purpose: 2D and 4D phase-contrast MRI (2DPC, 4D flow MRI) are increasingly being used to non-invasively diagnose pulmonary hypertension (PH). It was the goal of this study to compare 2DPC and 4D flow MRI in the pulmonary vessels with respect to previously established diagnostic parameters to distinguish healthy volunteers from patients diagnosed with PH.
Methods and Materials: 11 patients with PH (4f, 63±15y), 15 age-matched healthy volunteers (9f, 56±11y), and 20 young healthy volunteers (13f, 23±2y) were scanned at 3T (Philips Ingenia). A retrospective ECG-gated 4D flow MRI sequence with respiratory gating was applied. Data were reconstructed to spatial resolution=2mm^3 and temporal resolution=20 frames. A standard clinical 2DPC-MRI sequence with 40 frames was acquired during breath holds in the main pulmonary artery (MPA). GTFlow (GyroTools, CH) was used to extract various flow-, velocity- and vessel area-derived parameters.
Results: There was good agreement between 2DPC and 4D flow MRI across all participants with a tendency of 4D flow MRI to overestimate values. Only differences in flow volume and time to maximum flow revealed statistical significance, the average Bland-Altman differences were acceptably small. Both 2DPC and 4D flow MRI revealed concordant results to differentiate patients from healthy individuals, especially with strain (4D: Vol 34.8±13.3% vs. Pat 24.5±8.8%; 2D: Vol 41.2±12.4% vs. Pat 21.2±7.3%; for all p<0.05).
Conclusion: This study confirms that haemodynamic parameters used for the diagnosis in pulmonary hypertension can be gathered using 4D flow MRI within reasonable clinical limits of agreement. Despite its unfavourable spatial and lesser temporal resolution, the identification of diseased study participants was possible.

B-0723 11:43

Feasibility of a low dose and low contrast media protocol for CT pulmonary angiography

S. Suntharalingam, C. Mikat, Y. Erfanian, K. Nassenstein; *Essen/DE*

Purpose: To evaluate the image quality and radiation dose of a low dose and low contrast media protocol for CT pulmonary angiography (CTPA).
Methods and Materials: Sixty patients with suspected pulmonary embolism were examined with two different protocols (n = 30 each, group A, 100 kVp, ref. mAs 150, 60 ml of contrast medium; group B, 80 kVp, ref. mAs 115, 25 ml of contrast medium. Image quality and radiation dose were evaluated and compared.
Results: Signal intensities in main pulmonal artery (351.4 vs. 291.8; p=0.08), left pulmonal artery (339.2 vs. 311.6; p=0.42), right pulmonal artery (340.8 vs. 309.9; p=0.37), lobar artery (368.9 vs. 343.0; p=0.49), segmental artery (347.6 vs. 323.4; p=0.50) and subsegmental artery (334.4 vs. 330.4; p=0.91) were slightly, but not statistically significantly higher in group A. SNR and CNR values were comparable between both groups (all p>0.05). Subjective image analysis revealed no significant differences between the two groups. All exams were rated as good to excellent or adequate. Compared with group A, radiation dose of group B was reduced by 71.8 % (2.4 vs. 0.7 mSv; p<0.001).
Conclusion: A low dose protocol at 80 kV can obtain sufficient image quality for CT pulmonary angiography with 25 ml of contrast media and reduce radiation dose by 71.8 % compared to a standard protocol.

B-0724 11:51

Vascular rings: contrast-enhanced MR angiography in comprehensive evaluation of broncho-vascular anatomy in children.

E. Karavaeva[1], J. Finn[2]; [1]*Moscow/RU*, [2]*Los Angeles, CA/US (lenakara-23@mail.ru)*

Purpose: To evaluate feasibility and sufficiency of high resolution, contrast-enhanced MR Angiography (CEMRA) in detailed assessment of 3D vascular and proximal airway anatomy in children with suspected vascular rings.
Methods and Materials: 42 paediatric patients (25 male, 17 female; 6.14 +/- 4.07 years, range 1m to 13 y) with clinical suspicion of vascular rings underwent multiphase, high spatial resolution CEMRA at 3.0T (31 patients) or 1.5T (15 patients) with gadolinium-based contrast medium. Using standardised scoring system 2 independent radiologists scored the studies for image quality, artifacts, visibility of upper airways. Additionally, all studies were evaluated for presence of pathology, including vascular rings and trachea-bronchial compression, by the same two radiologists and a third independent radiologist. Correlation with chest x-ray was available in all patients and with chest CT in 12 patients.
Results: All scans were scored as highly diagnostic with good or excellent image quality. Visualisation of the trachea and bronchi was assessed as confident, the interobserver agreement was considered as 'good' and 'excellent' (Cohen's kappa ranged from 0.607 to 0.846 depending on scored segment). A total of 10 vascular rings with tracheobronchial compression were detected with excellent interobserver agreement (Fleiss' kappa = 1). The mean difference between MR and CT measurements of trachea diameter at 3 different levels was 0.45 +/- 0.3 mm.
Conclusion: High resolution CE MRA is feasible for confident assessment of both vascular and relevant 3D trachea-bronchial anatomy in children with suspected vascular rings, and may make supplemental CT imaging unnecessary in appropriate patient groups.

Lung image quality of a prototype ultra-high resolution CT scanner: comparison to current clinical standard

P. Rogalla[1], A. Sirajuddin[2], S. Kandel[1], J. Kavanagh[1], M. Prokop[3], A. Blum[4], J. Schuzer[1], B. Hoppel[1], M. Chen[2]; [1]*Toronto, ON/CA*, [2]*Bethesda, MD/US*, [3]*Nijmegen/NL*, [4]*Nancy/FR (Patrik.Rogalla@uhn.ca)*

Purpose: To compare the lung image quality of a prototype ultra-high resolution CT (UHR-CT) scanner with a current state-of-the-art CT scanner.
Methods and Materials: 20 patients (mean BMI 25.1 ± 3.1, age 55.5) underwent a chest CT on a prototype whole body (0.25mm x 128 detector matrix) scanner (Toshiba) for cancer staging. Images were compared to prior scans acquired on a standard CT (Vision, 0.5 x 80 detector matrix). Images were iteratively reconstructed on the clinical scanner at 0.5 mm and 512 image matrix (series I), and on the prototype scanner at 0.25 mm, 512 (series II) and 1024 image matrix (series III). Five blinded reviewers (1-24 years of expertise) forced-ranked the images in order of their individual preference. Image noise was measured in the aorta, muscle, air; radiation dose was recorded.
Results: Mean ranking for series I, II, II was 2.78, 2.15, and 1.07 (p<0.0001), with the exception of two patients ranked by three readers, the 0.25 mm slices at 1024 matrix always ranked best, followed but the 0.25 mm slices at 512 matrix (p=0.0013). Mean SD of image noise in air/muscle/aorta for series I, II, and III was 19.7/39.4/34.5, 25.2/57.9/50.0, and 33.5/77.7/69.0, respectively

(p<0.0001). Radiation dose was 18% higher on the prototype scanner (mean DLP: 386.8, SD 98.3) than on the clinical scanner (mean DLP: 325.4, SD 109.1).
Conclusion: Radiologists preferred the UHR-CT over the current clinical standard. Thinner slices at higher matrix improved subjective image quality of the lung at the cost of higher radiation dose.

B-0726 10:38

Prototype ultrahigh-resolution CT for chest imaging: initial human experience
S.M. Shanbhag[1], J.L. Schuzer[2], C. Steveson[3], S. Rollison[1], M.S. Stagliano[1], K.C. Bronson[1], M.Y. Chen[1]; [1]*Bethesda, MD/US*, [2]*Vernon Hills, IL/US*, [3]*Otawara/JP (Shanbhagsm@nhlbi.nih.gov)*

Purpose: To evaluate a prototype, ultrahigh-resolution computed tomography CT scanner which offers imaging at a significantly higher matrix (1024x1024) and spatial resolution (140 microns) for chest imaging.
Methods and Materials: 100 consecutive patients (age 49.9±16.8 years, BMI 24.7±3.8 kg/m^2) were prospectively enrolled for this IRB-approved study. Each patient underwent a helical CT on a prototype, ultrahigh-resolution CT with 128-detector rows and 0.25mm detector width. CT images were reconstructed at a standard resolution matrix of 512x512 and at high-resolution 1024x1024 matrix. Each set of reconstructions was graded for image quality by 2 expert readers blinded to clinical data and reconstruction on a Likert scale (1=excellent, 5=non-diagnostic) for noise, artefacts, contrast, small detail, lesion conspicuity, image sharpness and diagnostic confidence. Image noise was quantified.
Results: All CT acquisitions were diagnostic image quality. Image noise was higher on the 1024 compared to 512 matrix reconstruction (20.2±4.0 vs. 17.2±3.8, respectively, p<0.001) and had a worse rating (1.98±0.63 vs. 1.75± .61, respectively, p<0.001). However, 1024 matrix performed significantly better than 512 matrix with regard to artefacts (1.37±0.43 vs. 1.50±0.48, respectively, p<0.001), contrast (1.50±0.56 vs. 1.62±0.57, respectively, p<0.001), small detail (1.06±0.19 vs. 2.02±0.22, respectively, p<0.001), lesion conspicuity (1.08±0.23 vs. 2.02±0.24, respectively, p<0.001), image sharpness (1.09±0.24 vs. 2.02±0.28, respectively, p<0.001), and diagnostic confidence (1.09±0.25 vs. 1.18±0.34, respectively, p<0.001).
Conclusion: Ultrahigh-resolution CT with higher 1024x1024 image matrix improves image quality compared to conventional 512x512 image matrix reconstruction, despite a small increase in image noise. This technological advancement in resolution may enhance the detection of disease.

Overscanning in chest CT: comparison of incidence among five Swiss hospitals and its impact on radiation dose
F.R. Schwartz[1], B. Stieltjes[1], Z. Szucs-Farkas[2], A. Euler[1]; [1]*Basle/CH*, [2]*Biel/CH (fides.schwartz@usb.ch)*

Purpose: To compare the incidence of overscanning in chest CT among five Swiss hospitals and its impact on radiation dose.
Methods and Materials: Scout images of 250 chest CT scans from five hospitals (A-E), which participate in a regional dose registry, were reviewed using a radiation dose tracking software (RTS) (Radimetrics, Bayer Healthcare). The RTS offers the possibility to virtually alter the cranial and caudal scan limits on each scout image and to estimate the changes in radiation dose, based on Monte Carlo simulations. Incidence of cranial and caudal overscanning was assessed by comparing the actual scan limits of each scan to optimized scan limits determined by a third-year radiology resident. In the optimised scan limits, 2 cm of safety margin were added to the cranial and caudal anatomic borders to account for patient's respiration and operator dependency. Changes in effective dose were calculated by the RTS. Descriptive statistics and Wilcoxon matched pairs test were applied.
Results: Cranial overscanning was observed in 24%, 28%, 30%, 0%, 14% of scans; caudal overscanning in 66%, 32%, 6%, 10%, 6%; both cranial and caudal overscanning in 20%, 10%, 2%, 0%, 0% for hospital A, B, C, D and E, respectively. Simultaneous caudal and cranial overscanning increased the effective dose on average by 0.36 mSv, 0.37 mSv, 0.02 mSv, 0 mSv, 0 mSv for A, B, C, D, E, respectively.
Conclusion: Substantial differences in the incidence of overscanning in chest CT exist among different hospitals resulting in excessive effective dose to the patient.

B-0728 10:54

Radiation dose reduction using orthogonal tomogram associated with topogram-based automatic tube voltage and current modulation for lung CT scanning
X. Liu, L. Zhang; *Shenyang/CN (xiaofeicmu@sina.com)*

Purpose: A new feature for advanced CT is to use tomogram a priori knowledge to modulate tube voltage or current in the real acquisition. This study is to evaluate tomogram's effectiveness on radiation dose and image quality for a set of lung scanning follow-up patients.
Methods and Materials: 38 patients were enrolled in our study. Scanning protocol was identical for both baseline and follow-up examinations. However, in baseline, only anteroposterior (AP) tomogram was applied, while in the follow-up, both AP and lateral (LAT) tomograms were performed. Topogram-based longitudinal-angular automatic current control and automated tube potential selection were "on" during all the scans. Radiation dose, subjective and objective image quality evaluations were compared. Meanwhile, the dose reduction ratio was further analysed in different BMI groups using ANOVA.
Results: In 34.2% (13) of the patients, tube voltage was automatically adjusted to lower kV when using orthogonal tomogram. Radiation dose was lower in follow-up group with an average of 16.9% reduction (5.38±1.37 vs 4.47±1.56mSv, p<0.05). Image noise, signal-to-noise ratio and objective image quality showed no differences between baseline and follow-up. Dose reduction in different BMI groups was not equivalent which intends to be more benefit for overweighted populations.
Conclusion: Using orthogonal tomogram can affect not only tube current modulation but also the selection of tube voltage. Total radiation dosage can even be saved without any compromise on image quality. Furthermore, this advantage was found to be of much more benefit for oversized patients.

B-0729 11:02

Impact on image quality and radiation dose of a novel spectral filtration 150 kV tin-filtered chest CT protocol in patients after lung transplantation
A. Wresenegger[1], C. Schestak[1], H. Prosch[1], H. Ringl[1], G. Apfaltrer[2], P. Apfaltrer[1]; [1]*Vienna/AT*, [2]*Graz/AT (Alexander.wressnegger@meduniwien.ac.at)*

Purpose: The purpose of this study was to investigate the radiation dose and image quality of non-enhanced chest CT using spectral filtration with a novel 150kVSn filter in patients after lung transplantation.
Methods and Materials: This retrospective study included 35 patients (51.4% male, mean age 49.5±15.5 years) who had undergone routine unenhanced chest CT follow-up after lung transplantation on both, a second-generation dual-source CT system (DSCT) using standard chest CT protocol and on a third-generation DSCT using a novel spectral filtration chest protocol (150kVSn). Signal-to-noise (SNR) was measured in 6 standardised regions in lung and soft tissue window to assess objective image quality. Subjective image quality was graded on a 5-point Likert scale for the assessment of ground glass opacities, bronchiectasis, traction, consolidation, architectural deformation, volume loss and hilus retraction after lung transplantation. Radiation metrics were compared using Student's t test.
Results: All studies were considered of diagnostic quality. Mean DLP and effective dose were 77.7±33.8mGy*cm and 1.4±0.6mSv at Sn150 kVp chest protocol vs 196.4±57.5mGy*cm and 3.5±1.0 mSv at conventional chest CT protocol (p<0.001) equivalent to a 60% reduction in radiation using the novel Sn150 kVp. There was no significant difference in image noise (54.1±2.7HU vs 45.0±2.3HU; p=0.097) and SNR (4.1±3.5 vs 5.1±3.5; p=0.054) between 150kVSn-CT and standard protocol. The median score in subjective analysis was equal for both protocols [25th-75th percentile]: 1[1-2] vs 1[1-2], (p>0.05).
Conclusion: Using a non-contrast 150kVSn chest CT protocol allows for substantial radiation dose reduction without compromising diagnostic image quality in the follow-up of patients after lung transplantation.

Sub-millisievert (mSv) third-generation dual-source chest CT with advanced modeled iterative reconstruction: image quality and lesion conspicuity
F. Sodagari, H. Savas, R. Agrawal, T.H. Grant, V. Yaghmai; *Chicago, IL/US (Rishi.Agrawal@nm.org)*

Purpose: To determine the lowest CT radiation dose parameters for detection of various lung pathologies in a phantom model.
Methods and Materials: An anthropomorphic adult-sized chest phantom containing six pathologies (ground glass opacity, bronchial polyp, solid nodule, ground glass nodule, bronchiectasis, tree-in-bud) was scanned with a third-

generation dual-source scanner. Scans were performed with 70, 80, 100 and 120 kV and fixed mAs ranging from 7 to 75 mAs and were reconstructed using advanced modeled iterative reconstruction algorithm. Two blinded chest radiologists reviewed the images independently and scored overall image quality and lesion conspicuity using a five-point scale. A score of 3 was considered acceptable for both image quality and lesion conspicuity. Radiation dose and noise were recorded for each acquisition and CNR was calculated.
Results: The lowest radiation dose parameters with acceptable conspicuity score for bronchial polyp, solid nodule, ground glass nodule, ground glass opacity, and bronchiectasis were 70 kVp/7 mAs (0.05 mSv). The conspicuity for tree-in-bud pathology was acceptable at 70 kVp/40 mAs (0.28 mSv). The lesion conspicuity scores between the two radiologists were comparable (P>0.05) for all lung pathologies studied. The lowest radiation dose parameters for acceptable image quality were 70 kVp/10mAs (0.07 mSv). Subjective image quality was directly proportional to the CNR (r=0.736; P=0.015) and inversely proportional to the image noise (r= -0.925; P=0.0001) for each acquisition.
Conclusion: Robust reduction in radiation dose for chest CT examinations, at levels similar to a chest radiograph, is possible at low kV settings with advanced modeled iterative reconstruction.

Influence of reconstruction methods for lung densitometry among model-based and hybrid type IR and FBP methods on ADCT from standard to low-dose levels at QIBA phantom study

E. Suehiro[1], T. Sekitani[1], W. Tani[1], N. Negi[1], Y. Fujisawa[2], N. Sugihara[2], K. Fujii[2], T. Yoshikawa[1], Y. Ohno[1]; [1]*Kobe/JP*, [2]*Otawara/JP*
(yosirad@kobe-u.ac.jp)

Purpose: To directly compare the influence of reconstruction method on area-detector CT (ADCT) from standard- to low-dose levels to COPD density measurement accuracy in QIBA phantom study.
Methods and Materials: QIBA recommended phantom for CT densitometry standardisation was scanned on a ADCT system at three tube current as 400mA, 100mA, and 10mA levels. In this study, three reconstruction methods such as FIRST (i.e. model-based iterative reconstruction <IR>), AIDR 3D (i.e. hybrid-type IR) and FBP methods were applied. To determine the influence of reconstruction methods, correlations between measured and actual densities at different simulated phantoms within QIBA recommended phantom were statistically evaluated by Pearson's correlation analyses. To evaluate the influence of reconstruction method on ADCT to CT densitometry assessment for COPD, CT values within lung phantom between measured and actual values were compared among all methods by Tukey's HSD test. Finally, the limits of agreement of each scan was assessed by Bland-Altman's analysis.
Results: There were significant and excellent correlations between measured and actual CT values on each scan method at all tube current setting (r=0.999, p<0.0001). On comparison of CT density assessment, there were no significant difference among all reconstruction methods at three different tube current sets (p>0.05). The limits of agreement of each reconstruction method between measured and actual CT density at different tube current settings were ranged as follows: FIRST, -0.7−1.1HU; AIDR 3D, -2.5−-1.4HU; FBP, -3.5−-1.4HU.
Conclusion: Reconstruction methods on ADCT at different tube current settings have little influence to accuracy of CT densitometry in QIBA phantom study.

Influence of scan methods to lung density measurement accuracy using ADCT from standard- to low-dose CT levels at QIBA phantom study

N. Negi[1], T. Sekitani[1], E. Suehiro[1], W. Tani[1], Y. Fujisawa[2], N. Sugihara[2], K. Fujii[2], T. Yoshikawa[1], Y. Ohno[1]; [1]*Kobe/JP*, [2]*Otawara/JP*
(yosirad@kobe-u.ac.jp)

Purpose: To determine the influence of scan method difference on area-detector CT (ADCT) from standard- to low-dose CT levels for COPD density measurement accuracy in Quantitative Imaging Biomarker Alliance (QIBA) recommended phantom study.
Methods and Materials: QIBA recommended phantom for densitometry standardisation in COPD was scanned by means of helical scans as 64-detector row CT (HS 64) and 80-detector row CT (HS 80) and non-helical scan (i.e. wide-volume scan: WV) at tube currents as 400 mA (standard-dose), 100 mA (reduced-dose) and 50 mA (low-dose) levels. To determine the influence of scan method to COPD densitometry assessment, correlations between measured and actual densities were statistically evaluated by Pearson's correlation analyses. To evaluate the influence of scan methods on ADCT at different tube current set to CT densitometry assessment for COPD, CT values within lung phantom were compared among all methods by Tukey's HSD test. Finally, the limits of agreement of each scan was also assessed.
Results: There were significant and excellent correlations between measured and actual CT values on all data set (r=0.999, p<0.0001). On comparison of CT density assessment, there were no significant difference among all scan methods at different tube currents (p>0.05). The limits of agreement of each scan method between measured and actual CT density at different tube current settings were ranged as follows: HS 64, -6.9−-5.0HU; HS 80, -4.6−-2.5HU; and WV, -3.5−-1.4HU.
Conclusion: Scan methods at ADCT with different tube current settings have little influence to accuracy of CT densitometry in QIBA phantom study.

Effects of the ASiR-V algorithm on objective and subjective image quality in chest MDCT

D.C. Rotzinger, D. Racine, K. Alfudhili, N. Keller, F.R. Verdun, C. Beigelman-Aubry, F. Becce; *Lausanne/CH (david.rotzinger@chuv.ch)*

Purpose: To investigate the effects of implementing ASiR-V on subjective and objective image quality (IQ) using appropriate physical metrics, in routine oncologic chest MDCT. Secondly, to determine the optimal ASiR-V level for the analysis of lung parenchyma at regular dose level.
Methods and Materials: Twenty patients underwent oncologic thoraco-abdominal MDCT performed on a 64-MDCT scanner at regular dose level (CTDIvol=12mGy) with images reconstructed using FBP. The same patients subsequently underwent (mean time interval=10months) follow-up imaging on a 256-MDCT scanner with 20% dose reduction (CTDIvol=9.6mGy) with images reconstructed using six ASiR-V levels (0%-100%, 20% increments). Subjective IQ was assessed by two independent and blinded radiologists. Objective IQ was evaluated on patient MDCT images by measuring standard deviation (SD), SNR and CNR, and on phantom images by computing detectability indices (d') with the Non-prewhitening with eye filter model observer.
Results: Regarding subjective IQ comparison between both CT systems, ratings from the two observers diverged. However, in subjectively determining the optimal ASiR-V level, both observers preferred 80% due to perceived lack of subtle details at 100%, with substantial interrater agreement (weighted kappa=0.69). Concerning objective assessment, ASiR-V significantly impacted IQ. Increasing ASiR-V level up to 100% significantly decreased SD, while concomitantly increasing SNR and CNR (p<0.001) on clinical images. On phantom images, d' indices gradually increased to peak at ASiR-V 100% (p<0.001).
Conclusion: ASiR-V at a level of 80% in oncologic chest MDCT enhances objective IQ for the analysis of lung parenchyma, while concomitantly enabling a dose reduction of 20% as compared with FBP.

B-0734 11:42

Comparison of the diagnostic performance of ASIR-V ultra-low-dose and standard low-dose CT protocols for basic chest CT findings

M. Ludwig[1], J. Cohen[1], E. Reymond[1], B. Ycart[2], G. Ferretti[1]; [1]*La Tronche/FR*, [2]*Saint-Martin-d'Hères/FR*

Purpose: To evaluate diagnostic performances of ultra low-dose CT (ULDCT, DLP<10mGy.cm) vs Low dose CT (LDCT) for basic chest CT findings.
Methods and Materials: 3 radiologists of different experience reviewed 50 patients on ULDCT (Noise index:80, ASIR-V: 70%) and LDCT (Noise index:40, ASIR-V: 40%) consecutive acquisitions obtained on a GE-Healthcare Revolution CT scanner. For each patient and CT protocol, 37 items taken from the Fleischner glossary were rated on a 4 degrees certainty scale. Ratings were then compared with a proportion test. Interreader agreements were computed using Fleiss Kappa for each item; then mean of the differences between protocols was calculated using Student paired t-test.
Results: Mean patients' age and BMI were 61+/-29 years old and 24,4+/-9,3, respectively. Mean DLP was 8,7+/-0,9 mGy.cm and 98,3+/- 34,3 mGy.cm for LD and ULDCT acquisitions respectively. There were no significative differences for the ratings between CT protocols (p>0.05), except for traction bronchiectasis (p=0,001), crazy paving (p=0,047) and tree-in-bud disposition (p=0,012). Observers' confidence significantly decreased on ULDCT (181 vs 27 doubts, p=1.1*10^-26), especially for ground glass opacities and nodules, and emphysema. Mean of the differences of Fleiss kappa was significantly higher and positive within LDCT compared to ULDCT (0.12 ; p=3.9x10^-05).
Conclusion: An ASIR-V ultra-low-dose CT protocol significantly reduces radiation exposure with a conserved diagnostic performance for most chest CT-findings, at the cost of a decreased certainty and decreased interreader agreement.

Optimal low-dose chest CT parameters for monitoring interstitial lung disease: a systematic simulation study

S. Ley[1], L. Fidler[2], H. Schenk[1], M. Durand[3], T. Marras[2], N. Paul[2], S. Shapera[2], S. Mittoo[2]; [1]*Munich/DE*, [2]*Toronto, ON/CA*, [3]*Pietermaritzburg/ZA (ley@gmx.de)*

Purpose: HRCT is preferred imaging technique to evaluate interstitial lung disease (ILD). We set out to establish an optimal low-dose CT (LDCT) protocol for monitoring ILD to identify the lowest radiation dose with optimal diagnostic accuracy and image quality.
Methods and Materials: 25 Patients underwent HRCT (120kV, 50-300mA, 1mm thickness) during routine evaluation. Image reconstructions with varying combinations of tube current (50mA, 20mA, 10mA) and image slice thickness/increment (1/1mm, 3/2.4mm, 5/4mm) were simulated from raw data. Two radiologists independently reviewed all images and reported on image quality, ILD-specific features (ground-glass opacity, reticulation, honeycombing, disease extent), ILD pattern.
Results: 204 CTs were reviewed by each radiologist. There were no significant differences in sensitivity and specificity across LDCT imaging series. Diagnostic accuracy was best in 20mA series with a mean across group of 91%, compared with 50mA (84%, p=0.014) and 10mA series' (82%, p=0.018). Image quality was reduced in grouped 10mA (p=0.0003) and 1mm (p<0.0001) thickness series compared with other series. At 10mA series, a higher percentage of ground-glass opacity (p=0.003), reticulation (p=0.015), total extent of ILD (p=0.003) was reported. No difference in extent of honeycombing was found (p=0.227). Following successive evaluation of diagnostic accuracy and image quality between series, the 20mA/3mm, 20mA/5mm, 50mA/3mm, 50mA/5mm were found to be equivalent. Of these, the series with the lowest estimated radiation dose was 20mA/5mm.
Conclusion: Evaluating ILD patterns using a LDCT protocol of 20mA and 5mm slice thickness reduces patient radiation exposure without significantly compromising diagnostic accuracy and image quality in comparison to HRCT.

Diffusivity and diffusion anisotropy for diagnosis of prostate cancer: a systematic investigation of quantification strategies

S.H. Polanec, G. Wengert, H. Bickel, C. Spick, T.H. Helbich, M. Susani, K. Pinker, P.A.T. Baltzer; *Vienna/AT (stephan.polanec@meduniwien.ac.at)*

Purpose: To assess the impact of region-of-interest (ROI) statistics on diagnostic performance and reproducibility in the assessment of diffusivity and diffusion anisotropy for diagnosis of prostate cancer at 3T-MRI.
Methods and Materials: In this IRB-approved, retrospective study, 65 prostate lesions (35 malignant, 30 benign) verified by MRI-guided biopsy in 65 men (mean age 62.8y) were investigated. Two radiologists independently and repeatedly measured minimum, mean, and maximum Apparent Diffusion Coefficient (ADC) and Fractional Anisotropy (FA) on DTI-images (TR, TE, b-values: 1000mm2/; 6 diffusion directions) by placing a 2-dimensional region of interest around the lesions targeted by subsequent biopsy. Diagnostic performance and reproducibility statistics were calculated for all lesions and stratified by lesion location.
Results: Minimum ADC showed the best diagnostic performance (AUC 0.759). Dependent of the zonal location of a lesion in the transitional zone of the prostate, minimum and mean ADC values showed equal AUC (0.854, P>0.05). In the peripheral zone minimum ADC showed the best diagnostic performance (0.806). In the fibromuscular stroma minimum FA achieved the highest AUC (0.714). Minimum ADC showed highest intra- and interreader reproducibility.
Conclusion: Mean and minimum ADC values showed the best diagnostic performance and minimum ADC the highest reproducibility of all investigated parameters in diagnosis of prostate cancer. Diffusion anisotropy may be of particular value in the fibromuscular stroma.

B-0737 10:38

Diffusion-weighted imaging of the prostate: should we use quantitative metrics to better characterise focal lesions originating in the peripheral zone?

T. Pierre, L. Colleter, F. Beuvon, P. Legmann, F. Cornud; *Paris/FR (p_thibaut@hotmail.fr)*

Purpose: To compare the interreader agreement of the qualitative DW-MRI score ≥3 (PI-RADSv2), with that of quantitative DW-MRI parameters to characterise peripheral zone (PZ) focal lesions.
Methods and Materials: Two experienced radiologists in prostate MRI independently reviewed the T2W- and DW-MR images (computed b-value: 1500s/mm^2) to evaluate 92 DWI-score ≥ 3PZ focal lesions. Quantitative parameters were the mean ADC value, two different ADC ratios with two ROI's as reference areas: PZ mirror area (ADCrmirror) or the rest of the whole prostate surface (ADCrWP), and the mean whole-lesion ADC value with the 10th, 25th and 50th percentiles. Finally, very high b-values (b-3000 and b-6000s/mm^2) were computed and Signal Intensity Ratios (lesion/rest of the prostate surface) were calculated for b-values ≥1500s/mm². Surgical histology and MRI-TRUS fusion-biopsy findings were the reference standard for tumours and benign foci, respectively. Interreader agreement was assessed by the kappa and intraclass correlation coefficients (ICC). Univariate and multivariate regressions were used to determine which factor was the most predictive of cancer.
Results: Fifty abnormalities were malignant (50/92,54%). Interreader concordance for qualitative assessment was moderate (k=0.49 [95%CI:0.30-0.64]), but excellent for quantitative assessment (ICC≥0.80 [95%CI:0.70-0.88]) for all variables. At univariate analysis, all quantitative parameters were significant to predict cancer for both readers. At multivariate analysis, the only independent variable was the ADCrWP for both readers (reader1, OR=12.24 [95%CI:2.7-55.6], p=0.0012; reader 2, OR=12.86 [95%CI: 4.64-35.64], p<0.0001). Sensitivities and specificities were 76-72% and 93-83%, at a cut-off value of 0.62-0.60, respectively.
Conclusion: Quantitative DW-MRI improves the qualitative interreader concordance and the accuracy for the characterisation of focal PZ lesions.

B-0738 10:46

Diagnostic test accuracy meta-analysis of diffusion and T2 weighted-imaging for prostate cancer detection: which b-value is most accurate?

T. Syer, K.C. Godley, T. Smith, P. Malcolm; *Norwich/UK (kcgodley@googlemail.com)*

Purpose: To investigate the role of Diffusion-weighted imaging (DWI) and T_2-weighted imaging (T2WI) in combination for the detection of prostate cancer, specifically assessing the role of high *b*-values (&gt1,000), with a systematic review and meta-analysis of the published data.
Methods and Materials: The electronic databases MEDLINE, EMBASE and OpenSIGLE were searched between inception and 8th March 2016. Eligible studies were those that reported the sensitivity and specificity of both DWI and T2WI for the diagnosis of prostate cancer by visual assessment using a histopathological reference standard. The QUADAS-2 critical appraisal tool was used to assess the quality of included studies. A meta-analysis with pooling of sensitivity, specificity, was undertaken, as well as constructing a summary receiver operating characteristics (sROC) curve and determining the Area Under the Curve (AUC). Predetermined subgroup analysis was also performed.
Results: Twenty-six studies were included in the final analysis, evaluating 1,987 patients. The pooled sensitivity and specificity respectively was 0.68 (95% CI 0.67-0.69) and 0.84 (95% CI 0.84-0.85) and the sROC AUC was 0.83 (95% CI 0.796-0.861). Sub-group analysis showed significantly higher sensitivity using a *b*-value over 1000 (0.77 (95% CI 0.75-0.78)), compared to 1,000 and less (0.64 (95% CI 0.62-0.65)).
Conclusion: The diagnostic accuracy of DWI and T2WI for prostate cancer detection is good. The use of high *b*-values significantly improved the sensitivity while maintaining specificity. Therefore, *b*-values over 1000 should be considered for all DWI protocols for prostate cancer assessment.

B-0739 10:54

Prediction of extracapsular extension in prostate cancer using qualitative and quantitative multiparametric MRI

J. Kim, C. Kim, M.-R. Kwon, R. Kim, J. Yim, W. Kim; *Seoul/KR (ssakpo.kim@samsung.com)*

Purpose: To investigate the predictive value of multiparametric MR imaging (mpMRI) for extracapsular extension (ECE) in prostate cancer (PCa).
Methods and Materials: Enrolled 292 patients who received radical prostatectomy underwent preoperative mpMRI at 3T. For predicting ECE, the likelihood of ECE was assessed qualitatively on T2-weighted imaging (T2WI) and combined T2WI and diffusion-weighted imaging (DWI) or dynamic contrast-enhanced imaging (DCEI). Quantitative MRI parameters were

measured in PCa based on histopathological findings. Two predictive models of ECE including imaging and clinical parameters were developed using multivariate analysis: model 1 excluding combined T2WI and DWI and DCEI and model 2 excluding combined T2WI and DWI, and combined T2WI and DCEI. Diagnostic performance of imaging parameters and models was evaluated using the area under the receiver operating characteristics curve (Az).
Results: For predicting ECE, the specificity, accuracy and Az of combined T2WI and DWI or DCEI were statistically better than those of T2WI (P< 0.001), and all quantitative MRI parameters showed statistical difference between the patients with and without ECE (P< 0.001). On multivariate analysis, significant independent predictors in model 1 were combined T2WI and DWI, combined T2WI and DCEI and K^{trans} (P< 0.05). In model 2, significant predictors were combined T2WI and DWI and DCEI, K^{trans}, K_{ep} and Ve (P< 0.05). The Az values of model 1 and 2 were 0.944 and 0.957, respectively.
Conclusion: mpMRI may be useful to improve diagnostic accuracy of predictive models for ECE in PCa.

B-0740 11:02

Comparison between different DWI protocols using high b values with or without perfusion fraction in differentiating prostate cancer
E.L. Indino, M.D. Grompone, M. Del monte, D. Fierro, C. Catalano, V. Panebianco; *Rome/IT (elenaindino87@gmail.com)*

Purpose: To investigate the ability of a DWI/ADC protocol which exclude perfusion component in distinguishing prostate carcinoma(PCa) to normal prostatic gland and benign prostate hyperplasia (BPH),using histopathologic analysis as reference standard for tumour identification.
Methods and Materials: 120 patients with suspected PCa underwent mp-MRI of the prostate performed at 3.0T(GE MR750). 73 patients were histologically-proven PCa. Two different protocols of DWI/ADC were used: 1) b-values 0, 500, 1000, 3000 s/mm^2, and 2) b=200,500,1000,3000s/mm^2. Two radiologists blinded delineated probable tumour based on T2-weighted, DWI and ADC maps. DWI signal for ADC and ADC-P analyses were taken in pathologic (ROI1), contralateral (ROI2) and central gland(BPH) regions (ROI3).All analyses were performed using SPSS (version 22) and Spearman's rank correlation test was performed to determine the relationship between ADC, ADC-P with Gleason score(GS) and PIRADS.
Results: Differences between ADC and ADC-P values were detected for all the GS in all pathological ROIs. The percentage differences between the two measured parameters [(ADC-ADC-P)/ADC-P] corresponds to the perfusion component of the DWI signal. By using the Youden test, we found 5.71 and 4.6 mm^2/s as best ADC and ADC-P values, respectively. The ADC-P parameters showed the same PPV but higher values for PPN, sensitivity, specificity and accuracy of the diagnostic test with respect to ADC.
Conclusion: Our data showed that ADC-P maps which derived from protocol 2, which exclude b value lower than 200s/mm^2 (in order to exclude the perfusive contribution) can help in the differential diagnosis from significant tumour to indolent disease.

B-0741 11:10

High yield of DWI-based MR-guided targeted prostate biopsy with predominantly intermediate to high risk cancer
S. Heijmink, P. de Koekkoek-Doll, J. de Jong, H. van der Poel, R.G.H. Beets-Tan; *Amsterdam/NL (swheijmink@live.com)*

Purpose: The purpose of the study was to analyse the learning curve and the accuracy of DWI-based MR-guided prostate biopsy as well as determine the accuracy in detecting intermediate and high grade prostate cancer.
Methods and Materials: 66 patients with elevated PSA levels and previously negative TRUS-guided biopsy or low grade prostate cancer underwent a 3T mpMRI of the prostate, which included T2w, DWI and DCE imaging. This was followed by MR-guided in bore biopsy of lesions scored as suspicious of intermediate/high grade disease on DWI. Two radiologists without prior prostate MR-biopsy experience performed all procedures. Biopsy Gleason score was the standard of reference. In patients who subsequently underwent prostatectomy, results were also compared with prostate specimen histopathology.
Results: A total of 34/71 (48%) biopsies in 30/66 (45%) patients were positive for prostate cancer. The biopsy yield in the second half of patients was significantly higher than the first half of patients (36% vs 69%, p<0.05). In 65% (22/34) of biopsies, the detected cancer was Gleason 7 or higher. In 78% (14/18) patients who underwent prostatectomy, MR-guided biopsy correctly predicted the final prostatectomy Gleason score on prostatectomy as intermediate or high grade.
Conclusion: A learning curve was observed for DWI-based MR-guided biopsy, suggesting that at least 30 procedures have to be performed to provide a sufficient level of experience. A majority of cancers detected were intermediate/high grade. The biopsy Gleason score correlated well with the final score on prostatectomy, thereby reducing undergrading and optimizing patient risk stratification.

B-0742 11:18

Comparison of image quality and signal-to-noise ratio between four different diffusion-weighted sequences for MRI of the prostate
D. Stocker, A. Manoliu, A. Becker, B.K. Barth, D. Nanz, M. Klarhöfer, O.F. Donati; *Zurich/CH (daniel.stocker@usz.ch)*

Purpose: To compare image quality and signal-to-noise-ratio (SNR) of four different magnetic resonance (MR) diffusion-weighted imaging (DWI) sequences in the prostate.
Methods and Materials: Axial T2-weighted turbo-spin echo images (TSE-T2w) and axial DWI echo planar imaging (EPI) sequences, including single-shot spin-echo (ss-EPI), readout-segmented multi-shot (rss-EPI), selective-excitation reduced field of view (sTX-EPI) and prototype single-shot sequence applying slice-selective shim-settings (prot-EPI) sequences were acquired at 3T in ten healthy volunteers (mean age 25.9 ± 3.8; BMI 23.2 ± 3.0). Two radiologists, blinded to the type of DWI, independently rated DWI-sequences on a 5-point Likert scale regarding subjective image quality features (resolution, demarcation of prostate capsule, zonal anatomy). Interreader agreement was assessed using the intra-class correlation coefficient (ICC). Quantitative image analysis was performed, evaluating the SNR in the transitional and peripheral zone. Significant differences were calculated using the Wilcoxon rank sum test with Benjamini-Hochberg correction for qualitative parameters and analysis of variance (ANOVA) for quantitative parameters.
Results: Interreader agreement was good to excellent (ICC 0.712 - 0.792) for all qualitative features. Subjective IQ regarding "resolution" was significantly better for ss-EPI as compared to rss-EPI (p=0.031) and sTX-EPI (p=0.046) as well as for prot-EPI as compared to rss-EPI (p=0.031) and sTX-EPI (p=0.047). There was no significant difference regarding capsule demarcation and zonal anatomy. SNR was significantly higher in prot-EPI than sTX-EPI (p=0.015).
Conclusion: ss-EPI and prot-EPI showed a tendency towards superior image quality and SNR compared with rs-EPI and sTX-EPI.

Correlation between ADC and Gleason score in the evaluation of peripheral zone prostate cancer
G. Michelini, L. Panebianco, A. Mancini, A. Pace, C. Gianneramo, C. Marsecano, I. Capretti, R. Manetta, C. Masciocchi; *L'Aquila/IT (giuliamichelini.gm@gmail.com)*

Purpose: To evaluate the correlation between Apparent Diffusion Coefficient (ADC) obtained with b3000 DWI from 3T Multiparametric Magnetic Resonance of Prostate (mpMRI), and Gleason Score (GS) in patients with peripheral prostate cancer (CaP).
Methods and Materials: Between February and December 2015 we retrospectively evaluated 127 patients, aged 45-75 years, who underwent mpMRI 3T (mr750w GE, with both pelvic phased-array 32 channel coil and endorectal coil) for suspicious CaP. Exclusion criteria: patients previously subjected to radiotherapy or ormonotherapy, patients with general contraindications to mpMRI, patients with central zone lesions. 75 were found to be positive for peripheral zone CaP after Fusion biopsy (MRI-Transrectal Ultrasound Image Fusion Biopsy). ADC map was obtained from Diffusion Weighted Imaging (DWI) at b0 and b3000 mm^2/sec. Minimum (ADC_{min}) and mean (ADC_{mean}) ADC value of the suspected region were calculated, drawing a region of interest with a minimum area of 5 mm, excluding margins. The values were compared with GS.
Results: An inverse correlation between ADC and GS resulted. Malignant lesions had ADC_{min} e ADC_{med} values included between 500-1000 x10^{-6} mm^2/sec. 46 patients (61,3%) had ADC between 800-1000 x10^{-6}mm^2/sec; 44 of them (95,6%) had an histological GS between 5 and 7(3+4) and 2 (4,4%) had GS≥7(4+3). 29 patients (38,6%) had ADC between 500-800 x10^{-6}mm^2/sec; 28 of them (96,5%) had GS≥7(4+3) and 1 (3,5%) had GS<7(4+3).
Conclusion: Our experience with mpMRI confirmed an inverse correlation between ADC values and GS stages. Therefore, ADC value proves useful for noninvasive characterisation of prostate cancer aggressiveness and could improve therapeutic planning.

B-0744 11:34

Prostate MRI: relationship between apparent diffusion coefficent (ADC) and pathological Gleason score (pGS) in prostate cancer
S. Cavanna, A. De Libero, C. Arese, C. Saviolo, C. Lario, M. Petracchini, S. Cirillo; *Turin/IT (cavannaste@gmail.com)*

Purpose: The aim of our study was to investigate the correlation of DWI (ADC and ADCratio) with the pathological Gleason score (pGS) and subsequently its ability in predicting the aggressiveness of prostate cancer.
Methods and Materials: 41 patients with prostate cancer underwent multiparametric MRI scan with 1.5T and subsequently subjected to radical surgery. ADC and ADCratio (rADC) were calculated using a contralateral and

symmetrical area of healthy prostate ($rADC_{mirror}$) and bladder ($rADC_{bladder}$) as a reference. Patients were divided by three grouping methods: according to pGS, clinical risk or primary Gleason pattern. The degree of association between ADC or rADC and pGS was analyzed using ANOVA test and ROC curves.
Results: 3 patients presented a pGS of 6, 22 of 7 (3+4), 8 of 7 (4+3), 8 of 8. 25 patients had a primary Gleason pattern 3 and 16 a primary pattern 4. ADC and rADC showed a statistically significant association with the degree of tumour aggressiveness, being significantly lower in patients with higher tumour grade. $rADC_{mirror}$ presented the better diagnostic performance in discriminating between primary pattern 3 and 4, with an AUC of 0.835 ($p<0.001$). For this variable has been identified a cutoff value of $0.645x10^{-3}mm^2/s$ able to discriminate between the two different primary pattern with a sensitivity and specificity of 87% and 80% respectively.
Conclusion: ADC and rADC are significantly associated with Gleason score. The $rADC_{mirror}$ shows greater degree of association and the better diagnostic performance in identifying cancers with primary Gleason pattern 4.

B-0745 11:42

Diagnostic value of high-field MRI for Peyronie's disease
H. Wang, J. Guan, Y. Guo; *Guangzhou/CN (usefulkey0077@hotmail.com)*

Purpose: To analyse the MRI findings of Peyronie's disease and further to investigate the diagnostic value of using 3.0 Tesla MR.
Methods and Materials: 14 patients with clinically diagnosed Peyronie's disease underwent 3.0T MR examination using a loop coil (11cm) were included. MR Imaging protocol including routine sequences (T1WI, T2WI and enhanced T1WI) and susceptibility weighted imaging (SWI) was performed. Each patient received 2-4 times of penile ultrasound examinations previously (total 43 times of ultrasound), which were compared with MRI results.
Results: Totally 25 penile plaques of 14 patients were detected by MRI. 3 cases with 7 inflammatory plaques, 4 cases with 8 fibrotic plaques, and 7 cases with 10 calcified plaques were detected. All of 10 calcified plaques presented hypo-intense signal on SWI, which also can be stably detected by ultrasound. 7 cases with 10 calcified plaques were sensitively detected in all 20 times of ultrasound (20/20). Patients with inflammatory or fibrotic plaques could not be sensitively or accurately detected by ultrasound. Only 6 fibrotic plaques in 4 cases were found in 3 times of ultrasound (3/14). None of inflammatory plaques was detected by ultrasound (0/9). The combination of routine sequences and SWI was necessary for detection of calcified plaques, and the diagnostic rates of ultrasound for inflammatory (0/7) and fibrotic (6/8) plaques were significantly lower than MRI ($P<0.05$).
Conclusion: High-field MRI can provide high diagnostic sensitivity and accuracy for Peyronie's disease since plaques in all different stages can be detected by using multi-parametric MRI.

B-0746 11:50

"One-stop" evaluation of obstructive azoospermia: combined application of loop and body coil MR imaging
H. Wang, J. Guan, J. Lin, Y. Guo; *Guangzhou/CN (usefulkey0077@hotmail.com)*

Purpose: To evaluate the diagnostic value of combined loop and body coil MR imaging applied in "one stop" examination for obstructive azoospermia.
Methods and Materials: 78 infertile men with azoospermia undergoing 3.0 Tesla MR examination were prospectively recruited. Loop and body coil were alternatively used in pelvis scan. Epigastrium (mainly kidneys) will be included based on medical requirements during MRI scanning. Seminal tract as well as renal anatomy will be evaluated in "one stop". Subject including criteria: semen analysis, seminal plasma biochemistry and sex hormone tests within 2 weeks before MR examination, additional percutaneous testis biopsy within 2 months after MR scan also should be performed. MR findings were compared with final confirmed diagnostic results.
Results: Totally 42 patients were included, all lesions can be obviously observed on MR images. Lesions limited in scrotal were found in 23 patients (findings according to loop coil). Lesions in 11 cases were detected localised in pelvis (findings according to body coil). And multifocal lesions or syndrome were detected in 8 cases (findings according to combined coil). Lesions detection sensitivity according to loop coil, body coil and the two combination were 54.8% (23/42),26.2% (11/42),19.0% (8/42) respectively.
Conclusion: Abnormal findings in seminal tract can be clearly and completely shown on "one-stop" MRI examination method using the combination of loop and body coil at one time of MR scanning.

Is it possible to predict tumour burden of peritoneal carcinomatosis from ovarian cancer with PET/MRI?
M. Alemany, B. Jonsdottir, A. Bergman, H. Ahlström, K. Stålberg; *Uppsala/SE (montserrat.alemany.ripoll@akademiska.se)*

Purpose: Successful surgery of peritoneal carcinomatosis (PC) is correlated with tumour burden, often evaluated by peritoneal cancer index (PCI). Sensitivity of different imaging techniques in diagnosing PC varies broadly. Our main aim was to validate preoperative assessment of PCI with PET/MRI using surgical PCI as gold standard. A second aim was to evaluate if PET/MRI was superior to MRI alone for this assessment.
Methods and Materials: PET-MRI was performed in 24 patients with PC from ovarian cancer 0 to 29 days (mean: 9, median: 6) before cytoreductive surgery. A radiologist blinded to surgical-PCI calculated PET-MRI and MRI-PCI score for each patient, based on size and location of peritoneal implants (PCI range: 0-39). A PCI below 20 was considered low/moderate tumour burden whereas PCI over 20 indicated high tumour burden. MRI evaluation of PCI was based on DWI. Preoperative assessment of PCI imaging was compared with surgical PCI.
Results: Surgical PCI was <20 in 10/24 (41%) patients and > 20 in 12/24 (58%). PET/MRI classified correctly 9/10 (90%) patients as low/moderate tumour burden and correctly 12/14 (86%) as high tumour burden, accuracy 21/24 (87%). MRI alone classified correctly 10/10 (100%) patients as low/moderate and 11/14 (78%) as high tumour burden, accuracy 21/24 (87%). Correlation index between surgical PCI and imaging PCI was 0.77 for PET-MRI and 0.69 for MRI.
Conclusion: Our study showed a good correlation between imaging PCI (both for PET/MRI and MRI) and surgical PCI as gold standard. No significant difference was found between PET/MRI and MRI.

B-0748 10:47

Comparison of integrated ^{18}F-FDG PET/MRI and MRI alone for pre-therapeutic tumour staging of patients with primary cervical cancer
J. Grueneisen[1], M. Al-bayati[1], L.M. Sawicki[2], J. Kirchner[2], V. Ruhlmann[1], M. Forsting[1], A. Wetter[1], L. Umutlu[1]; [1]*Essen/DE*, [2]*Düsseldorf/DE (johannes.grueneisen@uk-essen.de)*

Purpose: To evaluate and compare the diagnostic performance of ^{18}F-FDG PET/MRI and MRI alone for dedicated primary tumour staging of cervical cancer patients.
Methods and Materials: A total of 47 consecutive patients with histopathologically confirmed cancers of the uterine cervix underwent a whole-body^{18}F-FDG PET/MR scan prior to the start of therapy. Two experienced physicians analysed the MR datasets, followed by an evaluation of ^{18}F-FDG PET/MR data. They were instructed to determine the local tumour spread of primary tumours as well as to identify the presence of nodal or distant metastases.
Results: ^{18}F-FDG PET/MRI allowed for a correct determination of the T-stage in 40 (85%) cases, while MRI alone enabled a correct evaluation of the tumour stage in 41 (87%) cases. In 22 of the 47 patients lymph node metastases were present. For the identification of nodal positive patients, ^{18}F-FDG PET/MR revealed higher values for sensitivity (86% vs. 73%), specificity (92% vs. 84%) and diagnostic accuracy (89% vs. 78%) in comparison to MRI alone. Additionally, ^{18}F-FDG PET/MR showed better results for the detection of distant metastases then MRI alone (sensitivity: 85% vs. 69%, specificity: 94% vs. 88%, diagnostic accuracy: 91% vs. 83%)
Conclusion: The results of the present study demonstrate the usefulness of ^{18}F-FDG PET data as a valuable additive to MRI alone for more accurate assessment of nodal or distant metastatic spread in patients with primary cervical cancer. For the determination of the local tumour spread ^{18}F-FDG PET data do not provide an additional benefit to MRI alone.

B-0749 10:55

Evaluation of a fast ^{68}Ga-DOTATOC PET/MRI protocol for whole-body staging of neuroendocrine tumours: a comparison with ^{68}Ga-DOTATOC PET/CT

L.M. Sawicki[1], C. Deuschl[2], K. Beiderwellen[2], T.D. Poeppel[2], P. Heusch[1], D. Fuehrer[2], M. Forsting[2], G. Antoch[1], L. Umutlu[2]; [1]*Düsseldorf/DE*, [2]*Essen/DE (Linomorris.sawicki@med.uni-duesseldorf.de)*

Purpose: To compare the diagnostic performance of a fast ^{68}Ga-DOTATOC PET/MRI protocol with ^{68}Ga-DOTATOC PET/CT in whole-body staging of patients with neuroendocrine tumours (NET).
Methods and Materials: The local ethics committee approved this study. Thirty consecutive patients with histopathologically confirmed NET underwent ^{68}Ga-DOTATOC PET/CT and ^{68}Ga-DOTATOC PET/MRI in a single injection protocol. For PET/MRI a fast (30min) whole-body protocol was applied. PET/CT and PET/MRI were retrospectively evaluated regarding lesion count, localisation, nature (NET/non-NET/indeterminate), and conspicuity (4-point scale). The reference standard was based on histopathology and follow-up imaging. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and diagnostic accuracy of PET/CT and PET/MRI were compared using McNemar's chi^2 test. Wilcoxon tests assessed differences in SUVmax and lesion conspicuity. Correlation analysis of SUVmax was performed using Pearson's correlation coefficient (r).
Results: According to the reference standard, 197 NET lesions were present in 25 patients. On a per-patient basis, PET/MRI and PET/CT each correctly identified 96.0% of these patients. In a lesion-based analysis, the sensitivity, specificity, PPV, NPV, and diagnostic accuracy of PET/MRI was 90.0%, 100%, 100%, 80%, and 92.9%, respectively. Corresponding values for PET/CT were 86.6%, 98.2%, 99.2%, 74.0%, and 89.8%. Differences in the diagnostic performances were not statistically significant (p=0.38). SUVmax was strongly correlated (r=0.86; p<0.001) and did not differ significantly (p=0.35). Overall and NET lesion conspicuity was significantly higher on PET/MRI than on PET/CT (p<0.01, each).
Conclusion: ^{68}Ga-DOTATOC PET/MRI provides an equivalent diagnostic performance for whole-body staging of NET patients as compared with PET/CT.

B-0750 11:03

Comparing the diagnostic performance of integrated 18F-FDG PET/MRI and MRI for the identification of local recurrences of soft tissue sarcomas

Y. Erfanian[1], J. Grueneisen[1], J. Kirschner[2], L. Podleska[1], T. Poepel[1], K. Herrmann[1], L. Umutlu[1]; [1]*Essen/DE*, [2]*Düsseldorf/DE (y.erfanian@gmail.com)*

Purpose: Comparing the diagnostic performance of integrated 18F-FDG PET/MRI and MRI for the identification of local recurrences of soft tissue sarcomas.
Methods and Materials: A total of 41 patients with a clinically suspected tumour relapse of STS underwent an 18F-FDG- PET/MRI examination for assessment of local recurrence. Two experienced physicians interpreted the MRI data and subsequently the PET/MRI datasets in two separate reading sessions and were instructed to identify potential local tumour recurrences. Additionally, the diagnostic confidence in each reading for the identification of malignant lesions was determined. A McNemar test was applied to test for differences of both ratings and a Wilcoxon signed-rank test was used to identify differences of the confidence levels. Histopathological verification as well as follow-up imaging was applied as the standard of reference.
Results: A tumour relapse was present in 27/41 patients. Calculated sensitivity, specificity, positive predictive value, negative predictive value and diagnostic accuracy for the detection of local tumour recurrence was 81%, 85%, 91%, 70%, 82% for MRI and 96%, 75%, 89%, 91%, 90% for PET/MRI (p > 0.05). Furthermore, PET/MRI showed significantly higher confidence levels (p<0.05) for the determination of malignant lesions.
Conclusion: Our results demonstrate 18F-FDG PET/MRI to be an excellent imaging method in the evaluation of recurrent STS after surgical excision, as it displays superior detection accuracy as compared to routine MRI follow-up examinations.

B-0751 11:11

Diagnostic value of bi-disciplinary PET/MRI reading for the assessment of malignancies

F. Celebi, B. Unalan, N.C. Balcı; *Istanbul/TR (elbuken.filiz@gmail.com)*

Purpose: To evaluate nuclear medicine and radiology joined PETMRI reading compared to separate evaluation of PET and MRI datasets.
Methods and Materials: PETMRI datasets of 53 patients with known primary malignancies were retrospectively evaluated. FDG PET and T1 weighted Turboflash fused images were read by a nuclear medicine physician, contrast enhanced Whole Body MRI without FDG PET fusion was read by a radiologist. All datasets were reevaluated in a joint session with the combination of contrast enhanced whole body MRI and FDG PET Turboflash MRI. Contrast enhanced Whole body MRI protocol consisted of dynamic contrast enhanced MRI of the upper abdomen with the use of 3D VIBE, contrast enhanced MRI of the whole body with the use of coronal 3D Dixon VIBE sequence.
Results: The mean numbers of malignancies on FDG PET T1 W Turboflash MRI and Whole Body Contrast Enhanced MRI were 11.8 ± 17.6 and 13.2 ± 18.5, respectively. There was significant difference for the total number of malignancies (p=0.031). The joint reading of FDG PET T1 W Turboflash MRI and Whole Body Contrast Enhanced MRI revealed mean number of 15.9 ± 22.4 malignancies. There was significant difference between joint reading and separate reading of contrast enhanced whole body MRI (p=0.005) or FDG PET T1 W Turboflash MRI (p=0.002).
Conclusion: Combined reading of PET and MRI datasets by a Radiologist and Nuclear Medicine physician depicts more malignancies than separate reading of datasets.

B-0752 11:19

Assessment of PET/MR, including DWI, for diagnosing skeletal muscle metastases

C. Giraudo, M. Weber, G. Karanikas, P.A.T. Baltzer, H. Markus, M. Mayerhoefer; *Vienna/AT (chiara.giraudo@meduniwien.ac.at)*

Purpose: To evaluate the diagnostic performance of PETMR, with and without DWI, for skeletal muscle metastases (SMM) in oncologic patients.
Methods and Materials: Patients with histological proven cancer who underwent a PETMR (fully integrated system), including whole-body-DWI, for staging or restaging from January 2014 until December 2015 were included in this retrospective study. PETMR was considered positive if a muscle lesion was visible on MR images (i.e., T1w and/or T2w) and showed a pathologic, not inflammatory, uptake (i.e., FDG, PSMA, Dotanoc); DWI was then separately assessed. Muscles of the following areas were investigated: neck, thorax, abdomen, pelvis, upper and lower extremities. Sensitivity and specificity were calculated using histology and/or follow-up/previous examination as reference standard. The relationship between SMM's metabolic activity (SUVmax, SUVmean) and cell-density (ADCmin, ADCmean) was examined (Pearson correlation).
Results: One-hundred-three patients met the inclusion criteria (70 males; mean age±SD 58.29±16.76 years; 47 staging and 56 restaging). Histology revealed lymphoma (n=64), prostate cancer (n=23), melanoma (n=6), breast cancer (n=2), soft tissue sarcoma, esophageal-, pancreatic-, bladder-, gastric-, ovarian-, thyroid- and neuroendocrine tumour (n=1,each). Overall six SMM were diagnosed in five patients (4.85%) at PETMR (83.3% [95%CI 35.88-99.58%] sensitivity, 100% [95%CI 96.27-100%] specificity). Seven SMM were diagnosed in six patients (5.8%) at PETMR-DWI (100% sensitivity [95%CI 54.07-100%], 100% specificity [95%CI 96.31-100%]). Pelvic muscles were mostly affected (i.e., four out of seven lesions). A negative non-significant relationship emerged between SUVmax and ADCmin (r=-.64; p=0.16) and between SUVmean and ADCmean (r=-.39; p=0.43).
Conclusion: Even if SMM rarely occur in oncologic patients, according to our preliminary results, DWI demonstrated to improve PETMR diagnostic performance, at staging and restaging.

Simultaneous C11 choline PET and multiparametric MRI in high-risk prostate cancer patients: interim report

L.-J. Wang, J.-R. Tseng, S.-P. Pang; *Taiwan/TW (lijenwang0918@gmail.com)*

Purpose: To evaluate the agreements of diagnosing lymph node and bone metastasis between C11 choline PET (chPET) and multiparametric prostate MRI (mpMRI) in high-risk prostate cancer (hrPCA) patients.
Methods and Materials: From January, 2014 to January, 2015, all consecutive hrPCA patients were prospectively enrolled for undergoing simultaneous chPET and mpMRI. Their ages, prostate surface antigen (PSA) titers before examination and Gleason scores (GS) of prostate cancer biopsies were recorded. Agreements of diagnoses of lymph node and bone metastases between chPET C11 and mpMRI were analysed.
Results: Twenty-six patients underwent PET/MRI and 4 patients were excluded by fitting exclusion criteria. The 22 patients had a mean age of 68.8 years, a mean PSA titer of 49.1 ng/mL and GS of biopsy specimens of 6-10. MRI and choline PET had concordant results of regional lymph node metastasis in 20 patients (90.9%) and discordant results in 2 patients (PET and MRI detect 1 more positive result, respectively). For non-regional lymph node metastasis, mp-MRI and chPET had concordant results in 21 patients (95.4%); chPET detected non-regional lymph node metastasis in one more patient than mpMRI. For bone metastasis, mpMRI and ch-PET had concordant results in 19 patients (86.4%); mpMRI detected bone metastasis in 3 more patients than ch-PET.

Conclusion: ch-PET and mp-MRI have good agreements of lymph node and bone metastasis in hr-PCA patients. Ch-PET is less sensitive in detecting bone metastasis but more sensitive in showing non-regional lymph node metastasis than mpMRI.

B-0754 11:35

Comparison of PET-CT MR (3.0T) with 68Ga-PSMA for evaluation of prostate cancer patients with biochemical recurrence

M. Garcia, O. Alonso, E. Henry; *Montevideo/UY (margarita.garciafontes@cudim.org)*

Purpose: The aim of this study was to compare the detection rate of PET-MR versus 68Ga-PSMA PET-CT in prostate cancer recurrence.
Methods and Materials: A sample of patients with PSA relapse were included. We used a trimodality PET-CT-MR (3.0 T) setup including a 64-slice PET-CT, with a dose of approximately 280MBq of 68Ga-PSMA. An abbreviated MRI protocol was used with panoramic and high-resolution thin slices with T2 sequence at prostate loggia and diffusion (DWI) and ADC maps. Two blinded and independent readers asessed all images.
Results: 37 patients were enrolled of whom 25 (68%) had undergone radical prostatectomy and 12 treated with radiotherapy. The median PSA level was 3.5ng-mL. Both techniques were positive in 20 patients (54%) and negative in 7 patients (19%). Eight patients were only positive with 68Ga-PSMA alone (22%) and 2 with MR only (5%). In 11 patients (30%), PET-CT showed metastatic lesions outside the pelvis. Local relapse was detected in 16 (43%) and 12 (32%) patients, pelvic bone metastases in 6 (16%) and 2 patients (5%), and pelvic lymph nodes in 11 (30%) and 3 (8%) patients, for PET-CT and MR, respectively. A statistically significant difference was found for lymph node relapses (P-0.013). MR was useful in indeterminate cases by means of PET-CT alone.
Conclusion: 68Ga-PSMA PET-CT detects better pelvic lymph nodes and extrapelvic metastasis and PET-CT-MR adds clinically relevant information for patient management.

B-0755 11:43

Evaluation of 18F-FDG PET and MR datasets in integrated PET/MRI: a comparison of different MR sequences for whole-body restaging of breast cancer patients

J. Grueneisen[1], A. Wetter[1], L.M. Sawicki[2], S. Kinner[1], V. Ruhlmann[1], M. Forsting[1], L. Umutlu[1]; [1]*Essen/DE*, [2]*Düsseldorf/DE (johannes.grueneisen@uk-essen.de)*

Purpose: To investigate the diagnostic value of different MR sequences and 18F-FDG PET data for whole-body restaging of breast cancer patients utilizing PET/MRI.
Methods and Materials: 36 patients with a suspected tumour recurrence of breast cancer were prospectively enrolled for a whole-body PET/MR examination. The MR protocol comprised: Diffusion-weighted imaging, a T2w HASTE and a post-contrast T1w VIBE sequence. Two readers were instructed to identify the total number of tumour lesions in subsequent MR and PET/MR readings, utilizing different MR sequence constellations for each PET/MR reading session. Additionally, the diagnostic confidence for each detected lesion (3-point ordinal scale) was qualitatively rated.
Results: Tumour recurrence was present in 25/36 (69%) patients. All three PET/MRI readings showed a significantly higher accuracy as well as higher confidence levels for the detection of recurrent breast cancer lesions when compared to MRI alone ($p<0.05$). Furthermore, all three PET/MR sequence constellations showed comparable diagnostic accuracy for the identification of recurrent tumour lesions ($p>0.05$), yet increasing diagnostic confidence levels after the application of contrast-agent. However, highest confidence levels were obtained, when all three MR sequences were used for image interpretation.
Conclusion: Integrated PET/MRI provides superior restaging of breast cancer patients than MRI alone. Facing the need for efficient whole-body PET/MR imaging, our results show the feasibility of fast and morphologically adequate PET/MR protocols. However, considering an equivalent accuracy for the detection of breast cancer recurrences in the three PET/MR readings, the application of contrast-agent and the inclusion of DWI in the study protocol seems to be debatable.

B-0756 11:51

The diagnostic value of hybrid PET/MRI in the assessment of gastrointestinal tumours

F. Celebi, B. Unalan, N.C. Balci; *Istanbul/TR (elbuken.filiz@gmail.com)*

Purpose: To evaluate the diagnostic performance of positron emission tomography (PET)/magnetic resonance (MR) imaging in the assessment of gastrointestinal tumours and metastases.
Methods and Materials: 44 patients with histopathologically proven primary gastrointestinal tumour underwent FDG PET/MR imaging for initial staging and therapy monitoring. PET/MR imaging was performed with the acquisition of axial serial contrast-enhanced 3D FS VIBE images in the upper abdomen, whole-body coronal FS VIBE Dixon and axial 3D FS VIBE for the brain.Total number of lesions determined on CE (contrast enhanced) PET/MR imaging were compared to NCE (non-contrast enhanced) PET data.
Results: Total number of lesions determined with CE PET/MR protocol were 106 HCC, 37 cholangiocellular carcinoma, 194 liver, 2 brain, 112 bone, 175 lymph node and 62 lung metastases. 7 patients were evaluated as peritoneal metastasis. With the use of FDG PET data alone 50 HCC, 24 cholangiocellular carcinoma, 130 liver, 1 brain, 49 bone, 175 lymph node and 20 lung metastases were determined. 3 patients were evaluated as peritoneal metastasis. CE FDG PET/MR was compared to NCE FDG PET data for the detection of lesions and statistically significant difference analysed between them ($p<0.03$)
Conclusion: CE FDG PET/MR protocol is more effective than NCE FDG PET protocol for lesion and metastasis detection in gastrointestinal tumours.

US-sialography in diagnostics ductal system of major salivary gland

Y. Vasil'eva; *Moscow/RU (Drugya@yandex.ru)*

Purpose: Efficiency evaluation of salivary ultrasonography with ductal system contrast (US-sialography) using universal liquid substance.
Methods and Materials: Echographic examination was performed on a total number of 73 patients (age 18 to 79) with confirmed chronic major salivary gland disorders as well as allergic reaction to iodine. Considering inability to perform an MSCT-sialography, all patients were examined using US-sialography with up to 4ml of normal saline solution in ductal system. Normal saline solution was used as a universal liquid substance for echographic imaging of the entire ductal system. For the purpose of keeping the solution inside the ductal system for its continuous tight filling, after contrast infusion the catheter was blocked by a plug without being removed from the opening of the duct. Examination was carried out using the iU-22 ultrasound system (Philips, Netherlands) and the dedicated compact pen-transducer with 7 to 15 MHz operating frequency range. Primary diagnostics and dynamic case observation (in 45% of cases) were performed.
Results: In 100% of cases US-sialography allowed not only to evaluate gland parenchyma, but also to visualise up to distal duct segments, give its full anatomic characteristics, define its pathological changes. All results had clinical confirmation.
Conclusion: US-sialography can be a method of choice in diagnostics of salivary gland ductal system disorders for patients with contraindications to MSCT-sialography and to avoid radiation exposure.

Key anatomical features of Vidian canal on skull base CT

M.E. Adin[1], C.A. Özmen[1], N. Aygün[2]; [1]*Diyarbakir/TR*, [2]*Baltimore, MD/US (emin.adin@gmail.com)*

Purpose: To investigate the key anatomical features of Vidian canal that have critical role in planning and performing endoscopic skull base surgeries.
Methods and Materials: We reviewed high-resolution skull base CT images of 640 consecutive subjects. Multiple anatomical features of Vidian canal were analysed in all three planes along with oblique reconstructions. Rostral-caudal course of the Vidian canal, length of the Vidian canal, dehiscence of the Vidian canal, and position of the Vidian canal with respect to petrous ICA were examined. Classification of the amount of pneumatisation around Vidian canal was done in four different degrees.
Results: The average length of the Vidian canal was 15.4 ± 2.0 mm in females and 16.6 ± 1.7 mm in males and difference between both genders was statistically significant ($P<0.001$). The most common rostral-caudal course of Vidian canal was medial to lateral and was followed by straight course, tortuous course, and lateral to medial course, respectively. The frequency of pneumatisation pattern was found as type 0, III, II and I, respectively. Of 342 evaluated instances, Vidian canal was located below the level of petrous ICA in

303 (89%) instances, at same level with petrous ICA in 25 (7%) instances, and above the level of petrous ICA in 14 (4.1%) instances.
Conclusion: Various anatomical features of the Vidian canal were defined. Unlike what was reported in most previous studies, we showed that inferior-medial drilling of the Vidian canal may not be always safe, as it could be located superior to the level of petrous ICA.

B-0759 10:55

Dynamic contrast-enhanced MRI of the TMJs in patients with juvenile idiopathic arthritis

P.A. Caruso; *Boston, MA/US (pcaruso@partners.org)*

Purpose: Our purpose is to determine the dynamic enhancement curves of inflamed TMJ synovia in juvenile idiopathic arthritis that may provide a basis for the assessment of response to therapeutic interventions such as intraarticular steroid injections.
Methods and Materials: MRI parameters include a pre-contrast coronal T1 sequence followed by 10 consecutive post-contrast T1-weighted sequences each with a scan time of 1 minute for a total duration of 10 minutes. A region of interest (ROI) was placed in the synovium of the left and right TMJ with a reference ROI placed in the longus capitus muscle belly. Dynamic enhancement characteristics of the inflamed TMJs were determined and compared to clinical exam findings of synovitis.
Results: The synovia in the JIA patients demonstrated an initial peak enhancement at 5 minutes after contrast administration followed by a second peak at 10 minutes and showed twice the intensity of enhancement compared to normal controls. The synovia of control subjects demonstrated peak enhancement at approximately 3-4 minutes after contrast administration and slowly decreased in enhancement thereafter. The synovia of asymptomatic TMJs in JIA patients showed a peak at 5 minutes but above that of control subjects without JIA.
Conclusion: This study demonstrates proof of concept and the utility of dynamic post-contrast-enhanced images of the TMJs in patients with synovitis. This method demonstrates peak enhancement of inflamed synovia and maximal difference between inflamed and non-inflamed synovia at 5 minutes postinjection, and may be utilised to evaluate treatment-related response in patients with JIA.

B-0760 11:03

CT findings in patients with zygomatic complex fractures and trismus

P.A. Caruso; *Boston, MA/US (pcaruso@partners.org)*

Purpose: A subset of patients with zygomatic complex fractures (ZCFs) develop trismus and limitation of jaw opening. We hypothesise that in the group with trismus the ZCF results in closer approximation of the zygoma to the coronoid process of the mandible.
Methods and Materials: The clinical and CT imaging findings of 30 patients, 22 male and 8 female (median age, 37 years; age range, 14-85 years), with zygomatic complex fractures, were retrospectively reviewed. Patients with mandibular fractures or h/o prior facial surgery were excluded. The CTs were reviewed for fractures in the maxillae, zygomae, sphenoid, and temporal bones, for retroposition of the fractured zygomatic body, and for the distance between the coronoid process of the mandible and the fractured zygomatic body, zygomatic arch, and the posterolateral wall of the maxilla. The results of the trismus and nontrismus groups were then compared by standard T test and a p value was calculated.
Results: 16 of the 30 patients reported trismus following ZCF. There were statistically significant differences between the trismus and nontrismus groups in the relative retroposition of the fractured zygomatic body compared to the unfractured side. In the group with trismus, the zygomatic body and the zygomatic arch more closely approximated the coronoid process compared to the non-trismus group and this difference reached statistical significance.
Conclusion: Our study confirms that in patients with ZCF fractures and trismus, the fractured zygoma more closely approaches the coronoid process compared to those patients with ZCF without trismsus.

B-0761 11:11

Cephalometric evaluation of soft tissue changes in the upper and lower lips and chin after gap arthroplasty for the correction of temporomandibular joint bony ankylosis

A.M.K.E. Ibrahim; *Cairo/EG (abeermk7@gmail.com)*

Purpose: Correction of postankylotic deformity is a major intention for patients with temporomandibular joint ankylosis (TMJ) ankylosis after release of ankylosis. The aim of present study is to evaluate the changes of soft tissue of the lips and chin area after gap arthroplasty.
Methods and Materials: Twenty-four patients suffering from TMJ ankylosis were subjected to gap arthroplasty. They were selected from Outpatient Clinic of Faculty of Oral and Dental Medicine, Cairo University. Lateral cephalometric view was performed preoperatively and 3 months postoperatively. Special reference points As, PrSs, Bs, PrIs, and Pogs were selected on the soft tissue cephalometric tracing of upper and lower lips and chin were measured in relation to vertical and horizontal axes. These points were assessed to evaluate their changes postoperatively.
Results: The entire group of patients (24 patients) showed statistically significant downward movement of soft tissue of the upper and lower lips, whereas the chin moved downward and backward 3 months postoperatively. In unilateral cases (12 patients), the upper lip did not moved downward as in bilateral cases (12 patients) postoperatively.
Conclusion: The present study revealed downward movement of the soft tissue of upper lip, lower lip, and chin 3 months postoperatively. The soft tissue of the chin also showed backward movement. These changes must be taken into consideration with surgical planning in postankylotic orthognathic surgery.

B-0762 11:19

The capabilities of ultrasound in the diagnosis of foreign bodies in the maxillofacial region

Y. Shumina; *Moscow/RU (yana.shu92@gmail.com)*

Purpose: To assess the capability of ultrasonography of soft tissue in the identification of foreign bodies in the maxillofacial region.
Methods and Materials: 18 patients aged 18 to 45 with suspicion regarding the existence of foreign bodies in maxillofacial region were surveyed . The study was carried out on ultrasonic scanner IU-22 (Philips, Netherlands) using intraoperative linear sensor with a frequency of 7-15MHz in B-mode and Color Doppler.
Results: The study revealed the following foreign bodies in the soft tissues of the maxillofacial region of 18 examined patients: intubation tube in the tear ducts (n=1), drainage tube in the parotid duct (n=2), mustache shrimp into the floor of the oral cavity (n=1), a fragment of plastic in the main excretory duct of the parotid gland (n=1), husk of sunflower seed in the area of the sublingual salivary gland duct (n=1), ear of cereal plants (rye) (n=1), glass splinters in the cheek area (n=2), helminth disease (dirofilariasis) of the upper eyelid (n=1) and parotid-masticatory area (n=1). There have also been identified fillers after contour plastics (n=7), silicone in the lip area (n=3), polyacrylamide gel in nasolabial fold (n=2), hyaluronic acid in nasolabial fold (n=2). 14 patients have been operated, 4 patients are subjected to dynamic ultrasound monitoring.
Conclusion: Thus, ultrasound allows to visualise the foreign bodies in the maxillofacial region, to determine their precise location, the depth of occurrence, the relation to surrounding structures and to predict the possible nature of it.

B-0763 11:27

Lateral cephalometric analysis for treatment planning in orthodontics based on MRI compared with radiographs: a feasibility study in children and adolescents

A. Heil, E. Lazo Gonzalez, T. Hilgenfeld, P. Kickingereder, A. Sommer, M. Bendszus, S. Heiland, C.J. Lux, S. Zingler; *Heidelberg/DE (alexander.heil@med.uni-heidelberg.de)*

Purpose: To evaluate whether magnetic resonance imaging (MRI) can serve as a non-ionizing alternative modality to lateral cephalometric radiographs (LCR, “gold standard”) in cephalometric analysis.
Methods and Materials: This prospective study was approved by the local research ethics committee, informed patient consent was obtained. The applied MRI technique was optimized for detection of cephalometric landmarks and geometric accuracy. Prior to orthodontic treatment, 20 patients (mean age ± SD, 13.95 years ± 5.34; 8 females) received MRI and LCR. MRI datasets were postprocessed into lateral cephalograms. Based on 19 landmarks 24 widely used cephalometric measurements (14 angles, 10 distances) were taken twice by two observers for both modalities. Statistical analysis was performed by using intraclass correlation coefficient (ICC), Bland-Altman analysis and two one-sided tests (TOST) with an equivalence margin of ± 2 °/mm.
Results: Geometric accuracy of the MRI technique was confirmed. Mean intraobserver ICC were 0.977/0.975 for MRI and 0.975/0.961 for LCR. Average interobserver ICC were 0.980 for MRI and 0.929 for LCR. Bland-Altman analysis showed high of levels agreement between the two modalities, bias range (mean ± SD) was -0.66 to 0.61 mm (0.06 ± 0.44) for distances and -1.33 to 1.14 ° (0.06 ± 0.71) for angles. Except for the interincisal angle (P = .17) all measurements were statistically equivalent (P < .05).
Conclusion: MRI datasets can be transformed into lateral cephalograms allowing reliable measurements as applied in orthodontic routine with high levels of agreement to the corresponding measurements on LCR. Thus, MRI-based orthodontic treatment planning appears feasible.

Assessment of SRCMT of nasal and paranasal sinus by ADC value

K. Xue, J. Cheng; *Zhengzhou/CN (xuekang08yx@163.com)*

Purpose: The apparent diffusion coefficient (ADC) value is a non-invasive imaging parameter that can be used to effectively assess small round cell malignant tumours (SRCMT) of nasal and paranasal sinus.
Methods and Materials: 143 patients with SRCMT and non-SRCMT of nasal and paranasal sinus were consecutively enrolled.All patients underwent DWI, and quantitative analysis of ADC values were performed.Difference in ADC values between SRCMT and non-SRCMT was evaluated. ROC were used to determine the cut-off points to differentiate SRCMT from non-SRCMT, and the areas under the ROC were calculated.
Results: All lesions were solitary. There were 98 SRCMT, of which 20 lesions were rhabdomyosarcoma (RMS), 19 lesions were non-Hodgkin's lymphoma (NHL),14 lesions were malignant melanoma (MM), 14 lesions were neuroendocrine carcinoma (NEC), 12 lesions were Ewing's sarcoma/primitive neuroectodermal tumour (Ewing/PNET), 11 lesions were extramedullary plasmacytoma (EMP), and 8 lesions were olfactory neuroblastoma (ON). There were 45 non-SRCMT, of which 28 lesions were squamous cell carcinoma (SCC) and 17 lesions were adenoid cystic carcinoma (ACC). The mean ADC value of SRCMT ($0.66\pm0.12\times10^{-3}$mm²/s) was significantly different (P<0.01) from non-SRCMT ($1.02\pm0.16\times10^{-3}$mm²/s). All of 7 kinds of SRCMT were divided into 3 groups according to ADC values: NHL/MM/NEC/EMP, RMS/Ewing/PNET and ON, there was statistically significant difference among all 3 Groups (F=39.743, P<0.01). The area under the ROC was 0.975.An ADC value of 0.82×10^{-3}mm²/s was used as the threshold with a sensitivity of 97.8%, specificity of 89.8%, and accuracy of 92.3%.
Conclusion: The ADC value is a non-invasive imaging parameter that can be used to effectively assess SRCMT of nasal and paranasal sinus.

B-0765 11:43

Imaging features of myoepithelial carcinoma in the nasopharynx and paranasal sinus

C. Zhang, J.-L. Cheng; *Zhengzhou/CN (13733891344@163.com)*

Purpose: To analyze the imaging features of myoepithelial carcinoma(MEC)in the nasopharynx and paranasal sinus.
Methods and Materials: 11 patients with MEC in the nasopharynx and paranasal sinus confirmed by pathology were analyzed retrospectively. 4 underwent CT, MR, DWI and DCE-MRI.3 underwent MR, DWI and DCE-MRI.4 underwent CT.
Results: 11 cases were one bilateral, irregular shape and unclear boundary.The diameter of tumours was larger than 2.3 cm. The aggressive nature was demonstrated by bone destruction and invasion of adjacent structures. Among 8 patients under going CT, tumour centres were located in nasopharynx in 4 cases,3 in maxillary sinus,1 in nasal cavity and ethmoid sinus.8 cases were soft tissue density.5 lesions demonstrated destruction of the adjacent bone structure.2 cases had cervical lymph node metastasis.1 lesion showed slight enhancement. Among 8 patients under going MRI, tumour centres were located in nasopharynx in 5 cases,1 in maxillary sinus and 1 in ethmoid sinus.On T_1WI,4 showed equal signal and 3 showed low signal.On T_2WI,7 showed sligthly high or high signal. After contrast agent injection, 6 patients showed obvious heterogeneous enhancement,1 showed obvious homogeneous enhancement and 1 with circular enhancement of cervical lymph node. The mean ADC value was$(0.87\pm0.04)\times10^{-3}$mm^2/s.
Conclusion: CT and MRI appearances can show tumours' features.MEC in the nasopharynx and paranasal sinus easily has osteolytic destruction on CT and owns certain characteristic features on MR and ADC value. These features are helpful to the clinical diagnosis and treatment plan formulation.

B-0766 11:51

Inflammatory pseudotumour (IPT) of the skull base. MR and CT findings

A. Lo Casto, P. Purpura, F. Di Naro, C. Lunetta, G. La Tona, S. Salerno; *Palermo/IT (pierpaolopurpura@gmail.com)*

Purpose: Inflammatory pseudotumour is a benign condition mimicking malignant tumours, due to its infiltrative behaviour. MR and CT findings in 4 patients affected by skull base IPT are described.
Methods and Materials: Clinical records and imaging findings of 4 patients (2 men, 2 women, age range 42-75 years), complaining multiple cranial nerve neuropathies, including tinnitus, dysphagia, hoarseness, dysphonia, and haemitongue palsy, were reviewed. Patients were studied by MR and CT of the head and neck with different clinical suspicion, as nasopharynx tumour, paraganglioma, otitis. The diagnosis of IPT was made basing on of clinical data, response to systemic corticosteroids and MR findings.
Results: On 4/4 patients the IPT was located in the carotid space, in two involving the hypoglossal canal. On 3/4 patients an otomastoiditis was present, two of them had diabetes, while the third had a nasopharynx carcinoma treated some years before by radiotherapy with osteonecrosis and recurrent bilateral petrous bone osteomyelitis. Masticatory space was involved in 2/4 patients, hemipharynx in 1/4 patients; 1/4 patients had a jugular vein and sigmoid sinus thrombosis. 2/4 patients had a hypoglossal nerve palsy. Typical MR findings were areas of moderately diffuse enhancement after i.v. Gadolinium, that showed only slight hyperintensity and/or hypointensity on T2 images. At MR follow up at 1-3 months findings were significantly decreased and symptoms dramatically improved.
Conclusion: Radiologists and other specialists should be aware of IPT among disease involving the skull base, in order to differentiate this condition especially from tumours and avoiding more and unnecessary invasive treatment.

Preoperative digital breast tomosynthesis added to conventional imaging: can we reduce the re-excision rate in patients with breast carcinoma?

A. Milan, G. Mariscotti, M. Durando, P. Campanino, E. Caramia, P. Fonio, G. Gandini; *Turin/IT (alessiamilan.ptc@gmail.com)*

Purpose: To compare the re-excision rate for positive or close margins in patients undergone to breast cancer surgical treatment, previously staged with 2D digital mammography (DM) and breast ultrasound (US) versus digital breast tomosynthesis (DBT) added to DM and US.
Methods and Materials: We conducted a retrospective observer study, including 925 patients with newly diagnosed breast cancer who consecutively underwent breast surgery (662 conservative surgeries, 263 non-conservative surgeries) between January 2010 and December 2015. Patients were divided into two groups: 1) 537 patients staged with DM+US; 2) 388 patients staged with DBT+DM+US. A statistical analysis was performed, assuming definitive histology as a gold standard, to compare the re-excision rates between the two groups (Chi-square test with Yates correction). Statistical significance was set at p<0.05.
Results: On a total of 73/925 (7.9%) patients with positive margins at definitive histology, in group 1 the re-excision rate (53/537, 10%) was significantly higher (p<0.01) than in group 2 (20/388, 5%). The re-excision planning was less extensive for patients in group 2 (1/20 mastectomies) compared to group 1 (20/53 mastectomies). The two groups did not significantly differ for breast cancer characteristics, age and risk factors.
Conclusion: In this series, the adjunction of DBT to preoperative DM and US significantly reduced the re-excision rate of breast cancer surgical treatment. Although this result is biased (not randomised), it may be interesting for next studies including patients staged with breast MRI.

B-0768 10:38

Preoperative staging in women with known breast cancers: comparison between digital breast tomosynthesis and magnetic resonance imaging

F. Galati, F. Marzocca, E. Miglio, M. Luciani, F. Pediconi, C. Catalano; *Rome/IT (francesca.galati3@gmail.com)*

Purpose: To evaluate the accuracy in tumour extent and size assessment of Digital Breast Tomosynthesis (DBT) and Magnetic Resonance Imaging (MRI) in women with known breast cancers.
Methods and Materials: From May 2014 to April 2016, 59 patients (mean age 54.9) with known breast cancer were enrolled. All patients underwent DCEMR exam using Gd-BOPTA and GE DISCOVERY 750 3T, with bilateral breast coil and dedicated protocol, and DBT projections with Siemens Mammomat Inspiration system. A radiologist with 15 years of experience in breast imaging, evaluated blindly each imaging set. Sensitivity, PPV and accuracy of MRI and DBT were calculated, using histology as the gold standard. McNemar test was used to compare MR and DBT sensitivity. Lesions' tumour size and correlation coefficient were also evaluated comparing MRI vs Histological Examination, DBT vs Histological Examination and MRI vs DBT. Measurements were considered concordant if they were within ±3 mm.
Results: On histological examination 71 lesions were detected. MRI had a sensitivity of 100%, PPV 93%, and accuracy 97%; DBT sensitivity was 81%, PPV 89%, and accuracy 77%. McNemar p-value was 0.0003. The correlation coefficient of MRI vs Histological Examination was 0.98, DBT vs Histological Examination was 0.92 and MRI vs DBT was 0.93.

Conclusion: MRI provided higher diagnostic performance than DBT in disease extent evaluation, especially in dense breasts. However, DBT showed good accuracy and sensitivity, proving to be a valid tool in pre-operative staging.

B-0769 10:46

Impact of an image fusion technique, a coordinated US and MRI system, on tissue sampling for conventional B-mode-occult, MRI-detected breast lesions a prospective multicenter study

S. Nakano[1], T. Uematsu[2], M. Futamura[3], T. Mizoo[4], S. Akashi-Tanaka[5], I. Isomoto[6], H. Satake[7], S. Yamamoto[8], M. Gosho[9]; [1]*Nagakute/JP*, [2]*Sunto-gun/JP*, [3]*Gifu/JP*, [4]*Okayama/JP*, [5]*Shimagawa-ku/JP*, [6]*Nagasaki/JP*, [7]*Nagoya/JP*, [8]*Ube/JP*, [9]*Tsukuba/JP*

Purpose: An image fusion technique has recently been developed that uses either real-time virtual sonography (RVS) or volume navigation (Vnav), and can overlay an US image with the MRI image of the same site in real time. The aim of this prospective multicenter study was to evaluate the utility of RVS/Vnav for conventional B-mode (cB-mode)-occult, MRI-detected breast lesions.
Methods and Materials: In 4 Japanese centres, 32 patients who had cB-mode-occult, MRI-detected lesions on prone MRI were enrolled in this study from 2014 to 2016. Written informed consent was acquired, and then an additional supine MRI using a body surface coil was performed. Targeted US using RVS/Vnav applied supine MRI data was performed after a repeat targeted US using cB-mode alone. Pathological findings were confirmed by a RVS/Vnav-guided vacuum-assisted biopsy or excision for targeted US-detected lesions.
Results: Of the 32 lesions, 1 (3%) was detected with repeat targeted US using cB-mode alone, whereas 30 (94%) were detected with targeted US using RVS/Vnav (p<0.0001). The mean lesion size on MRI was 14 mm. Lesion types based on enhancement patterns were 2 focus, 6 mass, and 22 non-mass. The mean RVS/Vnav examination time required to detect the target lesion was 6.4 min. The success rate of tissue sampling was 75% (24/32). Of the 24 lesions, 3 (13%) were DCIS and 2 (8%) were invasive ductal carcinoma.
Conclusion: Our results suggest that RVS/Vnav-guided biopsy is a time-efficient approach that increases the tissue sampling success rate for cB-mode-occult, MRI-detected lesions.

B-0770 10:54

Digital breast tomosynthesis plus mammography, magnetic resonance imaging plus mammography and mammography alone: a comparison of diagnostic performance in symptomatic women

W. Tang, W. Peng; *Shanghai/CN (12111230002@fudan.edu.cn)*

Purpose: To compare the diagnostic value of digital mammography (DM), digital breast tomosynthesis (DBT) plus (DM) and magnetic resonance imaging (MRI) plus DM in symptomatic women.
Methods and Materials: 197 patients with 238 histologically proven lesions underwent DM, DBT and MRI. All images were interpreted independently by two experienced radiologists. A receiver-operating characteristic (ROC) curve was used to evaluate the diagnostic performance of each method. The accuracy, sensitivity, specificity, positive predictive value (PPV) were compared using McNemar's test and Fisher's exact test. A Kappa test was used to assess the interobserver agreement.
Results: The diagnostic performance was lower in DM alone (Radiologist1 [R_1], 0.849; Radiologist2 [R_2], 0.850) than DBT (R_1, 0.907, P=0.0204; R_2, 0.900, P=0.0239) and MRI plus DM (R_1, 0.939, P=0.0006; R_2, 0.935, P=0.0009). However, the difference between DBT and MRI plus DM was not significant (R_1, P=0.1262; R_2, P=0.0843). The accuracy (R_1, 85.3%; R_2, 83.6%) and sensitivity (R_1, 92.1%; R_2, 90.8%) of DBT plus DM were lower than those of MRI plus DM (accuracy: R_1, 90.3%; R_2, 90.7%; sensitivity: R_1, 94.7%, R_2, 95.4%) but without statistical difference (accuracy: R_1, P=0.644; R_2, P=0.360; sensitivity: R_1, P=0.502; R_2, P=0.359).The interobserver agreement of each method was excellent (k=0.894, 0.919 and 0.882 for DM, DBT and MRI plus DM, respectively).
Conclusion: The diagnostic performance of DBT and MRI plus DM is superior to that of DM alone in symptomatic women; the accuracy and sensitivity of MRI plus DM is slightly better than that of DBT plus DM, but not statistically significant.

B-0771 11:02

Breast MRI for detecting and characterising papillary lesions: comparison with conventional digital ductography and histological findings

M. Moschetta, M. Telegrafo, C. De Leo, T. Introna, L. Coi, V. Ranieri, A. Cirilli, A. Stabile Ianora, G. Angelelli; *Bari/IT (marco.moschetta@gmail.com)*

Purpose: To evaluate the role of breast contrast-enhanced MR imaging (CE-MR) for detecting and characterising papillary lesions and to compare the obtained results with conventional digital ductography, having the histological findings as the reference standard.
Methods and Materials: 49 consecutive patients with spontaneous, unilateral, single-pore nipple discharge underwent conventional digital ductography and CE-MRI (1.5 Tesla device) with morphological (T2-TSE, STIR) and dynamic sequences (THRIVE). Sensitivity, specificity and diagnostic accuracy values for both ductography and CE-MRI were calculated having post-surgical histological examination (n=43) and 12 month MR follow-up (n=6) as the reference standard. The obtained performance values were compared by using Mc Nemar test searching for any statistical significant difference between the two imaging tools.
Results: CE-MRI detected papillary lesions in 41/49 (84%) patients (mass like enhancement, n=30 - papillomas; ductal enhancement, n=7 - papillomatosis; linear enhancement, n=4 - papillary carcinomas) with sensitivity, specificity and accuracy values of 95%, 100% and 96%, respectively. Conventional digital ductography detected papillary lesions in 33/49 (67%) patients (single filling defects, n=26 - papillomas; multiple filling defects, n=4 - papillomatosis; filling stops with ductal distortions, n=3; papillary carcinomas) with sensitivity, specificity and accuracy values of 77%, 100% and 80%, respectively. A significant difference between the two imaging tools was found in terms of sensitivity and diagnostic accuracy (p<0.05).
Conclusion: Breast CE-MRI represents an accurate and non-invasive tool for diagnosing and classifying papillary lesions with higher sensitivity and accuracy values as compared with conventional ductography.

B-0772 11:10

Does the immunohistochemical pattern of breast cancer influence the detection by mammography, US or tomosynthesis?

P. Bartolomé, A. Quílez, F. Martinez Regueira, A. Fernandez Montero, A. Elizalde, L. Pina; *Pamplona/ES (aquilez@unav.es)*

Purpose: To assess the influence of the immunohistochemical patterns in the sensitivity of mammography, tomosynthesis and US.
Methods and Materials: This retrospective, single-centre, lesion-based study was approved by the IRB. 247 invasive cancers, histologically confirmed, were reviewed from October 2011 to September 2016. One expert breast radiologist, blindly reviewed all the mammographic (MX), ultrasound (US) and tomosynthesis (DBT) examinations. All the cases were classified according to the BI-RADS categories, considering positive categories 3-5. The cancers were divided into 3 immunohistochemical patterns: Luminal A, Luminal B and non-Luminal (pure Her2 and triple negative). A McNemar test (IBM SPSS 21.0) was used to compare the sensitivity of the combination of different techniques in the three immunohistochemical patterns.
Results: The sensitivities of MX, MXUS and MXDBT for Luminal A were: 46%, 84% and 78%; for Luminal B: 60%, 90% and 74%; for non-Luminal: 65%, 93% and 73%. For both Luminal A and B, whatever the additional technique (US, DBT), the sensitivity was higher than MX alone (p<0.001). The comparison between MXUS and MXDBT was similar in Luminal A (84% vs 78%; p=0.18) but not for Luminal B (90% vs 74%; p<0.001). In the non-luminal group, the combination MXUS was superior to MXDBT (93% vs 73%; p<0.001) and MXDBT was similar to MX (73% vs 65%; p=0.25).
Conclusion: Additional US significantly increased the sensitivity of mammography in all immunohistochemical patterns, while tomosynthesis only in Luminal A and B. The combination mammography-US was better than mammography-DBT for Luminal B and non-Luminal cancers.

B-0773 11:18

Radiological and epidemiological features of breast cancer in women previously exposed to chest and mantle radiation therapy: single center experience

F. Cartia, A. Primolevo, C. Ferranti, G. Scaperrotta; *Milan/IT (francesco.cartia@gmail.com)*

Purpose: Aim of this study was to evaluate the epidemiological and radiological features of breast cancer in women previously exposed to chest radiation therapy.
Methods and Materials: From the paediatric registry we retrospectively analysed imaging of breast cancer in patients who had been exposed to radiation therapy at a young age.
Results: we identified 22 patients with 24 breast cancer who performed imaging studies in our Institute. The commonest reason for irradiation was Hodgkin's Lymphoma.Mean latency period between exposure and breast cancer presentation was 21.7 years.Mean dose given during radiation therapy was 33 Gy Nineteen of 24 tumours were invasive, 5 were ductal carcinoma insitu. The upper-outer quadrant was the commonest tumour location (15/24 cases).Detection rate for DM and US was 74% and 77% was respectively. In 23 mammograms available, 12 presented as a nodular mass and 5 showed microcalcifications only, 6 were occult to digital mammogram (DM).In 22 ultrasound (US) available 17 showed a hypoechoic mass.The predominant MR features in 8 cases available included: 5/8 mass-like lesions.Mass-like lesion presented irregular margins, homogenous contrast enhancement and hyperintensity on T2weighted images.Enhancement pattern "denditric" and "patchy" have been identified in non mass-like lesion.

Conclusion: women treated with supra-diaphragmatic radiation therapy in young age have a higher risk to develop breast cancer at an earlier age.Longterm active surveillance strategies including annual MR are mandatory, starting at least 8-10 years after primary radiation treatment, because BCs in this cohort is expected to develop more frequently before 50 years.

B-0774 11:26

MRI features, FDG PET/CT and clinical characteristics of triple negative breast cancer: comparison with non-triple negative breast cancer

T. Kang, K. Kim, Y. Kim, J. Seo, C. Hwang, Y. Cho, M. Lee; *Daejeon/KR (taesun524@naver.com)*

Purpose: To compare magnetic resonance (MRI) findings and standardised uptake values (SUV) in positron emission tomography-computed tomography (PET-CT) of triple-negative breast cancer (TNBC) with those of breast cancers that are either endocrine-receptor positive or HER-2 positive or triple positive (non-TNBC).
Methods and Materials: 120 breast cancer cases were examined in 116 women (mean age 54.17 years; range 30-87 years). Among them, 23 cases of surgically-confirmed TNBC and 97 cases of non-TNBC were identified. The cases were evaluated using MR (n=93) and PET-CT (n=91). MR findings were discussed in the aspect of the tumour shape, margin, internal enhancement, T2 signal intensity, and kinetic curve. Peak SUVs (p-SUV) of the cancer lesions were measured using PET-CT. Histologic grade was classified according to the degree of differentiation. These findings were compared between TNBC and non-TNBC.
Results: In MR, large size, circumscribed mass were significantly associated with TNBC ($p<0.05$). 12 of 15 masses (80%) had rim enhancement pattern in TNBC ($p<0.05$). In PET-CT, the p-SUV of TNBC (7.575±3.942) was significantly higher than that of non-TNBC (3.715±3.172) ($p<0.05$). In histopathology, TNBC (78.3%) had a higher proportion of poorly differentiated type than non-TNBC (46.4%).
Conclusion: TNBC has a tendency to have large round mass, a rim enhancement pattern in MR, a higher p-SUV in PET-CT and higher pathologic grade.

B-0775 11:34

Correlation of diffusion-weighted imaging with apparent diffusion coefficient value, the standardised uptake values of PET/CT with prognostic factors for breast cancer

T. Kang, K. Kim, Y. Kim, J. Seo, Y. Cho, C. Hwang, M. Lee; *Daejeon/KR (taesun524@naver.com)*

Purpose: This study was carried out to retrospectively correlate the apparent diffusion coefficient (ADC) value, peak standardised uptake value (pSUV) and pSUV/ADC with pathological and clinical prognostic factors in breast ductal calcinoma.
Methods and Materials: Sixty-two breast cancers of 58 women (range 30-87 years) who underwent MRI including DWI, FDG PET/CT and immunohistological staining of the surgical specimens were enrolled. The relationships of ADC value, pSUV and pSUV/ADC with clinicopathological prognostic factors (age, tumour size, histologic grade of tumour, hormone receptors, HER-2 expression status, nodal metastasis) were evaluated by using statistical methods.
Results: The histologic type of breast cancer included DCIS (n=10), IDC (n=52, grade 1= 10, grade 2=14, grade 3=28). As tumour size increased, pSUV and pSUV/ADC become higher ($p<0.05$). There was significant association between the ADC value and HER-2-negative expression. The pSUV/ADC was significantly associated with tumour size and histologic grade ($p<0.05$). As the histologic grade become higher, the pSUV/ADC increased. The nodal metastasis was significantly associated with ADC value, pSUV and pSUV/ADC. The characterisation accuracy of pSUV/ADC (76.4%) was higher than pSUV (73.7%) and ADC values (43.3%) alone for diagnosis of breast cancer.
Conclusion: pSUV and pSUV/ADC were correlated with nodal metastasis, tumour size and histologic grade. The ADC value was associated with nodal metastasis and HER-2-negative expression. The pSUV/ADC had a high accuracy for grading of breast cancer. Therefore, pSUV and ADC value are useful indexes for predicting the prognosis of breast cancers.

B-0776 11:42

The role of fusion between breast MRI and 18F-FDG PET in staging of breast cancer

A. Quilez[1], P. Bartolomé[1], P. Martinez Miravete[2], A. Elizalde[1], M. Garcia Velloso[1], M. Ribelles[1], A. Fernandez Montero[1]; [1]*Pamplona/ES*, [2]*Zaragoza/ES (aquilez@unav.es)*

Purpose: To evaluate the diagnostic accuracy of magnetic resonance imaging (MRI) fused with prone 18F-fluoro-deoxyglucose (FDG) positron emission tomography (PET) in primary tumour staging of patients with breast cancer.
Methods and Materials: This retrospective study included 45 women with 49 pathologically proven invasive breast carcinoma. MRI and prone PET/CT scans with time-of-flight and point-spread-function reconstruction were performed with the same dedicated breast coil. The studies were assessed by a radiologist and a nuclear medicine physician and the evaluation of fused images was made by consensus. The final diagnosis was based on pathology (90 lesions) or follow-up ≥24 months (17 lesions).
Results: The study included 72 malignant and 35 benign lesions with a median size of 1.8 cm (range 0.3-8.4 cm), being 31 focal, 9 multifocal and 9 multicentric cases. In lesion-by-lesion analysis, sensitivity, specificity, positive and negative predictive values were 97%, 80%, 91% and 93% for MRI, 96%, 71%, 87%, and 89% for prone PET, and 97%. 94%, 97% and 94% for MRI fused with PET. Areas under the curve (AUC) were 0.953, 0.850, and 0.983, respectively ($p<0.01$).
Conclusion: MRI fused with FDG-PET is more accurate than FDG-PET in primary tumour staging of breast cancer patients and increases the specificity of MRI.

B-0777 11:50

Sonographic and MRI evaluation of complex cystic lesions of the breast: imaging findings in malignancy

P. Gupta, M.B. Popli, N. Sharma, D. Arse; *New Delhi/IN (dr.pranavg@gmail.com)*

Purpose: The aim of this study was to evaluate complex cystic lesions (CCL) of breast by ultrasonography (USG) and advanced MRI techniques in order to differentiate benign lesions from malignant.
Methods and Materials: 160 patients presenting with palpable or mammographically detected breast lesions were evaluated using USG and 44 patients with 50 sonographically detected CCL were included in the study. Morphological characteristics were assessed on USG according to BI-RADS and lesions were subclassified into four types. Dynamic contrast enhanced MRI along with diffusion weighted imaging and MR spectroscopy were then used to further establish benign and malignant findings. All findings were correlated with histopathology which was taken as gold standard and appropriate statistical tools were applied.
Results: Of the 50 CCL, 32 proved to be benign while 18 were malignant on histopathology. The USG descriptors of irregular shape (88.8%), not circumscribed margins (66.7%) and anti parallel orientation (72.2%) showed high positive predictive value (PPV) for malignancy which was statistically significant ($p<0.001$). Among the four types of CCL, PPV for malignancy was highest for type IV lesions (70%). MRI features of heterogeneous enhancement (72.2%), Type III kinetic curve (72.2%), reduced apparent diffusion coefficient (100%) and tall Choline peak (94.4%) were strong predictors of malignancy. The kappa score of 0.780 between ultrasound and MRI shows good agreement between the two modalities.
Conclusion: Combination of USG and advanced MRI techniques provides a high level of diagnostic confidence in characterisation of CCL of the breast thus allowing early diagnosis of breast malignancies.

B-0778 10:30

Incidences of tumour progression and treatment-induced pseudoprogression in high-grade gliomas, a systematic review and meta-analysis.

A.W. Abbasi, H.E. Westerlaan, G.A. Holtman, K.M.A. Aden, P.J. van Laar, A. van der Hoorn; *Groningen/NL (a.van.der.hoorn@umcg.nl)*

Purpose: High-grade gliomas are the most common primary brain tumours. Treatment-induced pseudoprogression describes the false appearance of radiation-induced progression on MRI. Differentiation should be made between true tumour progression to correctly plan treatment. However, there is wide variation of reported pseudoprogression. We thus aimed to establish the incidence of treatment-induced pseudoprogression and tumour progression in high-grade glioma patients with a systematic review and meta-analysis.
Methods and Materials: We searched PubMed, Embase, and Web of Science on the incidence of treatment induced pseudoprogression and tumour progression in adult high-grade glioma patients from 2005. Histology or imaging follow-up was used as reference standard. Extracted data included number of patients with progression on T1 post-contrast and/or T2/FLAIR,

treatment-induced pseudoprogression and tumour progression. Study quality was assessed with the NIH Tool. Heterogeneity was tested with the chi-square and I^2. Pooling of the results was done with random models using metaprop in STATA.
Results: We identified 73 studies. MRI progression occurred in 2603 patients. Of these, 36%, (95%CI 33-40%) demonstrated treatment-induced pseudoprogression, 60% (95%CI 56-64%) tumour progression and unknown outcome was present in the remaining 4% (range 1-37%).
Conclusion: We demonstrated a higher than previously thought incidence of treatment induced progression. This highlighted the full extent of the limitation of conventional MRI as currently used in the RANO criteria for treatment evaluation in high-grade gliomas. The need for more accurate treatment response evaluation using advanced imaging to aid in greater diagnostic accuracy and more accurate therapeutic approach is underscored.

B-0779 10:38

MR perfusion perilesional oedema difference between glioblastoma and metastasis

F. Aparici, A. Perez Girbes, M. Mazon, J. Carrreres, J. Garcia; *Valencia/ES (aperezgirbes@gmail.com)*

Purpose: To analyse MR perfusion of the closest peritumoural oedema tumour to normal white matter in patients with glioblastoma or unique brain metastasis.
Methods and Materials: The study was conducted on patients diagnosed with brain tumours between January 2010 and December 2015, 15 GBM and 15 metastases, with histopathologic confirmation. We analysed for each area of oedema the CBV, CBF, MTT, Ktrans, ve and Kep. All perfusion biomarkers were normalised against the white matter contra-lateral unaffected by the lesion.
Results: The results show a greater heterogeneity in peritumoural oedema area in GBM patients relative to oedema concerning patients with metastases. A gradual retreat is observed in perfusion parameters of the oedema, much more pronounced in cases of GBM.
Conclusion: This work supports the hypothesis of GBM tumour infiltration in the perilesional oedema, distal to the area of enhancement.

B-0780 10:46

Diffusion tensor imaging metrics as a tool for the grading of cerebral gliomas with histopathological correlation

H.A.M.M. Abdel Daiem, A.M. Elnekiedy, M. Elsheikh, Y. Eladawy, R. Darweesh; *Alexandria/EG (hanan.morsi@yahoo.com)*

Purpose: To evaluate the role of quantitative diffusion tensor imaging measurements including, fractional anisotropy (FA) and mean diffusivity (MD) values in the grading of cerebral glioma.
Methods and Materials: 11 patients with gliomas of low histological grades (WHO grade I and II) and 15 patients with high histological grades gliomas (WHO grade III and IV) were examined by MRI 1.5T. Mean FA, FA tumour/normal tissue ratio in the solid tumour components and corresponding mean MD, MD tumour/normal tissue ratio were measured and compared statistically among different tumour grades.
Results: There was statistically significant difference in mean FA values and FA ratios between low grade gliomas (LGGs) and high grade gliomas (HGGs). LGGs showed low FA values and ratios (mean 0.19$\pm$0.06 and 0.40$\pm$0.07, respectively) compared to that of HGGs (mean 0.35$\pm$0.06 and 0.56$\pm$0.08, respectively) p<0.001. Mean MD values and ratios were significantly higher in LGGs (mean 1.49$\pm$0.47 and 1.95$\pm$0.64, respectively) than that of HGGs (mean 1.10$\pm$0.23 and 1.43$\pm$ 0.36, respectively) p<0.010 and 0.013 respectively.
Conclusion: MR diffusion tensor imaging metrics could increase the diagnostic accuracy in the preoperative grading of cerebral glioma.

B-0781 10:54

Diffusion-weighted imaging for predicting and monitoring primary central nervous system lymphoma treatment response

J.B. Wen, W.X.Z. Xu, D.Y. Geng; *Shanghai/CN (wen123jianbo@163.com)*

Purpose: This study assessed the minimum ADC correlated with treatment response in patients with primary central nervous system lymphoma undergoing methotrexate-based chemotherapy.
Methods and Materials: Thirty-five patients with primary central nervous system lymphoma underwent conventional MR imaging and DWI before chemotherapy and after 1 and 5 cycles of chemotherapy.Pretreatment minimum ADC, minimum ADC after 1 cycle, minimum ADC after 5 cycles, and change in minimum ADC were compared among the different response groups.The Pearson correlation test was calculated between these ADC parameters and tumour response.
Results: The pretreatment minimum ADC of the progressive disease group was lower than that of the complete response and partial response groups, but there was no significant difference among them. A comparison among groups showed that Minimum ADC after 1 cycle, minimum ADC after 5 cycles, minimum ADC change, and the percentage of minimum ADC change were all significantly different among the 3 groups. A significant positive correlation was observed between the percentage of minimum ADC after 1 cycle of chemotherapy and the size reduction percentage after 5 cycles of chemotherapy. The minimum ADC change and the percentage of minimum ADC change performed better in the differentiation of the final treatment response, specifically in complete response and partial response from progressive disease.
Conclusion: The minimum ADC after 1 cycle and minimum ADC changes were better correlated with the treatment response than the pretreatment minimum ADC. Minimum ADC after early therapy may potentially to be used to predict and monitor the response of primary central nervous system lymphoma to chemotherapy.

B-0782 11:02

True progression vs pseudoprogression in glioma: a comparative study of arterial spin labelling and dynamic susceptibility contrast imaging

Q. Xu[1], K. Xu[1], J. Wu[2], J. Qu[2]; [1]*Xuzhou/CN*, [2]*Shanghai/CN (xuqianxz@126.com)*

Purpose: The purpose of this study was to differentiate true progression from pseudoprogression of gliomas treated with concurrent chemoradiotherapy (CCRT) with temozolomide (TMZ) using 3D pseudo-continuous arterial spin labelling (3D-ASL) technique and dynamic susceptibility contrast perfusion magnetic resonance imaging (DSC-MRI).
Methods and Materials: Twenty-six consecutive patients who showed new or enlarged, contrast-enhancing lesions within the radiation field after CCRT were assessed by use of 3D-ASL and DSC-MRI. These patients were classified into groups of tumour recurrence (n=16) or pseudoprogression (n=10) based on pathologic analysis or clinical-radiologic follow-up. The extent of susceptibility artefacts in the enhanced lesions was scored from 1 to 3 (1 = no susceptibility artefacts and 3 = extensive susceptibility artefacts (maximum diameter>2 cm)). A quantitative analysis was performed with cerebral blood flow values (ASL-CBF), relative cerebral blood flow values (ASL-rCBF, DSC-rCBF) and relative cerebral blood volume values (DSC-rCBV) in the region of interest (ROI) with maximum signal enhancement.
Results: ASL had a lower susceptibility-artefact score than DSC-MRI (p=0.01). There was a statistically significant difference between tumour recurrence group and pseudoprogression group for all parameters. There was good correlation between DSC-rCBF and ASL-rCBF values, as well as DSC-rCBV and ASL-rCBF values with correlation coefficients of 0.8 and 0.727.
Conclusion: 3D-ASL is an alternative to DSC-MRI for the evaluation of perfusion in differentiating true progression from pseudoprogression of gliomas treated with CCRT. The method has fewer susceptibility artefacts than DSC-MRI and can be used in patients with renal failure because no contrast injection is needed.

B-0783 11:10

Necrosis in tumour bed-radiation necrosis vs tumour necrosis: is there any role of dynamic contrast-enhanced perfusion MRI? First step - clinical feasibility study

F. Mubarak; *Karachi/PK (fatima.mubarak@aku.edu)*

Purpose: To assess adequacy of cerebral blood volume (CBV) and permeability index in differentiating radiation necrosis and tumour growth.
Methods and Materials: In this study we analysed rCBV and permeability index from the enhancing areas to the contralateral white matter in10 post-treatment malignant brain lesions.The lesions were compatible with features of MR-morphological tumour progression. The diagnosis (real progression vs radiation necrosis) was determined by histopathology or by clinical/MRI-follow-up.
Results: Significant differences between tumour progression (N=5) and radiation necrosis (N=4) and mixed (N=1). An increased rCBV and permeability index is highly predictive of tumour progression.
Conclusion: Initial results of CBV and permeability map in differentiating tumour necrosis and tumour growth was highly promising.

B-0784 11:18

Prediction of survival in patients affected by Glioblastoma multiforme evaluated with perfusion MRI: a histogram analysis

A. Di Napoli, L. Pasquini, A. Romano, A. Boellis, A. Bozzao; *Rome/IT*

Purpose: Currently the most predictive prognostic marker for longer survival in patients with newly diagnosed glioblastoma is the MGMT promoter methylation status. The aim of this study was to verify which parameters rCBV data (kurtosis, skewness, average, maximum value, median) obtained by histogram analysis of perfusion acquisitions could predict the survival at 1 year in patients with GBM after surgical procedure.
Methods and Materials: Thirty-four patients with newly diagnosed histologically verified GBM were retrospectively evaluated. All patients received postoperative focal radiotherapy plus concomitant daily temozolomide, followed by adjuvant TMZ therapy. Each subject underwent the same MR

examination with standard sequences and dynamic susceptibility-weighted contrast-enhanced perfusion. The CBVratio was then automatically calculated by the software. Histograms were generated from multiple ROIs covering the tumour and the histogram pattern was statistically evaluated for kurtosis, skewness, mean, median and maximum value of rCBV. Survival curves of histogram parameters were performed and compared to methylation status of GBM.
Results: Only kurtosis showed a significant difference comparing subjects survived more and less than a year. A significant correlation was evident between OS and rCBV kurtosis. According to ROC analysis, the rCBV kurtosis value of 1,26 represented an optimized cutoff useful to distinguish subjects survived more and less than a year. Survival curves showed a better survival condition with rCBV kurtosis more than 1,26. No similar results were appreciable in survival curves of methylated and unmethylated subjects.
Conclusion: The histogram analysis could represent a valid method to predict survival in patients affected by GBM.

B-0785 11:26

Contrast-enhanced MRI vs contrast-enhanced ultrasound: a comparison in glioblastoma surgery using intra-operative fusion imaging
F. Prada[1], V. Vitale[2], M. Del Bene[1], C. Boffano[1], L.M. Sconfienza[1], G. Mauri[3], L. Solbiati[3], G. Sakas[4], F. DiMeco[1]; [1]*Milan/IT*, [2]*Lecco/IT*, [3]*Rozzano/IT*, [4]*Darmstadt/DE (io@lucasconfienza.it)*

Purpose: To compare intraoperative contrast enhanced ultrasound (CEUS) images to the correspondent co-planar T1 weighted contrast-enhanced magnetic resonance images (gdMRI) using fusion imaging between CEUS and pre-op MRI in glioblastoma (GBM).
Methods and Materials: Ten patients with GBM diagnosis were retrospectively enrolled. All patients underwent tumour excision guided by navigated intra-operative US (ioUS) based on fusion imaging between ioUS and pre-operative MRI. Navigated CEUS scans were performed after intravenous administration of ultrasound contrast agents (CA), before tumour resection. Using fusion imaging we compared CEUS contrast enhancement (location, morphology, margins, dimensions, and pattern) to that of gdMRI.
Results: Registration between pre-operative gdMRI and ioUS demonstrated an error less the 2mm. In all cases CEUS highlighted the lesion. Contrast enhancement of gdMRI and CEUS was superimposable in all cases for location, margins, dimensions, and morphology while the pattern was the same in 9/10 cases; in one case the pattern was different.
Conclusion: CEUS contrast enhancement location, margins, morphology, and dimensions are superimposable to that provided by pre-operative gdMRI in all cases; while the pattern is the same in most of the cases. Taking into account that the goal of GBM resection is to remove all the gdMRI enhanced area, the information obtained with CEUS are of paramount importance in surgical management of GBM.

B-0786 11:34

Could new reconstruction CT techniques challenge MRI for the detection of brain metastasis in the context of initial lung cancer staging?
D. Millon, D.L. Byl, S.E. Cambier, A.G. Van Maanen, A. Vlassenbroek, E.E. Coche; *Brussels/BE (domitille.millon@uclouvain.be)*

Purpose: To evaluate the diagnostic performance of brain CT images reconstructed with a model-based iterative algorithm and acquired at conventional and reduced dose in the staging work-up of lung cancer.
Methods and Materials: 115 patients with histologically proven lung cancer were prospectively included between July 2014 and September 2015. Patients underwent 2 brain CT acquisitions, during the same initial staging session. Acquisitions were performed on a 256-slice MDCT (Philips Healthcare, Cleveland OH) at standard (CTDIvol: 41.4mGy) and half dose (CTDIvol: 20.7mGy). Both images datasets were reconstructed with Filtered Back Projection (FBP) and model-based iterative reconstruction algorithm (IMR, Philips HealthCare, OH). Brain MRI was performed within 7 days and was considered as the gold standard. 2 blinded independent readers analysed the images. Diagnostic performance and inter-observer agreement were calculated.
Results: 93 patients underwent all examinations. MRI showed 56 metastasis on 17 patients. At the standard dose, 8 patients presented metastasis on both FBP and IMR CT images with 15 and 17 lesions, respectively. At half-dose, 6 (FBP) and 7 patients (IMR), presented 13 and 15 lesions, respectively. Specificity, negative and positive predictive values were excellent for all CT techniques.The test couldn't highlight any significant difference between the standard dose IMR and the half dose FBP techniques (p=0.12>0.05).
Conclusion: Even using new CT reconstructions techniques, MRI is still the best imaging tool to detect brain metastases at the initial staging of lung cancer. No significant difference could be demonstrated between the 2 CT techniques.

B-0787 11:42

Exact differentiation of tumoural borders in patients with glioma by MRS and diffusion magnetic resonance imaging
G. Amjad, D. Firouznia, D. Zeinalizadeh, H. Ghanaati, A. Jalali, M. Shakiba, P. Sabetrasekh, N. Ghavami; *Tehran/IR (Ghazal_1986_amjad@yahoo.com)*

Purpose: Most of patients with glioma are planned for surgical intervention in whom, exact localisation of tumour borders is so critical as this could optimize the surgery to remove as much as tissues involved by tumour and preserve intact tissues. Here, we want to assess the exact differentiation of tissues involved by glial tumoural cells vs non-involved areas by MRS and perfusion MRI.
Methods and Materials: Ten patients with glioma diagnosis based on conventional MRI features were enrolled [mean age: 35.3±13.2, range: 20-62, 6 males]. All patients underwent 3T MRI in which tumour mapping based on MRS was featured and according to this mapping, different tumoural and peritumoural locations [including tumoural core, infiltrative oedema, reactive oedema and normal tissue] were determined. Quantitative diffusion and MRS measurements on these locations were performed. Then, using a biopsy navigation system, biopsies were taken from different mentioned locations and histopathological assessment results were considered as gold standard. MRI quantitative measurements of different locations were compared together.
Results: Among 48 pathologic samples,36 (75%) contained tumoural cells [including 9 tumoural core, 26 infiltrative tissues and 1 necrosis]. Based on primary mapping, 7 (19.4%) of these positive samples were missed [five were diagnosed as reactive oedema and 2 as normal tissue] [kappa: 0.67, P value<0.001]. Mean of ADC was statistically higher in tumoural samples (P=0.002). Median of NAA and NAA/Chol was different between positive and negative samples (P value<0.001). Mean ADC and median Chol/NAA were statistically different in missed reactive oedema samples than normal and correctly diagnosed reactive oedema samples together (P values <0.05).
Conclusion: Detailed diffusion and MRS quantitative measurements could be new measurements for more exact delineating peritumoural borders of gliomas.

B-0788 11:50

Radiographic response of tectal gliomas following proton radiotherapy
P.A. Caruso; *Boston, MA/US (pcaruso@partners.org)*

Purpose: Proton radiotherapy is an effective modality for the treatment of paediatric brainstem tumours. Many tumours including tectal gliomas may respond to proton radiotherapy initially by increasing in size that may be misinterpreted as tumour progression. The purpose of our study is to assess the quantitative response of tectal gliomas by performing serial MRI measurements of tumour volume over time to identify a predictable trend in tumour response to proton radiotherapy.
Methods and Materials: Following IRB approval, a retrospective clinical database search was performed for patients with tectal gliomas. Patients aged 0 through 25 years with tectal gliomas who underwent proton radiotherapy were included. Patients with tumours previously treated with radiotherapy or surgical resection were excluded. Cubic volume measurements were obtained from FLAIR MRI scans at all available timepoints.
Results: Five subjects met inclusion criteria with median age 14.4 years (average, 16.2 years; range, 12.6-20.8 years). Median imaging follow-up was 2.6 years (average, 3.0 years; range, 1.4-5.4 years) with a median of 8 post-treatment timepoints (average, 7.6; range, 4-10). Each of the five tumours followed a pattern of post-radiotherapy enlargement followed by reduction in size. The peak tumour volume occurred at a median of 6.9 months (average, 6.2 months; range, 3.5-8.2 months) from initiation of radiotherapy.
Conclusion: Following proton radiotherapy, tectal gliomas demonstrate a predictable trend of enlargement and subsequent reduction in tumour size. This trend may be helpful in distinguishing radiographic response from tumour progression.

Ultra-fast ^{18}F-FDG PET/MRI compared to ^{18}F-FDG PET/CT and CT in whole-body staging of females with recurrent pelvic malignancies

J. Kirchner[1], L.M. Sawicki[1], S. Suntharalingam[2], J. Grüneisen[2], V. Ruhlmann[2], C. Deuschl[2], K. Herrmann[2], G. Antoch[1], L. Umutlu[2]; [1]*Düsseldorf/DE*, [2]*Essen/DE (Julian.Kirchner@med.uni-duesseldorf.de)*

Purpose: To evaluate the diagnostic feasibility of an ultra-fast ^{18}F-FDG PET/MRI protocol, including T2-w and contrast-enhanced T1-w imaging as well as metabolic assessment (PET) in comparison to 18F-FDG PET/CT and CT for whole-body staging of female patients with suspected recurrence of pelvic malignancies
Methods and Materials: 43 female patients with suspected tumour recurrence were included in this study. All patients underwent a PET/CT and a subsequent PET/MRI examination. Two readers were asked to evaluate ultra-fast PET/MRI, PET/CT as well as CT datasets of PET/CT separately for suspect lesions regarding lesion count, lesion localization and lesion characterization. Statistical analyses were performed both, on a per-patient and a per-lesion basis.
Results: Tumour relapse was present in 38 of 43 patients. Based on CT readings 25/38 tumour relapses were correctly identified. PET/CT enabled correct identification of 37/38 patients, PET/MRI correctly identified 36/38 patients with recurrent cancer. On a lesion-based analysis PET/MRI enabled the correct detection of more lesions, comprising a lesion-based sensitivity, specificity, positive predictive value, negative predictive value and diagnostic accuracy of 50%, 58%, 76%, 31%, and 53% for CT, 97%, 83%, 93%, 94%, and 92% for PET/CT and 98%, 83%, 94%, 94%, and 94% for PET/MRI, respectively. Mean scan duration of ultra-fast PET/MRI, PET/CT and whole-body CT amounted to 18.5 ± 1 minutes, 18.2 ± 1 minutes and 3.5 minutes, respectively.
Conclusion: Ultra-fast PET/MRI provides equivalent diagnostic performance and examination time when compared to PET/CT and superior diagnostic performance to CT in restaging female patients suspected to have recurrent pelvic cancer.

B-0790 10:47

Characterisation of complicated and recurrent urological infections using molecular imaging of the chemokine receptor CXCR4 in combination with diffusion-weighted MRI

K. Hueper[1], F. Gueler[1], J.H. Bräsen[1], H.-J. Wester[2], T.L. Ross[1], H. Haller[1], F. Wacker[1], F. Bengel[1], T. Derlin[1]; [1]*Hannover/DE*, [2]*Garchingen/DE (hueper.katja@mh-hannover.de)*

Purpose: To obtain mechanistic insights into complicated recurrent urological infections in patients after kidney transplantation using molecular imaging of chemokine receptor CXCR4-expression by means of positron emission tomography (PET) in combination with diffusion-weighted magnetic resonance imaging (MRI).
Methods and Materials: Twelve patients with suspected acute kidney transplant infection were examined using PET with the specific CXCR4-ligand, gallium-68- (Ga-68-)pentixafor as well as diffusion-weighted MRI (10 b-values). The spatial distribution and intensity of up-regulation of CXCR4-expression on PET and diffusion restriction as determined by apparent diffusion coefficients (ADCs) on MRI were analyzed, and compared to serum and urine analyses, microbiologic evaluation and immunohistochemistry of kidney biopsy specimens.
Results: Patterns consistent with acute transplant infection were detected in 7/12 patients on PET and MRI. In focal lesions, ADC was reduced compared to unaffected parenchyma (1.110±0.125 vs. 1.577±0.028*10^{-3} mm^2/s, p<0.001). Areas of ADC-reduction corresponded to up-regulated CXCR4-expression compared to parenchyma (SUVmean 5.37±2.37 vs. 3.63±1.92, p<0.01). In the other patients, imaging detected no signs of renal involvement, consistent with lower urinary tract infection. Leukocyturia was present in all patients with evidence for renal inflammation. Immunohistochemistry of biopsies of acute transplant infection showed CXCR4-expression in infiltrating leukocytes.
Conclusion: Combined PET/MR imaging with Ga-68-pentixafor detects acute renal infections and provides insights into the pathophysiology of the disease. Up-regulated CXCR4-expression in infiltrating leukocytes corresponded to areas of increased cell density on MRI. Combined PET/MRI may have the potential to confirm the presence, extent and localization of acute renal infection providing relevant information for the therapeutic management of patients.

B-0791 10:55

PET/MR radiogenomics of invasive ductal breast cancer: an exploratory study

O.A. Catalano[1], U. Mahmood[1], A. Soricelli[2], M. Salvatore[2], C. Catana[1], B.R. Rosen[1]; [1]*Boston, MA/US*, [2]*Naples/IT (onofriocatalano@yahoo.it)*

Purpose: To explore the potentialities of CE-FDG PET/MR to provide insights into genetics and grade of differentiation of ductal invasive breast cancer.
Methods and Materials: 21 non-operated invasive ductal breast cancer patients, with known degree of expression of oestrogen receptor (ER), progesterone receptor (PR), human epidermal growth factor 2 (HER2), antigen Ki-67 (Ki67), and histology grading, underwent CE-FDG PET/MR. SUV_{max}, $Ktrans_{mean}$, Kep_{mean}, Ve_{mean}, iAUC, and ADC_{mean} were compared with the expression of ER, PR, HER2, KI67 and with grading, using Student's t-test.
Results: Of the explored biomarkers only Kep_{mean}, ADC_{mean}, and SUV_{max} were capable of discriminating expression of ER, PR, HER2, Ki67, and grading. Higher Kep_{mean} and SUV_{max} differentiated ER- and PR- from ER and/or PR+ cancers (Kep_{mean} 9234±1320min^{-1}versus 6492±2359min^{-1}, p=0.011; SUV_{max} 14.19±7.17 versus 6.18±4.34, p=0.005). ADC_{mean}, Kep_{mean}, and SUV_{max} were higher in HER2- rather than in HER2+ tumours (ADC 1303±121 x10^{-6}mm^2/s versus 1022±280 x10^{-6}mm^2/s, p=0.009; Kep_{mean} 8599±2122min^{-1} versus 6322±2241min^{-1}, p=0.028, and SUV_{max} 11.79±7.65 versus 6.17±4.02, p=0.046, respectively). Only ADC_{mean} discriminated Ki67≤14% versus Ki67>14% cancers (964±242x10^{-6} mm^2/s versus 1252±214x10^{-6} mm^2/s, p=0.011). Both Kep_{mean} and SUV_{max} demonstrated lower values in G2 rather than in G3 cancers (Kep_{mean} 6638±2392 min^{-1} versus 8944±1765 min^{-1}, p=0.036; SUV_{max} 6.83±4.73 versus 12.89±8.08, p=0.042).
Conclusion: ADC_{mean}, Kep_{mean}, and SUV_{max} correlated with expression of ER, PR, HER2, and Ki67 in ductal breast cancer and also with grading. CE-FDG PET/MR has the potentiality to non-invasively provide insight into genetics and grading of invasive ductal breast cancer. This might aid better patient management optimizing personalized therapy.

B-0792 11:03

PET imaging of chemokine receptor CXCR4 in patients with primary breast carcinoma

T. Vag, A. Rossmann, S. Metz, J. Ettl, M. Niemeyer, H. Wester, M. Schwaiger; *Munich/DE (tibor.vag@tum.de)*

Purpose: CXCR4 is a chemokine receptor that was reported to be overexpressed in invasive breast cancer and seems to play a major role in signalling pathways of metastases. The aim of this study was to assess the feasibility of CXCR4-directed imaging in patients with breast cancer using the novel CXCR4-targeted PET probe 68Ga-pentixafor.
Methods and Materials: 12 patients suffering from primary breast cancer underwent PET imaging (either PET/MR or PET/CT) using 68Ga-pentixafor. The lesions included 10 invasive ductal carcinomas (IDC) and two invasive lobar cancers (ILC). Five patients were known to have lymph node or distant metastases detected by previously performed imaging modalities. Maximum standardised uptake values (SUVmax) and tumour-to-background ratios (T/B ratio) were determined in the breast cancer lesions.
Results: 8 of 12 primary breast cancers were visually detectable with a mean SUVmax of 2.75 (range 1.7 to 4.5) and a mean T/B ratio of 2.2. The visually undetectable lesions included the two cases of ILC, and two cases of IDC (G2). Highest SUVmax T/B rations of 4.37/3.9 and 4.5/3.5, respectively, were demonstrated in an IDC (G3) with evidence of bone and lymph node metastases and in an IDC (G2) without any metastases. A statistical significant correlation between SUVmax, T/B ratios and occurrence of metastases was not observed.
Conclusion: CXCR4-directed PET imaging of breast cancer is feasible. Based on our first observations in this small patient cohort, tracer accumulation was significantly higher in IDC compared to ILC.

Does bone scan add any value to whole body FDG-PET/CT in staging and restaging breast carcinoma?

M.M. Abouzied, H. Al-Refai, M. AlQahtani, A. Elsaadany, A. Almuhideb, A. Fathala, Z. Khan, A. Alsugair, A. Abu-zaid; *Riyadh/SA (mohei.abouzied@gmail.com)*

Purpose: To evaluate the efficacy of fluorine-18 fluorodeoxyglucose positron emission tomography/computed tomography (^{18}F-FDG PET/CT) compared to ^{99m}Tc-methylene diphosphonate (^{99m}Tc-MDP) bone scan in detecting bone metastases in patients with breast cancer.
Methods and Materials: Total of 526 patients with breast cancer were retrospectively identified in our database who had underwent ^{18}F-FDG PET/CT, from January 2006 to May 2016. Of whom, 133 patients met our inclusion criteria — namely, biopsy-proven breast cancer, and ^{18}F-FDG PET/CT and bone scan within 30 days. Comparison was made on a lesion-by-lesion analysis. MRI, multi-detector CT, and the clinical course of the patients were used as reference standard.
Results: ^{18}F-FDG PET/CT identified 506 bone lesions in 47 patients, in addition to distant metastases in solid organs (brain, lymph nodes, lung, liver and adrenals). Bone scan missed 4 patients with confirmed bone metastases and was false positive in 3 patients. ^{18}F-FDG PET/CT showed neither false-positive nor false-negative results. The overall sensitivity, specificity, and accuracy was 100, 100 and 100% for ^{18}F-FDG PET/CT and 91.5, 96.5 and 94.7%, for bone scan, respectively.
Conclusion: ^{18}F-FDG PET/CT is superior to ^{99m}Tc-MDP bone scan in detecting bone metastases from breast cancer, not adding benefit for bone scan.

B-0794 11:19

Correlation of apparent diffusion coefficient value on diffusion-weighted imaging and SUV values on PSMA PETCT in patients with biopsy-proven prostate cancer

S. Shivalingappa, K. Kallur, I. Desai, M.A. Kumar, G.R. Prashanth, S. Neelakantan, S. Sampangi, A. Kesari, P.S. Sridhar; *Bangalore/IN (dr.shivaswami@gmail.com)*

Purpose: Correlation of apparent diffusion coefficient value on diffusion-weighted imaging and SUV values on PSMA PETCT in patients with biopsy-proven prostate cancer.
Methods and Materials: This is a prospective study conducted in our hospital, department of molecular imaging over last 6 months. 22 patients with biopsy-proven prostate cancer were included. All these patients underwent PSMA PETCT imaging as a staging investigation and were subjected to prostatic pelvic MRI (3T SKYRA 48 channels). PSMA PETCT images were analysed on GE work station (AW 4.6). Mean and maximum SUV values were obtained. MRI images were analysed on MMWP work station and ROIs were drawn for the ADC values at the regions of elevated SUV values. ADC values were compared with SUV values using one-way Pearson bivariate relationships were determined between SUV and ADC. T2W MR images were also correlated with ADC values and PET-MRI fusion with T2 W axial images was performed to assess the extent of the lesion.
Results: There was a significant negative correlation between SUV max with mean ADC (r =-525, p=0.01). There was a significant negative correlation of max SUV with min ADC (r= -0.602, p=0.005). There was a significant negative correlation between min SUV with mean ADC (-0.61, p=0.004) . The ADC values were significantly low and mean SUV values were high with Gleason's score above 8.
Conclusion: Quantitative ADC values in correlation with PSMA PETCT help in localisation, assessing the extent of the disease and also determining the aggressiveness of the disease.

B-0795 11:27

Diagnostic accuracy of integrated 68-Ga-PET/MRI in suspected recurrent prostate cancer

S. Lütje[1], J. Cohnen[1], J. Grüneisen[1], L.M. Sawicki[2], T. Pöppel[1], L. Umutlu[1], A. Wetter[1]; [1]*Essen/DE*, [2]*Düsseldorf/DE (axel.wetter@uk-essen.de)*

Purpose: To evaluate diagnostic accuracy of ^{68}Ga-PSMA- PET/MRI in suspected recurrent prostate cancer.
Methods and Materials: 25 patients with suspected recurrent PCa underwent ^{68}Ga-PSMA PET/CT followed by integrated PET/MRI. Data from both investigations were analysed separately and compared regarding tumour detection rate, image quality and radiotracer uptake in tumour lesions and muscle tissue. Image analysis was prospectively performed by different groups of nuclear medicine physicians and radiologists with respect to the detection of lymph node metastases, bone metastases and local recurrence of the tumour. Image quality was evaluated visually based on a three-point ordinal scale.
Results: ^{68}Ga-PSMA-PET/MRI provided diagnostic image quality in all examined patients. Overall detectability of PET-positive lesions was higher with PET/MRI compared to PET/CT (43 vs 36), identifying 14 vs 9 PET-positive local recurrences, 23 vs 20 PET-positive lymph nodes, 2 vs 3 PET-positive soft-tissue lesions, and 4 vs 4 PET-positive bone lesions, respectively. Mean PET image quality obtained with ^{68}Ga-PSMA-PET/MRI and -PET/CT was 2.8±0.4 and 2.7±0.5, respectively (p=0.1604).
Conclusion: ^{68}Ga-PSMA-PET/MRI is superior to ^{68}Ga-PSMA-PET/CT in the detection of PSMA-expressing prostate bed recurrences and lymph node lesions and as reliable as ^{68}Ga-HBED-CC-PSMA-PET/CT in the detection of bone lesions.

B-0796 11:35

Detection efficacy of hybrid ^{68}Ga-PSMA ligand PET/CT in prostate cancer patients with biochemical recurrence after primary radiation therapy defined by Phoenix criteria

I. Einspieler, I. Rauscher, C. Düwel, M. Krönke, C. Rischpler, G. Habl, M. Schwaiger, T. Maurer, M. Eiber; *Munich/DE (ingo.einspieler@tum.de)*

Purpose: The aim of this study was to evaluate the detection rate of ^{68}Ga-PSMA PET/CT in patients with biochemical recurrent prostate cancer defined by Phoenix criteria after external beam radiotherapy or brachytherapy as primary treatment.
Methods and Materials: 118 patients were included for this retrospective analysis. Of these, 45 were receiving androgen deprivation therapy (ADT) within at least 6 months prior to the PET/CT. The detection rates were stratified by PSA. The influence of primary Gleason score (GS) and ADT was assessed. Correlations between standardised uptake values (SUV) and GS or ADT in patients with positive findings were analysed.
Results: 90.7% (107/118) patients showed pathological findings indicative for tumour recurrence in ^{68}Ga-PSMA PET/CT. The detection rates were 81.8% (36/44), 95.3% (41/43) and 96.8% (30/31) for PSA of 2 to <5, 5 to <10 and ≥10 ng/mL, respectively. The detection rate was significantly higher in patients with ADT (97.7%) vs without ADT (86.3%, p=0.0381), but independent from primary GS ≥8 (92.0%) vs ≤7 (90.2%, p=0.6346). SUVmax and SUVmean were significantly higher in patients with ADT (p=0.0025 and 0.0044, respectively) and a clear trend to higher values was observed for patients with GS ≥8 (p=0.0502 and 0.0514, respectively).
Conclusion: ^{68}Ga-PSMA PET/CT demonstrates high detection rates in patients with biochemical recurrence of prostate cancer after primary radiation therapy. The detection rate positively correlated to increasing PSA as well as concomitant ADT. ^{68}Ga-PSMA PET/CT enables discrimination of local vs systemic disease and thus might have a crucial impact on further clinical management.

B-0797 11:43

Improved detection of transosseous meningiomas using 68Ga-DOTATATE PET-CT compared to MRI

W.G. Kunz, L. Jungblut, P.M. Kazmierczak, A. Rominger, N.L. Albert, M.F. Reiser, C.C. Cyran; *Munich/DE (wolfgang.kunz@med.lmu.de)*

Purpose: To analyse the diagnostic performance of 68Ga-DOTATATE PET-CT and contrast-enhanced MRI for detection of transosseous extension of intracranial meningiomas and to find associations with imaging parameters.
Methods and Materials: In this retrospective study, subjects were selected from a cohort of 325 consecutive patients who underwent 68Ga-DOTATATE PET-CT of the head for evaluation of confirmed or suspected meningioma. Inclusion criteria were (1) MR imaging within 1 month of either pre- or postoperative matching PET-CT imaging, and (2) as standard of reference pathology-confirmed meningioma diagnosis with inclusion or exclusion of transosseous extension. Imaging was independently analyzed by two readers with respect to osseous involvement, absolute tracer uptake measured as SUVmax, volume of meningioma and surrounding edema. Chi-square, Mann-Whitney U or exact McNemar's tests as well as receiver operating characteristics (ROC) analyses were performed to compare variables and diagnostic test performance.
Results: Eighty-two patients fulfilled the inclusion criteria. Patients with transosseous meningiomas (n=67) showed significantly larger lesions (median 10ml vs 3ml, p=0.002) and significantly higher SUVmax (median 14 vs 8, p=0.032) compared to extraosseous meningiomas. 68Ga-DOTATATE PET-CT in comparison to MRI performed at a considerably higher sensitivity (98.5% vs 55.2%) while maintaining high specificity (86.7% vs 100.0%); statistically significant differences between the tests were observed (p<0.001). In ROC analysis, PET-CT assessment performed best (AUC: 0.933), followed by MRI assessment (0.866), meningioma volume (0.765) and SUVmax (0.680) while surrounding oedema added no valuable information (0.483).
Conclusion: 68Ga-DOTATATE PET-CT enables improved detection of the transosseous extension of intracranial meningiomas compared to MRI.

B-0798 11:51

Development of the helmet-neck PET prototype for high sensitivity brain imaging

H. Tashima[1], E. Yoshida[1], Y. Iwao[1], H. Wakizaka[1], Y. Takado[1], C. Seki[1], T. Suhara[1], T. Yamashita[2], T. Yamaya[1]; [1]*Chiba/JP*, [2]*Tokyo/JP*
(tashima.hideaki@qst.go.jp)

Purpose: There is an emerging demand for dedicated brain PET for the study and diagnosis of neurological disorders such as dementia. We have proposed a helmet PET geometry with add-on detector for high sensitivity, high resolution and low cost brain PET. Our first prototype had an add-on detector at the chin position (helmet-chin PET). However, the gantry design gave oppressive feeling to the patient and the movement of the chin detector was inconvenient for the patient set-up. On the other hand, our previous simulation showed that add-on detectors covering the neck has equivalent effect. In this study, therefore, we developed a helmet-neck PET, which has additional detectors at the neck.
Methods and Materials: We developed the helmet PET prototype using 54 four-layer depth-of-interaction detectors with 16×16×4 array of 2.8×2.8×7.5 mm^3 GSO crystals. In the prototype, 47 detectors were arrangement in a hemisphere, and seven detectors were placed as the add-on detector. We compared the helmet-chin PET and the helmet-neck PET regarding the effects of the add-on detectors for increasing the sensitivity.
Results: The sensitivity measured with a hemispherical phantom for the brain region was increased by 12% in the helmet-chin PET and by 19% in the helmet-neck PET compared with the geometry without add-on detectors. This is because the arrangement of the detector at chin required larger margin for designing gantry, in which detector position became farther than the case of neck.
Conclusion: The helmet-neck PET has promising performance for high sensitivity brain imaging and improved convenience for patient studies.

Errors in out of hours radiology reports due to telephone interruptions

G.P. Tarr, R. Mitchell; *Auckland/NZ (greg.tarr@otago.ac.nz)*

Purpose: Errors in out of hours radiology reports may contribute to adverse outcomes in emergency patients. Radiology trainees are often required to report in non-ideal environments with high acuity patients and frequent interruptions. While a number of studies have examined rates of reporting error, there is a paucity of data on factors contributing to error. The aim of this study was to assess whether phone call interruptions while reporting raised the risk of errors.
Methods and Materials: Institutional ethical approval was obtained with waiver for informed consent. Patients undergoing out of hours CT at our institution between May 2015 and March 2016 were included. Time stamps for the on-call radiology phone were obtained. Reporting errors were identified by the presence of a standard proforma inserted into each report when the responsible consultant judged that a clinically significant discrepancy had occurred between the preliminary and final reports. Statistical analysis was performed with Stata 13.0.
Results: A total of 4738 CTs with 260 errors (5.5%, 95% CI: 4.8 to 6.1%) were included. There were 14458 phone calls, with a median of 2 phone calls (IQR 1 to 6) received per during the creation of each report. There was no association between phone call interruptions and error rate. Errors were more frequent in junior registrar reports and in reports created later in shifts.
Conclusion: Phone call interruptions were not associated with increased risk for discrepancies in preliminary reports. Inexperience and fatigue may be more important risk factors.

Calculation of body weight by means of CT using dose modulation

D. Gascho, L. Ganzoni, M.J. Thali, T.D. Ruder; *Zurich/CH*
(dominic.gascho@irm.uzh.ch)

Purpose: Documentation of the visual appearance is required in any forensic report, including body weight of the decedent. Due to a failure of our in-house, floor-embedded weighting scale, we developed a method for body weight estimation based on post-mortem computed tomography (PMCT) using automated dose modulation. The aim of this study was to evaluate the correlation between effective milliampere second (mAs^{eff}) values, based on automatic exposure control, and body weight for the purpose of determining body weight just by the means of PMCT.
Methods and Materials: The study population comprised 349 (114 female, 234 male) decedents. In a retrospective evaluation the PMCT mAs^{eff} values of the automatically provided patient protocol were correlated with the actual body weight measurements (as performed by a calibrated weighting scale). Correlations were calculated for men/women both separately and together as well as with regard to the post-mortem interval (PMI).
Results: There was an excellent correlation between mAs^{eff} values and body weight for both men and women with a PMI of less than 4 days. Correlation significantly decreased in decomposed cadavers (PMI larger or equal 4 days). Based on the data a formula to calculate individual body weight based on mAs^{eff} values was developed.
Conclusion: This study offers a reliable mean to rapidly determine the body weight of non-decomposed human cadavers. The method shows potential for further application areas in clinical radiology, e.g. in paediatric radiology for weight-based application of contrast media for CT in the emergency room.

B-0801 10:55

The role of ultrasound screening in combat surgical trauma

E. Konjukhova, I. Aseeva, V. Trojan; *Moscow/RU*
(executive-committee@yandex.ru)

Purpose: Analyse complex ultrasound analysis of battle-scarred persons with the object to the early effective medical care at several kinds of surgical trauma during early examination phase and in temporal treatment.
Methods and Materials: It was examined totally 107 (100%) patients with combat trauma in different anatomical areas.
Results: The transabdominal analysis with intraoperative evidence elicited free water at 35 (33%) of patients, the spleen rupture at 2 (2%), the liver rupture at 1 (1%) patient, the kidneys subcapsular rupture at 2 (2%). During the low limbs veins US analysis, the thrombosis was elicited: the thrombus with floating apex in popliteal vein -1 (1%). The several localisation soft tissue haematomas were detected at 86 (80%) patients. The hydrothorax was elicited at 80 (75%) patients: the signs of pneumonia were suspected at 23 (21%) of patients, the lung atelectasis were suspected at 7 (6%) patients, all with later confirmation during the roentgenologic examination. In the same way, the fractures of one or more than one ribs with the later confirmation during the x-ray examination were diagnosed. The foreign bodies (debris) in soft tissue of buttock area and low limbs were found at 25 (23%) patients with confirmation during the CT examination.
Conclusion: It can concluded on the basis of our analysis that as a result of the timely performed US analysis at the screening phase, the definite and quick patient evacuation by designation with the object to the quality medical care under the armed conflicts and war conditions is possible to performing.

B-0802 11:03

MR perfusion to identify candidates more suitable to endovascular recanalisation therapy than iv-tPA in MCA occlusion

T. Mori, Y. Tanno, S. Kasakura, K. Yoshioka, N. Nakai; *Kamakura/JP*
(moritkama@icloud.com)

Purpose: To investigate if MR perfusion (MRp) can identify candidates suitable to endovascular therapy (EnT) rather than iv-tPA alone.
Methods and Materials: We included patients 1) admitted between 2005 and 2015 within 3.5 hours, 2) with MCA occlusion, 3) with DWI-ASPECTS of 6 or more, 4) with CBF-grade of 2 or 3 and 5) treated with iv-tPA alone. We defined proximal M1 occlusion as MCA-grade1, distal M1 occlusion as MCA-grade2, and M2 occlusion as MCA-grade3 and no occlusion on MRA as MCA-grade4. At the bilateral MCA territories, we compared time intensity curves (TIC) of MRp in the affected side (a) with contralateral side (c), defined TICa divided as TICc as CBF% and CBF% of less than 0.2 as CBF-grade1, CBF% of 0.2 or more and less than 0.7 as CBF-grade2 and CBF% of 0.7 or more as CBF-grade3. We evaluated relations among MCA-grade, CBF-grade and favorable clinical outcome (fCO) of mRS 0-2 at 3 months.

Results: Thirty-four patients were analyzed. Nine patients in MCA-grade1, 9 in MCA-grade2, 15 in MCA-grade3 and 1 in MCA-grade4. Twenty-three patients in CBF-grade2 and 11 in CBF-grade3. Only 2 patients (22%) obtained fCO in MCA-grade1. In MCA-grade2, 4 (57%) of 7 patients in CB-grade2 obtained fCO and 2 (100%) of 2 in CBF-grade3 obtained fCO. In MCA-grade3,6 (67%) of 9 in CBF-grade2 obtained fCO and 5 (83%) of 6 in CBF-grade3 obtained fCO. One patient in MCA-grade4 obtained fCO.
Conclusion: Patients with MCA-grade1, MCA-grade2 and CBF-grade2, or MCA-grade3 and CBF-grade 2 were candidates for EnT.

B-0803 11:11

Current imaging practice for potentially thrombolysable ischaemic strokes in NHS Lothian with the introduction of a thrombectomy service

D.A.J. Smith, G.J. McNeill; *Edinburgh/UK (derekxii@gmail.com)*

Purpose: Evaluation of current imaging practice for potentially thrombolysable ischaemic strokes and impact of a new CT angiography (CTA) policy identifying patients who may benefit from endovascular thrombectomy.
Methods and Materials: Retrospective review over 10 consecutive weeks from October 2015, and a further 10 weeks following new CTA/thrombectomy criteria in June 2016. Analysis of cases from the major emergency department in NHS Lothian, with primary outcomes including number of thrombolysis requests, imaging findings and CTAs performed anticipating thrombectomy. Secondary outcomes were inclusion of onset-time and NIH stroke scale (NIHSS) score in CT requests, radiologists' reporting time and proportion of cases progressing to thrombolysis/thrombectomy.
Results: 87 potential thrombolysis requests were analysed in the initial group. 74 did not demonstrate contraindication to thrombolysis (haemorrhage or tumour), 13 (18%) underwent thrombolysis. Five CTAs were performed, with significant arterial occlusion on three. One patient progressed to thrombectomy. 52 (60%) requests included a time-of-onset, only one with NIHSS score. Radiologists issued 59 (67%) of reports in under 1 hour.
Following the thrombectomy policy, 110 requests were analysed. Nine demonstrated imaging contraindications, with 22 (20%) receiving thrombolysis. Three CTAs were performed, but no treatable occlusions were identified. Two other patients were considered for thrombectomy, but CTA was not performed. No requests recorded NIHSS score, 83 (75%) included onset-time. 78 (71%) reports were issued in under 1 hour.
Conclusion: Increased awareness of thrombectomy criteria among referring teams and radiologists, with inclusion of onset-time and NIHSS in initial imaging requests, could aid triage and identification of thrombectomy candidates.

B-0804 11:19

Discrepancies between preliminary resident and finalised consultant reviewed CT brain reports

A.H. Rajaram; *Bangalore/IN (akashrajaram@gmail.com)*

Purpose: To determine the rate of discrepancy between preliminary resident and finalised consultant CT brain reports.
Methods and Materials: One radiologist retrospectively reviewed all the preliminary and final CT brain reports of patients presenting with acute neurological symptoms from March 2015 to February 2016. Of the 1543 scans, 1283 had a preliminary resident report followed by a consultant report and were evaluated for minor or major discrepancy. Major discrepancy was considered when the primary diagnosis was changed between the preliminary and final report. Minor discrepancy was considered when any other amendment was made between the preliminary and final report that did not affect the overall diagnosis.
Results: No discrepancy was seen in the final report of 161/1283 (12.54%) patients. 42 (3.27%) had a major discrepancy, out of which 19 (45.23%) were false negative and 11 (26.19%) were false positive for acute infarct. Others were false negative for contusion (n=4), subdural haemorrhage (n=3), space occupying lesion (n=3) and diffuse cerebral oedema (n=2). Major discrepancies were found in 2nd (n=20) and 3rd (n=22) year resident reports. There was no correlation between resident level of training and rate of discrepancy. Third year residents had an overall higher error rate. Second year residents had significantly more false positive misinterpretations ($p<0.05$). Common sites for misinterpretation were basi-frontal lobes and posterior fossa. Discrepancy rate was highest between 5:00 p.m. and 9:00 p.m.
Conclusion: There is a low discrepancy rate between preliminary resident and final reports. However, the resident reports may be further improved in certain areas.

B-0805 11:27

Validity of head CT examinations in the emergency department

L. Skrule, A. Tarasova, D. Sosars, A. Lice, M. Radzina; *Riga/LV (ligitaskrule@gmail.com)*

Purpose: To evaluate validity of head computed tomography (CT) examinations, their impact on patient radiation exposure risk and triage management.
Methods and Materials: This cross-sectional retrospective study enrolled patients with head CT scan at the emergency department, data were assessed within one calendar month from clinical university hospital. Computed tomography scan indications and results were analysed according to the diagnostic hypothesis in admission documents, CT request forms in combination with patient clinical symptoms and history.
Results: A total of 647 consecutive CT procedures were performed in the emergency department. There were 343 (53.01%) male and 304 (46.98%) female, mean age 54 years (range 18-94). Pathology was proved in 226 (34.93%) patients (symptomatic 101/226 patients), with high correlation between referral and final diagnosis only in symptomatic patients with trauma and cerebrovascular disorders ($p=0.0001$). In asymptomatic group 46/144 (31.9%) patients had pathological CT findings (11 cerebrovascular, 3 tumours, 32 trauma, 26 other entities, e.g. arteriovenous malformation and intracranial aneurysm) with no statistically significant OR differences among patients with or without symptoms. Mean radiation exposure for all scanned patients were DLP 1186 mGy*cm (IQ range 572-1275) with estimated effective dose 2.60 mSv.
Conclusion: Considering high rate of emergency head CT scans with normal findings in symptomatic patients and unnecessary radiation exposure, the minor rate of asymptomatic patients with pathology, we need additional clinical criteria for validation of this examination, omitting patients with trauma and cerebrovascular disorders.

B-0806 11:35

Syncope, vertigo and seizure: what is the utility of imaging in the emergency department?

K. Ozturk, C. Bilgin, E. Ozturk, M. Parlak; *Bursa/TR (keremov54@hotmail.com)*

Purpose: Our purpose was to evaluate abnormal findings on cranial CT or MR in patients admitted to the emergency department with either one or in combination of symptoms such as vertigo, syncope or seizure.
Methods and Materials: The database were retrospectively reviewed for all patients underwent cranial CT or MRI, having the symptoms of syncope, seizure or vertigo. Patients were included only if they were from the emergency department and excluded if were under 18 years of age, had known recent intracranial pathology, having a history of trauma. Primary outcome was assumed as abnormal head CT or MRI including intracranial haemorrhage, infarction, acute or subacute stroke and newly diagnosed brain mass. Concurrent clinical symptoms and age were evaluated with logistic regression analysis, important parameters to indicate pathology in either CT or MR scan with either symptoms were investigated.
Results: Total of 24210 head CT and 4502 cranial MRI were searched, 2537 CT and 655 MRI were found to be eligible for this study. 1230 (38%) syncope, 1413 (44%) vertigo and 549 (18%) seizure were identified. Of those in head CT scan, only 60 (2.3%) patients have had clinically significant pathology requiring admission to the hospital. However, in 43 (6.5%) of MRI studies significant abnormalities has been noted.
Conclusion: Our study indicates that most patients presenting with vertigo, syncope or seizure may not take advantage of head CT and MRI. Abnormal findings related to the syncope were observed in only 37 patient, vertigo in 42 patients and seizure in 24 patients.

The role of radiology in body identification and in determination of the cause of death in shipwrecked refugee casualties

G. Lo Re[1], A. Argo[1], S. Zerbo[1], S. Salerno[1], D. Mazzarelli[2], M. Midiri[1], C. Cattaneo[2], R. Lagalla[1]; [1]*Palermo/IT*, [2]*Milan/IT (giuseppe.lore12@gmail.com)*

Purpose: In April 2015 an overcrowded boat with an estimated 700 migrants drowned off the Libyan coasts. Italian navy recovered the boat and thanks to a "Memorandum of Understanding" between the Ministry of Interiors, the Ministry of Education and the Commissioner's-Office-for-Missing-Persons, post mortem

activities aimed at the identification of the victims was signed. Cadavers were recovered and kept inside body bags in refrigerated trucks. Forensic pathologists and anthropologists from several Italian Universities, were recruited along with the Police Forces for this activity. Radiologists were asked to cooperated in this activity in order to facilitate identification and give a proper burial to these migrants.
Methods and Materials: In July 2016, 149 body bags were scanned before conventional autopsy through a mobile 8-channel-CT placed at the NATO's Melilli base in Sicily, next to the tents where forensic studies were being performed. Images were studied according to the guidelines provided by the Internal Ministry through a workstation with MPR, MIP and 3D-VR reconstructions.
Results: Study of number, type, congruency, calluses, fractures and anthropometric measurements of bones, teeth, growth-plate cartilages and internal/external genitals helped in sex and age assessment. Foreign objects were encountered in many cases: some of them were potentially dangerous for the coroners, while others were useful for body identification.
Conclusion: Our data clearly demonstrate the pivotal role of radiology in mass disasters and when anthropological identification is required. We also demonstrate that radiological assessment in mass disasters is feasible, but full cooperation between different medical and legal professional figures is advisable.

Thoraco-abdominal injuries of manual and device-assisted resuscitation on postmortem CT
A.R. Bayat, D.G.H. Bosboom, W.M. Prokop, M. Brouwer, W.M. Klein;
Nijmegen/NL (alireza.bayat@radboudumc.nl)

Purpose: Resuscitation has been associated with different kind of injuries, such as fractures of sternum and ribs. Device-assisted resuscitation seems to use more power than manual CPR. We compared fractures and haemorrhages of cadavers who died after either manual or device-assisted resuscitation.
Methods and Materials: We retrospectively included cadavers who had undergone total body postmortem CT (PMCT) if aged >18 years and natural cause of death, and divided into 3 groups: no CPR versus manual CPR versus device-assisted CPR (AutoPulse). The resuscitation injuries scored at PMCT were: rib fracture anterior or posterior, sternal and spine fractures, pneumothorax, pleural haemorrhages (HU>25), pleural fluids in mm (HU<25), haemoperitoneum (HU>25), retroperitoneal haemorrhages (HU>25), lacerations of the abdominal organs (surrounding fluid (HU>25) and induration of the epigastric fat. Univariate analyses with χ^2 and Mann-Whitney U tests were performed.
Results: 93 Cadavers with PMCT were included: 26 after device-assisted CPR, 23 manual CPR and 44 no CPR. The cadavers without CPR showed no injuries. Significantly more rib fractures (20 vs 6, p<0.001) and especially posterior were identified in the device-assisted CPR cadavers than in the manual CPR cadavers (12 vs 9, p=0.016). Other injuries including haematothorax, fractured vertebra and liver laceration were not different between the CPR groups.
Conclusion: Both manual and device-assisted CPR result in several serious injuries. Posterior rib fractures are significantly found more after device-assisted CPR. Prospective study is needed to investigate the effective and traumatic results of manual versus device-assisted CPR.

Subtendinous extensor carpi ulnaris (ECU) bone marrow edema as a predictor of peripheral triangular fibrocartilage tears and ECU tendon pathology
M.T. Nevalainen[1], A.C. Zoga[2], W.B. Morrison[2], J.B. Roedl[2]; [1]*Oulu/FI*, [2]*Philadelphia, PA/US (mikaneva@paju.oulu.fi)*

Purpose: To determine the association between peripheral triangular fibrocartilage (TFC) tears and extensor carpi ulnaris (ECU) pathology and to evaluate subtendinous ECU bone marrow edema (BME) at the styloid process of the ulna as a diagnostic marker for TFC and ECU pathology on MRI.
Methods and Materials: The presence of TFC tears, ECU pathology (tenosynovitis, tendinosis, tears and subluxation) and subtendinous ECU BME were determined on MRI and correlated with arthroscopy. These findings were assessed in a study group of 64 patients with peripheral TFC tears and in two age- and sex-matched control groups: 64 patients with central TFC tears, and 64 patients without TFC tears (all proven with arthroscopy).
Results: Among the 64 patients without TFC tears on arthroscopy, 1.2% (8/60) had ECU pathology (all with mild ECU tendinosis, no ECU tenosynovitis, no ECU subluxation) and 0% (0/60) had subtendinous ECU BME. In the 64 patients with central TFC tears on arthroscopy, 9 (1.4%) had ECU pathology and 0% (0/60) had subtendinous ECU BME. Among the 64 patients with peripheral TFC tears, 46/60 (78%) had ECU pathology and 34/60 (70%) had subtendinous ECU BME. All 34 patients with subtendinous ECU BME (100% specificity) had both a peripheral TFC tear and ECU pathology (combined injury). 45/46 of patients with a combined injury had subtendinous BME yielding a 98% sensitivity.
Conclusion: Peripheral TFC tears are highly associated with ECU pathology. Subtendinous ECU BME on MRI indicates a combined peripheral TFC and ECU injury with 100% specificity and 98% sensitivity.

B-0810 10:38

The posterior radioscaphoid angle is related to the severity of degenerative cartilage damage of the wrist in patients with scaphoid nonunion
C.M. Phan, A. Miquel, C. Pradel, C. Quach, Y. Menu, M.D. Crema; *Paris/FR (catherine.phan@aphp.fr)*

Purpose: To determine whether the posterior radioscaphoid angle evaluated on CT-arthrography, reflecting posterior displacement of the distal pole in cases of scaphoid nonunion, is related to the cartilage damage severity of the wrist.
Methods and Materials: CT-arthrography images from 35 patients with scaphoid nonunion (cases) and from 35 patients without fractures or ligament injury (controls) were retrospectively reviewed by one experienced musculoskeletal radiologist. Cartilage morphology of the wrist including both radiocarpal and midcarpal joints was graded from 0 to 6 using a modified WORMS system. Scaphoid nonunion advanced collapse (SNAC) was graded from 0 to 3. Five carpal angles were assessed: radio-scaphoid (RS), posterior radioscaphoid (PRS), radio-lunate (RL), scapho-lunate (SL), and capito-lunate (CL). Independent sample T test was performed to test if carpal angles were able to discriminate cases from controls, as well as the different SNAC grades. Pearson correlation analysis was used to assess the correlations between carpal angles and the sum of WORMS scores (severity of the global cartilage damage).
Results: All carpal angles were able to discriminate between cases and controls (p<0.001). Only the PRS angle was able to discriminate between radiocarpal (SNAC 1 and 2) and midcarpal (SNAC 3) involvement (116.1±12.8 vs. 127.9±13.6; p=0.015). The PRS angle (0.70) better correlated with the severity of global cartilage damage than did the SL (0.64) and RS (0.46) angles (p <0.0001).
Conclusion: The PRS angle was able to discriminate between radiocarpal and midcarpal involvement (SNAC) and demonstrated better correlation with global cartilage damage severity in patients with scaphoid nonunion.

B-0811 10:46

Diffusion tensor imaging in carpal tunnel syndrome (CTS): is there any correlation with ultrasound?
M.M.H. Abd Ellah, C. Kremser, W. Jaschke, E. Gizewski, A.S. Klauser;
Innsbruck/AT (dr_m_hamdy2006@hotmail.com)

Purpose: To study the correlation between quantitative analysis of diffusion tensor imaging (DTI) of median nerve (MN) and CTS severity determined by delta cross-sectional area measurement (Δ-CSA).
Methods and Materials: Thirty-seven CTS patients (25 females and 12 males) [mean age 58.11± Std] were examined using a 3T MR scanner (Skyra, Erlangen, Germany). The examination protocol included diffusion tensor imaging (DTI) in addition to routine sequences (coronal T1 VIBE, axial T1 and T2 TIRM) for anatomical correlation. All patients underwent ultrasound examination using 5-18 MHz (HI Vision Preirus, Hitachi Aloka Medical, Ltd, Tokyo) for diagnosis of CTS. Δ-CSA measurement represented the difference in CSA between MN at distal forearm and carpal tunnel. Patients were divided into three groups based on Δ-CSA (mild, moderate and severe). Mean apparent diffusion coefficient (ADC) and fractional anisotropy (FA) were correlated to Δ-CSA.
Results: Patients were classified as follows (mild = 8, moderate = 9 and severe = 25). Mean ADC and FA values were $1.482x10^{-3}$ and $0.541x10^{-3,}$ respectively. A significant mild to moderate correlation was shown between FA and Δ-CSA (r=0.311, *P*=0.044), however, no correlation between ADC and Δ-CSA. Mean FA values were 602.4, 560.2 and 523 for mild, moderate and severe groups, respectively, with a significant difference between severe and mild groups (*P*=0.027).

Conclusion: Quantitative analysis of diffusion using ADC and FA proved feasible with a mild to moderate correlation between FA and severity grade of CTS determined by Δ-CSA, with a significant difference between severe and mild groups.

B-0812 10:54

Comparison of T2 BLADE PD and isotropic three-dimensional fast spin echo cube (3D T2 SPACE) sequences with conventional protocols in wrist lesions using 3T MRI

H. Soroush, H. Naghibi, M. Shakiba, F. Faeghi, H. Hashemi; *Tehran/IR (SOROUSH_HEDAYAT@YAHOO.COM)*

Purpose: Magnetic Resonance Imaging (MRI) of wrist is a useful diagnostic method for different wrist structures, however the efficacy could be optimized. In this study we compared new protocols of 3D T2SPACE, PD BLADE and T2 BLADE with the conventional protocols, including T2 FSE, PD FSE and T1 FSE for wrist imaging.
Methods and Materials: Twenty patients (12 men) with history of wrist trauma or suspected wrist lesions were enrolled. All protocols were carried out on all patients; then quality of each protocols was assessed by two musculoskeletal radiologists and one hand surgeon.In addition, signal to noise ratio (SNR) and contrast to noise ratio (CNR) in specific regions of interests (ROIs) [including TFCC,cartilage and bone] were measured. At the end, all of qualitative and quantitative assessments were compared between protocols.
Results: SNR of cartilage, TFCC on 3D T2SPACE and T1 FSE was better than other sequences (P<0.001). SNR of bone on PD BLADE was significantly higher than that of conventional protocols (P<0.001). PD BLADE images showed significantly higher bone-cartilage CNR and bone-TFCC CNR (P<0.001 to P<0.001). CNR of cartilage-TFCC on T1 FSE was better than other sequences, but no statistically significant difference was seen. Qualitative assessment showed better wrist imaging in SPACE and BLADE protocols in comparison to conventional sequences (P<0.001).
Conclusion: PD BLADE, 3D T2SPACE and T2 BLADE MRI protocols were superior compared to conventional sequences in wrist imaging. High-SNR and CNR in SPACE and BLADE MR sequences could be a promising method to diagnose wrist lesion.

B-0813 11:02

Injuries of the finger in rock climber

F. Schellhammer[1], T. Schwarz[2], A. Boberg[3], K.-A. Riel[4], A. Vantorre[3]; [1]*Cologne/DE*, [2]*Gelnhausen/DE*, [3]*Frankfurt a. Main/DE*, [4]*Groß-Gerau/DE (fschellhammer@severinskloesterchen.de)*

Purpose: Indoor rock climbing is gaining increasing popularity. Thus the incidence of climbing related injuries is rising. About 40% of these are to the fingers. Out of the entirety of injuries of the upper extremity, we demonstrate lesions of the finger which were evident in a network for rock climbing medicine.
Methods and Materials: Between 05/2012 and 06/2016, a total of 227 finger injuries were seen. Following clinical examination, MR-imaging was performed. In case of a lesion to the flexor-tendon-pulley-system, a 4-step grading system was used.
Results: MR-imaging disclosed characteristic dilatation and thickening of the interdigital joint capsule in almost all cases. Stress fractures were evident in 19 cases (adult fracture: 1, physeal fracture: 18). Capsular lesions were seen in 6 cases (capsular rupture: 4, plantar plate rupture: 2). Lesions of the flexor tendon were found in 39 cases. 1 lumbrical shift syndrome and 1 calcified stenosis of the A2-annular pulley were disclosed. Lesions of the flexor-tendon-pulley-system were seen in 162 cases (GI: n=22, GII: n=103, GIII: n=46, GIV: n=1).
Conclusion: Knowledge of the anatomy and the biomechanics is important to differentiate physiologic chances from true injuries. MR-imaging is important for classification of GII lesions of the flexor-tendon-pulley-system, which are the most common and of high sport physiologic importance. Furthermore, MR-imaging allows distinguishing complex lesions, which may require surgical repair.

B-0814 11:10

Impact of delimitation on the healing of rotator cuff injury after a tension band arthroscopic repair

C. Dekimpe, O. Andreani, C. Ranc, N. Amoretti, P. Boileau; *Nice/FR (dekimpe.chloe@gmail.com)*

Purpose: Arthroscopic repair of transfixing rotator cuff lesions using the « tension band » technique gives good results. The impact of tendon delamination is less known than the degree of tendon retraction on the anatomical result. The aim of our study was to assess the impact of delamination on tendon healing after arthroscopic cuff repair made with the « tension band » technique.
Methods and Materials: 117 patients with a transfixing lesion of the rotator cuff operated thanks to the « tension band » technique, over a 5-year period, were clinically and anatomically evaluated. The delaminated or not status of the rotator cuff injury and the stage of retraction was set intraoperatively. All patients had a 6 months minimum follow-up. Tendon healing was evaluated by ultrasound and functional outcome using the adjusted Constant score.
Results: 80 patients had a non-delaminated rotator cuff injury and 37 a delaminated one. The healing rate was 78% and 57% respectively (p = 0.0287). Patients were comparable preoperatively in terms of age, sex, BMI, Subjective Shoulder Value, strength and adjusted Constant score. There were no significant differences in the subgroup analysis for the stage 1(77% versus 75%), and stage 2 (75% versus 60%) retracted lésions. There was a significant difference for the stage 3 retracted lesions (83% versus 45%; p <0.05).
Conclusion: Delamination appears as a key factor in the healing of arthroscopic repair of rotator cuff lesions. Ultrasound was a useful tool to assess the anatomical result of the surgery.

B-0815 11:18

Combined quantitative MR imaging assessment of the rotator cuff integrity at 3.0T by multi-echo Dixon-based fat quantification and diffusion tensor imaging

Q.M. Hamie, L. Issler, E. Ulbrich, D. Nanz, N.A. Farshad-Amacker, R. Guggenberger; *Zurich/CH (mustafa.hamie@usz.ch)*

Purpose: To establish quantitatively normative values of fractional fat content (FF%) and diffusion tensor imaging (DTI) parameters (fractional anisotropy [FA] and apparent diffusion coefficient [ADC]) of normal rotator cuff (RC)-muscles.
Methods and Materials: 40 patients underwent standard direct MR arthrography of the shoulder including 3D multi-echo Dixon and 3D echo-planar DTI sequences (15 gradient encoding directions, b-value 600 s/mm^2) at equal spatial resolution. RC-muscles and tendons were qualitatively assessed. Goutallier gradings >1 and tendon tears were excluded from further analysis. FF%, FA and ADC were evaluated quantitatively by region-of-interest (ROI) measurements at Y-position of the scapula by two independent radiologists. Intraclass correlation coefficients (ICC) were calculated. Pearson correlation, Student's t-test, Chi-Square test and one-way ANOVA testing were performed to correlate measurements with age and gender and to compare different RC muscles and two Goutallier groups (0 and 1).
Results: Interreader agreements for quantitative measurements were perfect (ICC: 0.90-0.99). Goutallier 0 muscles showed significant positive correlations of FF% and FA with age (R=0.269, p<0.01 and 0.206, p<0.05) as well as FF% with FA (R=0.351, p<0.001). Significant differences were seen among different RC muscles in Goutallier group 0 for FF% and ADC (p=0.011 and p=0.001) but not in Goutallier group 1 (p>0.05). ADC is significantly different between Goutallier groups for all RC muscles (p<0.05).
Conclusion: Quantitative MR assessment of RC-muscle integrity delivers high interreader agreement. In normal RC muscles FF% and FA increase significantly with age. ADC allows best to differentiate between Goutallier group 0 and 1 in all RC-muscles.

B-0816 11:26

Preoperative MR imaging characteristics of full-thickness rotator cuff tendon tears do not correlate with changes in clinical outcome scores following repair

P.C. Thurlow, R. Kijowski; *Madison, WI/US (pthurlow@uwhealth.org)*

Purpose: The purpose of this study was to evaluate whether preoperative MR imaging features of full-thickness rotator cuff tears correlated with changes in subjective and functional outcomes following surgical repair.
Methods and Materials: This retrospective study included 208 patients who underwent conventional shoulder MRI examination within 12 months of full-thickness rotator cuff tendon tear repair and performed preoperative and 12 month postoperative clinical outcome scoring. Clinical outcome scoring systems utilised were SF-12, QuickDASH, and SANE. A musculoskeletal radiologist evaluated all MRI for tear size, tendon retraction, tendinosis, atrophy, fatty infiltration, glenohumeral cartilage loss, biceps tendinosis or tear, and labral tear. Pearson correlation coefficients, Student's t-test, and one-way ANOVA was used to analyse for statistically significant correlation between clinical outcome score changes and MR imaging features.
Results: Overall, there were statistically significant postoperative improvements in SANE scores, QuickDASH scores, and bodily pain, physical functioning, and physical health composite scale scores from the SF-12 (p<0.01). Female patients demonstrated greater improvement in QuickDASH scores than did male patients (p<0.05). Average size of the tears measured 2.6 cm in anteroposterior dimension with an average of 2.3 cm of retraction. There was no statistically significant correlation between any of the measured MR imaging characteristics and postoperative changes in SF-12, QuickDASH, or SANE clinical outcome scores.
Conclusion: MR imaging features of full-thickness rotator cuff tendon tears do not correlate with changes in clinical outcome scores following repair of full thickness rotator cuff tears.

B-0817 11:34

Associating MRI findings of adhesive capsulitis with the clinical orthopedic exam

C.K. Ho, E.S. Gould, M. Huang, M. Badalamente, J. Yang, D. Yin;
Stony Brook, NY/US (corey.ho@stonybrookmedicine.edu)

Purpose: The purpose of our study is to investigate the association of MRI findings of adhesive capsulitis (AC) with the clinical examination.
Methods and Materials: Following IRB approval, 256 subjects with untreated, unilateral idiopathic AC for 3 to 12 months were enrolled in a clinical trial for treatment and all received shoulder MRI. Clinical evaluation included calculation of American Shoulder and Elbow Surgeons Shoulder function and pain scores, and multi-directional shoulder range of motion (ROM). Two radiologists blindly reviewed the studies for AC MR Characteristics. The most prevalent findings were graded using a 4-point Likert scale (normal, mild, moderate, and severe), including coracohumeral ligament thickening, capsular thickening at axillary pouch, edema within axillary pouch, and synovitis along superior border of subscapularis tendon, and overall assessment of AC severity.One-way Analysis-of-Variance models were used with significance level set at 0.05.
Results: Multi-directional ROM and clinical exam scores were grouped, thus, our p-values are reported as a range. All MRI findings showed some significant correlation. Edema within axillary pouch was associated with clinical exam scores (p 0.004-0.035), active ROM (p <0.001-0.021), and passive ROM (p <0.001-0.007). Overall assessment of AC severity was associated with the clinical exam scores (p <0.001-0.005), active ROM (p <0.001-0.041), and passive ROM (p <0.001-0.028). These two findings demonstrated most significant association.
Conclusion: The strong association between MRI characteristics and clinical exam scores in patients with clinically confirmed AC suggests MRI can serve as a tool for grading severity and therefore guide clinical treatment.

B-0818 11:42

Glenoid surface measuraments by means of 3D MRI: comparison between healthy volunteers and first time dislocators

G. Foti, E. Demozzi, P. Avanzi, G. Carbognin; *Negrar/IT (gfoti81@yahoo.it)*

Purpose: To identify any differences in glenoid area measuraments in healthy volunteers, in comparison to post-traumatic and non-traumatic anterior shoulder dislocators.
Methods and Materials: IRB approval was obtained for this prospective study and written informed consent was obtained from patients enrolled. A total of 124 patients (84 males, 40 females; range 14-62 years) studied with MRI including an isotropic 3D sequence were evaluated. By using the best-fit circle method, glenoid surface area was measured in the following patients subgroups: GR1=35 healthy volunteers; GR2=54 post-traumatic dislocators; GR3=35 non-traumatic dislocators. Two measurements were performed by two experienced radiologists, independently, on a dedicated workstation with at least 1 month gap. Differences between subgroups were calculated by using Student t test and Pearson correlation. A value of p<0.05 was considered statistically significant. Intra and Inter-reader variation was determined with the interclass correlation coefficient.
Results: As regards glenoid surface area, differences were not significant between GR1 (mean 484, range 355-562 square millimiters) and GR2 (mean 491, range 364-586 square millimiters); conversely a significant difference (p=0.025) was determined between GR1 and GR3 (mean and range values of 441 and 323-537 square millimiters, respectively) and between GR2 and GR3 (p=0.02). The difference was not significant when comparing GR2 to GR3 (mean 6.2%, range 1-27%). There was excellent intra- and inter-reader correlation (R=0.94 and R=0.98 respectively).
Conclusion: Glenoid area of patients undergoing non-traumatic shoulder dislocation is significantly smaller if compared to a control-group of healthy volunteers and to patients undergoing post-traumatic shoulder dislocation.

B-0819 11:50

Added value of combined acromiohumeral distance and critical shoulder angle measurements on conventional radiographs for the prediction of rotator cuff pathology

Q.M. Hamie, V. Grunder, T. Finkenstädt, M. Marcon, N.A. Farshad-Amacker, R. Guggenberger; *Zurich/CH (mustafa.hamie@usz.ch)*

Purpose: To investigate the role of acromiohumeral distance (AHD) and critical shoulder angle (CSA) measurements from conventional radiographs (CR) in isolation and combined as predictors of transmural rotator cuff tendon tears (RCT) and critical fatty degeneration (CFD).
Methods and Materials: In this retrospective study in 127 AHD and CSA were measured on CR. MR Arthrograms served as reference standard and were screened for RCT and CFD (Goutallier stages ≥2). Statistical analysis for inter-reader agreement, Spearman's rank correlation, linear stepwise regression and diagnostic performance at different cut-off values for AHD and CSA both isolated and combined were performed.
Results: In 90 subjects (17 females, mean age 36.1±14.1) no RCT were found on MR imaging and served as control group. In 37 patients (13 females, mean age 58.7±13.2) at least one RCT was found. Inter-reader agreements rated between κ=0.42-0.82 for categorical and 0.91-0.96 for continuous variables. No significant correlation of AHD and CSA with either age or gender was seen (p=0.28 and p=0.74, respectively). Case group had significantly smaller mean AHD (8.7±3.2 vs 10.8±2.2 mm; p<0.001) and larger mean CSA (36.5±4.5° vs 33.1± 4.0°; p<0.001). Combination of AHD-CSA-measurements increased specificity and positive predictive value (PPV) for prediction of RCT and CFD.
Conclusion: RCT and CFD correlate with smaller AHD and larger CSA. Combination of AHD and CSA measurements leads to increased specificity and PPV for detection of RCT or CFD. Goutallier stage of the infraspinate muscle is associated with small AHD and large CSA.

An investigation of mobile phone use in the radiology department and the success of an awareness campaign at reducing the associated nosocomial infection risks

C. Crofton, S. Foley; *Dublin/IE (crofton.ciara@gmail.com)*

Purpose: To determine whether a mobile phone infection control awareness campaign will improve radiographers' phone and hand hygiene practices.
Methods and Materials: 36 radiographers in two tertiary hospitals (convenience sampling) volunteered to have their mobile phones swabbed and tested using an adenosine triphosphate (ATP) meter to numerically quantify surface cleanliness. A survey determined their current practices and awareness levels. Subsequently, a poster campaign took place for one month in one hospital. The ATP testing and survey were repeated in both sites and compared. Changes were measured using simple descriptive analysis and Wilcoxon signed rank testing (survey data) and Mann Whitney U testing (ATP results).
Results: 100% (n=36) of radiographers used their phone at work. However, the majority were uninformed of the associated infection risks with only 6% being informed. 33% had been performing adequate phone disinfection and 0% performed adequate hand hygiene following phone use. Following the campaign, there was a significant improvement (p=0.028) in the frequency of phone disinfection. Utilisation of the optimal phone disinfection method increased (33% vs 7% in control). The ATP meter readings showed numerical reductions (p>0.05) and there were negligible changes in hand hygiene practices. Radiographers considered the ATP testing just as effective as the campaign at improving their awareness.
Conclusion: Radiographers are unaware of mobile phone infection risks. Although significant improvements in phone cleanliness and hygiene habits were not achieved, the improvements in phone hygiene practices indicate that an awareness campaign could play an important role as an educational tool to improve awareness.

B-0821 10:38

The radiologist and the radiographer: how do they compare in image quality judgement?

R.G.L. Decoster, R. Toomey, M.-L. Bulter; *Dublin/IE (decoster.robin@gmail.com)*

Purpose: In radiology departments, radiographers are concerned with the production of the radiograph, and radiologists report the findings. Disagreement on the clinical acceptability of radiographs may lead to unnecessary retakes or insufficient image quality to report on, with a needless exposure of patients in both cases. This study compares the agreement on image quality and clinical acceptability between these professions.
Methods and Materials: Five radiographers and five radiologists evaluated the image quality of 22 chest radiographs using, respectively, a secondary and a primary class monitor to mimic reality. Participants rated the reproduction of five anatomical structures on a scale from 1 to 5. These data were assessed using a VGC approach. They also judged the clinical acceptability of the radiograph using the RadLex categories and expressed their confidence concerning their decision. The responses for the two groups were compared using Nagelkerke Pseudo R-Square.

Results: No significant (p>0.05) difference was found in the area under the curve between the groups for none of the structures. The judgement of clinical acceptability by radiographers is significantly different (Pseudo-R^2 0.076, p<0.01) from the radiologists. Radiographers rejected 21% more radiographs then the radiologists and were less confident in 29% of their decisions, especially in cases with limited quality.
Conclusion: These findings indicate that radiographers and radiologists agree on the evaluation of anatomical structures. On the contrary, they do not agree on the clinical acceptability, indicating that the decision of accepting or rejecting a radiograph is based on other information then purely the visualisation of anatomy.

B-0822 10:46

Patient perceptions of radiation therapist communication skills
S. Teixeira, L.P.V. Ribeiro, A.F. Abrantes, M. Ramos, F. Serra, O. Lesyuk, S. Rodrigues; *Faro/PT (lpribeiro@ualg.pt)*

Purpose: The improvement of results in healthcare through the transmission of information to the patient within a relation of empathy and trust is already a verified hypothesis. Healthcare professionals should base themselves on interpersonal competences throughout their daily work routine, to promote quality in radiotherapy, patient safety and technical excellence. The aim of this study was the exploration of patient's perceptions regarding the performance of the radiation therapist in terms of interpersonal communication skills.
Methods and Materials: The instrument used was the questionnaire "Communication Assessment Tool" (Makoul et al. 2007) adapted to the professional reality of the radiation therapists. A total of 118 valid questionnaires (including 15 questions with a 5 point Likert scale) from patients aged between 22 to 87 years old from a private radiotherapy center. The patients have performed at least 5 radiotherapy sessions to be included in this study.
Results: The internal consistency of the questionnaire was excelent (Cronbach's alpha = 0.97). Highest ratings were for radiation therapist behavior items, such as "paying attention to the patients" (4.45), "respect for the patients" (4.43) and "using comprehensive language and terms" (4.42). Lowest ratings were "explained the treatment plan" (4.00), "encouraged to make questions" (4.07) and other items related with being involved in decision-making process.
Conclusion: Patients demonstrated high levels of confidence in their therapist and feel well treated during the sessions. Despite the overall positive results, "Radiation Therapist - Patient" relationships can be strengthened and patient outcomes improved through improved communication.

B-0823 10:54

Evidence-based practice in radiology: the radiographer perspective
C. Costa[1], A.F. Abrantes[1], L.P.V. Ribeiro[1], K.B. Azevedo[1], R.P.P. Almeida[1], O. Lesyuk[1], C.A. Silva[2]; [1]*Faro/PT*, [2]*Évora/PT (kbazevedo@ualg.pt)*

Purpose: Analyse the application of the Evidence-Based Practice (EBP) in Radiology by the radiographers' in their daily practice in CT departments.
Methods and Materials: A self-applied questionnaire to assess EBP was addressed to 97 radiographers working in 5 public hospitals. A total of 65 valid questionnaires (including 3 main sections with a total of 103 items, and a 7 point Likert scale format) were interpreted and statistically analysed through descriptive statistics. T-student and ANOVA tests were used for groups' comparison.
Results: 80% of radiographers applied the principles of EBP in their daily practice. However, the major limiting factors highlighted by the radiographers for the application of EBP were: "Knowledge to transfer the results of literature/scientific articles in their daily practice" (18,5%), "Existence of legislation/regulation about practices" (18,5%), "Knowledge of EBP concepts" (15,4%) and "Professional motivation" (15,4%). Regarding the training and updating of knowledge, the item "Specific training to be able to apply an EBP model in professional activity" had the highest mean score (5,25) and the item "Regular attendance in courses about EBP and research topics" had the lowest (3,49).
Conclusion: Despite the general application of EBP by radiographers, thanks to regular consultation of CT guidelines and decision-making processes based on literature review and scientific articles, this group of professionals would benefit from further training. Such approach would be well received and help the radiographers to enhance their knowledge and technical skills, which would ultimately result in an increase of the deparment's quality.

B-0824 11:02

Radiographers knowledge about infection control measures during radiological examinations
M. Ramalho, L.P.V. Ribeiro, A.F. Abrantes, O. Lesyuk, S. Rodrigues, A.M. Ribeiro, J.P. Pinheiro, R.P.P. Almeida; *Faro/PT (jppinheiro@ualg.pt)*

Purpose: To Assess the appropriate use of infection control principles/measures by radiographers during radiological examinations and to establish whether infection control guidelines are necessary.
Methods and Materials: A self-applied questionnaire about infection prevention and control measures was applied to 48 radiographers within 3 different public hospitals. Besides, using an observational grid, 20 of them were observed during the performance of radiological examinations to check if the infection prevention measures were applied. Efficiency of alcohol based solution and hand-scrubbing technique were evaluated with ultraviolet light after procedure.
Results: 58,3% of radiographers had training in hospital infection control measures and 62,5% of them indicated the use of individual equipment protection, such as gloves and aprons when necessary. During the observation, only 1 radiographer disinfected their hands before placing gloves and 8 of them never did it after removing gloves. During the evaluation of hand scrubbing technique using ultraviolet light, it was observed that only 20% of radiographers presented a total area of disinfected hand.
Conclusion: Radiographers were aware of infection control guidelines but several of them failed to apply these procedures during the radiological examinations. Therefore, radiographers must be given periodic training in infection control procedures, written protocols and legislation must be outlined to monitor the use of infection control procedures during work and there should be a periodic monitoring of practice of infection control procedures by radiographers.

B-0825 11:10

Humour: what do they think? On opinions of students and professional radiographers
E. Cordier[1], S. Lantheaume[2], L. Motak[3]; [1]*Grenoble/FR*, [2]*Guilherand-Granges/FR*, [3]*Aix-en-Provence/FR (cordieretienne@gmail.com)*

Purpose: To gather opinions of radiographers regarding the use of humour among students and professionals, and to apprehend possible positive and/or negative impacts of its use on the care relationship.
Methods and Materials: *Sample.* Six hundred forty-one senior radiographers and 411 first, second or third year undergraduate radiographers, for a total sample of 1052 subjects from all over France. *Material.* Within a quantitative phase, both professionals radiographers and radiographers-in-training were assessed on several Likert-type scales involving concepts such as the functions of humour, and a second, qualitative phase based on open survey questions further focused on investigating the most salient concepts, notably within the senior radiographer sample.
Results: Although radiographer apprentices saw the major benefits of humour in their relationships with patients (i.e. building a trust relationship, distraction technique), the senior radiographers put forward benefits especially regarding their colleagues or their own person (pleasant working environment, coping strategy during stressful events). Positive aspects of humour do prevail over the negative ones in both radiographer groups, but professionals emphasize the contextualized aspects of humour and warn that it may infringe on patients and their dignity.
Conclusion: Considering humour as a personal and a professional value among the samples studied opens new perspectives on use of humour and its training within both institutional and educational contexts, preventing any possible harmful use.

B-0826 11:18

Consultant radiographers: a study to assess activity and impact
B. Snaith, A. McGuinness, A. Coates, L. Field, R. Clarke, S. Yunis; *Wakefield/UK (bev.snaith@midyorks.nhs.uk)*

Purpose: Consultant radiographers' roles are currently unique to the UK and evidence of their impact is limited, particularly at an organisational level. This study reviews the activity of consultant practitioners across their 4 key functions (clinical practice, leadership, research and education), evidencing the impact this has on patients, staff and the organisation.
Methods and Materials: The study was a prospective exploratory study using activity diaries and comprised interval sampling by 6 consultant radiographers employed within a busy multisite English NHS Trust. All radiographers work a standard 37.5 hour week across a range of specialities/modalities. Data were collected using a coded list and recorded in fifteen-minute intervals over the period of one week to establish the relative hours of activity.
Results: The mean number of hours worked within the study week was 45.8 (range 41.3-50.8). All individuals evidenced activities in the 4 key functions; however, the proportions varied. Clinical work predominated and comprised

43.9% of the worked hours (mean=20.1). Support for other staff was a key component of all roles, undertaking one-on-one teaching or assessment, case discussion or problem solving. The individuals evidenced strategic working at an organisational and national level. Multi-tasking was common, with interruptions of work a feature of the accessibility of the role.
Conclusion: This localised study provides a snapshot of the breadth and complexity of the activities performed by consultant radiographers. The individuals appear to be routinely performing functions which have an impact on patients, colleagues, the organisation and profession.

Assessment of image quality criteria from digital radiography
A. Mendes, A.M. Ribeiro, L.P.V. Ribeiro, A.F. Abrantes, R.P.P. Almeida, K.B. Azevedo, S. Rodrigues; *Faro/PT (lpribeiro@ualg.pt)*

Purpose: To assess the image quality criteria from examinations in digital radiography based on quality control charts and to demonstrate the importance of implementing an image quality control system.
Methods and Materials: A retrospective study was conducted in a public radiology department using a random sample of 1200 radiographs grouped in 60 smaller samples, each one with 20 radiographs. Using a checklist based on the "*American College of Radiology Practice Guidelines for the Performance* of abdominal, chest and extremities radiographs", the conformities and non-conformities found were recorded and used to establish three types of quality control chars: (1) the proportion of conformities and non-conformities (p chart); (2) the total number of non-conformity exams (np chart) and (3) the total number of non-conformities in each sample (c chart), in order to suggest corrective actions for improvement.
Results: Considering all exams, 473 were classified as non-conform (39.42%) and 727 were classified as conform (60.58%). Considering the non-conform exams group, the quality criteria "incomplete or incorrect image post-processing" presented the highest number of non-conformities (58,92%), followed by "incorrect patient positioning" (35,32%) and "artefacts" (5,77%). Chest radiograph showed the highest number of non-conformities (174).
Conclusion: The existence of suitable quality control of the image is essential to achieve high quality standards. Strategies for improving radiographers performance must be implemented to ensure that digital radiography examinations are performed in compliance with all the quality criteria established.

B-0828 11:34

Computer-assisted diagnostics and the importance of optimised integration into the clinical setting
T. Butcher[1], C. Goncalves[1], S. Shah[1], S.P. Kelavkar[1], M. Johnson[1], P. Harman[1], P. Guyler[1], A. Kuhn[2], I. Grunwald[1]; [1]*Southend-on-Sea/UK*, [2]*Worcester, MA/US*

Purpose: The CE-marked e-ASPECTS software (Brainomix, Oxford) assists clinicians in detecting areas of acute ischaemic stroke on CT using the validated ASPECTS score. Instant access to the processed results is crucial in stroke and depends on optimised software integration into the clinical pathway. We evaluated the main 3 integration strategies available.
Methods and Materials: Feasibility, time and user friendliness (questionnaire) of the following integration options were evaluated. 1) Images for processing sent from CT to cloud-based server, results returned to PACS. 2) Images sent from PACS to local sever, processed images returned to PACS. 3) Images automatically sent from CT to hospital-based server (accessible via ipad user interface), results returned to PACS.
Results: All 3 integration solutions were feasible. Local server compared to cloud-based processing significantly decreased time ($p<0.05$), the remote Internet transfer adding 2 minutes. Transferring images from PACS for post-processing incurred varying time delay, depending on PACS data load and system (max 6 min). Option 2 required most user interaction, associated with potential user errors. The fastest solution (Option 3) allowed near instant access to post-processed images (<1min) via a hospital-based server, utilising a dedicated iPad interface. This was also judged as the user-friendliest option in the acute setting. In the non-acute setting Option 2 was also judged to be important to accommodate requirements of different users (e.g. researchers, neurologists).
Conclusion: The value of computer-assisted diagnostics can be increased by optimised integration into the clinical pathway, thus increasing user friendliness, speed and potentially outcome.

The implementation of a radiology hospital inpatient turnaround team (HITT) to reduce radiology waiting times
C. Roche, G. Naughton, T. Fallon, T. Glavey, S. Ruddy, S. McNulty; *Galway/IE (stevemac182@hotmail.com)*

Purpose: To estabish a radiology "Hospital Inpatient Turnaround Team" (HITT). To reduce inpatient radiology waiting times through better integration and organisation of staff and resources.
Methods and Materials: A series of radiology multidisciplinary team meetings culminated with the establishment of a radiology HITT, with representation from all relevant disciplines. Regular HITT meetings resulted in many changes being implemented in order to improve departmental efficiency. The HITT developed a clear inpatient workflow process and introduced brief daily meetings between the scheduling radiographer, clerical officer and porter. Necessary resources such as IT support were also addressed. A "turnaround time" KPI was introduced to measure the time from an x-ray order being placed to the time that order was completed on the RIS. Updates on this KPI were posted weekly around the department. A competition to name the inpatient radiography area was held to improve morale and highlight departmental focus on the area. The PACS manager carried out a retrospective audit to measure how these changes had influenced the KPI.
Results: The audit demonstrated reduction in mean inpatient waiting times of 26.2%. Median inpatient waiting times also decreased from 3 hours, 34 minutes to 2 hours, 38minutes; a reduction of 30.7%.
Conclusion: Significant improvements in efficiency are possible through closer integration of the many disciplines that make up a radiology department. The creation of a multidisciplinary team to implement a clear workflow process, with input from all disciplines, can lead to decreases in median inpatient radiology waiting times of over 30%.

B-0830 11:50

Infection control for x-ray cassettes in a radiology department
A. Brás, K.B. Azevedo, A.F. Abrantes, L.P.V. Ribeiro, S. Rodrigues, A.M. Ribeiro, R.P.P. Almeida; *Faro/PT (kbazevedo@ualg.pt)*

Purpose: To verify if the presence of pathogens in contact areas of x-ray cassettes (Image Plates) can cause nosocomial infections and to establish whether infection control guidelines are necessary.
Methods and Materials: The methodology used consisted, initially, in observing hygiene practices performed by radiographers in the cleaning of x-ray cassettes, through an observation grid. After, the second fase involved the swabbing of contact areas to check the general levels of bacterial contamination and also to verify the presence or absence of payhogen agents.
Results: The results demonstrated that there were large levels of growth of samples taken from contact areas and developed in the Microbiology Department. The existence of colonies varies according to the method for obtaining samples from contact areas. Streptococcus, Staphylococcus epidermidis, Staphylococcus aureus, Enterococcus and Proteus were all identified.
Conclusion: In order for cross contamination to be kept to a minimum an effective infection control policy needs to be employed and this should be to carry out regular cleaning of contact areas of x-ray cassettes (Image Plates). Therefore, radiographers must be given periodic training in infection control procedures, written protocols and legislation must be outlined to monitor the use of infection control procedures during work and there shoud be a periodic monitoring of practice of infection control procedures by radiographers.

Diagnostic performance of stress Echo, SPECT, PET, stress CMR, CTCA, CTP and FFRCT for the assessment of CAD vs invasive FFR: a meta-analysis

G. Pontone[1], A. Guaricci[2], M. Verdecchia[3], D. Andreini[1], M. Guglielmo[1], A. Baggiano[1], P. Carità[4], G. Ferro[4], M. Pepi[1]; [1]*Milan/IT*, [2]*Bari/IT*, [3]*Chieti/IT*, [4]*Palermo/IT (gianluca.pontone@ccfm.it)*

Purpose: Stress echocardiography (Echo),stress single photon emission computed tomography (SPECT), positron emission tomography (PET),stress cardiac magnetic resonance (CMR), cardiac computed tomography (CTCA), stress computed tomography(CTP) and computed tomography fractional flow reserve (FFRCT) have been proposed as gatekeeper to invasive coronary angiography (ICA).We sought to determine the diagnostic accuracy of all these non-invasive tests as compared to invasive FFR(FFRi) for the detection of haemodynamically significant coronary artery disease(CAD).
Methods and Materials: We searched for studies evaluating Echo, SPECT, PET, CMR, CTCA, CTP and FFRCT for non-invasive diagnosis of functionally significant CAD compared with FFRi. Inclusion criteria were English language, clinical indication of index test for suspected CAD, raw data of pervessel and/or perpatient model available or derivable and FFRi as reference standard.Pooled diagnostic accuracy (Ac) vs FFRi were assessed and compared.
Results: We analysed data (14256 vessels and 6285 patients) from 97 out of 638 relevant abstracts of fulltext articles. At vessel level the mean prevalence of CAD was 29.63% and the diagnostic accuracy of Echo, SPECT, PET, CMR, CTCA alone,CTP, FFRCT, CTCA+PET, CTCA+CTP and CTCA+FFRCT were 82% (7885), 75% (7377), 87% (8588), 89% (8890), 76% (7577), 86% (8488), 79% (7782), 93% (9195), 88% (8690), 80% (7289), respectively. At patient level the mean prevalence of CAD was 45.1% and the diagnostic accuracy of Echo, SPECT, PET, CMR, CTCA alone, CTP, FFRCT, CTCA+PET, CTCA+CTP were 77 (7481), 77 (7580), 87% (8489), 87%(8589), 69% (6771), 86% (8290), 79% (7682), 91% (8795), 88% (8492), respectively. CTCA+PET showed the highest accuracy at vesselbased analysis (p<0.001) while CTCA+PET showed similar accuracy vs CTCA+CTP and CMR but higher accuracy as compared to other non-invasive tests(p<0.001).
Conclusion: In patients with intermediate prevalence of CAD, CTCA+PET, CTCA+CTP or CMR are all more accurate to detect haemodinamically significant CAD. Echo, SPECT and CTCA are less suited to this aim.

B-0832 10:38

Diagnostic accuracy of rapid on-site fractional flow reserve CT

P. Maurovich-Horvat[1], M. Kolossvary[1], J. Karady[1], P.A. Ball[2], S. Kelly[2], D. Fitzsimons[2], C. Celeng[1], B. Merkely[1], P.M. Donnelly[2]; [1]*Budapest/HU*, [2]*Belfast/UK (maurovich.horvat@gmail.com)*

Purpose: Fractional flow reserve derived from coronary CT angiography (FFR-CT) is a novel tool for the diagnosis of ischemic coronary lesions. Our aim was to evaluate the diagnostic performance of a novel on-site FFR-CT. Furthermore, we sought to determine if the diagnostic performance is altered by the adjustments to the lumen segmentation performed by two different readers.
Methods and Materials: We have enrolled consecutive patients who underwent coronary CTA and invasive coronary angiography (ICA) in two centres. ICA examinations with FFR measurements were performed within 60 days after the coronary CTA. An FFR value ≤ 0.8 was considered haemodynamically significant. All coronary CTA scans were evaluated by two readers, who manually adjusted the semi-automated coronary lumen segmentations.
Results: In total 44 patients (mean age 63.0±8.0 years, 24.4% female) were enrolled in our two-centre prospective study. Overall, we analysed 60 coronary atherosclerotic lesions. Average quantitative coronary CT cross-sectional area stenosis was 60.3±19.7%. The average FFR-CT was 0.77±0.15 and 33 (54.1%) lesions were considered to be haemodynamically significant (FFR-CT≤0.8). Sensitivity of FFR-CT was 90.5%, specificity 71.8%, positive predictive value 63.3%, negative predictive value 93.3% and accuracy of 78.3%. Area under the receiver operating curve of the two expert readers did not show any significant difference (0.89 versus 0.88; p=0.63).
Conclusion: Rapid on-site FFR-CT simulation is feasible and it has excellent diagnostic performance. Importantly, the diagnostic performance did not differ between the readers who corrected the automated lumen contour segmentations.

B-0833 10:46

Non-invasive assessment of coronary stenoses by CT myocardial perfusion imaging during pharmacologic coronary vasodilatation

R. Boughrarou, B. Mansouri; *Algiers/DZ (rafikalinda@hotmail.com)*

Purpose: Computed tomography angiography (CTA) has be shown to be accurate in detecting anatomic coronary arterial obstruction, but is limited for the detection of myocardial ischaemia. The primary aim of this study was to assess the accuracy of 320-row computed tomography perfusion imaging (CTP) to detect atherosclerosis causing myocardial ischaemia.
Methods and Materials: One hundred patients underwent a comprehensive cardiac computed tomography (CT) protocol that included 320- CTA, followed by dipyridamole stress CTP. CTA was evaluated for stenosis. CTP images were analysed for the presence of subendocardial perfusion deficits, using the transmural perfusion ratio (TPR) and 17 segments model.
Results: The protocol was successfully completed for 100 patients, with an average radiation dose of 14mSv. CTA alone was a limited predictor of myocardial ischaemia. CTP was a better predictor of myocardial ischaemia, with a sensitivity, specificity, PPV and NPV of 94%, 71%, 69%, 95%, respectively; using quantitative angiography and SPECT, as gold standard.
Conclusion: Computed tomography perfusion imaging with rest and dipyridamole stress 320- row CT is accurate in detecting atherosclerosis causing myocardial ischaemia.

B-0834 10:54

Prognostic value of coronary CT angiography-derived fractional flow reserve of non-culprit lesions in patients with acute coronary syndrome

T.M. Duguay, C. Tesche, C.N. De Cecco, H. Lin, M.H. Albrecht, A. Varga-Szemes, D. De Santis, U. Ebersberger, U.J. Schoepf; *Charleston, SC/US (duguay@musc.edu)*

Purpose: To investigate the prognostic value of coronary CT angiography (CCTA)-derived fractional flow reserve (CT-FFR) assessment of non-culprit lesions in patients with acute coronary syndrome (ACS).
Methods and Materials: 48 patients (55.8±9.6 years, 60% male) admitted for ACS who underwent dual-source CCTA followed by invasive coronary angiography (ICA) were retrospectively analyzed. ACS-related culprit lesions on CCTA were identified using ICA. Non-culprit lesions with ≥30% luminal stenosis on CCTA that were considered non-critical on ICA were evaluated using CT-FFR for the presence of lesion-specific ischemia. Follow-up was performed to monitor the occurrence of major adverse cardiac events (MACE) related to the non-culprit lesions. The prognostic value of CT-FFR to predict MACE was assessed.
Results: CT-FFR evaluation showed 23 of 81 non-culprit lesions had lesion-specific ischemia. MACE occurred in 14 patients (29%) (2 cardiac deaths, 12 additional ACS cases related to a non-culprit lesion; median follow-up interval: 19.5 months). The following markers carried predictive value with a univariable Cox regression analysis (hazard ratio [HR]): Dyslipidemia (HR 2.35, *p*=0.048), diabetes mellitus (HR 2.98, *p*=0.036), and CT-FFR ≤0.80 (HR 3.77, *p*=0.007). In a risk-adjusted model controlled for diabetes mellitus and dyslipidemia, CT-FFR ≤0.80 (HR 1.78, *p*=0.047) remained a predictor for MACE. A combined model receiver operating characteristics analysis including clinical characteristics and CT-FFR (AUC 0.77) showed incremental discriminatory power compared to clinical characteristics alone (AUC 0.65, *p*=0.034).
Conclusion: CT-FFR accurately depicts the haemodynamic significance of non-culprit lesions in patients with ACS and portends prognostic value in identifying patients at risk for future MACE.

Improved on-site FFR-CT accuracy by coronary tree standardisation

H. Nickisch[1], M. Freiman[2], S. Prevrhal[1], M. Vembar[3], P. Donnely[4], P. Maurovich-Horvat[5], L. Goshen[2], H. Schmitt[1]; [1]*Hamburg/DE*, [2]*Haifa/IL*, [3]*Cleveland, OH/US*, [4]*Belfast/UK*, [5]*Budapest/HU (hannes.nickisch@philips.com)*

Purpose: Fractional flow reserve (FFR) simulation based on standard coronary CT angiography (CCTA) may be an alternative to invasive FFR measurements. This study evaluated the robustness of our toolchain to generate patient-specific coronary tree models and simulate FFR against variations in manual input, with the goal to allow full on-site processing.
Methods and Materials: We collected CCTA datasets from 44 subjects from two different sites, along with invasive reference FFR measurements

conducted on 60 coronary lesions. Readers at both sites used our software to manually adjust the automatic extraction of coronary centerlines and lumen. From these, complete coronary trees were generated and then standardised following specific rules and geometric constraints to reduce operator and image quality dependency. FFR was simulated from both complete and standardised coronary trees using a non-linear, machine learning-accelerated lumped model trained earlier on computational fluid dynamics simulations. We finally used invasive FFR measurements as the reference standard with a cut-off value of 0.8 to determine changes in predictive performance and diagnostic accuracy resulting from coronary tree standardisation.
Results: Standardising the trees improved the diagnostic accuracy and area under the ROC curve for the two readers from 73±1.3% to 78±1.6% and 0.83±0.01 to 0.89±0.014 (reader 1), and 70±1.4% to 77±1.6% and 0.81±0.015 to 0.88±0.009 (reader 2), respectively. Furthermore, the variance between the two readers is reduced.
Conclusion: Coronary tree standardisation prior to patient-specific non-invasive FFR simulation can reduce operator dependency thereby improving CCTA-based lesion specific ischaemia assessment.

Non-invasive on-site estimation of fractional flow reserve: initial experience using coronary CTA-derived patient-specific lumped parameter models

R.W. van Hamersvelt[1], M. Voskuil[1], P. Maurovich-Horvat[2], P.A. de Jong[1], M.J. Willemink[1], T. Leiner[1]; [1]*Utrecht/NL*, [2]*Budapest/HU*
(R.w.vanhamersvelt-3@umcutrecht.nl)

Purpose: To report initial experiences with a novel coronary computed tomography angiography (cCTA)-derived algorithm for on-site non-invasive estimation of fractional flow reserve (FFR) based on patient-specific lumped parametric models.
Methods and Materials: Fourteen patients who underwent a cCTA (256-slice CT scanner) and an invasive catheter-based FFR measurements of 17 coronary segments were retrospectively selected. Haemodynamically significant stenoses were defined as FFR≤0.8. FFRct measurements were performed on the 17 segments and compared to the invasive FFR measurements in a blinded fashion. For FFRct, a prototype based on patient-specific lumped parameter models was used. In each coronary artery, the observer semi-automatically defined the centre line, subsequently lumen segmentation was automatically performed and manually corrected. The location for FFRct simulation was selected to match that of the pressure wire used for invasive FFR. Time was measured for each FFRct simulation.
Results: Total simulation time after the completion of segmentation was ≤10 seconds. True haemodynamically significant stenoses (invasive FFR≤0.8) were present in 5 patients (36%) and 6 (35%) segments. FFRct identified 5 (100%) patients and 5 segments (83%) with significant stenosis correctly. On a per-segment basis, our initial results showed a performance (%true), sensitivity, specificity, positive predictive value and negative predictive value of 71%, 83%, 63%, 55% and 88%, respectively. On a per-patient basis this was 79%, 100%, 67%, 63% and 100%, respectively.
Conclusion: These preliminary results suggest that this rapid, on-site FFRct prototype, based on lumped parameter models, has the potential identify haemodynamically significant stenosis.

Stress-rest CMR for the assessment of myocardial perfusion reserve index modification after coronary sinus stent implantantion

A. Palmisano, A. Esposito, A. Botta, F. Giannini, A. Colombo, F. De Cobelli, A. Del Maschio; *Milan/IT (palmisano.anna@hsr.it)*

Purpose: The management of patients with angina refractory to revascularisation procedures and medical therapy is challenge. The implantation of a coronary sinus stent named "Reducer" seems to improve patient' symptoms but the physiopathological mechanism underlying this effect is not clear. Aim of the study was to evaluate the modification in myocardial perfusion reserve occurring after Reducer implantation using a stress-rest CMR study.
Methods and Materials: 9 patients eligible for implantation of the "Reducer" underwent clinical evaluation (CCS Angina Class and 6minutesWT) and a stress-rest CMR study with dipyridamole before the implantation and after 3 months. Segmental and global myocardial perfusion reserve index (MPRI) was measured using stress-rest CMR. Simultaneously, MRI morpho-function parameters of LV were analysed.
Results: All patients reported an improvement of ≥ 2 CCS ($p < 0.0001$) and a 60% increase in the average distance during the 6minutesWT ($p=0,004$). The global value of MPRI has increased on average by 35% ($p=0.047$). The analysis per cardiac segments showed, patient by patient, an increase of MPRI in the ischemic territories on average by 72% ($p=0.03$) while the necrotic areas, post-infarction, present in 2/9 patients, did not show significant changes ($p=0.623$).
Conclusion: The preliminary data of this study suggest, for the first time, that this device is really able to determine a positive redistribution of myocardial blood flow, providing a new insight about its pathophysiological mechanism of action, with consequent improvement of angina symptoms, quality of life and exercise tolerance.

B-0838 11:26

Inversion of T1 reactivity in patients with caffeine intake prior to adenosine myocardial perfusion imaging

D. Kuijpers, R. van Dijk, N. Prakken, R. Vliegenthart, P. van Dijkman, P. van der Harst, M. Oudkerk; *Groningen/NL (r.van.dijk02@umcg.nl)*

Purpose: Caffeine intake before adenosine stress myocardial perfusion imaging may cause false negative findings. We hypothesised that the antagonistic effect of caffeine can be measured by T1 relaxation times in rest and adenosine cardiac magnetic resonance imaging (CMR), as T1 mapping techniques are sensitive to changes in myocardial blood volume.
Methods and Materials: CMR was performed in 105 consecutive patients at 1.5T using a Modified Look-Locker Inversion Recovery sequence with stress and rest T1 mapping. The change in T1 (T1 reactivity) was calculated by subtracting $T1_{stress}$ from $T1_{rest}$. Self-reported caffeine intake was <4 hours (<4H) prior to CMR in fifteen patients and >8 hours (>8H) in ten patients. These groups were compared to a control group of fifty patients with normal CMR, twelve patients with myocardial infarction, and eighteen patients with myocardial ischaemia.
Results: T1 reactivity in the <4H group showed an inverted response of -7.8% and (T1rest 975 ± 42 ms, T1stress 898 ± 51 ms, $p<0.0005$) and was significantly lower as compared to both the >8H (T1 reactivity +1.8%, T1rest979 ms, T1stress 997 ms), and the control group (T1 reactivity +4.3%, T1rest 977 ± 40 ms, T1stress 1018 ± 40 ms), $p<0.0005$. Ischaemic and infarcted myocardium showed minimal T1 reactivity (0.2 and 0.3 %, respectively).
Conclusion: Caffeine intake prior to adenosine MR perfusion causes an inversion of the effects of adenosine as measured by T1 mapping. T1 reactivity can be used the assess the adequacy of adenosine during vasodilator MR perfusion.

B-0839 11:34

Dynamic CT analysis of myocardial perfusion parameters comparing different temporal sampling rates using a third generation dual-source CT

M. van Assen[1], G. Pelgrim[1], E. Slager[1], S. van Tuijl[2], U.J. Schoepf[3], R. Vliegenthart[1], M. Oudkerk[1]; [1]*Groningen/NL*, [2]*Eindhoven/NL*, [3]*Charleston, SC/US (m.van.assen@umcg.nl)*

Purpose: To evaluate the influence of different temporal sampling rates, in dynamic CT myocardial perfusion imaging (CTMPI) on myocardial blood flow (MBF) using a 3th generation dual-source CT (DSCT), in an ex-vivo porcine heart model.
Methods and Materials: Three porcine hearts were perfused with an isolated heart model in Langendorff mode (Physioheart®, LifeTec Group, Eindhoven, The Netherlands). Haemodynamic monitoring was performed during the experiment. Third generation DSCT was used to perform dynamic CTMPI in three different modes: electrocardiographic (ECG)-triggered shuttle-mode (70kVp,350mAs/rot,z-range10.2cm) and non-shuttle-mode with continuous

stationary tube rotation (70KVp, 230mAs/rot, z-range 5.8cm, merged A and B-tube) and in non-ECG-triggered continuous-rotation-mode (70kVp, 230mAs/rot, z-range 5.8cm). Multiple fractional flow reverse (FFR) values were simulated in the circumflex artery by artificially creating a stenosis. The ECG-triggered scan were analysed with Volume Perfusion CT (VPCT) Myocardium software. The non-ECG triggered scans were analysed with MASS research version combined with an in-house Matlab script. MBF(mL/g/min) was calculated for non-ischaemic segments only.True MBF was calculated using input flow in non-stenosis situation and weight of the hearts.
Results: Heart rate, model blood flow and blood pressure were stable during the experiments. Significant differences were found between shuttle, non-shuttle and continuous-mode with median MBF 0.87 (IQR:0.72-1.00), 1.20 (IQR:1.07-1.30) and 1.65 (IQR:1.40-1.88), respectively. The median MBF values increased 44% by increasing the temporal sampling rate from shuttle to non-shuttle mode and by 98% increasing the sampling rate from shuttle to continuous mode.
Conclusion: Dynamic CTMPI using increased temporal sampling rates, results in higher and more accurate MBF values compared to the currently used shuttle technique.

Coronary CT angiography with computational fractional flow reserve for therapeutic decision making
T.M. Duguay, C. Tesche, C.N. De Cecco, J.W. Nance, M.H. Albrecht, D. De Santis, M.C. Langenbach, A. Varga-Szemes, U.J. Schoepf;
Charleston, SC/US (duguay@musc.edu)

Purpose: To investigate the performance of coronary CT angiography (cCTA) with computational fractional flow reserve (cFFR) compared to invasive coronary angiography (ICA) with fractional flow reserve (FFR) for therapeutic decision making in patients suspected of having coronary artery disease (CAD).
Methods and Materials: 74 patients (62.2±10.6 years, 62% male) who underwent a clinically indicated dual-source cCTA and ICA with FFR measurement for the assessment of CAD within 3 months were retrospectively analyzed. cCTA datasets were visually evaluated for the presence of significant CAD (≥50% stenosis). cFFR calculation for the functional assessment of CAD significance was performed. The therapeutic strategy and appropriate revascularization procedure were defined using cCTA and cFFR. The diagnostic accuracy for detecting obstructive CAD and selection of therapeutic strategy was calculated and compared using ICA as the reference standard.
Results: 36 patients (49%) had obstructive CAD based on ICA. The diagnostic accuracy for cCTA to identify obstructive CAD and to select the appropriate therapeutic strategy was 86% and 85%, respectively. cCTA with cFFR yielded significantly superior diagnostic accuracy over cCTA alone for the detection of obstructive CAD and the selection of the correct therapeutic decision with 99% and 99%, respectively.
Conclusion: cCTA alone shows modest performance while cCTA with cFFR showed excellent diagnostic accuracy in identifying patients with and without need of revascularization and in selecting the appropriate revascularization strategy in patients with suspected CAD. cCTA with cFFR has the potential to reduce unnecessary ICA procedures showing non-obstructive CAD and to inform therapeutic decision making for revascularization.

Splenic switch-off: a reliablesign of understress by Adenosin?
A.S. Sträter, J. Nadjiri, M. Rasper, T. Stadlbauer, H.-H. Eckstein, E.J. Rummeny, A. Huber; *Munich/DE (Alexandra.Straeter@gmail.com)*

Purpose: While myocardium shows a faster and greater enhancement under adenosin-stress it was recently described spleen enhancement under adenosin stress decreases compared to rest. It was proposed patients that without this signal are understressed. MR scans (stress and rest) were performed to investigate 1. number of patients with no splenicswitch-off and 2. number of patients with decreased myocardial Perfusion reserve index (MPRI) but no relevant coronary artery disease.
Methods and Materials: MR Perfusion scans were performed in 37 patients with suspision of coronary artery disease. SR-gradientecho-sequence in a 3 tesla MR scanner was used. All scans were followed by a selective coronar-angiographie done for clinical indications. Peak Enhancement (PE) is the difference of maximum signalintensity and baseline signalintensity. Upslope is the gradient from the footpoint to the maximum of the signal-intensity-curve. The quotient of stress-valueand rest-value is the MPRI.
Results: For PE myocardium had a mean of 48± 13, spleen of 56 ± 23 at rest. Under adneosin-stress mean was 60 ±17 for myocardium, 48± 28 for spleen. In the selective coronaryangiographie 57 % (21 of 37 patients) had one relevant coronary artery stenosis. PE showed splenic switch-off in 59 % (22 of 37 patients) by analysing PE. 60 % without splenic switch-off showed normal MPRIUpslope while 40 % (6 of 15) decreased MPRIUpslope (<1,5). In patients with no splenic switch-off and decreased MPRIUpslope 50 % showed a relevant coronary artery Stenosis in invasive coronary angiographie.
Conclusion: Splenic switch-off showed a low specificity for detection of understress in adenosin-stress perfusion-scans.

Implementation of size specific dose estimates (SSDE) into an automated institutional CT dose monitoring system: feasibility and initial results
N. Heinzler, C. Thomas, O. Bethge, P. Kröpil, G. Antoch, J. Boos;
Düsseldorf/DE

Purpose: To implement SSDE calculation based on water-equivalent diameters (Dw) of all slices of the CT scan volume into automated CT dose monitoring and to compare SSDE values with scanner indicated CTDIvol in chest and abdominal CT.
Methods and Materials: 1476 consecutive clinical abdominal and chest CT examinations (517 chest/905 abdominal, age 62±15yrs; 850male/626female, BMI 25.5±5.0kg/m²) were analysed. An in-house developed Matlab image segmentation device (The Mathworks, Natick, MA) was used to automatically calculate Dw of every slice of the scan volume. SSDE were automatically calculated using the mean Dw of the scan volume and transferred into the institutional CT dose monitoring software. Two radiologists independently evaluated the accuracy of the image segmentation algorithm in 100 consecutive CTs (one random slice per exam) on a 5-point scale (1=false segmentation, 5=perfect segmentation). SSDE values were compared to CTDIvol.
Results: The accuracy of the image segmentation algorithm was excellent (median rating 5, inter quartile range 4-5) and false segmentation was not identified. Automated calculation and transfer of SSDE into the CT dose monitoring system was successful in 1476/1476 (100%) exams. SSDE were higher compared with CTDIvol in chest CT (5.8±3.6mGy vs. 5.4±3.2mGy) and in abdominal CT (10.7±6.1mGy vs. 8.8±5.6mGy)(p<0.001, respectively).
Conclusion: Automated correction of CT dose data to patient size using SSDE based on mean water-equivalent diameter of the scan volume is feasible. Implementation into automated CT dose monitoring allows for large scale analysis and initial results demonstrate that mean SSDE is higher than the uncorrected CTDIvol in abdominal and chest CT.

B-0843 10:38

How to reduce the overdose in conventional x-rays using a centralised electronic system in paediatric patients
E. Fraile[1], C. Benito[1], P. Fraga[2], J. Azpeitia[3], J. Albillos[1], E. Dominguez[4], J. Galobardes[5]; [1]*S. Sebastian de los Reyes/ES*, [2]*Coslada/ES*, [3]*Madrid/ES*, [4]*Arganda del Rey/ES*, [5]*Parla/ES (eduardo.fraile@salud.madrid.org)*

Purpose: To analyse the causes of alerts of overdose in conventional x-ray departments using and electronic centralise system and how we can reduce it using continuing education programmes.
Methods and Materials: We compare the number of alerts examination in conventional x-ray using a centralise electronic platform in six general hospitals in patient under 21, before and after implementation of educational programme for radiographers. The electronic system of record dose per examination allows us to know the causes of overdose and implementation solutions to fix it.
Results: We analysed 21778 examines from six hospitals during one month, of which 4024 were patients under 21. The number of alerts were 3796 (17.4%) and 191 (4.74%) were in patients under 21. The main causes were problems related with collimation and radiographer technique applied. After six month and the implementation of educational programme to the technician, the dose of radiation decrease between a 20% and 8% depended on age and type of examination.
Conclusion: Dose control systems and programmes of continuing education allow us reduce the overdose in paediatrics patients in conventional x-ray.

B-0844 10:46

Optimising cardiac CTA procedures: a practical multi-step approach using a dose management software

T. De Bondt[1], R. Salgado[1], M. Faure[1], P. Van Herck[1], F. Zanca[2], B. Shivalkar[1], P. Parizel[1]; [1]*Antwerp/BE*, [2]*Buc/FR (timo.debondt@gmail.com)*

Purpose: Defining an optimization strategy for cardiac CTA procedures and assessing its impact on radiation dose and image quality (IQ), using a dose management solution.
Methods and Materials: Data from 362 ECG-gated cardiac CTA procedures performed on a GE VCT 64-slice scanner were collected during a 5-month period, using DoseWatch (GE Healthcare). As data showed that dose exceeded the national dose reference level (DRL), multi-disciplinary meetings were held between radiologists, cardiologists, imaging technicians and a medical physicist to define a prudent 4-step plan aiming to optimize cardiac CTA doses. Interventions consisted of: 1/ protocol standardization, 2/ mAs range reduction for zero calcium-score patients, 3/ mAs range reduction for all patients with normal weight, 4/ scan length reduction. IQ was evaluated by a radiologist and a cardiologist, using the IQ-voting system in DoseWatch.
Results: Before the interventions, average DLP and CTDI were 741 mGy.cm and 42.12 mGy respectively - both above the DRLs of 490 mGy.cm and 35 mGy. Each step of the plan gradually reduced patient dose, with a final result of 556 mGy.cm and 33.73 mGy. Step 4 was less effective, because imaging technicians were reluctant to reduce the scan margin at the cost of missing relevant anatomy. IQ ratings indicate no diagnostic value loss.
Conclusion: Using a multi-step approach, we were able to reduce dose by approximately 25%. Open discussions across specializations and education of imaging technicians are of capital importance to safeguard quality of healthcare. Dose management software tools facilitate responsible optimization processes, with regard for IQ.

B-0845 10:54

Potential dose reduction in abdominal computed tomography using a model-based iterative reconstruction algorithm

B. Kataria[1], J. Nilsson Althén[1], Ö. Smedby[2], A. Persson[1], H. Sökjer[1], M. Sandborg[1]; [1]*Linköping/SE*, [2]*Stockholm/SE (bharti.kataria@liu.se)*

Purpose: The main advantage of Model-based Iterative Reconstruction (MBIR), as an alternative to filtered back projection (FBP), is noise reduction which may facilitate reduction in patient dose. The aim is to compare visual image quality in an abdominal CT examination between FBP and a commercial MBIR (ADMIRE) and to estimate potential dose reduction while image quality is maintained.
Methods and Materials: Fifty patients referred for an abdominal CT examination were recruited. A Siemens dual-source Somatom Force was used to obtain three data sets per patient with 30%, 70% and 100% tube loads. Four image criteria from the European Guidelines for Image Criteria for CT, together with overall noise and image quality were assessed in a pairwise fashion by five radiologists. Visual Grading Regression (VGR) was used to estimate potential dose reduction, controlling for fixed and random effects, when comparing FBP with MBIR. Weighted kappa (κ_w) was used to calculate inter-observer and intra-observer agreements. The limit of significance was set at p=0.05.
Results: A significant strong effect of log mAs and ADMIRE was seen, with potential dose reduction of 22-47% for strength 3 and 34-74% for strength 5 compared with FBP ($p< 0.001$) for almost all image criteria. Inter-observer reliability showed an agreement of 71-76% (κ_w 0.201 to 0.286) and intra-observer reliability (κ_w 0.525 to 0.783) with an agreement of 82-96%.
Conclusion: MBIR (ADMIRE) showed improved image quality compared with FBP. A positive correlation between ADMIRE strength and increasing potential dose reduction was found for some, but not all, image criteria.

B-0846 11:02

Determination of iterative reconstruction dose reduction potentials in CTA with a novel image quality assessment method based on forced-choice comparisons

S. Ellmann[1], F. Kammerer[1], M. Brand[1], T. Allmendinger[2], M.S. May[1], M. Uder[1], M. Lell[3], M. Kramer[1]; [1]*Erlangen/DE*, [2]*Forchheim/DE, Erlangen/DE*, [3]*Nürnberg/DE (stephan.ellmann@uk-erlangen.de)*

Purpose: Iterative reconstructions (IR) permit CT dose-reduction potential. Diagnostic quality of dose-reduced images is mostly assessed using Likert-scales, but their ordinal character prohibits calculations of e.g. standard deviations or confidence intervals. This study presents a novel image quality assessment method devoid of statistical restrictions accompanying Likert Scales and exemplarily determined dose-reduction potentials of Circle-of-Willis CTA.
Methods and Materials: Dose-reduced CTA images of 10 patients undergoing head CTA were reconstructed using Sinogram-affirmed iterative reconstruction (SAFIRE) and compared with full-dose FBP in pairwise manner by five observers with 3,000 ratings in total. Images differed in the degree of dose reduction, IR-strength (3 vs 5) and the size of the vessels of interest.
Regression curves were calculated from the observers' preferences for dose-reduced IR over FBP images. Regression curve progression facilitated conclusions on the level where dose-level IR-images were equal to full-dose-FBP images in terms of vessel definition.
Results: Dose reduction potential in head CTA was significantly dependent on the size of the vessel of interest and on the strength of the IR algorithm. Large vessels reconstructed with SAFIRE 5 offered a dose reduction potential of 84% (95% CI 82.9-85.8%), whereas small vessels reconstructed with SAFIRE 3 permitted dose reductions of 40% (35.2-45.8%).
Conclusion: This study presents a novel method to determine CT dose reduction potentials, which in contrast to other established methods permits exact calculations and versatile statistical analyses. For an exemplary investigation of Circle-of-Willis CTA, considerable radiation dose reductions were achievable, which were nonetheless dependent on vessel situation and clinical question.

B-0847 11:10

Image quality of ultra-low-dose CT examinations in overweighed patients using iterative model-based reconstruction

N. Große Hokamp, K. Slebocki, K. Mamadov, J. Salem, J. Herden, D. Maintz, D.-H. Chang; *Cologne/DE (nils.grosse-hokamp@uk-koeln.de)*

Purpose: Iterative model-based reconstruction methods (IMR) enable improvement of image quality. Purpose of this study was to assess image quality and diagnostic confidence in overweighed patients in ultra-low-dose CT examinations (ULD-CT).
Methods and Materials: Image quality and radiation dose (dose-length product) were retrospectively reviewed for overweighed patients (BMI ≥ 25 kg/m^2) who underwent ULD-CT for the evaluation of acute flank pain and suspected urolithiasis. All scans were performed at 100 kVp and a fixed tube current (50mAs). Images were reconstructed using filtered back projection (FBP), iterative reconstruction (iDose) and IMR. Image quality was objectively evaluated as contrast-to-noise-ratio (CNR) and subjectively by 2 readers for diagnostic confidence, delineation of ureters, noise and sharpness on a 4-point Likert Scale, respectively. Statistic significance was assessed using ANOVA and Friedman-Multiple-Comparison-Testing with Bonferoni and Dunn post-hoc.
Results: 20 patients with a BMI of 31.6 ± 7.4 kg/m^2 were enrolled in this study. Urolithiasis was detected in 17 patients (85%). Mean DLP was 106.8 ± 34,3 mGy*cm.In relative terms, use of IMR yielded a 370% and 122% improvement in CNR relative to FBP and iDose ($p\leq0.001$). Subjective image quality with IMR always received higher ratings as compared to FBP and iDose for all criteria and from both readers. In particular, diagnostic confidence was significantly higher using IMR (3.2/4, 2.4/4 vs. 1.6/4 $p\leq0.05$).
Conclusion: ULD-CT protocol using IMR in overweighed patients was feasible in all examinations. IMR should be preferred to FBP and iDose as both image quality and diagnostic confidence are improved.

B-0848 11:18

Improved image quality of low-dose CT combining with iterative model reconstruction algorithm for response assessment in patients after treatment of malignant tumour

X. Xin[1], J. Shen[1], S. Yang[1], S. Liu[1], M. Wang[1], A. Hu[1], Y. Jiang[2], Z. Sheng[1], Q. Han[2]; [1]*Nanjing/CN*, [2]*Shanghai/CN (yanjiangcs@hotmail.com)*

Purpose: To evaluate the image quality of low-dose CT combining with iterative model reconstruction (IMR) algorithm for response assessment in patients after treatment of malignant tumour.
Methods and Materials: 47 patients (mean age 57.8±10.9, 30 men, BMI 22.09±2.35kg/m^2) after treatment of malignant tumour underwent chest and abdomen CT twice for response assessment with an interval of 6 months according to clinical routine. The first CT scans were performed with routine dose (RD) protocol at 120kV and images were reconstructed with filtered back projection (FBP) algorithm; while the second scans were performed with low-dose (LD) protocol at 100kV and images were reconstructed with FBP and IMR respectively. All scans were performed using automatic tube current modulation technique with image quality index of 18. Objective image quality including CT attenuation, image noise, and CNR, subjective image quality including artefacts,visualization of small structures and diagnostic confidence, as well as lesion detection were assessed and compared.
Results: Effective radiation dose of LD-CT scans was reduced 51.5% compared to RD-CT scans (30.5±7.4mSv vs. 14.8±2.7mSv). Higher CT

attenuation were found in both LD-IMR and LD-FBP images compared to RD-FBP images. Better subjective image quality and CNR as well as lower objective noise were found in LD-IMR images (all, p<0.05). Two small lesions (diameter <= 1cm) were missed on LD-FBP images, which can be observed in LD-IMR images.
Conclusion: IMR can help 50% radiation dose reduction without compromising image quality in patients after treatment of malignant tumours to repeated chest and abdomen CT for response assessment.

B-0849 11:26

Reduction of iodinated contrast dose and increase quality of practice on CTPA with a programme for data recording and dose personalisation P3T and the use of an 18G for venous access

M. Perez-Pena, E. Diaz, J. Vazquez, I. Gutiérrez, S. Shehadeh, C. Quispe, C. Huerta, H. Bernardo, R. Diaz; *Mieres/ES (mar_perez@yahoo.com)*

Purpose: We present our experience in the performance of CT of pulmonary arteries (CTPA) using a programme for iodinated contrast data recording and dose personalisation P3T, and a venous access of 18G on antecubital location.
Methods and Materials: 125 patients underwent CTPA (January-June 2016), 64 women-61 men, using a programme for iodinated contrast data recording and dose personalisation that calculates amount of contrast based on various factors, among which weight is the most determinant. We used a venous access of 18G needle placed on the elbow flexure. We analysed our data using SPSS V.11 and compared with our old protocol, in which we used a fixed amount of 90 ml.
Results: Our results showed a significant difference on the amount of contrast used, mean value 79,5ml per patient in comparison to 90ml of our old protocol (p< 0,001), with a decrease in contrast injected per patient of -10,44ml (95% confidence interval (-12.05, -8.83). There is also significant difference between men and women related to weight (p<0,001). Mean flux was 5,9ml/sec, and by using a venous catheter of 18G placed in the elbow flexure we suffered one extravasation. This programme provides a data recording of the injection protocol and sends a report to the PACS.
Conclusion: The use of P3T on CTPA decreases the dose required antecubital location of needle and 18 gauge decreases extravasations P3T provides a data recording of the injection protocol and sends a report to the PACS, thus increasing the quality of practice.

B-0850 11:34

Comparison of radiation dosage and image quality: digital breast tomosynthesis (DBT) vs full-field digital mammography (FFDM)

Y. Choi[1], O. Woo[1], H. Shin[1], G. Choi[1], K. Cho[1], B. Seo[2]; [1]*Seoul/KR*, [2]*Ansan/KR (yoom880103@gmail.com)*

Purpose: With increasing concern of individual radiation exposure doses, studies analyzing radiation dosage in breast imaging modalities are required. Aim of this study is to compare radiation dosage and image quality between DBT and FFDM.
Methods and Materials: 221 patients (mean age 51.7 years) who studied both DBT and FFDM were retrospectively reviewed. Radiation dosage data were obtained by radiation dosage scoring and monitoring program: Radimetrics (Bayer HealthCare, Whippany, NJ). Entrance dose and mean glandular doses in each breast were obtained in both imaging modalities. To compare the image quality of DBT with two-dimensional synthesized mammogram (2DSM) and FFDM, 5-point scoring system for lesion clarity was assessed and compared. The parameters of radiation dosages (entrance dose, mean glandular dose), and image quality (lesion clarity scoring) were compared between two modalities by using paired t-test and Wilcoxon rank sum test.
Results: For entrance dose, DBT had lower mean dosage (12.7mGy) compared with FFDM (28.3mGy, p-value <0.0001). Mean glandular doses for both breasts were lower in DBT (Left 3.34, Right 3.42) compared with FFDM (Left 3.98, Right 4.02, p-value 0.03, 0.008). The lesion clarity score was higher in DBT with 2DSM (mean score 4.59) compared with FFDM (3.32, p-value <0.0001).
Conclusion: DBT showed lower radiation entrance dose and also lower mean glandular doses to both breasts compared with FFDM. Also, DBT with 2DSM had better image quality than FFDM, suggesting that DBT may have a potential to be performed as an alternative to FFDM.

B-0851 11:42

Effect of QuantaStream denoising on image quality and diagnostic accuracy of low-dose CT in patients with suspected appendicitis

M.M. Kolb[1], C. Storz[1], J. Kim[2], D. Ketelsen[1], F. Bamberg[1], K. Nikolaou[1], A.E. Othman[1]; [1]*Tübingen/DE*, [2]*Seoul/KR (m_m_kolb@web.de)*

Purpose: To determine the effect of a novel denoising technique on image quality and diagnostic accuracy on low-dose CT in patients with suspected appendicitis.
Methods and Materials: 50 consecutive patients with suspected appendicitis who underwent contrast-enhanced abdominal CT (120kV, CARE dose reference 160-200mAs) were retrospectively included. Low-dose CT datasets were generated using realistic reduced dose simulation at 25% of the original exposition. Low-dose datasets were then denoised using a novel QuantaStream technique. All original, low-dose (ND25) and denoised (D25) datasets (n=150) were evaluated regarding objective (signal-to-noise ratio, SNR), subjective image quality (5-point Likert scale by overall quality, image noise, and diagnostic confidence) and appendicitical signs (including perforation or abscess formation) by two independent readers.
Results: SNR of ND25 were significantly lowest (p<.001) with no significant difference between original and D25 (p>0.14). Similarly, subjective image quality was rated highest for original and D25 and lowest for ND25 (all p<.05). Appendicitis was correctly identified in all datasets (n=24, sensitivity: 1.00, NPV: 1.00). Diagnostic confidence was highest for original, followed by D25 and was lowest for ND25 (p=.001). Presence of complications was correctly identified on original and D25 datasets (sensitivity: 1.00, NPV: 1.00) whereas 3 and 1 features were not identified on ND25 (respectively sensitivity: .75/.92, NPV: .25/75). Inter-reader agreements were perfect for original and D25 (κ=1.0) and fair for ND25 (κ=0.66).
Conclusion: QuantaStream Denoising of lower dose abdominal CTs (25% of original exposition) maintains high diagnostics image quality and diagnostic accuracy in patients with suspected acute appendicitis and associated complications.

B-0852 11:50

The analysis of 2-year cumulative effective radiation dose and cumulative organ dose on regular follow-up CT scans in patients with breast cancer

J. Lee, H. Yong, O. Woo, E.-Y. Kang, G. Choi, Y. Choi; *Seoul/KR (ljw2000e@naver.com)*

Purpose: The aim of this study is to evaluate 2-year cumulative effective radiation dose and cumulative organ dose on regular follow-up CT scans in patients with breast cancer and to establish personalised low-dose CT protocol.
Methods and Materials: A retrospective study was performed on the patients with breast cancer who were diagnosed and managed consistently on the basis of routine breast cancer follow-up protocol between January 2012 and June 2016. Based on ICRP 103, the cumulative effective radiation doses of each patient for 2-year follow-up were analysed using the commercial radiation management software (Radimetrics, Bayer healthcare). The personalized effective doses on each organ were analysed in detail by the software-providing Monte Carlo simulation.
Results: A total of 3822 CT scans on 490 patients was evaluated (age 52.32 ± 10.69). The mean scan number on each patient was 7.8 ± 4.54. Each patient was exposed 95.54 ± 63.24 mSv of radiation for 2 years. The cumulative CT radiation dose was significantly higher in patient with lymph node metastasis (p=0.00). The HER-2 positive patients were more exposed to radiation compared to estrogen or progesterone receptor positive patient (p=0.00). There was no difference in the cumulative effective radiation dose with different age groups.
Conclusion: To acknowledge how much radiation exposed to a patient is a starting point of management of radiation exposure for patients with long-term CT follow-up. Precise and personalized protocol as well as iterative reconstruction may reduce hazard from unnecessary radiation exposure.

A new brick in the wall? Use of vessel wall magnetic resonance imaging in the evaluation of intracranial vasculopathies

M. Reis Lima, M. Longo, R. Menegatti, J. dos Santos Muller, F. Aesse, B. Bressan Valentini, L. Vedolin; *Porto Alegre/BR (marjanalima@hotmail.com)*

Purpose: Vessel wall magnetic resonance imaging (VWMRI) is a tool in development that presents as an alternative for differentiation of cerebral vasculopathies. This study aims to evaluate applicability in differentiating intracranial atherosclerosis (IA), central nervous system vasculitis (CNSV) and reversible cerebral vasoconstriction syndrome (RCVS).
Methods and Materials: This is a retrospective cohort study. We reviewed imaging findings in patients who went through VWMRI for suspected intracranial vasculopathy. Among findings, we considered specially thickening and enhancement, which were correlated with gold-standard diagnosis (clinical and biochemical parameters).
Results: 18 patients were evaluated, with 37 altered vessels - 11 RCVS, 14 CNSV and 12 IA. 11 patients with CNSV presented wall thickening, while only 1 RCVS patient had it (p=0,008). There was no difference in thickening between CNSV and IA (p=0,586). All patients with CNSV and IA presented enhancement, while none RCVS had it. Between groups there were significant differences in enhancement: CNSV presented higher enhancement degree compared with IA (p=0,08). Regarding the pattern, CNSV showed diffuse pattern while IA showed heterogeneous pattern (p=0,002). In some cases, we noticed wall enhancement in V4 segment of vertebral arteries without other changes.
Conclusion: Our evaluation's preliminary results show satisfactory performance in differential diagnosis of intracranial vascular pathologies.

B-0854 10:38

Diagnostic performance of different perfusion algorithms for the detection of cerebral vasospasm

S. Afat[1], C. Brockmann[1], O. Nikoubashman[1], M. Müller[1], M. Brockmann[2], K. Nikolaou[3], M. Wiesmann[1], A. Othman[3]; [1]*Aachen/DE*, [2]*Mainz/DE*, [3]*Tübingen/DE (safat@ukaachen.de)*

Purpose: In this study, we aimed to assess the diagnostic performance of different perfusion algorithms for the detection of cerebral vasospasm as compared to angiography.
Methods and Materials: 39 datasets from 25 patients (57.5±10.8y) with suspected cerebral vasospasm were included. Volume Perfusion CT (VPCT) and angiography were performed within 6 hours. Perfusion maps were generated using a maximum slope (MS) and a deconvolution-based approach (DC). Two blinded neuroradiologists evaluated presence and severity of vasospasm on MS and DC perfusion maps on a 3-point Likert scale (0=no vasospasm, 1=vasospasm affecting <50%, 2=vasospasm affecting >50% of vascular territory). A third neuroradiologist assessed the angiography using the same 3-point Likert scale. Perfusion maps were evaluated regarding diagnostic accuracy for vasospasm with angiography as reference. Correlation analysis on perfusion maps and on angiography was performed. The agreement between MS and DC and the inter-reader agreement was assessed.
Results: DC perfusion maps yielded significantly higher diagnostic accuracy than MS perfusion maps (DC: AUC=.821; MS: AUC=.755; p=.014) with remarkably higher sensitivity for DC compared to MS (DC: sensitivity=.724; MS: sensitivity=.590). Findings on DC maps showed significantly higher correlation with angiography compared to MS (DC: R=.664; MS: R=565; p=.007). Findings in MS and DC showed substantial agreement (Kappa=.732). Regarding inter-reader analysis, (almost) perfect inter-reader agreement was observed for both MS and DC maps (Kappa≥.980).
Conclusion: Results of this study indicate that DC yields significantly higher diagnostic accuracy for the detection of cerebral vasospasm and higher correlation with angiographic findings compared to MS.

Monitoring cerebral perfusion change after revascularisation by using arterial spin labeling in patients with Moyamoya disease

S. Lee, T. Yun, R.-E. Yoo, K. Kang, S. Choi, J.-H. Kim, H.-S. Kang, C.-H. Sohn, M. Han; *Seoul/KR (seunghyun.lee.22@gmail.com)*

Purpose: To evaluate whether arterial spin labeling (ASL) MRI can help identify the change in cerebral blood flow (CBF), collateral blood flow, and anastomosis site patency after revascularisation in patients with moyamoya disease (MMD).
Methods and Materials: This retrospective study was conducted in 140 patients with MMD who underwent middle cerebral artery (MCA)-superficial temporal artery anastomosis. Pre- and early/late postoperative ASL and digital subtraction angiography images were analysed. The absolute CBF (CBF_{MCA}) and normalised CBF values adjusted with respect to non-anastomosis side ($nCBF_{MCA}$) and cerebellum ($nCBF_{CbII}$) were calculated in MCA territory. A collateral grading in MCA territory according to ASPECTS methodology and an anastomosis site patency were also assessed. The change in CBF was compared by using one-way analysis of variance with a Bonferroni correction for multiple comparisons, and inter-modality agreement was determined by kappa statistics.
Results: Significant increases in CBF_{MCA}, $nCBF_{MCA}$, and $nCBF_{CbII}$ were found after revascularisation (for pre- and early/late postoperative values, CBF_{MCA}; 35.2 [ml/100g/min]) ± 7.8, 56.3 ± 16.8, 51.5 ± 12.0, $nCBF_{MCA}$; 0.74 ± 0.12, 1.17 ± 0.23, 1.12 ± 0.16, and $nCBF_{CbII}$; 0.73 ± 0.14, 1.11 ± 0.25, 1.01 ± 0.18, respectively, P values < .001 for all). The agreements for collateral grading and anastomosis patency were moderate to good, with weighted kappa values of 0.77 (0.74-0.79) and 0.49 (0.32-0.66), respectively.
Conclusion: ASL MRI can identify the perfusional change after revascularisation, and it has the potential to serve as a non-invasive imaging tool to monitor the perfusional change after revascularisation in patients with MMD.

B-0856 10:54

Evaluation of AICA and vestibulocochlear nerve relationship in patients with vertigo

A. Öztek, I. Çakar, K. Karaali, U. Şenol; *Antalya/TR (alpoztek@gmail.com)*

Purpose: To establish the course of AICA, type of contact with the vestibulocochlear nerve (CN-VIII) and vascular contact at the root entry zone (REZ) in patients with vertigo.
Methods and Materials: CISS images of 125 consecutive patients who had temporal MRI were retrospectively evaluated by the radiologists independently. The course of AICA was: cisternal, abutting the internal acoustic meatus, looping into the proximal or distal half of IAC. Its relation to the CN-VIII was: touching, looping around, indenting or not touching it. Contact by any vessel in REZ was also noted. The control group consisted of asymptomatic sides of patients with unilateral symptoms and patients with symptoms not related to the CN-VIII. Types of AICA course, types of contact with the CN-VIII and presence of vascular contact at REZ were compared in symptomatic patients and the control group.
Results: Fifty-eight patients had vertigo and 67 patients were in the control group. Vascular contact near the origin of the nerve was significantly more common in the vertigo group (p<0.001). AICA loops into the proximal or distal halves of the IAC were more common in the vertigo group (p=0.041). There was no relationship between the type of contact and the presence of vertigo (p=0.264). There was good agreement between the two radiologists regarding vascular contact at REZ (K=0.650); but poor agreement in evaluation of the type of contact of AICA (K=0.422).
Conclusion: AICA loops into the IAC and vascular contact at REZ are more common in patients with vertigo.

B-0857 11:02

Impact of the global outflow angle on recanalisation after endovascular treatment of MCA bifurcation aneurysms

Y. de la Torre; *Poitiers/FR (yannick.delatorre@outlook.fr)*

Purpose: Intracranial aneurysm recanalization after endovascular treatment remains a major problem. The main goal of this study was to find new predictive factors of recanalization after EVT, by calculating 3D angle values between the arteries of the MCA bifurcation, and in particular the Global Outflow Angle.
Methods and Materials: Ninety-six aneurysms of MCA bifurcation, ruptured or not, treated only by endovascular approach, were included. Clinical factors, aneurysm anatomic parameters, postoperative occlusion class, percentage of packing volume and morphological parameters were studied. Angles were measured in 3D reconstructions of initial DSA, using three-dimensional coordinates of key points. The Global Outflow Angle was the sum of the two lateral angles of MCA bifurcations.

Results: Recanalization occurred in 25 cases (26%), retreatment performed in 11 cases (11%). Only one patient (1%) had a rebleeding. Univariate analysis established as predictive factors of recanalization: high blood pressure, the aneurysm size, neck size, postoperative occlusion class, the percentage of packing volume, the two Outflow Angles, and the Global Outflow Angle. Multivariate analysis established two independent risk factors of recanalization: the Global Outflow Angle (OR=1.05; 95% CI, 1.02-1.08; p<0.002) and the aneurysm width (OR=0.67; 95% CI, 0.46-0.96; p=0.031). A Global Outflow Angle threshold <192° was found to be a risk factor of recanalization (OR=13.75; 95% CI, 4.46-42.44).
Conclusion: This study emphasizes that a new parameter, the Global Outflow Angle, could be predictive of recanalization for MCA bifurcation aneurysms treated by EVT. This should be kept in mind during the periprocedural management of this subgroup of patients.

B-0858 11:10

Role of endovascular intervention in intracranial arterial pseudoaneurysms

N. Khandelwal, C.K. Ahuja, V. Gupta, A. Kumar, P. Singh, K.K. Mukherjee; *Chandigarh/IN (ajay2509@gmail.com)*

Purpose: Latrogenic traumatic intracranial aneurysms are rare occurrences, but their clinical impact is significant due to the high risk of intracranial haemorrhage and eventual demise. We describe a short series of 11 such cases and discuss the diagnosis and management of these.
Methods and Materials: Last 8 years database of the Interventional neuroradiology section was analysed. All cases of intracranial pseudoaneurysms were extracted and the records were analysed pertaining to the following parameters: primary disease, intervention done, secondary complaints, imaging, treatment offered, if any and follow-up.
Results: 11 cases of iatrogenic intracranial pseudoaneurysms were extracted from the last 8 years DSA database. Of these, 7 were secondary to transsphenoidal surgery for pituitary macroadenomas, 2 were the result of transcranial surgery for meningiomas and the remaining 2 secondary to surgical clipping of ruptured aneurysms. Eight patients were managed by endovascular means (endosaccular coiling and parent artery occlusion/trapping using sandwich technique). Of these, 1 patient had undergone stent graft placement but eventually required a parent artery occlusion due to significant endoleak. Three patients succumbed due to massive bleed prior to any attempt of treatment. All the patients treated had a successful outcome, the follow-up duration being 3 months to 18 months.
Conclusion: Endovascular management with embolisation currently forms the mainstay of treatment of intracranial pseudoaneurysms with reasonably good success rates. Quick diagnosis and prompt treatment is the key to prevent fatality.

B-0859 11:18

Endovascular therapy vs thrombolysis in patients with anterior circulation stroke in everyday clinical practice

M. Politi, M. Alexandrou, B. Gemes, C. Roth, P. Papanagiotou; *Bremen/DE (mariapoliti@hotmail.com)*

Purpose: In patients with large vessel occlusions, endovascular treatment has been shown to be superior to intravenous thrombolysis in recent trials. The aim of this study was to analyse the impact of endovascular treatment on clinical and radiological outcome in everyday clinical practice.
Methods and Materials: We compared the rates of good outcome (modified Rankin scale ≤ 2 at discharge) and in-hospital mortality in patients with distal intracranial carotid artery, M1 and M2 occlusions during two time periods. From January 2008 to October 2012, a total of 509 patients were treated with intravenous thrombolysis and from November 2012 to December 2014, a total of 270 patients received endovascular treatment (with or without intravenous thrombolysis).
Results: Significantly, more patients in the endovascular treatment group than in the intravenous thrombolysis group had a good outcome (37% vs. 27%, $p < 0.01$). An excellent clinical outcome (mRS 0-1) was seen in 20% of the patients in the endovascular treatment group vs 13% of the patients in the intravenous thrombolysis group. There was no difference concerning in-hospital mortality in the two groups.
Conclusion: In everyday clinical practice and compared with intravenous thrombolysis, endovascular treatment significantly improved clinical outcome.

B-0860 11:26

Hypoplasia of the anterior cerebral artery A1 segment is a risk factor for post-treatment recanalisation of anterior communicating artery aneurysms

V. Onofrj, M. Cortes, D. Tampieri; *Montreal, QC/CA (valeriaonofrj@gmail.com)*

Purpose: The purpose of this study is to assess an association between the presence of anatomical variants of the anterior cerebral artery (ACA) in patients receiving treatment for an anterior communicating artery (ACoA) aneurysm and post-treatment recurrence.
Methods and Materials: 194 patients received treatment with coiling for an ACoA aneurysm between 2001 and 2016. Presence of anatomical variants of the ACAs and ACoAs were retrospectively assessed and the geometry of the aneurysm was evaluated by assessing if the aneurysm main axis direction was parallel to that of the parent vessel. 113 of the treated patients received regular follow-up with MRA and/or angiography up to 6 years after treatment. Aneurysm neck and sac recanalisation were measured at each follow-up. We analysed the association between recanalisation of the aneurysm, the presence of anatomic variant of the anterior cerebral artery and the aneurysm configuration.
Results: In 48% of patients hypoplasia of the A1 segment contralateral to the side of the aneurysm was identified. 58% of the aneurysms were oriented parallel to the parent vessel. Aneurysm size and shape were similar between groups ($p>0.05$). Overall recurrence was significantly more frequent in patients with A1 hypoplasia ($P<0.01$) and in patients with both A1 aplasia and which aneurysms main axis was oriented parallel to the axis of the parent artery ($p=0.03$). Cox regression showed A1 hypoplasia was a significant predictor of time to recurrence (hazards ratio=2.48, 95% CI, $p<0.01$).
Conclusion: A1 hypoplasia is a predictor of post-treatment recanalisation of ACoA aneurysms.

B-0861 11:34

Role of CT and MR angiography in follow-up of intracranial aneurysms

N. Khandelwal, C.K. Ahuja, V. Gupta, A. Kumar, S.K. Gupta; *Chandigarh/IN (ajay2509@gmail.com)*

Purpose: Intrarterial digital subtraction angiography (IADSA) is currently the gold standard for the follow-up of treated intracranial aneurysms. The study evaluated the performance of CTA and MRA in the follow-up evaluation of clipped and coiled aneurysms.
Methods and Materials: After institute IRB approval, a total of 42 patients (47 intracranial aneurysms) were enrolled in the study which comprised clipping arm (Group I; 24 patients; 29 aneurysms) and coiling arm (Group II; 18 patients; 18 aneurysms). CTA, DSA and MRA were performed within 1 week of each other. The following parameters were assessed: the quality of the images, the presence of clip/coils and motion artefacts, presence/absence of the aneurysm remnant, completeness of the occlusion of the aneurysm, duration of examination and cost of the study.
Results: Reasonably good aneurysm detectability was obtained in 70.2% patients (combined groups I and II) by CTA; 96.7% in group I and 27.8% in group II. CTA underestimated residual aneurysm size (2.214±1.4392 mm) compared to 3D-DSA (2.7727±1.67874) which; however, was not significant. 100% aneurysm detectability was achieved in all patients on MRA in Group II; however, it was less than 60% in Group I (done in only 10 patients). Mean size was nearly similar (2.875±1.6520 mm) with 3D-DSA (2.946±1.7012). Procedure duration, cost and adverse effects of both CTA and MRA were significantly less as compared to DSA.
Conclusion: CTA is a reasonably efficacious alternative to DSA in detection of clipped aneurysm remnants while MRA performs well for the detection of coiled aneurysm remnants.

B-0862 11:42

Sinovenous outflow restriction outweighs cortical venous drainage as a parameter associated with haemorrhage in dural arteriovenous fistulas in the transverse-sigmoid sinus

Y.-S. Hu, C.-J. Lin, H.-M. Wu, W.-Y. Guo, C.-B. Luo, C.-C. Wu, W.-Y. Chung, K.-D. Liu, H.-C. Yang; *Taipei/TW (sam6526@hotmail.com)*

Purpose: The haemorrhage rates in dural arteriovenous fistulas (DAVFs) with cortical venous drainage (CVD) vary widely and sinovenous outflow restriction (SOR) contributes to haemorrhage. We hypothesize that SOR plays a more important role in DAVF haemorrhage than does CVD.
Methods and Materials: Retrospectively (1995-2016) recruited 163 cases of DAVFs in the transverse-sigmoid (T-S) sinus were divided into haemorrhage and non-haemorrhage groups based on initial presentation. Their angiograms and magnetic resonance imaging were evaluated, with evaluators grading the sinovenous outflow patency as the combined sinovenous conduit score (CCS), ranging from 0 (total occlusion) to 8 (fully patent). The median CCS was compared between the haemorrhage and non-haemorrhage groups. We

established 2 logistic regression models based on the CVD and CCS, respectively, to compare their performances in predicting DAVF haemorrhage.
Results: Sinovenous outflow was significantly more restrictive (lower median CCS) in the haemorrhage group than in the non-haemorrhage group (1 versus 6.5; $p < 0.001$). A CCS ≤ 2 best discriminated between the groups with a sensitivity of 90.0% and a specificity of 88.1%. By contrast, CVD predicted the presence of haemorrhage with a sensitivity of 80.0% and a specificity of 73.4%. The CCS model had a better predictive performance than did the CVD model ($p = 0.018$).
Conclusion: The grading system semiquantifies SOR and SOR may represent a stronger imaging parameter associated with haemorrhage in DAVFs of T-S sinus than does CVD, which may offer potential guidance in therapeutic decision making.

Ruptured MCA aneurysms with a concomitant intraparenchymal haematoma: single centre treatment strategy evaluation in 81 patients

I.A.J. Zijlstra; *Amsterdam/NL (ij.a.zijlstra@amc.uva.nl)*

Purpose: The prognosis of patients with ruptured middle cerebral artery (MCA) aneurysms and an associated intraparenchymal haematoma (IPH) is bad, even after aggressive surgical therapy. The role of the haematoma volume in determining treatment strategy has not been extensively studied and little data are available on coiling with or without clot removal in these patients.
Methods and Materials: We retrospectively studied the clinical data and the imaging of consecutive patients with a ruptured MCA aneurysm and an IPH admitted between January 2006 and December 2015. The influence of IPH +/- intrasylvian haematoma volume (ISH) on the followed treatment strategies (coiling or clipping with or without clot removal and/ or decompression) and on clinical outcome was evaluated.
Results: Outcome data were available in 76 patients. Overall favorable outcome (mRs 0-3) rates after 3-6 months and mortality rates were 54%/ 18% after coiling and 43%/ 38% after clipping (p=0.46/ 0.10). Brain stem compression (BSC) before treatment was significantly associated with worse clinical outcome (p<0.01), IPH + ISH volume not. In patients with brain stem compression that needed decompression favorable clinical outcome rates and mortality rates were 11%/44% after coiling and 23%/ 54% after clipping.
Conclusion: Brain stem compression is a more important factor than IPH (+ISH volume) in determining the treatment strategy of patients with a ruptured MCA aneurysm and an associated IPH. In patients with BSC, clipping with decompression might be the preferred treatment strategy. In patients without BSC the treatment strategy can be based on aneurysm configuration and local expertise.

Definition of age dependent reference values for diameter of the common bile duct and pancreatic duct on MRCP from a population based cohort study

M.-L. Kromrey, F. Kasprowicz, J. Mayerle, M.M. Lerch, J.-P. Kühn, G. Beyer; *Greifswald/DE (marie-luise.kromrey@uni-greifswald.de)*

Purpose: To define new reference values for diameters of pancreaticobiliary ducts on magnetic resonance cholangiopancreatography (MRCP) in general population and to identify factors influencing duct size.
Methods and Materials: Study subjects were recruited from the population based Study of Health in Pomerania (SHIP) and had whole body MRI + MRCP (1,5T). Diameters of pancreatic duct (PD) and common bile duct (CBD) were measured on MRCP before and after administration of secretin by an investigator blinded to other subject data.
Results: 1,385 subjects were initially scanned, 865 measured PDs and 938 CBDs were included for further analysis (median age 53y, 48.5% female). Subjects were excluded for missing data or evidence of pancreaticobiliary disease. The diameters increased with age (PD median (range) 1.-3. Quartile: 20-29y 1,33mm (1.20 - 1.57), >70y 2.49 (1.85 - 3.01); CBD median (range) 1.-3. Quartile: 20-29y 4.53 (3.87 - 5.17), >70y 6.50 (5.10 - 8.23)) and the historic upper limit of normal of 3mm for PD and 7mm for CBD were exceeded by 11% and 18.2% respectively. Subjects that underwent cholecystectomy presented with significantly increased diameter of CBD, but not PD (CBDw/oCCE: 5.30mm±1.893 SD vs. CBDw/CCE: 8.18mm±2.841 SD, p<0.01; PDw/oCCE: 1.84mm±.778 SD vs. PDw/CCE: 2.06mm±.868 SD, p>0.01).
Conclusion: Up to 18% of healthy volunteers would have undergone diagnostic workup for enlarged CBD or PD above the current reference standard. The width of the pancreaticobiliary ducts increases in an age dependent manner in asymptomatic volunteers. An increase of the CBD after cholecystectomy can be observed, the PD remains unaffected.

B-0865 10:38

CT texture analysis of downstaged ductal adenocarcinoma after chemoteraphy in predicting treatment response

M. D'Onofrio, V. Ciaravino, N. Cardobi, R. De Robertis, R. Pozzi-Mucelli; *Verona/IT (valentinaciaravino@gmail.com)*

Purpose: To evaluate the added value of CT texture analysis in the estimation of tissue changes in resected ductal adenocarcinoma after chemotherapy.
Methods and Materials: Patients with ductal adenocarcinoma downstaged after neoadjuvant treatment and therefore resected were included in this study. All the tumours were unresectable or borderline resectable at first evaluation. A pre-treatment and post-treatment CT study were obtained. The pancreatic phase of pre- and post-treatment CT study were used to evaluate the texture analysis. Tumour volume reduction was obtained in all cases based on which successfully tumour resection was performed in all cases. CT texture analysis results (Mean Value, Variance, Skewness, Kurtosis, Entropia) were compared by using Wilcoxon correlation test.
Results: 17 patients reached the resectable stage after neoadjuvant treatment. CT texture analysis was finalized in all cases. The comparison between Mean Value, Variance, Skewness and Entropia pre-treatment (MV median = 1082.70; V median = 876.31; S median = -0.23; E = 0,5520) in respect to post-treatment results (MV median = 1081.10; V median = 28.14; S median = - 0.09; E = 0,5520) shows no statistical significant difference (p > 0.05). The comparison between Kurtosis pre-treatment (K median=0.34) and Kurtosis post-treatment (K median -0.51) shows statistical significant difference (p < 0.05). Pathological correlation were performed.
Conclusion: This preliminary results on CT texture analysis of downstaged ductal adenocarcinoma show that this evaluation may represent an added value in the judgment of changes in tumour tissue, especially in those cases of ductal adenocarcinoma with no evident downsizing after chemotherapy.

B-0867 10:46

Patient-adapted respiratory training improves image quality of respiratory-triggered 3D MRCP in painful pancreaticobiliary disorders

L. Zhu, Z.-Y. Sun, D. Liu, P. Li, H.-D. Xue, Z.-Y. Jin; *Beijing/CN (zhuliang_pumc@163.com)*

Purpose: To compare the image quality of respiratory-triggered magnetic resonance cholangiopancreatography (RT-MRCP) with and without a patient-adapted respiratory training before the examination, in clinical patients with painful pancreaticobiliary disorders.
Methods and Materials: Hospitalised patients with painful pancreaticobiliary disorders who were scheduled for MRCP study were prospectively enrolled (n=31). The maximal numerical rating scale (NRS) of abdominal pain during the course of disease and the immediate NRS before the MRCP examination were recorded. Patient-adapted respiratory training was conducted before the examination. A sex- and age-matched group of patients with painful pancreaticobiliary diseases who underwent MRCP during the same time period served as control (n=62), who received ordinary instructions only. Acquisition time was recorded. General image quality, visualization of 12 segments of the pancreaticobiliary tree and diagnostic confidence based on 3D MRCP images were rated on a five-point scale and compared between the two groups.
Results: Maximal and immediate NRS of pain was comparable between the two groups. Image quality and diagnostic confidence were significantly improved (p<0.01 and p=0.02) in patients receiving respiratory training. Visualisation of left intrahepatic duct (p=0.02 for the trunk and p<0.01 for medial and lateral branches) and pancreatic duct (p<0.01 for head, body and tail segments) was also significantly better. The other segments showed no significant difference. The acquisition time was shorter (176±54s vs 253±67s, p<0.01) in the group with patient-adapted respiratory training.
Conclusion: Patient-adapted respiratory training is feasible in clinical practice and improves the image quality of RT-MRCP in patients with painful pancreaticobiliary disorders.

B-0868 10:54

Bile duct obstruction: diagnosis using contrast-enhanced ultrasound (CEUS)

F.J.P. Fontán, A.R. Reboredo, S. García Dubra, C. Rodríguez López, F. Vidal Filgueira; *Corunna/ES (carmenrlopez86@gmail.com)*

Purpose: The aim of this study was to investigate the value of contrast-enhanced ultrasound (CEUS) for evaluating biliary obstruction and in differentiating between benign and malignant causes.
Methods and Materials: Between November 2006 and September 2016, 124 patients with bile duct dilatation without visible cause in baseline ultrasound underwent CEUS study. All ultrasound studies were performed by the same radiologist .The enhancement and posterior washout were analysed in real time all along the study duration (5'). Final diagnosis provided by CEUS was compared with histologic diagnosis (47.58%) or with radiologic follow-up with TC, RM or ERCP.
Results: Final diagnoses included 89 malignant lesions (cholangiocarcinoma n=41, pancreatic carcinoma n=19, metastases n=16, hepatocarcinoma n=4, gallbladder carcinoma n=4, ampullary carcinoma n=2, lymphoma n=2 and neuroendocrine pancreatic tumour n=1); and 34 patients with benign condition, (lithiasis or sludge n=24, pancreatitis n=2, abscess n=1, xanthogranulomatous cholecystitis n=1, pancreatic serous cystoadenoma n=1, biliar elastance loss=4 and indeterminate n=2). CEUS correctly identified 74 of 89 malignant lesions (sensibility 83,14%) and 26 of 35 benign lesions (specificity 74.28%). The positive predictive value was 89.15% while the negative predictive value was 63.41%.
Conclusion: CEUS is useful to differentiate between benign and malignant causes of biliary obstruction, improves the detection of bile duct invasion in hepatic neoplasms and permits better evaluation of intra- and extraductal extension of hilar hepatobiliary tumours.

B-0869 11:02

Impact of MR elastography in patients with biliary obstruction

D. Kim, Y. Jeong, M.-S. Park, M. Kim; *Seoul/KR (kdk7118@yuhs.ac)*

Purpose: To investigate the impact of liver stiffness measured by MR elastography in patients with cholestasis due to biliary obstruction.
Methods and Materials: Sixty-nine patients who underwent pancreaticobiliary MR with MRE without history of diffuse liver disease were retrospectively included. Quantitative MR parameters including liver stiffness (LS), ADC, R2*, and fat fraction (FF) were measured. Laboratory results including aspartate transaminase (AST), alanine transaminase (ALT), total bilirubin (TB) were obtained. Patients were divided into two groups: patients with normal bilirubin level (group 1) and patients with cholestasis (group 2). Quantitative parameters were compared by independent t-test between two groups. Correlation between parameters was analyzed by Pearson correlation. Diagnostic performance and clinical impact of MR parameters was analyzed by ROC.

Results: Forty-nine patients classified into group 1 and twenty patients belonged to group 2. LS was higher in group 2 (3.8 ± 0.7 kPa) than group 1 (2.8 ± 0.5, p < 0.001), whereas other MR parameters were not different between two groups. There were positive correlation between LS and TB (r=0.611, P < 0.001), as well as the level of AST (r=0.350, P=0.004) and ALT (r=0.258, P=0.035). Furthermore, there was negative correlation between the degree of biliary decompression 1 week after bile drainage and LS (r= -0.71, P=0.003). When cut-off value was set at 4.0 kPa using ROC curve, the sensitivity and specificity for predicting biliary decompression was 84.6% and 100%, respectively.
Conclusion: LS measured by MRE increased as increasing cholestasis and can be a predictive factor for biliary decompression after biliary drainage.

B-0870 11:10

Validation of feasibility of MRI for measurement of depth of tumour invasion in distal bile duct cancer

J. Lee, N. Han, J. Kim, M. Kim, B. Park, D. Sung, K. Sim, S. Cho; *Seoul/KR (serendipish@gmail.com)*

Purpose: The aim of this study was to develop and validate a method for measuring depth of tumour invasion (DoI) on MRI and to investigate the diagnostic performance of measured DoI for the stratification of T classification in patients with distal bile duct cancer.
Methods and Materials: In this retrospective, institutional review board-approved study, 54 patients (30 men, 24 women; age range, 43-81 years) with distal bile duct cancer with available preoperative MRI were registered. A study coordinator and a pathologist developed 'provisional method' for measuring DoI based on published studies. Thereafter, 'improved method' was developed after compensating the defect. Two reviewers independently measured DoI on MRI using 'improved method' and correlations with histopathologic reference standard were evaluated by intraclass correlation (ICC). To evaluate the diagnostic performance of MRI for T classification using DoI, the study population was radiologically and histopathologically assigned into three groups according to the DoI.
Results: ICC between reviewers' measured DoI using 'improved method' and histopathologic DoI was very good or good (ICC coefficient, 0.885 and 0.784) and its' values were significantly higher than that using 'provisional method' (ICC coefficient, 0.501; p-value = 0.00000 and 0.00075). The overall accuracy of the use of MRI for stratifying bile duct tumours using DoI was 68.5 % to 85.2 %.
Conclusion: With the suggested method for measuring DoI on MRI in our study, we can reliably measure DoI on MRI T2-weighted image and MRI is a feasible tool for the preoperative T classification based on DoI.

B-0871 11:18

CT differentiation of benign and malignant gallbladder wall thickening

H. Yang[1], J. Lee[1], S. Lee[1], J. Park[2]; [1]*Seoul/KR*, [2]*Busan/KR (gedanken.yang@gmail.com)*

Purpose: To retrospectively analyse the CT imaging features to characterise gallbladder wall thickening as benign or malignant.
Methods and Materials: CT scans obtained including the portal venous phase in 108 patients with pathologically proven benign (n = 68), uncertain of malignant potential (n = 3), or malignant (n = 41) gallbladder wall thickening were retrospectively reviewed. Two blinded readers independently analysed concentricity, evenness, mucosal smoothness and layered pattern of the gallbladder wall thickening. Presence of multiple tiny enhancing dots in the thickened gallbladder wall, so-called "strawberry dot sign", was also investigated.
Results: Concentric and even wall thickening, smooth contour of the mucosa and double layering enhancement were significant predictors for benign gallbladder wall thickening (p&lt: 0.01 for each finding). Strawberry dot sign was significantly more frequent in benign wall thickening (p&lt: 0.01), particularly in adenomyomatosis (p>0.05). Sensitivities of strawberry dot sign in diagnosing adenomyomatosis were 92% in the reader 1 and 100% in the reader 2. On the contrary, strawberry dot sign was not observed in 70% (reader 1) and 68% (reader 2) of the cases with malignant diseases or uncertain of malignant potential entities.
Conclusion: Analysing the contour and layering of gallbladder wall thickening, and presence of strawberry dot sign on CT is helpful in differentiating benign entities from malignancy.

B-0872 11:26

Bile leakages after hepatic surgery and orthotopic liver transplantation: value of Gd-EOB-DTPA-enhanced MR cholangiography

F. Pacciardi, R. Cervelli, P. Boraschi, F. Donati, S. Salemi, R. Gigoni, M. Della Pina, F. Falaschi, D. Caramella; *Pisa/IT (federica.pacciardi@libero.it)*

Purpose: To assess the diagnostic value of Gd-EOB-DTPA-enhanced MR cholangiography in the detection of bile leakages after hepatic surgery and orthotopic liver transplantation.
Methods and Materials: Thirty-two patients with previous hepatic resection (n=20) or orthotopic liver transplantation (n=12) underwent MR imaging at 1.5T/3T device due to strong suspicion of bile leak, based on a combination of clinical, laboratory and previous imaging findings. After the acquisition of axial T1w/T2w images and conventional MR cholangiography (thin-slab 3D FRFSE and thick-slab SSFSE T2w sequences), 3D fat-suppressed coronal and axial LAVA sequences were performed before, 20 minutes and between 25 and 120 minutes after intravenous administration of 10ml Gd-EOB-DTPA (Primovist®, Bayer HealthCare). Two radiologists in conference evaluated all the images for the presence or absence of bile leak, and its location when present. Imaging results were correlated with direct cholangiography, percutaneous drainage of fluid collection and/or imaging follow-up.
Results: A well-defined collection containing contrast material was detected in 14 out of our 32 patients (one false negative case on MRI). Gd-EOB-DTPA-enhanced MR cholangiography yielded an overall sensitivity of 93%, specificity of 100%, PPV of 100%, NPV of 94% and accuracy of 97% for the diagnosis of an active bile leak. However, the sensitivity of 20 minutes delayed MR images was 47%.
Conclusion: Gd-EOB-DTPA-enhanced MR cholangiography utilizing delayed phase images is a highly reliable technique for the detection of active bile leakages after hepatic surgery and orthotopic liver transplantation. The images obtained 25-120 minutes after hepato-biliary contrast agent injection significantly increased the detection of leaks.

B-0873 11:34

Diagnostic value of Gd-EOB-DTPA-enhanced MR cholangiography in non-invasive detection of postoperative bile leakage

M. Kul, G.A. Erden, E. Düsünceli Atman; *Ankara/TR (melahatkul@yahoo.com)*

Purpose: To assess the value of dynamic T1-weighted (T1w) gadolinium ethoxybenzyl diethylentriamine penta-acetic acid (Gd-EOB-DTPA)-enhanced MR Cholangiography (MRC) for the diagnosis of active bile leaks.
Methods and Materials: A total of 28 patients with suspected biliary leakage who underwent routine T2w-MRC and T1w-GD-EOB-DTPA-enhanced MRC at our institution from February 2013 to June 2016 were included in this study. The image sets were retrospectively analysed in consensus by 3 radiologists. T1-weighted -Gd-EOB-DTPA-enhanced MRC findings were correlated with clinical data, follow-up examinations and findings of invasive-/surgical procedures. Patients with positive bile leak findings in Gd-EOB-DTPA-enhanced MRC were divided in hepatobiliary phase (HBP) (20-30 min) and delayed phase (DP) group (60-390 min) according to elapsed time until detection of bile leak after Gd-EOB-DTPA injection. These groups were compared in terms of laboratory test results (total bilirubin, liver function tests) and presence of bile duct dilatation in T2w-MRC images.
Results: The accuracy, sensitivity and specificity of dynamic Gd-EOB-DTPA-enhanced T1w-MRC in detection of biliary leaks were 92.9%, 90.5%, and 100%; respectively (P<0.001). Nineteen of 28 patients had bile leak findings in MRC, with 7 patients (36.8%) in HBP group and 12 patients (63.2%) in DP group. There was no statistically significant difference in terms of laboratory test results and presence of bile duct dilatation between HBP and DP group (P>0.05).
Conclusion: Dynamic T1-weighted Gd-EOB-DTPA-enhanced MRC is a useful non-invasive diagnostic tool to detect bile leak and prolonged delayed phase imaging may be required if extravasation of Gd-EOB-DTPA is not visible in HBP.

B-0874 11:48

An investigation into the use and outcomes of percutaneous transhepatic cholangiogram (PTC)

M. Renton, A. Ganeshan; *Birmingham/UK (mary.renton@nhs.net)*

Purpose: Percutaneous transhepatic cholangiogram (PTC) provides imaging of the biliary system. PTC is indicated for investigation and treatment of biliary obstruction. We investigate the use of PTC and factors that potentially predict outcomes.
Methods and Materials: We conducted a one-year retrospective case-note review of PTC procedures at Birmingham Heartlands hospital from September 2014. The following was recorded:-Patient: diagnosis and bloods-Procedure: intervention, antibiotics and technical success-Outcomes: bloods (day 1, 7 and month 1) and complications.

Results: 162 PTCs were performed in n=108 (59 male, mean 70.4 years). Malignant disease accounted for 76% of diagnoses, with 91% palliative cases. Baseline bloods included: bilirubin 194.73umol/L, albumin 23.09g/L and INR 1.25 with 16.3% >1.4. Procedures included 115 drains, 28 biopsies and 54 stents. Reduction in bilirubin occurred at day 1 (13.48 ±7.6), 7 (64.63 ±101.2) and persisted at month 1 (132.03 ±139.9). Sepsis occurred in 19% and fatal haemorrhagic pancreatitis developed in one patient. Hospital stay was 9.83days (±11.9) with 9% failed discharges. 7- and 30-day mortality were 12 (11%) and 28 (26%), respectively. Baseline bilirubin, haemoglobin and INR predicted mortality (p=0.015, 0.014, 0.018). Baseline albumin predicted delta bilirubin post-PTC (at all follow-up intervals p=0.02, 0.046 and 0.041) and hospital stay (p=0.002). Benign disease is a negative predictor for sepsis, p=0.006.
Conclusion: PTC is primarily used for palliative management of malignancy. It has a high technical success rate with substantial risk. Bilirubin, haemoglobin and INR should be considered in risk profiling to optimise patient selection.

B-0875 10:30

Feasibility of high-resolution MR lymphangiography in planning lymphaticovenous anastomosis treatment: a single-centre experience
F. Gentili, F.G. Mazzei, P. Gennaro, D. Notaro, A. Fausto, M.A. Mazzei, L. Volterrani; *Siena/IT (francescogentili@gmail.com)*

Purpose: To demonstrate the feasibility of MR lymphangiography (MRL) for imaging lymphatic vessels in patients with lymphoedema, its accuracy in distinguishing lymphatic vessels from veins, and its utility for planning lymphaticovenous anastomosis (LVA) treatment.
Methods and Materials: We prospectively enrolled 16 consecutive patients (13 female, range 18-70). All the patients underwent MRL, using a 1.5 T MR unit (Signa Twin Speed Hdxt; GE), after the intracutaneous injection of gadobenate dimeglumine (Gd-BOPTA) with a little dose of lidocaine into the interdigital webs of the dorsal foot or hand. Lymphatic vessels and veins identified for the LVA at MRL were histologically confirmed after surgery. Enhancement of lymphatic vessels and veins at different times after injection of contrast medium and their diameters were measured.
Results: Pathological lymphatic vessels were clearly recognised because of their tortuous and beaded appearance, whereas, the adjacent veins were straight with focal bulging only at the level of venous valve; the enhancement kinetic of the two different structures were different ($p<0.05$); the mean diameter of affected lymphatic vessels was similar to the adjacent veins ($p>0.05$). Thirty-four out of 38 specimens of presumed lymphatic vessels at MRI, collected during surgery, resulted positive at the immunoistochemical marker d2-40, with a significant association (Chi square=40.421, DF=1, $p<0.05$, contingency coefficient 0.644).
Conclusion: MRL is easy and safe to use and combines extensive informations on the anatomy and functionality of lymphatic vessels and veins in a single process; therefore, it could be useful in planning LVA treatment in patients with lymphoedema.

B-0876 10:38

Vector flow imaging evaluation of stenotic and functioning haemodialytic accesses
M. Raciti[1], I. Fiorina[1], A. Goddi[2], F. Calliada[1]; [1]*Pavia/IT*, [2]*Varese/IT (mariavittoria.raciti@libero.it)*

Purpose: The aim of this retrospective study is to evaluate the different features of the flow in arteriovenous fistulas (AVFs) between well functioning and stenotic accesses through vector flow imaging and in comparison with conventional Doppler.
Methods and Materials: Ultrasound VFI describes the flow through the use of many coloured vectors, representing velocity, magnitude and direction in every point of the vessel. 2 experienced radiologists examined vascular accesses of 6 patients (2 females, 4 males; age ranging from 32 to 83 years, median age 57.5 years), comparing vector flow imaging and Doppler through Resona 7 ultrasound scanner (Mindray, Shenzen, China).
Results: Doppler examination showed the presence of significant stenosis in 2 cases and good AVFs patency in 4 patients but did not provide any information regarding the flow layers' direction. VFI evidenced the presence of high-velocity vectors (mean 45-50 cm/s) directed against the vascular walls in correspondence of the stenosis, despite lower velocity orthogonal arrows (mean 20-25 cm/s) in well-functioning accesses.
Conclusion: The development of significant stenosis in arteriovenous fistulas could be correlated with wall shear stress, determined by the presence of orthogonal components of the flow against the vessel wall. VFI can help to show and identify high-velocity vectors facing the vascular surface. Further studies are in progress to demonstrate this relationship.

Acute or subacute DVT - role of real time elastography for determining the age of thrombi
A. Aslan[1], E. Ayaz[1], H. Barutca[1], C. Kocaaslan[1], M. Aslan[1], I. Inan[2], S. Sahin[1], A. Yıkılmaz[1]; [1]*Istanbul/TR*, [2]*Adıyaman/TR (ercan_ayaz@yahoo.com)*

Purpose: Exact age of deep venous thrombosis (DVT) is of high importance for an appropriate treatment. The elasticity imaging could be a good way to estimate the age of DVT. In this study, real time elastography (RTE) which measures the hardness of tissue is used to detect and characterise changes in stiffness of thrombus in vessels semiquantitatively.
Methods and Materials: Patients who were diagnosed with CDUS and serum D-dimer level as acute DVT were enrolled into study and scheduled for follow-up imaging by CDUS after 15-30 days from initial diagnosis. RTE was performed together with CDUS and stiffness of thrombi classified into 3 as soft, intermediate, hard.
Results: 44 patients of acute DVT were enrolled in the study and 27 of them came back for control imaging. RTE could not be performed in 3 patients with acute DVT and 6 patients with subacute DVT. The elasticity patterns of 41 acute DVT were; 10 (24.4%) hard, 20 (48.8%) intermediate, 11 (26.8%) soft. The elasticity patterns of 21 subacute DVT were; 8 (38.1%) hard, 7 (33.3%) intermediate, 6 (28.6%) soft. But there was no statistically significant difference between elasticity patterns of acute and subacute DVT ($p = 0.463$)
Conclusion: In contrast to most of the previous studies which were strongly suggest that RTE can determine the age of DVT, we did not find any statistical significant difference between acute and subacute DVT in terms of tissue stiffness that is obtained by RTE.

B-0878 10:54

Venous thromboembolism in radiation oncology: retrospective trial
M. Cherkashin, N. Berezina, A. Serov, N. Vorobyov; *St. Petersburg/RU (mikhail.a.cherkashin@gmail.com)*

Purpose: To generate clinical evidence for VTE risk assessment in patients with radiation therapy.
Methods and Materials: In retrospective analysis, 3280 medical record were included (1612: RT and 1668: chemotherapy). Inclusion criteria: RT in outpatient setting, chemotherapy in outpatient setting. Exclusion criteria: combined radiochemotherapy, hospitalisation, central venous catheter, palliative treatment. We have selected 360 patients, stratified into 3 groups: group I (n=120) 3D-conformal RT for brain tumours or brain metastasis; group II (n=120) RT for body tumours (abdominal, retroabdominal, pelvic, chest, breast); group III (n=120) was control - brain and body tumours on chemotherapy. Mean fraction numbers - 25 (11 - 32), mean total dose - 52 Gy.
Results: Deep vein thrombosis (DVT) was detected in 7 cases (5.8%) in group I, in group II - 2 cases and in control - 1 case. VTE patients has a different tumours (right parietal area astrocytoma, brain trunk tumour, skull basis cancer, rectal cancer, breast cancer). 3 patients were available for long-term outcomes assessment (12 months after RT). During 1-year period we haven't detected thrombosis recurrence. Posthrombotic disease was developed without severe venous insufficiency. Difference between VTE incidence for group I and group III characterised by statistical significance ($p<0.05$). Risk difference for these groups was 5% ($p<0.05$)
Conclusion: External beam radiation therapy potentially may be an independent risk factor for VTE development in outpatient setting. These patients need to be strongly assessed for VTE prophylaxis

B-0879 11:02

Anatomy of the collateral venous drainage in late pregnancy in different positions
S.A. Mirjalili, G.P. Tarr, G. Williams, P. Stone; *Auckland/NZ (greg.tarr@otago.ac.nz)*

Purpose: Sleeping position has been associated with stillbirth, with increased risk in supine position. The gravid uterus can cause hypotension by compression of the inferior vena (IVC), but the path of venous drainage is not known in this setting. The aim of this study is to investigate collateral systemic venous drainage in late pregnancy in different positions.

Methods and Materials: After obtaining ethics approval and written consent, 5 healthy pregnant women 35-38 weeks gestation underwent MR in supine and left decubitus position (Siemens Skyra 3T) with T2 TRUFI and phase contrast flow. Measurements were obtained of cardiac output, calibre of inferior vena cava, azygous vein and abdominal aorta). Paired t-tests were used to compare intra-individual measurements.
Results: Cardiac output was unchanged in both positions. The IVC was completely collapsed at its origin in supine position in all cases. Compared to the decubitus position, supine positioning was associated with decreased cross sectional area of the IVC at the level of the liver (3.5 cm^2 [95% CI 2.7 to 4.3 cm^2] vs 5.5 cm^2 [95% CI 3.8 to 7.1 cm^2], p = 0.049) and increased cross sectional area of the azygous vein (0.36 [95% CI 0.03 to 0.68 cm^2] vs 0.77 cm^2 [0.48 to 1.06 cm^2], p = 0.008).
Conclusion: Healthy pregnant women without symptomatic supine hypotension maintain cardiac output when lying flat with increased distention of collateral venous drainage via the azygous venous system. These findings may help elucidate the contribution of systemic venous drainage to risk of stillbirth.

B-0880 11:10

Role of MRI in detecting lower limb incompetent perforator veins
B.K. Soni[1], H. Sahni[2], A. N[1]; [1]*Bangalore/IN*, [2]*Jorhat/IN*
(taureandoc@gmail.com)

Purpose: To differential incompetent perforators from competent perforator on the basis of size on MRI.
Methods and Materials: The prospective study was carried out in 30 patients during a period of six months at a tertiary care hospital in India after approval from institutional ethical committee. There were a total of 81 perforators studied and evaluated by both colour Doppler and True FISP, fat saturated axial sequence of MRI. The number and location of the perforators detected on Colour Doppler and MRI were documented and correlated.
Results: The study results shows that any perforator more than or equal to 2.8mm has got a positive predictive value of more than 95% for being incompetent and any perforator more than or equal to 3.4mm has got a 100% positive predictive value for being incompetent. The mean diameter of incompetent perforator was 3.57 and that of competent perforator was 2.27mm.
Conclusion: Addition of MRI to the colour Doppler in assessment of incompetent perforators in assessment of varicose veins is of tremendous importance especially in those patients planned for Foam Sclerotherapy. It is non-operator dependent and entire set of images is available for review and comparison.

B-0881 11:18

Recent diagnostic opportunities in ultrasound diagnostics of lower extremities deep veins thrombosis
A. Demidova, A. Zubarev, N. Krivosheeva, I. Rychkova; *Moscow/RU*
(333555.78@mail.ru)

Purpose: The aim of our study was to analyse physical basis and assess opportunities and advantages of new ultrasound technologies quantitative assessment of acoustic structures (Acoustic Structure Quantification, ASQ), ultrasound elastography (USE), mapping of microvascular bedflow with high spatial and temporal resolution (Superb Microvascular Imaging, SMI) in evaluation of patients with venous thrombosis of lower extremities.
Methods and Materials: The study involved 72 patients (41 men - 56,9% and 31 women - 43,1%) aged 42-85 with venous thrombosis of lower extremities (144 lower extremities). All patients had undergone standard ultrasound investigation including B-mode, colour duplex or power Doppler imaging modes. In addition to standard modes we used new ultrasound technologies announced by Toshiba Medical Systems in ultrasound system Aplio™ 500.
Results: We assessed condition of main veins of lower extremities, including revealing of thrombotic changes and estimation of the spreading level and composition of thrombotic masses. During dynamic follow-up signs of the initial stages of recanalisation were revealed and comparison of thrombolysis process intensity with further follow-up studies was performed. A significant advantage of new technologies in comparison with a standard ultrasound examination was established.
Conclusion: ASQ, USE and SMI of Toshiba Medical Systems can be effectively used for examining patients with venous thrombosis in the system of inferior vena cava. Taking into consideration the fact that these technologies are highly informative, not time consuming and simple in everyday use they can be recommended to be included into standard ultrasound investigation for precise assessment of revealed abnormalities.

B-0882 11:26

MR-venography in the diagnosis of post-thrombotic iliac vein obstruction and extravascular compression
V. Shebryakov, Y. Stoyko, M. Yashkin, G. Karmazanovskiy, D. Lutarevich;
Moscow/RU (VSHEBRYAKOV@MAIL.RU)

Purpose: Evaluate the information value of magnetic resonance imaging (MRI) in the diagnosis of post-thrombotic iliac vein obstruction and extravascular compression.
Methods and Materials: The study included 28 patients with CVD (clinical class C3-C6 according to the CEAP classification), including 7 men and 21 women. The average age was 43.6±11.6 years. Studies were performed from December, 2014 to June, 2016 on Optima MR360 MRI using a special protocol non contrast MR-venography in the sequences: 1. BH FIESTA (TRA, COR, SAG) using samples of Valsalva; 2. INHANCE 3D (SAG or COR) on the free breathing, with subsequent MIP and 3D reconstruction. Scan time no more than 15 min.
Results: Thirteen patients have been diagnosed with stenosis of the left common iliac vein due to compression of the right common iliac artery, with the lumen of the left common iliac vein was 4.1±1.6 mm, and the length of stenosis was 16.8±5.5 mm. One patient underwent stenting of left common iliac vein (self-expanding stent Wall-stent Uni Endoprotesis) with the syndrome Mey-Turner, the velocity of blood flow on Doppler ultrasound before the operation had the following characteristics: 55-63 cm/sec before stenosis and 84-110 cm/sec after. After stenting, the linear velocity of blood flow in the OPV was 40-45 cm/sec.
Conclusion: Non-contrast MR-venography is the most optimal screening method in the diagnosis of the causes of extra - and intravenous pathology of the IVC and its basin. 3D-reconstruction of the IVC and iliac veins can be used for planning reconstructive, corrective and reconstructive operations.

B-0883 11:34

Arterialisation of venous thrombosis as an indicator of tumoural vascular spread
G.G. Leal, J. Crosta, M. Centurion, M. Diaz Fusi, D. Sanchez, F. Abramzon;
Buenos Aires/AR (grettelealh@gmail.com)

Purpose: To describe the sonographic findings of venous thrombosis with arterial vascularisation within the tumour thrombus associated disease. Demonstrate the presence of arterial flow with color Doppler and spectral in the thrombotic material. Report enhancement with contrast ev of these thrombosis in the tomographic study. Emphasise the importance of these signs to suspect the presence of a tumour and vascular spread it.
Methods and Materials: Descriptive study. Case series. Ultrasonographic and tomographic images of three patients of our institution without prior cancer diagnosis, in which deep vein thrombosis by Doppler ultrasound was diagnosed in different anatomical territories are presented. Also presented with color Doppler and spectral, arterialisation of thrombosis, detected as arterial flows within the venous lumen occupied. It was detected in a nearby tumour posteriorly, checking vascular spread. Tumour pathologies were detected hepatocellular carcinoma, uterine sarcoma and pancreatic adenocarcinoma.
Results: Images are shown with the following findings: the presence of venous thrombosis level, arterial flows into the venous thrombus, the existence of tumoural pathology associated to thrombosis, enhancement with contrast ev. Thrombus in tomographic study. In US Doppler of the three patients it was observed thrombotic material endoluminal level in the scanned veins, with blood flow within the thrombus. Arterialisation demonstrated by spectral analysis. Also completed checking tomographic study thrombus enhancement with contrast ev.
Conclusion: The arterialisation venous thrombus in patients with no known history of tumour pathology should be suspected a hidden tumour and must be emphasised in the search for a primary for a final diagnosis.

B-0884 11:42

Time of flight MR venography - an important tool for evaluation of lower limb venous abnormalities
M.M. Kulkarin; *Mumbai/IN (makarand_kul@yahoo.com)*

Purpose: Time of flight (TOF) MR venography (MRV) is an effective, non-contrast technique which gives a road map of deep venous system to vascular surgeons. Doppler is an operator dependant modality leading to discrepancy in Interpretation. Contrast CT and contrast MRV lead to contamination of superficial veins and arteries leading to difficulty in visualisation of deep venous system.
Methods and Materials: We studied 175 patients of venous insufficiency on TOF MRV and Doppler. MRV was performed on 1.5 and 3 Tesla MRI with patient in supine position using surface body array coil. The saturation band was placed at the kidney level to block the arterial signals. Doppler was performed independently.

Results: We found discrepancy between the Doppler and TOF MRV in 44 patients (25%). Doppler was normal in 16 patients (9.4%) while MRV showed evidences of chronic deep vein thrombosis, mainly in pelvic veins. MRV gave important information about other causes of venous insufficiency like pelvic vein compression by adjacent artery (89%) or by tumour (1.6%). MRV also helped in therapeutic planning (venoplasty) in the patients with deep vein thrombosis in pelvic veins.
Conclusion: TOF MRV is an important adjuvant to Doppler in evaluation of patients with lower limb venous insufficiency with main advantage in the diagnosis of the pelvic vein abnormalities. It gives an anatomical depiction for the vascular surgeon while doing interventions. Due to static images, it is difficult to diagnose varicose veins and incompetent perforators which is limitation of this modality.

B-0885 11:50

May-Thurner syndrome: no pain, no gain
P. Armelin; *Campinas/BR (plinioarmelin@hotmail.com)*

Purpose: To spread knowledge of this disease and demonstrate the technical aspects of angiotomography for the accurate diagnosis, its treatment and possible complications.
Methods and Materials: We selected 20 cases with suspicion of May-Thurner syndrome. Patients underwent angiotomography with podalic contrast injection technique.The podalic venous puncture is more painful than the antecubital vein. However, the contrast injection flow is lower. The collateral circulation is better demonstrated, as well the identification of complications.
Results: The May-Thurner syndrome is a rare disease caused by compression of the left common iliac vein by the right common iliac artery, providing a number of symptoms depending on the degree of compression. Among them: asymmetrical swelling of the left lower limb, pain, unilateral varicose veins, ulcers and deep vein thrombosis. The syndrome is diagnosed in 2-5% of patients with chronic venous diseases. Most patients are women between the 2nd and 4th decades of life. This technique showed to be superior to the conventional techniques, such as Doppler ultrassound, conventional angiotomography, conventional angioresonance and venography. The endovascular treatment is safe, effective and reduces symptoms in most patients. It is associated with high rates of vascular patency and is the best option compared to conventional techniques and clinical treatment.
Conclusion: The angiotomography with podalic contrast injection technique was more effective in screening and diagnosis of May-Thurner syndrome, enabling the treatment planning and assessment of associated complications.

Psoas muscle density predicts survival of cirrhotic patients undergoing transjugular intrahepatic portosystemic shunt
M. Shoreibah, S. Kim, S. Moawad, A. Abouarab, K. Mahmoud, B. Jackson, M.O. Massoud, S. Saddekni, A.M.K. Abdel Aal; *Birmingham, AL/US (snkim@uabmc.edu)*

Purpose: Sarcopenia is a common complication in cirrhotic patients and is also an independent predictor of survival in patients undergoing liver transplantation. The purpose of our study is to determine if the psoas muscle density (PD) can be used as a predictor of survival in cirrhotic patients who had transjugular intrahepatic portosystemic shunt (TIPS) placement.
Methods and Materials: We retrospectively reviewed the medical records of 216 patients who had TIPS placed between June 2005 and June 2015. We compared PD using the non-enhanced pre-TIPS CT scans. The primary endpoint was to determine if PD correlates with patient survival after TIPS. The secondary endpoint was to determine a threshold sensitivity of pre-TIPS PD for assessing mortality.
Results: The study included 134 (62%) males, 148 Caucasians (68.5%) with an average age of 56 years (SD=9.6). The main causes of cirrhosis were nonalcoholic steatohepatitis (30.6%), hepatitis C (23.2%), & alcoholic cirrhosis (20.8%). No significant difference between the pre-TIPS PD in the different etiologic groups (p=0.95). TIPS was performed for intractable ascites & variceal bleeding in 50.9% and 49.1% of the patients respectively. Mean MELD score was 13 and 16 before and after TIPS respectively. A higher pre-TIPS PD was associated with lower risk of mortality [HR= 0.52, 95%CI (0.32, 0.85), p=0.0088]. Threshold sensitivity of pre-TIPS psoas muscle density for assessing mortality was 43.63 HU (p=0.0049).
Conclusion: PD is a predictor of survival after TIPS placement in cirrhotic patients. A PD of more than 43.63 HU is associated with lower risk of mortality.

5 years of portal vein embolisation prior to major hepatectomy
J.H. Luz, P. Luz, H. Gouveia, H. Martin, I. Faria, R. Souza, H. de Souza; *Rio de Janeiro/BR (jhugoluz@gmail.com)*

Purpose: To assess the efficacy, safety and lessons learned from portal vein embolisation prior to major hepatectomy, performed along 5 years in a single reference cancer centre, applying cyanoacrylate and lipiodol mixture as the embolic material.
Methods and Materials: From August 2011 through August 2016 forty-one patients (mean age: 55.9 years [5-80 year]) underwent trans-hepatic portal vein embolisation for colorectal liver metastases (n=29), hepatocellular carcinoma (n=2), cholangiocarcinoma (n=5), occult primary liver metastases (n=1), Wilms tumour liver metastases (n=1), Gist liver metastases (n=1) and hepatoblastoma (n=2). Assessment of future liver remnant was achieved by computed tomography volumetric measurements before and 4 weeks after portal vein embolisation. Adverse events were recorded for all patients.
Results: Technical success was 98% (one patient was submitted to a second portal embolisation procedure because of a patent segment VI branch). Three serious complications occurred: 1 patient died within 30 days of portal vein embolisation due to progressive liver insufficiency, 1 patient had unintentional cyanoacrylate migration to liver segment III and 1 patient developed a large biloma which was drained percutaneously. Resection was performed in 29/41 patients. After the waiting period (follow-up computed tomography was performed 21-46 days [median, 31 days]), the future liver remnant volume and future liver remnant to total liver volume ratio increased significantly (from a median value of 491g to 654g - Wilcoxon signed rank test p<0.001).
Conclusion: Although portal vein embolisation with cyanoacrylate-lipiodol mixture effectively produces future liver remnant augmentation, proficiency in the embolic agent usage must accompany this type of technique.

B-0888 10:46

Transjugular intrahahepatic stent-shunt (TIPSS) placement using C-arm cone-beam CT (CBCT) real-time 3-D-guidance-initial clinical experience
G. Böning[1], W. Lüdemann[1], J. Chapiro[2], M. Jonczyk[1], G. Wieners[1], D. Schnapauff[1], B. Gebauer[1], R.W. Günther[1], F. Streitparth[1]; [1]*Berlin/DE*, [2]*New Haven, CT/US (georg.boening@charite.de)*

Purpose: One of the technically most challenging procedures in interventional radiology is the placement of a transjugular intrahahepatic stent shunt (TIPSS). Aim of this study was to evaluate the feasibility of Cone-Beam CT (CBCT)-based real-time 3-D-guidance in TIPSS placement and relative dose of CBCT.
Methods and Materials: Real-time, 3-D-guidance based on a C-arm acquired CBCT (Allura Xper FD20 and XperCT, Philips Healthcare, Andover, USA) was used in 13 patients. Indications for TIPSS placement were therapy-refractory ascites in 12 cases and acute bleeding in 1 patient. Technical success of TIPSS-placement, puncture-time to assess portal-venous system, number of punctures needed and applied radiation dose of the intervention as well as relative dose of CBCT were documented.
Results: TIPSS could be successfully implanted in 12 of 13 patients (92 %). CBCT-based guidance for portal vein puncture was possible in all patients. Due to difficult anatomical situation in one patient the TIPSS could not be implanted neither after using additional US-guidance. Mean puncture time was 12±14 minutes, with 3±3 punctures needed in the 12 patients with technical success. During intervention total applied dose (dose area product, DAP) was 479±222Gy/cm². Relative dose of CBCT was 5±3%.
Conclusion: The use of CBCT-based real-time 3-D-guidance for portal vein puncture in TIPSS-placement was feasible and the relative dose of CBCT is low compared to total dose of intervention. This guidance technique has the potential to facilitate the TIPSS implantation, which has to be proven in further studies.

Worsening of sarcopenia after transjugular intrahepatic portosystemic shunt
A.M.K. Abdel Aal, S. Kim, S. Moawad, B. Jackson, A. Abouarab, K. Mahmoud, N. Ghaleb, M.O. Massoud; *Birmingham, AL/US (akamel@uabmc.edu)*

Purpose: Sarcopenia is a common complication in cirrhotic patients and adversely affects the morbidity and mortality in these patients. The purpose of our study is to determine the change in psoas muscle density (PD) after

transjugular intrahepatic portosystemic shunt (TIPS) placement and its correlation with model of end-stage liver disease (MELD) score.
Methods and Materials: We retrospectively reviewed the medical records of 84 patients who had TIPS placed between June 2005 and June 2015. We compared the PD on the pre and post-TIPS non-enhanced CT scans.
Results: The study included 60 males (71.4%), 62 Caucasians (73.8%) with an average age of 53.9 years (SD=7.9). TIPS was performed for intractable ascites (50.9%) and for variceal bleeding (49.1%). There was a decrease in the PD (47.98 to 46.34HU) after TIPS placement but was not statistically significant (p=0.14). The change in PD did not vary significantly based on the MELD score. There was a significant increase in the MELD score after TIPS (12 to 15, p<0.0001) and decrease in serum albumin (2.8 to 2.61g/dL,p=0.04). There was no significant correlation between the change in PD and MELD score (r=0.03, p=0.81) or serum albumin (r=-0.09, p=0.40). There was a statistically significant negative correlation between PD and BUN (r=-0.301, p=0.0053), Cr (r=-0.221, p=0.0446), and bilirubin (r=-0.290,p=0.0082) after TIPS.
Conclusion: PD worsens after TIPS placement in cirrhotic patients. The change in PD does not correlate with MELD score or serum albumin. Further prospective studies with larger patient population are required to assess the validity of these results.

Transjugular intrahepatic portosystemic shunt prior to abdominal surgery: outcomes in cirrhotic patients

M. Shoreibah, S. Kim, M. Naseemuddin, A. Abouarab, K. Mahmoud, S. Moawad, A.M.K. Abdel Aal; *Birmingham, AL/US (snkim@uabmc.edu)*

Purpose: Abdominal surgery in patients with liver disease has been associated with an increased risk of perioperative mortality related to increased porto-systemic gradient (PSG). The purpose of our study is to evaluate pre-operative Transjugular intrahepatic portosystemic shunt (TIPS) placement in patients with cirrhosis and its effect on perioperative mortality.
Methods and Materials: A retrospective study of 16 patients with cirrhosis who had TIPS placement prior to abdominal surgery between 2010 and 2015. We used the Mayo Clinic post-operative (PO) mortality risk calculator to determine the expected 30-day mortality and compared it to the observed mortality in our cohort.
Results: Sixteen patients with cirrhosis (75% males, mean age of 50.3+10 years) were included. Fifteen patients had decompensated cirrhosis (ascites: 93%, variceal bleeding: 26.7% and hepatic encephalopathy: 60.0%) while 1 patient had ascites due allograft dysfunction after orthotopic liver transplant. The mean PSG was reduced from 14.8±5.0 mmHg pre-TIPS to 5.3±2.7 mmHg. The MELD score increased from 13.6±4.4 to 15.7±4.5. Median time to surgery was 39 days. Median hospital stay was 4 days. The mean expected PO 30-day mortality risk was 27.3±21.6%. Observed 30-day PO mortality rate was found to be 0%. Data was available on 12/16 patients at one year and the observed mortality was 8%. One patient, with a PO 30-day mortality risk of 43.6%, died (78 days from the procedure) and 5 patients received liver transplant.
Conclusion: Our retrospective review indicates that pre-operative TIPS placement in patients with decompensated cirrhosis, especially ascites, can help reduce the PO mortality.

Correlation between port-systemic pressure gradient and changes in platelet count following transjugular intrahepatic portosystemic shunt

A.M.K. Abdel Aal, S. Kim, M. Shoreibah, M. Babi, B. Jackson, M. Massoud, S. Moawad, A. Abouarab, A.S. Moustafa, S. Saddekni; *Birmingham, AL/US (snkim@uabmc.edu)*

Purpose: Platelet count is an important laboratory metric that reflects the change in portal pressure after transjugular intrahepatic portosystemic shunt (TIPS) placement. The purpose of this study is to demonstrate if there is a correlation between the changes in platelet count after TIPS with the change in portosystemic pressure gradient (PSG).
Methods and Materials: We retrospectively reviewed the medical records of 306 patients who had TIPS placed between January 2004 and December 2015. We stratified the patients into 4 groups according to the pre-TIPS platelet count: group1 (0-20), group2 (20-50), group3 (50-100), group4 (100-150). We calculated the percent change in platelet count before and after TIPS as well as the percent change in PSG for each group.
Results: The study included 193 (63%) males and 113 (37%) females, 208 Caucasians (68%), with a mean age of 56.6 years. There was an overall increase in the platelet count after TIPS (mean=17%, SD=62%). Patients in groups 1,2,3 and 4 showing a mean of 243%, 59%, 25% and 0.26% increase in platelet counts respectively which was significant between the groups. There was a negative correlation between the change in the platelet count and the change in PSG which decreased after TIPS (mean=67%, SD=17%) and was not significantly different between the groups.
Conclusion: Pre-TIPS platelet count is an important indicator of the improvement in platelet count after TIPS. The change in the platelet count correlates with the change in PSG, and can be used as an indicator for improvement of PSG after TIPS.
Author Disclosures:
A.M.K. Abdel Aal: Consultant; St jude medical, Boston Scientific, WL Gore, Baxter Healthcare, Bard Peripheral Vascular Inc.. Grant Recipient; BTG, Covidien, Bard, Boston Scientific, Sirtex. Research/Grant Support; Celonova, Boston Scientific. **S. Saddekni:** Consultant; St Jude Medical.

Use of C-arm cone-beam CT for intraprocedural image fusion and 3D guidance in portal vein embolisation

W. Lüdemann[1], G. Böning[1], J. Chapiro[2], M. Jonczyk[1], R.W. Günther[1], B. Gebauer[1], B. Hamm[1], F. Streitparth[1]; [1]*Berlin/DE*, [2]*New Haven, CT/US (willie-magnus.luedemann@charite.de)*

Purpose: Portal vein embolisation (PVE) is applied to patients with extended oncologic liver disease and is meant to induce hyperplasia of non-embolised liver segments to make surgery feasible. Sonographic guidance is the gold standard for percutaneous portal vein access. This study evaluated the feasibility and safety of C-arm cone-beam computed tomography (CBCT) for needle guidance.
Methods and Materials: 10 patients with an indication for PVE and limited sonographic visualisability of the intrahepatic portal vein or unsuccessful previous PVE procedure were enrolled. Puncture was performed under 3D needle guidance in a volumetric data set. CT or MR baseline scans were either registered to a native CBCT or a contrast enhanced CBCT was generated. Technical feasibility, technical success, dose parameters as well as puncture time, defined as time between CBCT acquisition and successful portal vein access were evaluated.
Results: All interventions were technically successful. The mean number of puncture attempts was 4±3. The mean applied dose (dose area product, DAP) of the interventions was 346±251 Gy/cm². The relative share of CBCT-related radiation exposure in relation to the entire intervention was 5.9±3.4%. The puncture time was 20.1±17.8 minutes.
Conclusion: CBCT-guided PVE is feasible and safe and the relative dose of CBCT is low compared to total dose of intervention. This technique may be a promising approach especially for difficult anatomic situations that limit the use of sonography for needle guidance.

Portal vein malignant thrombus recanalisation by endoportal RFA with metal stent placement (VesOpen procedure): rationale, technique and application

M. Mizandari[1], T. Azrumelashvili[1], N. Habib[2]; [1]*Tbilisi/GE*, [2]*London/UK (mgmizandari@gmail.com)*

Purpose: The novel technique of PV thrombus recanalisation is presented.
Methods and Materials: 18 patients underwent percutaneous endoportal RF treatment attempt. PV tributary is accessed under US guidance; manipulation by 5 Fr diameter guiding catheter is used to conduct the guidewire across the blocked segment and portography is performed. 15 Watts power was applied for 2 minutes using bipolar endoluminal RF device (Habib™ EndoHPB, EMcision Ltd., London, UK), placed in PV blocked segment according the guidewire. The number of RF application sessions depends on tumour thrombus extent as shown on portography. After RF application self-expanding 14 mm diameter vascular stent is positioned and PV patency restoration is documented by final portography. Procedure is completed by procedure track RF ablation and/or coil embolisation.
Results: The procedure was completed in 13 (72.2%) cases; in 3 (16.7%) cases we could not conduct the wire across the thrombus; in 2 (1.1%) cases we failed to conduct the RF device and procedure was completed by stenting. Portal vein obstructed segment showed the restored blood flow in all completed cases as documented by postprocedure portography, follow-up Doppler and CT studies; this resulted in liver function improvement in 8 (61.5%) of procedure technical success cases. Recanalised PV patency varied from 3 weeks to 22 months; in 4 cases patients underwent successful TACE procedure after PV recanalisation.
Conclusion: PV thrombus percutaneous recanalisation by endoportal RFA with subsequent stenting is an effective technique and should be suggested as a possible treatment option for HCC patients, complicated with PVT.

B-0895 11:34

Spontaneous portosystemic shunts embolisation in cirrhotic patients with recurrent hepatic encephalopathy: more than ten years of experience

C. Parra-Fariñas, M. Perez Lafuente, I. Díez Miranda, C. González-Junyent, Q. Ordi-Camprubí, M. Salcedo Allende, S. Dyer Hartnett, J. Prat Matifoll, A. Segarra Medrano; *Barcelona/ES (carmenparrafarinas@gmail.com)*

Purpose: Spontaneous portosystemic shunts (SPSS) provide an explanation for hepatic encephalopathy (HE) persistence in cirrhotic patients. Medical treatment alone may have limited success and frequently needs subsequent hospitalisation. This study aimed to assess the efficacy and safety of SPSS endovascular management.
Methods and Materials: From February 2002 to October 2016, a prospective study of 36 consecutive cirrhotic therapy-refractory HE patients who underwent SPSS embolisation was performed. Baseline characteristics, diagnostic workup, therapeutic method, and clinical and radiological outcomes were recorded.
Results: Mean age was 61.8±14.6, 52.8% male. Chronic liver damage was caused by alcoholic abuse (34.7%), HCV (23.1%), cryptogenic (23.1%), non-alcoholic steatohepatitis (11.5%), primary biliary cirrhosis (3.8%), and autoimmune hepatitis (3.8%). Prior to embolisation, seven patients had liver transplants. Doppler-colour ultrasound, CT-angiography and/or portography provided proof of the shunt. SPSS included spleno-renal (67.6%), meso-caval/renal (20.6%), gastro-azygos/renal (8.8%), and recanalised para-umbilical veins (3.0%). Approaches were common femoral vein (61.5%), internal jugular vein (26.9%), transhepatic (7.7%), and transplenic (3.9%). Used materials were coils (72.0%), occlusion devices (24.0%), or combination (4.0%). Secondary procedures were performed in four patients after identification of revascularised SPSS. All patients improved autonomy and decreased severity of the worst HE episode. Follow-up range was 3-31 months. One patient had transient low cardiac output due to acute shunt-closure. There were no other procedure-related complications, portal hypertensive gastropathy or varices development.
Conclusion: SPSS embolisation served as an effective and safe complementary or curative treatment for cirrhotic patients with recurrent HE, even after liver transplantation, improving quality of life by reduction of hospitalisations.

Safety of catheter embolisation of pulmonary AVMs in Osler patients: evaluation of peri-interventional complications on pre- and post-interventional MRI

G. Schneider, P. Raczeck, L. Fenzel, A. Bücker, A. Massmann; *Homburg/DE (dr.guenther.schneider@uks.eu)*

Purpose: Recommended treatment of PAVMs in HHT patients (hereditary haemorrhagic telangiectasia/Osler disease) is catheter embolisation. To evaluate safety of this procedure we evaluated patients undergoing PAVM treatment pre- and post-intervention by MRI for detection of clinical insignificant cerebral infarctions.
Methods and Materials: 94 HHT patients (male/female = 40/54; mean age 45.7+/-16.7 (range 5-86)) with pre-diagnosed PAVMs underwent embolisation therapy. The number of PAVMs treated per patient ranged from 1 to 8 PAVMs. Depending on the size of the feeding vessel and the anatomical situation either coils or vascular plugs were used for embolisation. During the procedure, each patient received iv injection of 2500 IE heparin. MRI was performed immediately before and 4 hours and 3 months post-embolisation therapy applying a T2w sequence and DWI.
Results: DWI post-interventional therapy only showed small, diffuse clinical silent emboli in one patient who underwent re-embolization of a vessel previously treated with tungsten coils that corroded over time. The patient already before treatment had several episodes of brain emboli and re-embolisation had to be performed in the already placed coils for anatomic reasons. Post-re-embolisation the patient did not experience any further brain emboli. All other patients, either initial- or re-embolisation did not show any pre-interventional ischaemic brain lesion.
Conclusion: This prospective study in 94 patients undergoing interventional treatment of PAVMs shows that catheter embolisation, using the described technique, is a safe method for treatment and does not even result in clinical inconspicuous cerebral ischaemia.

Automated computer-based analysis of all multiparametric MRI data (T2w, DWI and dynamic data) in prostate cancer diagnostics: a useful tool to detect clinically relevant PCA?

A. Thon[1], I. Papgeorgiou[1], A. Malich[1], U. Teichgräber[2]; [1]*Nordhausen/DE*, [2]*Jena/DE (annika_thon@web.de)*

Purpose: Quantitative assessment of multiparametric MRI by means of computer-aided diagnosis (CAD) is the current challenge in prostatic cancer (PCa) diagnostics. An innovative CAD-software (Watson Elementary™) was proposed to achieve high sensitivity, specificity as well as to predict Gleason grade. The aim wa to assess Watson Elementary™ accuracy in our hospital´s database of MRI-guided prostate biopsies.
Methods and Materials: We retrospectively evaluated 104 MR-guided biopsied histologically verified lesions (47 PCa, 57 benign) from 79, 64.61±6.64 y.o. patients using 3T T2w, ADC (b-values 0; 100; 400; 1000) and dynamic contrast enhancement series. Watson Elementary™ computes a scalar MRI-based Gleason grade predictor termed “malignancy attention index” (MAI). The MAI-outcome of predefined ROIs was compared with the histologic outcome of the corresponding biopsy cores at the exact position of the biopsy (needle imaging during biopsy).
Results: CAD detected 36/104 lesions, thus revealing a sensitivity of 34.62% for mixed dignity lesions and 46.80% for PCa with false negative rate 0.53/pt. Specificity for PCa turned out to be 75.43% with positive predictive value 61.11%, negative predictive value 63.23% and false discovery rate 38.89%. CAD detected PCa and benign lesions with equal probability (P 0.06, χ^2 test) and the computed ‘malignancy attention index’ (MAI) revealed no significant correlation with Gleason grade (P 0.60, Pearson correlation). Receiver operating characteristic (ROC) analysis suggests a poor predictive value for MAI with AUC < 0.65.
Conclusion: Watson Elementary™ did not qualify for PCa diagnostics and Gleason grade prediction, image-guided biopsy remains the golden standard. Controversies with previously published outcomes of the same CAD-Software will be discussed.

B-0898 10:47

Target performance of MRI-ultrasound fusion guided prostate biopsy in a cohort of patients with suspected prostate cancer

M. Zadory[1], J.-L. Fehr[1], C. Moeckel[1], S. Hailemariam[2], J. Froehlich[1], M.A. Patak[1]; [1]*Zurich/CH*, [2]*Aarau/CH (matthias.zadory@akroswiss.ch)*

Purpose: To determine the target performance of the ARTEMIS MRI-ultrasound fusion guided prostate biopsy (ART-PBx) procedure to detect clinical significant prostate cancer.
Methods and Materials: In a single-centre study we retrospectively reviewed 245 patients with suspected prostate cancer who underwent in total 293 prostate biopsies. Subjects had all undergone a standardized multi-parametric MRI (indication: PSA rise / abnormal digital rectal exam) resulting in a cancer suspicious lesions. Lesions with high PIRADS classification (3, 4 or 5) underwent a standardized ART-PBx procedure by fusing the previously acquired MR images to biopsy ultrasound using the ARTEMIS-System. Subsequently, histopathological results were correlated with MRI findings indicating the target performance of the ART-PBx procedure. Furthermore, the target performance was subanalysed for the single lesions based on their initial PIRADS classification (excluding unclassified lesions).
Results: The final study population consisted of 194 patients with a mean age of 67 ± 1 years, and with an average PSA of 8.05 ± 0.82 ng/ml. 129 out of 243 cancer-suspicious lesions were positively biopsied for clinical significant prostate cancer yielding an overall ART-PBx target performance of 53.1%. On a patient level, 56.3% of 194 patients were positive. Sub-analysis of the PIRADS criteria delivered an escalating target performance increasing with the PIRADS scoring (PIRADS 3: 14,7%, PIRADS 4: 39.8%, PIRADS 5: 71.4% of all lesions, respectively).

Conclusion: The target performance of ART-PBx to detect clinical significant prostate cancer is robust increasing with higher PIRADS scoring advocating the use of MRI to select patient and lesion candidates for biopsies.

B-0899 10:55

Improvement of biopsy accuracy (target in target) with WATSON elementary CAD system in the detection rate of prostate cancer (csPCa): histopathological correlation

R. Campa, V. Salvo; *Rome/IT*

Purpose: To validate the role of a new algorithm based on a per voxel correlation with malignancy Watson elementary CAD system in the detection rate of clinically significant prostate cancer (PCa).
Methods and Materials: 3T multiparametric MRI (mpMRI), including T2-weighted, diffusion-weighted, and dynamic contrast-enhanced MRI and targeted biopsy of 31 consecutive patients have been performed. The target biopsy area according to PIRADS (V.2) has been considered. Two radiologists retrospectively re-evaluated the exams using PI-RADS v2 and WATSON elementary ® CAD system. The MRI data were compared with histopathological whole-mount step-section slides.
Results: Overall performance for detection rate biopsy was 85% for clinically significant cancer (csPCa) for both PIRADS and Watson systems; in addition, the CAD increases the percentage of tumour per core (25%), targeting the precise zone into the lesion to be biopsied (target in target).
Conclusion: The diagnostic performance of WATSON elementary in the detection rate of PCa is similar to PI-RADS v2. Furthermore, the Watson CAD is useful in identifying the most involved area by cancer within the focus bordered with MRI. So Watson can help in directing the prostatic targeted biopsy to improve the detection rate of biopsy in terms of percentage of tumour per core.

B-0900 11:03

Correlation between PIRADS score and fusion MR-TRUS biopsies (FMR-TB) in the detection of prostate cancer: a monocentric experience

L. Panebianco, G. Michelini, A. Mancini, A. Pace, C. Gianneramo, C. Marsecano, I. Capretti, R. Manetta, C. Masciocchi; *L'Aquila/IT (panebianco.luca@gmail.com)*

Purpose: To compare FMR-TB outcomes with PIRADS score assessed with pre-biopsy MRI.
Methods and Materials: In a period between 2/2015 and 10/2015, FMR-TB outcomes of 46 patients were retrospectively analysed in comparison with PIRADS2 v2 score assigned with pre-biopsy MRI. 2 patients were excluded from the study for previous radical prostatectomy, 1 for radiotherapic treatment. Exams were performed with a 3T scanner using both endorectal and surface 32-channel body coil.
Results: For correlation purposes we considered bioptic findings of prostatic intraepithelial neoplasia (PIN) as negatives, since these alterations are clearly beyond current MRI detection possibilities. 3 patients were scored with PIRADS 1, and their biopsy outcomes were all negative (normal prostatic tissue). 18 patients were scored with PIRADS 2; of these, 4 were assessed as adenomatous hyperplasia, 11 as chronic inflammation, 2 as high-grade (PIN), 1 as adenocarcinoma Gleason 6 (3+3). 4 patients were scored with PIRADS 3; at the biopsy, one was assessed as high-grade PIN and 3 as adenocarcinoma Gleason 6 (3+3). 11 patients were scored with PIRADS 4; of these, 3 were adenomatous hyperplasia, 6 adenocarcinoma Gleason 6 (3+3), 2 adenocarcinoma Gleason 7 (3+4). 7 patients were scored with PIRADS 5; of these, 1 was regular prostatic tissue, 1 adenocarcinoma Gleason 5 (3+2), 1 adenocarcinoma Gleason 6 (3+3), 3 adenocarcinoma Gleason 7 (4+3), 1 adenocarcinoma Gleason 9 (4+5).
Conclusion: MRI evaluation using PIRADS score correlates well with localisation and histologic nature of prostatic pathology.

B-0901 11:11

Sensitivity and negative predictive value of multiparametric MRI utilising PI-RADSvs2: a validation study using MRI/transrectal ultrasound (TRUS) fusion biopsy

M. Nguyentat, A. Ushinsky, C. Green, C. Lall, T.B. Nguyen, R. Houshyar; *Orange, CA/US (TanBNguyen@gmail.com)*

Purpose: Use a combination biopsy method (12-core plus MRI/TRUS fusion biopsies) to evaluate the accuracy of multiparametric MRI (mpMRI), utilising Prostate Imaging - Reporting and Data System version 2 (PI-RADSv2), for detecting clinically significant prostate cancer (csPCa) in the overall gland, the peripheral zone (PZ) and transitional zone (PZ).
Methods and Materials: An IRB approved retrospective analysis of patients who underwent prostate mpMRI and subsequent MRI/TRUS fusion biopsy was performed. We identified 137 men with a total of 231 mpMRI prostate lesions. Subjects were retrospectively graded utilising PI-RADSv2 criteria by a radiologist blinded to biopsy results. Spearman's correlation, chi-squared analysis, and logistic regression were performed. A multiparametric predictive model for csPCa was developed.
Results: There was positive correlation between PI-RADSv2 score and Gleason score ($p < 0.001$). For csPCa in the PZ, mpMRI had a 100% sensitivity, 100% negative predictive value (NPV), 9.0% specificity, and 35.9% positive predictive value (PPV), compared to 100%, 100%, 41.1%, and 27.1%, respectively, for TZ lesions. When predicting csPCa, employing PI-RADSv2 score in a multiparametric model with predictive factors for csPCa (BMI, PSA density, DRE result) increased the AUC from 0.797 to 0.886 (95% CI 0.030 - 0.039, $p < 0.01$).
Conclusion: PI-RADSv2 in conjunction with 12-core and MRI/TRUS fusion biopsies is accurate in detecting csPca with excellent sensitivity and NPV for both PZ and TZ lesions. However, compared to PZ lesions, the specificity and AUC for TZ lesions is greater. PI-RADSv2 contributes to a highly accurate predictive model when included in a multivariate analysis.

B-0902 11:19

The role of semi-quantitative dynamic contrast-enhanced MR imaging in characterisation of prostate cancer

Y. Yeo, S. Kim, Y. Nam; *Taegu/KR (omiri86@naver.com)*

Purpose: To retrospectively assess diagnostic value of semi-quantitative DCE-MR imaging in characterisation of prostate cancer.
Methods and Materials: 102 consecutive patients underwent DCE imaging. Regions of interest were drawn on 288 foci, including 133 cancers (Gleason grade 6 [30], Gleason grade 7 [72] and Gleason grade 8 or higher [31]), 55 benign hyperplasia and 100 healthy-tissues, by using histopathologic correlation. Semi-quantitative parameters derived from time-intensity curves (C_{peak}, TTP, Wash-in and Wash-out), and the curves types were evaluated as following type 0, 1, 2, or 3. The *k* was calculated to evaluate inter-radiologist agreement for the curve types of different tissue types and Gleason grades. Comparisons between these groups were performed by using one-way analysis of variance.
Results: The agreements between curve types were excellent (all $k \geq 0.85$). The values of C_{peak} and Wash-in in overall cancer foci and Gleason grade 8 or higher were significantly higher than those of healthy-tissue foci and Gleason grade 6, respectively (C_{peak}: 130.3±15.43 and 138.3±27.23 vs 115.3±13.24 and 122.3±23.43; P=0.032 and P=0.014, Wash-in: 18.8±9.55 and 26.5±8.62 vs 9.2±4.73 and 12.7±7.93; P=0.025 and P=0.010). The values of Wash-out in overall cancer foci and Gleason grade 8 or higher were significantly lower than those of healthy-tissue foci and Gleason grade 6, respectively (-0.52±1.59 and -0.75 ± 1.48 vs 0.37±1.72 and -0.44 ± 1.68; P=0.026 and P=0.020).
Conclusion: Semi-quantitative DCE-MR imaging poorly perform for differentiation of cancer from benign hyperplasia and healthy-tissue. Only Gleason grade 6 potentially enabled differentiation of Gleason grade 8 or higher in cancer grading.

B-0903 11:27

Searching for prostate cancer by fully automated magnetic resonance imaging classification: deep learning vs non-deep learning

L. Wang; *Wuhan/CN (1311935212@qq.com)*

Purpose: To develop deep learning with deep convolutional neural network (DCNN) versus non-deep learning methods to distinguish PCa from prostate benign conditions (BCs) including prostatitis and prostate benign hyperplasia (BPH).
Methods and Materials: We obtain 2,602 MR images of the prostate. We use deep learning with deep convolutional neural network (DCNN) versus non-deep learning methods to distinguish PCa from prostate benign conditions (BCs) including prostatitis and prostate benign hyperplasia (BPH). We validate the difference in fully automated PCa differentiation from prostate BCs between two methods was statistically significant (p-value<=0.05).
Results: Deep learning demonstrates fully automated PCa differentiation aggressiveness with accuracy of 63.6% for Gleason score (GS)<=6, 60.0% for GS 7 and 89.5% for GS>=8.
Conclusion: Our results suggest that deep learning with DCCN can be used to assist, or even partly replace radiologist to search for PCa by fully automated MR imaging classification.

B-0904 11:35

Detection of MRI index lesion with transrectal ultrasound-MRI fusion-guided prostate biopsies: is it correspondent with histopathology?

M. Del Monte, V. Salvo, M. Grompone, E. Indino, V. Panebianco, C. Catalano; *Rome/IT (delmonte_maurizio85@libero.it)*

Purpose: To assess the histopathological correspondence of "MRI index lesion" between magnetic resonance imaging (MRI)/ transrectal ultrasonography (TRUS) fusion and radical prostatectomy.
Methods and Materials: We enrolled 101 consecutive patients treated with radical prostatectomy for a clinically localised prostate cancer detected on magnetic resonance imaging (MRI)/transrectal ultrasonography (TRUS) fusion.

For each patient 3 to 5 biopsy specimen was performed for each “MRI index lesion". A correlation analysis between magnetic resonance imaging (MRI)/transrectal ultrasonography (TRUS) fusion and pathological findings of radical prostatectomy was performed.
Results: We found with regard to the “MRI index lesion” a detection rate of 100% for the dimensions (from 7 mm to 30 mm); the correspondence between biopsy and prostatectomy results was 83% in terms of Gleason score. In the 36% of patients the “MRI index lesion” corresponds to the more aggressive lesion.
Conclusion: MRI-transrectal ultrasound fusion biopsy shows a good correlation between “MRI index lesion” and definitive histopathological diagnosis.

B-0905 11:43

Detection of potentially malignant lesions of the prostate gland with targeted biopsy using a computer-assisted diagnostic tool based on multiparametric MRI

E. Alberioli, C. Cicero, B. De Concilio, A. Casarin, S. Canestrini, G. Zeccolini, A. Celia, L. Genesio, A. Guarise; *Bassano del Grappa/IT (enricoalberioli@gmail.com)*

Purpose: To estimate the capability of a computer-assisted diagnostic system (Watson Elementary®), based on the analysis of MR images, in identifying and localising potentially malignant lesions within the prostate gland.
Methods and Materials: 33 patients with suspected prostate gland malignancy were studied with multiparametric MRI, applying the European Society of Urogenital Radiology criteria; these sequences were used by an automated analysis tool to localise suspected lesions by the fusion of various series. The PI-RADS values of the studied lesions were 3 in 2 cases, 4 in 15 cases and 5 in 16 cases. Targeted biopsies were performed in all patients.
Results: Of 33 patients who underwent to targeted biopsy, in 20/33 (60,6%) patients the suspected lesion was confirmed to be malignant (prostate cancer) and in 13/33 (39,4%) the biopsied lesion resulted to be benign prostatic hyperplasia. PI-RADS was 5 in 13/16 cases of malignancy and in 3/16 cases of benign lesions. In 1/14 patients the suspected lesion at mpMRI was considered as a negative area by the automated diagnostic system while resulted to be prostate cancer at biopsy. The obtained sensitivity was of 95%, while no true negative cases resulted from this study.
Conclusion: The automated analysis system, thanks to the fusion of multiparametric MR images, has to be considered as an efficient additional tool available to the radiologist to improve the ability to identify, localise and biopsy potential malignant lesions of the prostate gland.

Peripheral prostatic cancer detection in a biopsy-naive patient population: a biparametric MR study

G. Rusconi, A. Stanzione, S. Cocozza, N. Longo, A. Brunetti, M. Imbriaco; *Naples/IT (rusconi.giovanni@gmail.com)*

Purpose: Recent evidences suggested that Biparametric Magnetic Resonance Imaging (BP-MRI) is a feasible tool for detection of prostatic cancer (PCa). However, no direct evidences with respect to the zonal prostatic anatomy are available. Therefore, we aimed to analyse the diagnostic accuracy of a BP-MRI protocol to identify PCa of the peripheral zone, which is the most frequent localisation, in a biopsy-naïve patient population.
Methods and Materials: From an initial group of 84 patients (mean age: 66±9 years old) with suspicion of PCa, based on abnormal prostate-specific antigen (PSA) levels and/or digital rectal examination, 29 cases of PCa of the peripheral zone were identified. All included patients underwent a MR scan, including a T2-weighted imaging and diffusion-weighted imaging (with the correspondent apparent diffusion coefficient maps). All subjects subsequently underwent a prostate biopsy. Two radiologists reviewed prostate MR scan to establish a radiological diagnosis.
Results: The mean PSA level of these patients was 9.9±11.1 ng/ml, with a Gleason score ranging from 2+4 to 5+4. The evaluation of the sequences included in the BP-MRI protocol showed an accurate performance in terms of diagnostic accuracy (92.2%), correctly identifying 24/29 subjects with peripheral PCa (82.8% of sensitivity), with only one false negative (97.9% of specificity).
Conclusion: Our results confirm that BP-MRI prostate protocol is feasible for the detection of a PCa of the peripheral zone, showing both a high sensitivity and specificity and suggesting its possible inclusion in clinical routine diagnostic protocols for PCa imaging.

CT-based tumour response criteria compared after combined treatment for liver metastases of colorectal cancer

A. Varotto[1], L. Di Grazia[2], C. Aliberti[1], F. Bergamo[1], M. Nardin[1], F. Pomerri[1]; [1]*Padua/IT*, [2]*Chioggia/IT (ale.varotto86@gmail.com)*

Purpose: The aim of this analysis is to compare different tumour response criteria (TRC) after chemotherapy combined with bevacizumab in liver metastases from colorectal cancer (mCRC) to ascertain the best early prognostic indicator of response.
Methods and Materials: 103 target liver metastases from 65 mCRC patients treated with chemoterapy plus bevacizumab were examined at the Istituto Oncologico Veneto IOV-IRCSS (March 2008-January 2013). All patients had baseline CT and at least one follow-up scan. Tumour response was retrospectively analyzed by two radiologists using RECIST1.1, modified Choi, and Chun morphologic criteria. Tumour response, classified as good (complete or partial response) or poor (stable or progressive disease), was compared with progression-free survival (PFS) at first follow-up (t1) and time of best response. Interobserver agreement and concordance between TRC were measured.
Results: At t1, 32.31% showed a good response according to RECIST1.1 (median PFS 11.1), 84.62% according to Choi (median PFS 10.8). These percentages rose to 49.23% (median PFS 12.1) and 87.69% (median PFS 10.8), respectively, at the time of best response. According to Chun, 67.69% showed a good response at the time of best response (median PFS 10.8). The Choi criteria detected a higher proportion of good responders at t1, showing a better correlation with PFS; all methods correlated with PFS at the time of best response.
Conclusion: The Choi criteria proved more consistent in the early detection of response in mCRC treated with chemotherapy plus bevacizumab, underscoring the importance of using these criteria in the early assessment of response to combined treatment.

B-0909 10:38

Towards volumetric thresholds in RECIST 1.1: therapeutic response assessment in hepatic metastases

K.S. Winter, F.O. Hofmann, K.M. Thierfelder, N. Hesse, A.B. Baumann, V. Heinemann, M.F. Reiser, W.H. Sommer, M. D'Anastasi; *Munich/DE (stella.winter@med.uni-muenchen.de)*

Purpose: To empirically determine thresholds for volumetric assessment of liver metastases in line with standardised unidimensional thresholds (RECIST 1.1).
Methods and Materials: This study included patients with metastatic colorectal cancer from a multicentre clinical phase III trial who had undergone CT at baseline and follow-up. The longest axial lesion diameters were determined according to RECIST 1.1. Lesion volumes were calculated using semi-automatic segmentation. The sum of diameters and volumes of 1, up to 2 and up to 5 metastases were compared to all previous examinations. Volumetric thresholds corresponding to RECIST 1.1 thresholds (-30% and +20%) were each predicted using a regression model. Sensitivity analysis was performed to assess the concordance of the proposed thresholds with the weight-maximising thresholds and the results from regression. Classification concordance for measurements of up to 2 metastases was analysed.
Results: For measurements of up to 2 metastases, 348 patients with a total of 629 metastases were included, resulting in 4773 value pairs. Regression analysis yielded volumetric thresholds of -65.3% and +64.6%, corresponding to a diameter change of -30% and +20%. When comparing measurements of unidimensional RECIST assessment with volumetric measurements, there was concordance of significant progress (>+20% diameter / >+65% volume) in 98.0% and of non-significant progress (<+20% / <+65%) in 87.2% of the cases. Concordance of significant response (<-30% / <-65%) was found in 87.8% and of non-significant response (>-30% / >-65%) in 94.4% of the cases.
Conclusion: The evaluation of patients with hepatic metastases yields volumetric thresholds corresponding to RECIST 1.1 of +65% and -65%.

Tumour response criteria after first line combined therapy (Bevacizumab + Chemotherapy) in unresectable liver metastases of colorectal cancer: RECIST 1.1 vs Choi in short-term follow-up

E. Raimondi, M. Bassi, G. De Paoli Barbato, S. Gamanji, M. Tilli, R. Rizzati, M. Giganti, G. Benea; *Ferrara/IT (edoardo.raimondi@unife.it)*

Purpose: Evaluate the predictive value of RECIST 1.1 and Choi criteria for early response to first line combined therapy.
Methods and Materials: Forty-one patients with colorectal-liver metastases (CLM) were retrospectively observed after first-line therapy, imaged with MD-CT at baseline and after therapy at 2 and 5 months (T1/T2). Tumour responses following RECIST 1.1 and Choi criteria were paired with time-to-progression (TTP) and overall-survival (OS).
Results: Median-TTP was 281 days (95% CI:175.555-386.445) for RECIST, 361 days (95% CI:324.131-397.869) for Choi; median-OS was 644 days (95% CI:457.624-708.376). At T1-RECIST showed no complete response (CR), while 14pts (34.1%) showed partial response (PR). Stable disease (SD) was found in 16pts (39%), whereas 11pts (26.8%) showed PD. At T1-Choi, no patient qualified for CR, 37pts (90.2%) showed PR, 3pts (7.3%) SD, and 1pt (2.4%) PD. At T2-RECIST, 6pts (14.6%) showed PR, 24pts (58.8%) SD and 11pts (26.8%) PD. At T2-Choi, 23pts (56.1%) showed PR, 10pts (24.4%) SD, and 8pts (19.5%), rated PR at T1-Choi, were rated PD. Based on TTP data, we categorised pts as Responders (CR+PR+SD) and Non-Responders (PD); we compared mTTP among these subgroups showing shorter mTTP for NR vs R (T1 99 vs 375 days, p<0.0001; T2 172 vs 357 days p<0.0001) according to RECIST, while significant-shorter mTTP for NR vs R (172 vs 357 days p<0.0001) only at T2 according to Choi criteria.
Conclusion: The best predictive marker of therapeutic response in this setting of cancer treatment seems to be the absence of progression, no matter which response evaluation criteria applied.

B-0911 10:54

TACE therapy assessment of HCC using iodine concentration in comparison with volume perfusion CT and RECIST/mRECIST

W. Thaiss[1], U. Haberland[2], S. Kaufmann[1], C. Kloth[1], H. Preibsch[1], D. Ketelsen[1], K. Nikolaou[1], M. Horger[1], A.W. Sauter[3]; [1]*Tübingen/DE*, [2]*Forchheim/DE*, [3]*Basle/CH (alexander.sauter.imaging@googlemail.com)*

Purpose: Assessment of pre- and posttreatment iodine concentration (IC) using 80 kVp CT as response assessment marker of transarterial chemoembolization (TACE) in hepatocellular carcinoma (HCC) lesions and comparison with volume perfusion CT (VPCT) and response evaluation criteria in solid tumours (RECIST, mRECIST).
Methods and Materials: 33 HCC lesions in 25 patients who underwent VPCT before and after TACE were included. Iodine maps 7 sec after aortic peak enhancement (APE) were processed and lesion iodine concentrations were calculated. VPCT and angiography were read in consensus to classify responding and non-responding lesions.
Results: In responding HCC lesions, IC was 118.1 ± 47.0 mg/100 mL (before TACE) and 17.0 ± 25.2 mg/100 mL (after TACE), BF 90.1 ± 28.7 mL/100 mL/min (before TACE) and 32.1 ± 19.0 mL/100 mL/min (after TACE). In non-responding lesions, IC was 100.9 ± 43.6 mg/100 mL (before TACE) and 118.8 ± 50.6 mg/100 mL (after TACE), BF 76.8 ± 35.6 mL/100 mL/min (before TACE) and 73.5 ± 36.1 mL/100 mL/min (after TACE). Absolute differences (before and after TACE) in IC revealed a sensitivity of 95.8% and specificity of 88.9%, absolute differences in BF reached a sensitivity of 66.7% and specificity of 88.9%. IC only derived from posttreatment measurements was on a par with pre- and post-TACE parameter differences.
Conclusion: IC 7 sec after APE is a useful perfusion marker for TACE response monitoring in HCC. This information can be used for further radiation dose savings in VPCT and optimization of dual energy CT acquisition.

Discrimination malignant from bland portal vein thrombosis: could DWI MRI help?

A.K. Fayed, M. Rezk, H. Samy, R. Hachem, A.H.K. Abdelmaksoud, B.E. Mahmoud Hussein, M.F. Osman; *Cairo/EG (ahmedkarm@outlook.com)*

Purpose: to determine the role of DW imaging in differentiating between the benign and malignant portal vein thrombosis in patient with HCC.
Methods and Materials: 74 patients with pathological or radiological proof of HCC and visible portal vein thrombosis were examined using 3 T MR Unit Philips scanner via abdominal surface coil. Axial T1 ,T2 and SPAIR sequences as well as DWI were performed before the dynamic study using single-shot spin echo echoplanar sequence with scan time 3-4 min. ADC values were calculated via ROIs of the hepatic tumour and the portal vein thrombus. The mean and standard deviation of the ADC as well as the ratio of the ADC of the thrombus to the ADC of the tumour were calculated and compared in each group by using the t-test. P value of 0.05 was chosen as the threshold for statistical significance.
Results: No statistically significant difference was between the ADC of HCC in the neoplastic and bland cohorts (P = 0.843). No statistically significant differences between the ADC values of the thrombi in the neoplastic and bland cohorts (P = 0.584). ADC ratio was significantly different between the neoplastic and bland cohorts (P= 0.001). The cutoff of value = 1.2 mm 2 /sec for the ADC ratio helped distinguish between neoplastic and bland portal vein thrombi with 98% sensitivity and 70% specificity.
Conclusion: ADC ratio may have a role in differentiation between the malignant and bland portal vein thrombosis.

Dynamic contrast-enhanced CT-protocol for detection of colorectal liver metastases

L. Van Camp[1], P. Deak[2], M. Haspeslagh[1], K. Coenegrachts[1]; [1]*Bruges/BE*, [2]*Milwaukee, WI/US (laurent.vancamp@gmail.com)*

Purpose: To compare a dynamic contrast-enhanced (DCE) CT-protocol with venous CT-protocol for detecting colorectal liver metastases (CRLMs).
Methods and Materials: A DCE-CT protocol (Johnson-Wilson model) and venous CT scan were performed using Revolution CT (GEHC, Milwaukee, USA). Twenty patients (naïve to anti-tumour treatment) were examined. DCE-CT of the liver was performed using 50 ml of contrast agent (Xenetix® 350, Guerbet, France), followed by a saline flush of 40 ml injected at 4 ml/s. 5 s after start of IV injection, DCE-CT was performed. The first 23 DCE-CT scans were performed every 2 s, followed by 9 DCE-CT scans every 10 s. A second contrast agent injection of 40 ml was performed and venous CT was acquired at the end of injection. Perfusion maps were calculated. The number of detected CRLMs using perfusion maps (e.g. permeability surface area product (PS), blood volume (BV), hepatic arterial blood flow (hep.art.BF)) was compared with venous CT.
Results: 86 CRLMs were detected only on perfusion maps with hep.art.BF and BV parameter. Untreated CRLMs showed an elevated hep.art.BF and decreased BV parameter. Venous CT missed 5 CRLMs (2 missed (diameter 10 mm and 14 mm) in a patient having 4 CRLMs; 1 missed (diameter 15mm) in a patient having 1 CRLM; 2 missed (diameter 10 mm and 12 mm) in a patient having 2 CRLMs). Paired sample t-test results in t = 1.751 with significance of 0.096.
Conclusion: DCE-CT protocol appears to increase detection of CRLMs especially for lesions less than 15mm when compared with venous CT.

B-0914 11:18

Tumour subregion analysis of colorectal liver metastases using DCE-MRI: comparison with histological subregions and impact on PK analysis

J.M. Franklin[1], B. Irving[1], B.W. Papiez[1], J. Kallehauge[1], E.M. Anderson[1], L. Wang[1], R. Goldin[2], M. Brady[1], F.V. Gleeson[1]; [1]*Oxford/UK*, [2]*London/UK (jamiemfranklin@hotmail.com)*

Purpose: To use a novel segmentation methodology based on dynamic contrast-enhanced MRI (DCE-MRI) to define tumour subregions, to compare these with histology, and to use these to compare extracted pharmacokinetic (PK) parameters between tumour subregions.
Methods and Materials: This ethically approved prospective study recruited eight patients with CRC and ≥1 hepatic metastasis scheduled for hepatic resection from December 2013. Patients underwent DCE-MRI pre-metastasectomy. Histological sections of resection specimens were spatially matched to DCE-MRI acquisitions and used to define histological subregions of viable and non-viable tumour. A semi-automated voxel-wise image segmentation algorithm based on the DCE-MRI contrast-uptake curves was used to define imaging subregions of viable and non-viable tumour. Overlap of histologically-defined and imaging subregions was compared using the Dice similarity coefficient (DSC). DCE-MRI PK parameters were compared for the whole tumour and histological and imaging subregions (Student T-test).
Results: Direct histological comparison with imaging was possible in six patients. Mean DSC for viable tumour subregions defined by imaging and histology was 0.783 (range 0.635-0.930). There were significant differences between K^{trans} for viable and non-viable subregions ($p<0.05$) and between whole lesions and viable subregions ($p<0.05$). For k_{ep} ,a trend towards significant differences between viable and non-viable subregions ($p=0.05$) and a significant difference between whole lesions and viable subregions ($p<0.05$) were observed.
Conclusion: We demonstrate good concordance of viable tumour segmentation based on pre-operative DCE-MRI, with a post-operative histological gold-standard. This can be used to extract tumour-specific values from quantitative image analysis, and could improve treatment response assessment in clinical practice.

Perfusion CT changes in liver metastases from pancreatic neuroendocrine tumours during everolimus treatment

M. D'Onofrio, V. Ciaravino, S. Crosara, R. De Robertis, R. Pozzi-Mucelli; *Verona/IT (valentinaciaravino@gmail.com)*

Purpose: To evaluate modifications of perfusional parameters assessed by perfusion CT (P-CT) in liver metastases (LM) from pancreatic neuroendocrine tumours (PanNETs) during everolimus treatment, aiming to identify responding patients at an early stage of treatment.
Methods and Materials: All patients with LM from G1-2 PanNETs undergoing everolimus treatment between January 2013 and January 2015 were prospectively evaluated with PCT at baseline (T0), after 2 (T1) and 4 (T2) months of therapy. Treatment response was evaluated using RECIST 1.1 criteria. Size, perfusion (PF), blood volume (BV), peak enhancement intensity (PEI) and time to peak (TTP) of each lesion were calculated; morphological and perfusional modifications were compared between responder and non-responder lesions.
Results: Thirty-three LM from 9 patients with G1-2 PanNETs were prospectively evaluated: 23/33 (69.7%) were responders, 10/33 (30.3%) were non-responders. Among perfusional parameters, only PEI significantly differed between the two groups at baseline (p=0.043). BV increase was the most significant perfusional modification to identify responding lesions, even at an early stage of treatment (T1), with high positive predictive value (89.47%). A trend towards PEI decrease in responding lesions was observed; combining PEI decrease with BV increase did not improve response prediction. PF and TTP modifications were not significantly different between responders group and non-responders.
Conclusion: P-CT seems to be useful for response prediction to everolimus in LM from PanNETs. Baseline PEI values are significantly higher in responding compared to non-responding lesions. Significant BV increase was found in responding lesions, with high predictive value of response even in an early phase.

B-0916 11:38

Improved PET/CT-discrimination of hepatocellular cancer after carbohydrate-restricted diet and delayed imaging?

C. Cronberg, P. Björkman, L.-L. Johansson, S. Valind, P. Wollmer, S. Zackrisson; *Malmö/SE (carin.cronberg@med.lu.se)*

Purpose: Hepatocellular cancer (HCC) is often diagnosed too late. Using diet restrictions and delayed ^{18}F-FDG PET/CT imaging we investigated the potential effect on enhanced tumour detection in relation to the background parenchyma.
Methods and Materials: 18 patients with chronic hepatitis B or C and a lesion suspicious of HCC were included. ^{18}F-FDG PET/CT with a full dose CT-scan including intravenous and oral contrast media was performed 1 hour after FDG-injection. At 3 hours a PET scan was performed with low dose CT. After 48 hours on carbohydrate-restricted diet patients were examined by another two low dose PET/CT:s at 1 and 3 hours. Lesion SUV_{max}, liver SUV_{mean}, ratio lesion/liver reported as median and interquartile range in relation to change over time and diet were assessed using Wilcoxon signed-rank test.
Results: Lesion SUV_{max} decreased significantly over time, median -0,6 (IQR -0,7 to -0,3), ($p<0,05$) as did SUV_{mean} of the liver, median -0,3 (IQR -0,4 to -0,2). However, the ratio lesion/liver did not change significantly, median -0.1 (IQR -0,2 to 0,1). After carbohydrate-restricted diet SUV_{mean} of the liver was significantly higher than after normal diet after 1 hour (median 0,1; IQR 0-0,5 but not after 3. Lesion SUV_{max} or the ratio lesion/liver was not enhanced by carbohydrate depletion.
Conclusion: In this limited study sample the visibility of HCC was not enhanced by carbohydrate depletion or delayed imaging. SUV decreased slightly more over time in the parenchyma indicating that even later imaging in a larger study, may demonstrate such an effect more clearly.

Mixed hepato-cholangiocellular carcinoma: LI-RADS analysis and radiologic-pathologic correlation

C. Khouri Chalouhi, F. Alessandrino, L. Di Tommaso, M. Roncalli, L. Balzarini; *Rozzano/IT (claudiakhouri@msn.com)*

Purpose: To correlate biphenotypic hepatic tumour imaging features analysed with LI-RADS categories to their relative histopathological composition of intrahepatic cholangiocarcinoma, hepatocellular carcinoma and stem cells.
Methods and Materials: We reviewed a total of 20 patients (6 females, mean age±SD: 69 ± 7.22 years; range: 78-47 years) with histologically confirmed biphenotypic hepatic tumour who underwent 9 contrast-enhanced CT and 11 contrast-enhanced MRI before liver resection. Imaging findings were classified into three categories, according to LI-RADS classification, as follows: hepatocellular carcinoma, probably hepatocellular carcinoma, and intrahepatic cholangiocarcinoma. Chi-square ($\chi 2$) or Fisher exact test was performed to assess the statistical association between LI-RADS categories and prevalent pathologic morphology or prevalent stem cell morphology.
Results: In total, 6 cases were labeled as hepatocellular carcinoma (5MR, 1 CT), 10 cases as intrahepatic cholangiocarcinoma (4 MR, 6 CT) and 4 cases (2 MR, 2 CT) as probably hepatocellular carcinoma according to LI-RADS classification. No significant association between imaging diagnosis and prevalent pathologic morphology and prevalent stem cells morphology was observed. Concerning association between single imaging features and prevalent pathologic morphology, only capsular retraction was significantly associated with prevalent intrahepatic cholangiocarcinoma pathologic morphology (p=0.03).
Conclusion: Our study showed that differentiation of biphenotypic hepatic tumours on the basis of LI-RADS categories is not feasible, when their relative histopathological composition is taken into account. Association between single imaging features and prevalent pathologic morphology was observed only for capsular retraction, significantly more frequent in cases with prevalent intrahepatic cholangiocarcinoma pathologic morphology.

Benefits and risks of preoperative axillary staging in a low-risk screening population

M. Wallis[1], F. Kilburn-Toppin[1], K. Taylor[1], S. Taylor-Phillips[2]; [1]*Cambridge/UK*, [2]*Coventry/UK (matthew.wallis@addenbrookes.nhs.uk)*

Purpose: Preoperative staging of the axilla with ultrasound and needle biopsy is said to preferentially identify women with higher risk disease allowing node positive women to go direct to axillary node dissection (ALND) or neoadjuvant chemotherapy (NAC). ACOSOG-Z0011 questions the need for ALND in women with low risk axillary disease suggesting that some women with positive needle biopsy are being over treated.We sought to identify the risks and benefits for a population who should be at low risk.
Methods and Materials: All surgically treated invasive cancers detected between 01/04/2008 and 31/03/2016 were extracted from the records of one UK breast screening service. Axillary staging was compared with final pathology and treatment.
Results: 193 of 899 (21.7%) surgically treated invasive cancers were node positive. 101 (11.4%) had an axillary biopsy, 63 were positive (32.6% of the node positive cases). Of these 26 (41.3%) had NAC and 37 (58.7%) proceeded directly to ANLD, of which 18 (48%) had 3 or more nodes positive. 69.8% of women with a positive needle biopsy were heavily node positive or promoted to NAC compared to 23 (17.7%) of the 130 women with a positive sentinel lymph node biopsy. Balanced against this 19 (30%) were potentially over treated with ALND (mean node count 14.6).
Conclusion: This series confirms preoperative axillary staging picks up advanced disease but significant numbers of women are being potentially over treated. A much larger data set is required to predict who benefits from preoperative axillary staging. We are seeking funding to analyse UK data set.

Dynamic contrast-enhanced magnetic resonance imaging and diffusion-weighted imaging for the prediction of axillary lymph node metastasis in early breast cancer

E.H. Jeong, E.J. Choi, E.H. Park, J.S. Song; *Jeonju-si/KR (ceh914@hanmail.net)*

Purpose: To evaluate dynamic contrast-enhanced breast magnetic resonance imaging (DCE-MRI) and diffusion weighted imaging (DWI) features for axillary lymph node (ALN) metastasis in the early breast cancer.
Methods and Materials: From January 2011 to April 2015, we retrospectively reviewed 580 early breast cancer patients. Among them, 240 patients who underwent 3.0-T DCE-MRI, including DWI with b value 0 and 1,000 s/mm^2, were enrolled. We compared MRI features (background parenchymal enhancement, internal enhancement, adjacent vessel sign, whole-breast vascularity, initial enhancement pattern, kinetic curve types, quantitative kinetic parameters, tumour-apparent diffusion coefficient (ADC), pretumoural maximum-ADC, and peritumour-tumour ADC ratio) and clinico-pathologic

variables (age, stage, histologic grade, nuclear grade, existence of lymphovascular invasion and extensive intraductal carcinoma component, and immunohistochemical profiles) between patients with ALN metastasis and no LN metastasis.
Results: On breast MRI, moderate or prominent ipsilateral whole-breast vascularity (moderate, odds ratio [OR], 3.45; 95% confidence intervals [CI], 1.28-9.51 vs. prominent, OR, 15.59; 95% CI, 2.52-96.46), signal enhancement ratio (SER) (OR, 1.68; 95% CI, 1.09-2.59), and peritumour-tumour ADC ratio (OR, 6.77; 95% CI, 2.41-18.99) were independently associated with ALN metastasis. Among clinico-pathologic variables, HER-2 positivity was independently associated with ALN metastasis (OR, 23.71; 95% CI, 10.50-53.54). The area under the receiver operating characteristic curves (AUC) of combining the selected MRI features and clinic-pathologic variables was higher than that of clinico-pathologic variables. (P < 0.05).
Conclusion: On breast MRI, moderate or prominent increased whole breast vascularity, SER, and peritumour-tumour ADC ratio could be useful for predicting ALN metastasis in patients with early breast cancer.

The diagnostic performance of gadofosveset-enhanced axillary MRI for nodal (re-)staging in breast cancer patients: final results of a validation study

T. van Nijnatten[1], R.-J. Schipper[1], M. Smidt[1], P. Nelemans[1], B. de Vries[2], L. van Roozendaal[1], J. Wildberger[1], M.B.I. Lobbes[1], R.G.H. Beets-Tan[3]; [1]*Maastricht/NL*, [2]*Heerlen/NL*, [3]*Amsterdam/NL* *(t.vannijnatten@maastrichtuniversity.nl)*

Purpose: To evaluate the diagnostic performance of gadofosveset-enhanced axillary MRI for nodal (re-)staging in newly diagnosed breast cancer patients.
Methods and Materials: Ninety patients underwent dedicated axillary MRI, consisting of standard T2W-MRI and gadofosveset-enhanced T1W-MRI (GDF-MRI). Two radiologists independently scored each lymph node on a confidence scale, first on T2W-MRI, subsequently adjusting the score based on the GDF-MRI if necessary. Diagnostic performance parameters were calculated based on node-by-node and patient-by-patient validation with histopathology of axillary surgery as gold standard. To investigate the presence of a learning curve for reading GDF-MRI, diagnostic performance of the first 30 patients was compared to patients 31-60 and to the last 30 patients.
Results: Overall, node-by-node validation on T2W and GDF-MRI, showed a diagnostic performance with an AUC of 0.760 and 0.819 (p=0.022) for reader 1 and AUC of 0.771 and 0.771 (p=0.997) for reader 2. For patient-by-patient validation, AUC of standard and GDF-MRI were 0.749 and 0.770 (p=0.731) and 0.785 and 0.721 (p=0.156), for reader 1 and 2 respectively. The AUC for reader 1 of the first 30 patients was 0.671, improving to 0.727 (p=0.745) after 60 patients and further improving to 0.906 (p=0.089) for the remaining 30 cases. Sensitivity, specificity, PPV and NPV were 28.6%,82.6%,33.3% and 79.2% and improved to 50.0%,87.5%,50.0%, and 87.5% for reader 1. The AUC of reader 2 improved from 0.742 to 0.774 (p=0.598).
Conclusion: The current study demonstrated that GDF-MRI has potential as non-invasive method for nodal (re-)staging in breast cancer. A learning curve exists for reading GDF-MRI.

Are MR morphological and dimensional lymph node features predictive of axillary metastasis in breast cancer?

F. De Narda, A. Linda, R. Girometti, C. Zuiani; *Udine/IT (denardaf@gmail.com)*

Purpose: To investigate whether standard MR Mammography (MRM) performed for pre-operative staging of breast cancer may predict axillary metastasis evaluating morphological and dimensional lymph node (LN) features.
Methods and Materials: We retrospectively evaluated 306 consecutively patients with newly diagnosed invasive primary breast cancer who underwent preoperative MRM and pathological N-staging after surgery between September 2012 and June 2014. A state-of-the-art MRM protocol was performed, with no additional dedicated axillary sequences. According to histopathological results, patients were assessed to LN metastasis (LNM) or no-LNM group. Images were evaluated by two radiologists in consensus who recorded the presence of irregular margins, cortical inhomogeneity, loss of fatty hilum, perifocal edema, short axis diameter exceeding 1 cm, long axis to short axis ratio smaller than 1,5 cm and asymmetry. Imaging findings were compared among LNM and no-LNM patients using chi-square test. Multivariate logistic regression analysis was performed to determine whether MR findings predict LNM.
Results: Among 306 patients, 118 (38,6%) presented LNM. With the exception of the margins irregularity, all the features considered demonstrated a significant difference (p<0.05) between LNM and no-LNM groups. In particular, cortical inhomogeneity, loss of fatty hilum, perifocal edema, short axis diameter and asymmetry showed a p<0,001 while long axis to short axis ratio demonstrated a p=0,035. Our multivariate analysis showed that only short axis was independently associated with LNM (p<0,001) with an OR of 21,81 (CI 4,96-95,90).
Conclusion: Short axis diameter of axillary LN greater than 1 cm is predictive of LNM in breast cancer patients on standard MRM.

B-0923 11:02

Differentiating between benign and malignant axillary lymph nodes in breast cancer patients using sono-elastography and diffusion-weighted MRI

Y.M. Abdo, M. Abdel Latif, M. Shady; *Mansoura/EG* *(yaramohamedabdo@gmail.com)*

Purpose: To evaluate feasibility of sonoelastography and DWI in differentiating benign from malignant axillary lymph nodes.
Methods and Materials: From July 2014 to July 2015, 30 patients with enlarged axillary LNs were enrolled in this prospective study. First, B mode US was done to assess 4 morphological criteria; T diameter, L/T ratio, cortical thickness and hilum state. Then, sonoelastography was done to determine Elasticity score and Strain ratio. After that, DWI was done for visual assessment and estimation of ADC values. LNs were divided into benign (12 LNs) and malignant (18 LNs) groups based on pathological results. In the two groups, ES and visual DWI were compared using chi-squared test, SR and ADC values were compared using t test. ROC curve analysis was constructed to obtain best cut-off values.
Results: Elasticity Score >2 and restricted diffusion were significantly associated with malignancy (P <0.0001),(P= 0.0002) respectively. The Mean SR of malignant nodes (8.26) was significantly higher than that of benign nodes (2.08) (P <0.0001). The Mean ADC value of malignant nodes (0.7) was significantly lower than that of benign nodes (1.4) (P <0.0001). Comparing results of the three imaging modalities showed that DWI had higher sensitivity and accuracy (100%, 96.4%, respectively) than sonoelastography (88.89%, 93.33%, respectively) with both modalities having the same specificity (91.67%). while both DWI and sonoelastography had higher sensitivity, specificity, accuracy than B-mode ultrasound (77.78%, 66.7%, 73.3% respectively).
Conclusion: Sonoelastography and DWI improve the characterization of enlarged axillary lymph nodes than B-mode Ultrasound. Therefore, reducing the unnecessary invasive biopsies.

B-0924 11:10

Role of IVIM MRI: predicting axillary lymph node metastases in breast malignancies

R. Balaji; *Chennai/IN (ravikanthbalaji@gmail.com)*

Purpose: To evaluate potential for using IVIM MRI to predict axillary lymph node metastases in patients with invasive breast cancer.
Methods and Materials: 36 patients with invasive breast malignancies underwent DCE MRI using 8 channel dedicated breast coil on a 1.5 Tesla scanner (Achieva, The Best, Netherlands). IVIM images were acquired in an axial plane with 11 b values - 0, 20, 30, 50, 80, 100, 200, 400, 80, 1000 and 1200 s/mm^2. Nodes more than or equal to 1 cm were included in the study. 110 nodes were found suitable and evaluated for IVIM parameters - f fraction that represents vascular volume fraction, D the true diffusion coefficient and and D* that represents pseudo diffusion coefficient. This was correlated with histopathology results.
Results: Nodal metastases were observed in 71 nodes. The mean size of the metastatic nodes was larger than that of benign nodes- 1.3 cm versus 0,85 cm. ADC and D values of metastatic nodes were lower while f values were higher. Malignant nodes ADC 0.93 x 10^{-3} mm^2/s D value 0..82,x 10^{-3} mm^2/s, f values 12 % D* 13.95. Benign nodes ADC 1.9 x 10^{-3} mm^2/s D value 1.73, x 10^{-3} mm^2/s, f values 5 % D* 33.6.
Conclusion: Bio imaging markers derived from IVIM studies may provide a more reliable method of distinguishing benign from malignant axillary nodes in patients with invasive breast malignancies.

Axillary assesment in breast cancer: imaging features to improve detection of metastasis

L. Metaxa, R. Aggarwal, A. Khan, L. Jones, T. Suaris; *London/UK* *(lindamet25@gmail.com)*

Purpose: Determine the sensitivity/specificity for detecting axillary lymph node (LN) metastases on preoperative US according to cortical thickness. Explore why some metastatic LN appeared 'normal' on US: false negatives (FN).
Methods and Materials: We performed a retrospective analysis on 627 patients, with primary breast cancer, between 1/1/2012-31/12/2015, undergoing surgical breast and axillary procedure at our institution. We recorded morphology and size of LN. LN with cortical thickness above 2.3mm were considered abnormal and underwent pre-surgical sampling.

Results: 607 patients with valid data were included in further analysis. The metastatic IDC cases were 17.0% of all cases, with PPV 53.4% in the pre-surgery imaging. However, 46.6% of those were FN. In 81.5% of all cases, the LN reported as normal with a FN rate of 9.7%(49/495). In 18.5% of all cases the LN reported as abnormal, with PPV 49.1%. but, in the pre-surgical sampling, 37.5% reported as abnormal (FN for biopsy 11.6%). Our sensitivity was 83.5% and specificity 63.4%. Regarding morphology of LNs, 3.1% cases had round shape with PPV 100%. 96.9% LN were ovoid with PPV14,3%.
Conclusion: 48 patients had FN assessment of the axilla with cortical thickness cut off at 2.3 mm (9.7% of all cases, 46.6% of the metastatic IDC). Is there a better modality, that can detect the metastasis to the LN? Our sensitivity/specificity are within national standards. Can we improve with more structured scanning technique for the axilla. Focus for the future is on morphology and number of abnormal nodes, as these factors guide management of axillary disease.

B-0926 11:26

Predicting axillary lymph node metastasis in breast cancer with multimodality imaging

J. Cho, J. Moon, S. Koh, H. Hwang, S. Park; *Anyang si/KR (cobblack@hallym.or.kr)*

Purpose: The purpose of this retrospective study is to compare the diagnostic performances of mammography, ultrasound (US), magnetic resonance imaging (MRI) and positron emission tomography/computed tomography (PET/CT) and their various combinations to evaluate preoperative axillary lymph node metastasis (ALNM).
Methods and Materials: From January 2011 to December 2014, we included 322 patients with breast cancer completed four preoperative imaging examinations (mammography, US, MRI and PET/CT) up to 3 weeks before surgery. All patients underwent breast conserving surgery or mastectomy and either ipsilateral sentinel lymph node biopsy (SLNB) or axillary lymph node dissection (ALND). The pathology from either ANLM or SLNB was used as the reference standard. The diagnostic performance, sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of each modality and their various combinations (i.e., combinations of two, three, or all four modalities) were evaluated.
Results: Out of all possible combinations, mammography and US (MG+US) showed the best diagnostic performance. Regarding each single modality, mammography showed the highest specificity, however, its sensitivity was much lower than the other types of imaging. Furthermore, US revealed the highest diagnostic performance compared with the other three imaging modalities. The combination of all four imaging combination showed the highest sensitivity.
Conclusion: Routine basic studies using MG+US are enough for patients with breast cancer prior to ALNM. The addition of other modalities (e.g., MRI or PET/CT) is not necessary to evaluate ALNM; in fact it might decrease the specificity and PPV.

B-0927 11:34

Whole-body MRI DWIBS vs FDG-PET/CT in assessment of breast cancer patients

M.M.A. Rezk, M. Maher, Y. Labib, N. Abdelshafi, E. Elfayoumy, M. Gomaa, N. Abdelrazek, H. Fathy, M. Kotb; *Cairo/EG (medical1430@yahoo.com)*

Purpose: To assess the diagnostic performance of WB-DWIBS versus FDG-PET/CT in assessment of breast cancer patients.
Methods and Materials: 50 patients with pathologically proven breast cancer underwent both F-18-FDG-PET/CT and WB-MRI/DWIBS. The sequences acquired are whole-body DWI, coronal T1 and coronal STIR. FDG-PET/CT was performed on an integrated PET/CT system. Whole-body F18 FDG-PET/CT was performed using standard technique. Both F-18-FDG-PET/CT and WB-MRI/DWIBS were independently interpreted using visual qualitative and quantitative analysis in the term of SUVmax and ADC values respectively. Using pathological data and/or combined clinical/radiological follow-up as a reference standard, sensitivity, specificity, PPV, NPV and overall accuracy were estimated for both techniques.
Results: F-18-FDG-PET/CT demonstrated slightly higher specificity indices than MR-DWIBS while the MR-DWIBS displays higher sensitivity indices than FDG-PET/CT in particular in loco-regional assessment. In addition, high sensitivity indices of DWIBS were depicted in assessment of nodal and bone marrow lesions with fair specificity indices. A high degree of agreement also existed between DWIBS and PET/CT with little better accuracy of FDG-PET/CT more appreciated in the pulmonary lesions assessment.
Conclusion: WB-MRI/DWIBS is a promising tool in evaluation of loco-regional breast cancer and assessment of metastasis with no radiation exposure.

B-0928 11:42

The research of radiological methods reliability

G. Letautaite; *Vilnius/LT (g.letautaite@gmail.com)*

Purpose: To assess the sensitivity of mamography, ultrasonography (US) and magnetic resonance (MR) imaging in detection of multifocal/multicentric breast cancer.
Methods and Materials: The study was carried out using data of 2015-2016 from National Cancer Institute (Lithuania) and 2016 from private clinics Affidea (Lithuania). All the results were anonymous. Results of bilateral mammography, US and contrast-enchanced MRI were analysed from 456 consecutive findings with known or suspected invasive breast cancer of which 52 were found multifocal/multicentric BC. All the results were correlated with histopathologic findings. Statistical analysis was performed by using SPSS software version 23, for statistical reliability to check the use of $\chi 2$ test and t-test for independent samples. Selected statistical significance level of $p<0,05$.
Results: The final research group included 52 patients and it was 11,4% from all MRI examinations. The average age ±SD 50,7±10,54 years. Multifocal/multicentric BC were seen in 71% of the ultrasound examination, 56% of mammography examination and 100% of MRI. Sensitivity of US is 71%, 55,85% of mammography examination and 100% of MRI. Histological analyses of multifocal/multicentric BC: 23,53% invasive lobular carcinoma, 70,59% invasive ductal carcinoma, 5,88% invasive lobular and ductal carcinoma. Spread to lymph nodes was detected in 47,06%.
Conclusion: MRI is the most sensitive techniqe to detect multifocal/multicentric BC, US showed higher sensitivity than mammography according to results of 2015-2016. Standard test methods should be used in conjunction with MRI for assessing multifocal/multicentric BC because it would be more sensitive than any other individual test.

Patterns of aging in functional connectivity: the Rotterdam study

H.I. Zonneveld, R.H.R. Pruim, D. Bos, H.V. Vrooman, W.J. Niessen, M.A. Ikram, M.W. Vernooij; *Rotterdam/NL (h.zonneveld@erasmusmc.nl)*

Purpose: Non-invasive markers for preclinical dementia are much needed. Structural brain changes are promising, but occur rather late in the disease process. Functional connectivity changes may yield earlier markers of dementia. Yet, little is known on how functional connectivity changes as individuals age. Therefore, we investigated the association of age with functional connectivity, using resting state fMRI, in middle-aged and elderly persons.
Methods and Materials: 2,398 stroke-free and non-demented persons from the population-based Rotterdam study (mean age 65.7 years, 54.4% women) underwent brain MRI on a 1.5 Tesla scanner. We studied age-related changes in resting state functional connectivity (RSFC) for ten well-known resting state networks derived from our data, using FMRIB software library. We used non-parametric permutation testing on linear regression models to study how RSFC differed within and between these networks with aging, and whether these RSFC changes were independent of macrostructural MRI markers (e.g., global grey matter volume, white matter lesions) and cardiovascular risk factors.
Results: With increasing age, higher and lower connectivity was observed within and between the ten resting state networks. Associations became weaker after adjustments for macrostructural MRI markers and cardiovascular risk factors.
Conclusion: In a community-dwelling population, resting state functional connectivity changes with age. The observed higher connectivity with increasing age in some networks may suggest a compensation mechanism of the brain in response to decreased connectivity in other networks. Further research needs to explore the (spatial) role of structural MRI markers as a mediator in the association between age and functional connectivity.

The neural substrate of cognition: the Rotterdam study

H.I. Zonneveld, G.V. Roshchupkin, H.H.H. Adams, W.J. Niessen, M.A. Ikram, M.W. Vernooij; *Rotterdam/NL (h.zonneveld@erasmusmc.nl)*

Purpose: Variations in cognition are thought to be reflected in the structure of the brain. Yet, global measurements of brain structure (e.g. brain volume) do not account for all variability in brain morphology. Hypothesis-free approaches that study brain structure at the highest resolution, i.e. the voxel, in relation to cognitive ability are typically lacking or underpowered. We investigated the neural substrate of cognition in the large population-based Rotterdam study including middle-aged and elderly subjects.
Methods and Materials: 4,480 stroke-free and non-demented persons (mean age 66.3 (±10.3) years; 55.8% women) underwent brain MRI including high-resolution 3D T1-weighting imaging. Cognition was assessed using an extensive cognitive test battery and grouped into four independent domains (fine motor speed, executive functioning, memory and information processing speed). Voxel-based morphometry (with permutation testing) was performed to investigate the association between local grey matter density and cognitive function.
Results: Memory was associated with higher grey matter density in the thalamus and both hippocampi. Lower grey matter density in Broca's area was related to worse executive functioning. Executive functioning was associated with higher and lower grey matter density in different parts of both putamina. Fine motor speed was related to higher grey matter density in both caudate nuclei, right putamen and with lower density in the cingulate gyrus.
Conclusion: Associations of grey matter density with cognition are localised to specific parts of the brain. Both positive and negative associations were observed within the same structure. Detailed brain maps of cognition may provide insight into the pathways of cognitive decline.
Author Disclosures:

B-0931 10:46

Hippocampal subregions provide information beyond gross hippocampal volume for cognitive function and risk of dementia

T.E. Evans[1], H.H.H. Adams[1], S. Licher[1], F.J. Wolters[1], A. van der Lugt[1], M. Ikram[1], M. O'Sullivan[2], M.W. Vernooij[1], M. Ikram[1]; [1]*Rotterdam/NL*, [2]*London/UK (t.evans@erasmusmc.nl)*

Purpose: Hippocampal volume is related to various cognitive functions as well as risk of dementia. The hippocampus is a complex and highly organised structure, consisting of various subregions. Research on hippocampal subregions has focused on memory and subtasks. It remains unclear how hippocampal subregions relate to other cognitive domains and risk of dementia.
Methods and Materials: From the population-based Rotterdam ,study 5,035 non-demented and stroke-free persons underwent MRI (1.5T) followed by automatic segmentation of the hippocampus and its subregions using the FreeSurfer software (version 6.0). A cognitive test battery was used to assess a range of cognitive functions. Subsequently, persons were followed up for the incident dementia. Association of the hippocampal subregion volumes with cognition and incident dementia was tested using linear and Cox regression models, respectively. All analyses were adjusted for age, sex, education, and gross volume of the hippocampus.
Results: Mean age was 64.33 years (SD 10.58) with 56% women. The volume of the hippocampal fimbria, fissure, pre-subiculum and subiculum showed the most significant associations with all cognitive domains, except memory. During follow-up (mean 5.5 years), 76 persons became demented. Subiculum volume was associated with risk of dementia (hazard ratio per decrease in 1 SD volume: 6.70, 95% CI: 3.39, 13.24; P: 4.33 $^{x10-08}$, adjusted for gross volume and CV risk factors).
Conclusion: Hippocampal subregions provide additional information beyond its gross volume for various aspects of cognitive functioning, but surprisingly not for memory. Furthermore, our results suggest that the subiculum is a marker for predicting dementia.

B-0932 10:54

Acupoint-specific effect of acupuncture in Alzheimer's disease: a functional MRI study

Y. Shan[1], Y. Bian[2], Z. Wang[1], Z. Zhao[1], M. Zhang[1], J. Lu[1], K. Li[1]; [1]*Beijing/CN*, [2]*Hefei/CN (shanyiedu@hotmail.com)*

Purpose: Acupuncture has been a major therapeutic method in Chinese medicine for treating Alzheimer's disease (AD) with validation and safety. In this study, we use functional magnetic resonance imaging (fMRI) to investigate the acupoint-specific effect of acupuncture in treating for AD.
Methods and Materials: 35 subjects were recruited including 21 patients with AD (followed DSM-IV and NINCDS-ADRDA criteria) and 14 age-matched healthy controls. AD patients were randomly divided into real and sham acupoint groups. MRI data acquisition was performed on a 3-Tesla scanner (Verio; Siemens, Germany). We adopted a 16-minute single-block experimental design to obtain functional images: After acquiring baseline data for 3 minutes, acupuncture stimulation was administered while fMRI went on scanning for the next 3 minutes. Finally, needles were withdrawn and the scan continued acquiring data for another 10 minutes. Data analysis was performed using AFNI software. Intra-group comparisons were performed through paired t-test between two statistical maps.
Results: In AD patients, acupuncture at real acupoints activated brain areas primarily in the left uvula, right superior temporal gyrus and right uncus. However, acupuncture at sham acupoints only activated areas in the left insula. Brain regions that were activated more by real acupoint were mostly located in the left medial frontal gyrus, while brain areas in the right lentiform nucleus/putamen and right insula showed less activation. In healthy controls, acupuncture at real acupoints activated extensive regions in bilateral cortical structures.
Conclusion: Acupoint-specific effect of acupuncture demonstrated with fMRI may help to facilitate its clinical use in AD treatment.

B-0933 11:02

Application of multi-echo T2 relaxation technique in Alzheimer's dementia and Mild Cognitive Impairment

E. Kavroulakis, G. Kalaitzakis, P. Simos, I. Zaganas, T.G. Maris, E. Papadaki; *Iraklion/GR (fpapada@otenet.gr)*

Purpose: Multi-echo T2 relaxation technique provides quantitative measurements of the long-T2 component (80-100ms), attributed to intra/extracellular brain water and short -T2 component (20-35ms) originating from myelin water. Myelin water fraction (MWF) correlates with histological measures of myelin in animal and human brains. The aim of this study is to investigate: (1) regional changes in long/short-T_2 and MWF values in the normal appearing white matter (NAWM) of Alzheimer's Disease (AD) and Mild Cognitive Impairment (MCI) patients, (2) associations between MWF/ T2 values and neuropsychiatric test scores and 3) indirect impact of age on neuropsychiatric function, through changes in T2 /MWF values.
Methods and Materials: Multiple Echo Spin Echo (MESE) sequence with 32 echoes and detailed neuropsychological assessment was performed in 25 AD, 43 MCI and 35 healthy controls (HC). MWF/ T2 values were measured in 20 NAWM areas.
Results: AD patients showed significantly increased long-T2, increased short -T2 and reduced MWF values in temporal, parietal and periventricular NAWM, compared to HC and MCI patients. MWF/ T2 values in several NAWM regions correlated with neuropsychiatric test scores in MCI patients, who have, also, age-related increases on Dementia Rating Scale (DRS) scores and decline in episodic memory capacity, through Short-T2 and MWF values.
Conclusion: There are changes in short-T2, MWF and long-T2 values in NAWM areas of AD and MCI patients, probably due to demyelination, coupled with axonal loss and gliosis. Enhanced age-related demyelination exists in prodromal dementia states (MCI) and is associated with the severity of episodic memory deficiency and DRS scores.

B-0934 11:10

Characterising brain iron deposition in patients with subcortical vascular mild cognitive impairment using QSM: a potential biomarker

Y. Sun, Y. Zhou, Y. Wang, X. Han, W. Ding, Y. Zhang, Q. Xu, J. Xu; *Shanghai/CN (cjs1119@hotmail.com)*

Purpose: The presence and pattern of iron accumulation in subcortical vascular mild cognitive impairment (svMCI) or their effects on cognition has rarely been investigated. The aim of this study was to examine the brain iron deposition in svMCI patients using quantitative susceptibility mapping (QSM) and its correlation with the severity of cognitive impairment.
Methods and Materials: Twenty svMCI patients and 19 controls were recruited and underwent QSM using a 3.0T MRI system. Susceptibility maps were reconstructed from a vivo data. Then, regions of interest were drawn manually on the map of each subject. The inter-group differences of susceptibility value were explored in deep gray matter nuclei including bilateral subthalamic nucleus, head of caudate nucleus, globus pallidus, putamen, hippocampus, substantia nigra, and red nucleus. The correlations between regional iron deposition and the composite z-score, memory z-score, language z-score, attention/executive z-score and visuospatial z-score were assessed partial using correlation analysis, with age and gender as covariates.
Results: Susceptibility values were found to be elevated within bilateral hippocampus and right putamen in svMCI group compared with controls. The susceptibility value in right hippocampus was negatively correlated with memory z-score and positively correlated with language z-score, the susceptibility value in right putamen was negatively correlated with attention/executive z-score in svMCI group. However, composite z-score were not related to susceptibility values.

Conclusion: Our result suggests that brain iron deposition which relation to cognition indicates the clinical relevance of the biomarker. It provides further evidence for the pathophysiological mechanism underlying the cognitive deficit in svMCI patients.

B-0935 11:18

Diffusion tensor imaging for evaluating changes in the microstructural integrity of white matter in patients with mild cognitive impairment

A.A. Ojeda, P. Acevedo, M.B. Nallino, N. Lori; *Rosario/AR (ojedaheleg@hotmail.com)*

Purpose: Neuroscientists have focused increasing attention on white matter connections in the brain and on the effects of ageing and cognitive impairment. Novel methods of neuroimaging like diffusion tensor imaging (DTI)have enabled biological tissue to be investigated in vivo. White matter (WM) fractional anisotropy (FA) is thought to be related to WM integrity and decline in FA is often used as an index of decreasing WM health. The goal of this paper is to detect white matter abnormalities not shown with conventional acquisition sequences in patients with mild cognitive impairment compared to cognitively normal subjects.
Methods and Materials: We prospectively recruited 18 people with mild cognitive disorders without or with mild unspecific WM abnormalities and 8 healthy control subjects age-controlled. They were scanned on a 3T MRI with 3D FLAIR, T1 weighted 3D sequences, T2* and DTI 6 directions. DTI preprocessing and voxelwise statistical analysis diffusion data were performed using FSL tools, to calculate voxel wise differences between MCI and controls.
Results: Compared to controls, MCI subjects revealed low FA predominantly in posterior body of the corpus callosum, left cingulate gyrus (anterior portion), and right anterior corona radiata all with p<0.05; and anterior cingulum with p<0.07. The mean FA values were calculated for the most significant voxel in these regions, and for each of the 2 groups.
Conclusion: The results suggest that patients with MCI show microstructural abnormalities of specific WM fibers compared to controls, which may give an insight of early landscape pathology in cognitive disorders.

B-0936 11:26

A normal swallow tail sign on MRI has high negative predictive value in Lewy body dementia

S. Shams[1], D. Fällmar[2], S. Schwarz[3], L.-O. Wahlund[1], D. van Westen[4], O. Hansson[4], E.-M.B. Larsson[2], S. Haller[2]; [1]*Stockholm/SE*, [2]*Uppsala/SE*, [3]*Nottingham/UK*, [4]*Lund/SE (sara.shams@ki.se)*

Purpose: MRI has a blind spot for the diagnosis of Lewy body dementia (LBD), in the absence of simple MRI signs. The swallow tail sign has been proposed as an accurate sign for Parkinson Disease (PD). Due to similar disease pathophysiology between PD and LBD, we hypothesised that this sign would be likewise applicable in LBD.
Methods and Materials: This retrospective cross-sectional multicenter study received institutional review board approval. We included 97 patients (mean age 65±10, 46%female), consisting of: controls (n=21), LBD (n=19), frontotemporal lobe dementia (n=20), Alzheimer's disease (n=20) and mild cognitive impairment (n=17). All patients underwent brain MRI, with susceptibility weighted imaging at 1.5T (n= 46) / 3.0T (n= 51). The swallow tail sign was assessed independently by two experienced raters, and consensus reading was done with a third, in case of discordance.
Results: Inter-rater agreement was moderate (kappa 0.4) between raters (1.5 & 3.0T). An abnormal swallow tail sign was most common in LBD 63% (95%CI: 41-85%, p<0.001) and had a predictive value only in LBD with an odds ratio of 9 (95% CI: 3-28, p<0.001), on 1.5T and 3T. On 1.5 and 3.0T / 1.5T / 3.0T values in LBD were respectively, sensitivity 63% / 60% / 64%; negative predictive value 89% / 93% / 86%; accuracy 76% / 71% / 80%.
Conclusion: Assessment of the swallow tail sign is clinically applicable during the work-up of dementia on 1.5 and 3.0T scanners, with higher accuracy at 3.0T. Due to the high sensitivity and negative predictive value, a normal swallow tail suggests exclusion of a LBD diagnosis.

B-0937 11:34

Follow-up research in patients with amnestic mild cognitive impairment using 3D arterial spin labelling

Y. Liu, H. Yuan, X. Zeng, Z. Wang; *Beijing/CN (lyyulia@163.com)*

Purpose: To follow up the changes of cerebral blood flow (CBF) values in patients with amnestic mild cognitive impairment (aMCI) using 3D pseudo-continuous arterial spin labeling (pcASL).
Methods and Materials: Patients with aMCI (n=10, mean age 74.80±3.26 years) were recruited. All patients were follow-up, the average scanning interval was (10.36±2.14) months. MMSE and MoCA scores were measured twice. All MRI examinations were performed on a GE750 3.0T scanner. 3D pcASL and 3D-SPGR sequences were employed. All patients were scanned twice. Voxel-based analysis was used to analyze CBF data (SPM8). CBF values (First time) were compared with CBF values (Second time) in patients with aMCI.
Results: 1. The first test: mean MMSE scores were (26.80±1.48), mean MoCA scores were (22.70±2.45). Follow up: mean MMSE scores were (26.50±0.85), mean MoCA scores were (22.60±2.32). There were no significant differences of MMSE scores and MoCA scores between the first test and the second test in patients with aMCI(*P*>0.05).
2.Compared to patients with aMCI (First time), we found significant decreases of CBF values in left middle temporal gyrus and left inferior temporal gyrus in patients with aMCI (Second time) (P<0.001, T=4.50, uncorrected for multiple comparisons, cluster size>50).
Conclusion: There were more areas involved in aMCI patients with the progress of the disease. Although there were no scores changes, CBF values might serve as a more sensitive tool to detect and characterize subtle changes in patients with aMCI.

B-0938 11:42

Dynamical analysis techniques for connective graph networks

A. Meyer-Baese; *Tallahassee, FL/US (ameyerbaese@fsu.edu)*

Purpose: Neurodegenerative disease evolution is poorly understood and treatment strategies are consequently only limited efficient. Fusing modern dynamic graph network theory and modelling strategies at different timescales yields a novel transformational paradigm in neurodegenerative diseases research regarding disease evolution at the patient level, treatment response evaluation and revealing some central mechanism in a network that drives alterations in many diseases.
Methods and Materials: The structure of many functional connective networks is determined by a sparse graph structure; however, containing many hubs. While static graph network theory helps modelling and understanding a "snapshot" in the disease evolution described by the graph structure, the longitudinal time behaviour is poorly understood since a modelling paradigm of the dynamic transient graph behaviour was missing. We propose to model and analyse functional connectivity networks in neurodegenerative diseases as two timescale sparse dynamic graph networks with hubs (clusters) representing the fast sub-system and the interconnections between hubs the slow sub-system.
Results: This novel modelling paradigm will help determining the so-called controlling regions in functional connectivity networks which are the "key drivers" when it comes to control the dynamics of the network. We will present a simple method to detect those drivers and will show how they impact the disease evolution.
Conclusion: We have established a new method to detect the key nodes that control the aberrant dynamics of the functional connectivity network and have tremendous applications on the understanding of disease evolution and the subsequent development of therapeutic solutions.

B-0939 11:50

Specificity of white matter hyperintensitiy location related to cognition

L. Lampe[1], S. Kharabian-Masouleh[1], J. Kynast[1], C.J. Steele[2], V. Witte[1], M.L. Schroeter[1], A. Villringer[1], P.-L. Bazin[1]; [1]*Leipzig/DE*, [2]*Montreal, QC/CA (lampe@cbs.mpg.de)*

Purpose: White matter hyperintensities (WMH), a correlate of cerebrovascular disease, are related to dementia. We assessed how the WMH location in the white matter affects different cognitive functions.
Methods and Materials: WMH were assessed with T1-weighted MPRAGE and FLAIR (1 mm isovoxel respectively) in 700 healthy, elderly participants (60-82 years) via LesionTOADS, a revalidated segmentation algorithm originally designed for multiple sclerosis lesions. Cognitive factors were extracted with an exploratory factor analysis (16 cognitive variables from a cognitive testing battery, including CERAD and SIDAM). Binary WMH masks were registered into standardized space, multiplied by z-scored values of cognitive factor, and added to return WMH probability masks.
Results: Factor 1 (executive function), Factor 2 (memory/learning), and Factor 3 (motor speed performance) were significantly related to total WMH volume. All three cognitive factors showed circumscribed clusters in different locations throughout the white matter. Factor 1 was primarily clustered in the frontal white matter adjacent to the frontal horns; Factor 2 showed the highest cluster size in the parietal white matter; Factor 3 was related to WMH clustering in the upper deep white matter, including the corticospinal tract. All clusters were symmetrical.
Conclusion: WMH have differing impacts on cognitive functions depending on their location in the white matter. Frontal WMH are mostly related to executive function, WMH in the parietal white matter are more related to worse performance in memory/learning, and WMH in the upper deep white matter is mostly related to a decrease in motor speed performance.

New insights in the risk of breast cancer recurrences in BRCA1, BRCA2 and CHEK2 patients

H. Ghunaim[1], C. Anthierens[2], A. Laenen[2], J. Soens[2], P. Neven[2], K. Punie[2], A. Smeets[2], H. Wildiers[2], C. Van Ongeval[2]; [1]*Medina/SA*, [2]*Leuven/BE (dr.had.g@hotmail.com)*

Purpose: To adjust follow-up strategies, prevalence of breast cancer recurrence (BCR) and contralateral BCR (CBCR) in BRCA1, BRCA2 and CHEK2 patients compared to a control group with sporadic breast cancer (CG) was investigated.
Methods and Materials: In a retrospective analysis (2000-2014), 278 gene mutation carriers (GMC) were diagnosed with breast cancer (98 BRCA1, 133 BRCA2, 45 CHEK2) as first cancer event. Risk of BCR was compared to CG (4,638), analyzing time interval between breast cancer and first BCR/CBCR and between first and second BCR. Cox regression was used, correcting for age, grade, ER and lymph node status.
Results: Average age at diagnosis is 44.0y in GMC, 59.0y in CG. Grade 3 tumours were most frequently seen in BRCA1 (70.41%), compared to BRCA2 (45.31%), CHEK2 (42.22%) and CG (38.57%). The risk of first recurrence is significantly higher in the 3 GMC groups compared to CG: hazard ratio (HR) of 4.6 (2.245; 9.654) in CHEK2, 3.1 (1.731; 5.642) in BRCA2 and 3.6 (1.839; 7.138) in BRCA1, with the highest risk of first BCR after 3 years for CHEK2 (11.59%), compared to 5% (BRCA groups) and 1.74% (CG). In 16% BRCA1 and 15% BRCA2 a second recurrence was found. The risk of CBCR is also significantly higher in the 3 GM groups compared to CG: CHEK2 (HR 9.7), BRCA2 (5.8), BRCA1 (8).
Conclusion: BCR risk is significantly higher in BRCA1/2 and CHEK2 compared to CG, with CHEK2 showing most frequently a second BC and a CBCR: adjustment of radiological/clinical follow-up strategies is necessary.

B-0941 10:38

Enhanced breast cancer screening for increased risk women with a family history: is it worthwhile?

L. Davies[1], G. Stevens[2], D. Bailey[3], M. Lewis[3], A. Murray[2], K. Gower Thomas[2]; [1]*Swansea/UK*, [2]*Cardiff/UK*, [3]*Pontypridd/UK (kgt77@hotmail.co.uk)*

Purpose: Women referred on the basis of possible familial higher risk for developing breast cancer are offered early annual breast cancer screening. The effectiveness of such enhanced screening programmes has been questioned and we present our results following the implementation of such a service in Wales.
Methods and Materials: Prospectively collected data were available for all women referred for enhanced screening by genetic services since its inception in 2001. This aggregate data included numbers of referral, screen episodes and cancers detected.
Results: Genetic service referred 4,807 women for enhanced screening. There were 4,601 prevalent and 17,669 incident screen episodes. Uptake of prevalent screen was 95.7%, with 9.9% of those women recalled and 20 cancers identified (0.43% of women screened). Incident screens had a 5.6% recall rate and detected a further 64 cancers (0.36% of screen episodes). The screen detected and interval cancer rates were 3.8 and 1.5 per 1000 screens, respectively. For this enhanced programme the sensitivity, specificity and positive predictive values were 71.2%, 93.8% and 5.8%, respectively. The screening programme detected 71.2% of the cancers in this group.
Conclusion: The enhanced screening service for women at additional familial risk had a 60% lower cancer detection rate per screen compared with the routine programme and thus may be resulting in harm from unnecessary investigations and emotional distress. However, on a pragmatic level over 70% of cancers in this group are detected at enhanced screening. Alternative, less resource intensive screening programmes should be explored for women at increased familial risk.

B-0942 10:46

Rim sign and histogram analysis of apparent diffusion coefficient value on diffusion-weighted MRI in triple-negative breast cancer: comparison with ER-positive subtype

Y. Choi, S. Kim, B. Kang, K. Lee; *Seoul/KR (charismakkang@hanmail.net)*

Purpose: To compare the clinicopathologic and diffusion-weighted MRI features between triple-negative and ER-positive breast cancer and to investigate their correlation with recurrence.
Methods and Materials: 221 breast cancer patients with pre-operative MRI taken from August 2009 to March 2015 were retrospectively included. All patients had pathologically confirmed diagnosis of invasive ductal carcinoma and were grouped into ER-positive (149) and triple-negative (72) subtypes. DWI rim sign and various ADC parameters (mean, mode, 25, 50, 75 percentile, skewness, and kurtosis) between ER-positive and triple-negative subtypes were compared. The same comparison was made between recurred (11) and non-recurred (211) patients. Univariate and multivariate regression analysis were used for statistical comparison.
Results: 221 breast cancer patients with pre-operative MRI taken from August 2009 to March 2015 were retrospectively included. All patients had pathologically confirmed diagnosis of invasive ductal carcinoma and were grouped into ER-positive (149) and triple-negative (72) subtypes. DWI rim sign and various ADC parameters (mean, mode, 25, 50, 75 percentile, skewness and kurtosis) between ER-positive and triple-negative subtypes were compared. The same comparison was made between recurred (11) and non-recurred (211) patients. Univariate and multivariate regression analysis were used for statistical comparison.
Conclusion: Poor histologic grade, higher Ki-67 and higher ADC kurtosis value were correlated with triple-negative subtype. More DWI rim signs and higher ADC values were found in recurrent patients. Rim signs and histogram analysis of ADC values are helpful parameters in predicting prognosis of breast cancer.

B-0943 10:54

Significance of parametric diffusion tensor imaging correlation with immunochemistry of pathology

T.-H. Chang, H.-H. Hsu; *Taipei/TW (m10708@mail.ndmctsgh.edu.tw)*

Purpose: IHC stains of breast cancer pathology, including ER, PR, and HER2, are important to breast cancer treatment. Our goal is to observe the relationships between the parameters of diffusion tensor imaging (DTI) and IHC stains.
Methods and Materials: During 2014-2015, 34 breast cancers were included for breast DTI examination randomly. Breast DTI were performed by 1.5T whole body MRI scanner (GE HDx) with 8-channel breast coils with the following protocols, TE: minimal, TR: 6275, FOV: 21, slice: 5.0mm, b value: 0/600, 6 directions, matrix: 96x96. DTI parameters were selected and calculated on the AW server (GE®). The region of interests of tumours were judged by a senior radiologist, who is an expert on breast MRI for 9 years. Statics were calculated by MedCalc® 16.4.3 version (2016).
Results: Of these 34 breast cancers cases, 8 cases were DCIS, and 26 cases were invasive carcinoma. Parametric DTI (λ_1, λ_2, λ_3, λ_1-λ_3, FA, anisotropic index, ADC) reveals no significant relationship with IHC stains (ER/PR/Her2). However, anisotrpic index and λ_1-λ_3 revealed significant results on the Box-and-whisker graphs. In the scatter diagrams, “ER” revealed significance on the anisotropic index. The correlation coefficient (r) was calculated as -0.4294 (p=0.0286). Additionally, most of invasive carcinomas revealed peritumoural anisotropy on the FA maps (22/26), and more than half of DCIS cases showed no peritumoural anisotropy (5/8).
Conclusion: Anisotropic index of DTI revealed significance over the “ER stain”. It can be meaningful in the treatment of breast cancer. The phenomenon of peritumoural anisotropy might predict invasive cancer.

B-0944 11:02

Utility of 18F-FDG PET/CT and MRI imaging findings for predicting the clinicopathologic subtypes of triple negative breast cancer

K. Kubota, T. Fujioka, A. Toriihara, Y. Saida, U. Tateishi; *Tokyo/JP (kbtmrad@tmd.ac.jp)*

Purpose: Breast cancer is known to be a heterogeneous group of distinct disease entities, and the treatment approach is sophisticated based on each intrinsic subtypes. Genetically, triple-negative breast cancer (TNBC) is classified into 7 subtypes, and pathological classification corresponding to these subtypes has been known. We assessed the utility of 18F-FDG PET/CT and MRI imaging findings for predicting the clinicopathological subtypes of TNBC.
Methods and Materials: We retrospectively analysed the cases of 46 patients with TNBC of over 10mm in diameter who underwent 18F-FDG-PET/CT and/or MRI before therapy. The maximum standardised uptake value (SUVmax) was evaluated on FDG-PET/CT. Tumour shape, margins, size, and kinetic patterns

and intratumoural necrosis were evaluated on dynamic contrast-enhanced MRI. The imaging findings of each subtype were retrospectively evaluated with pathological diagnoses.
Results: There were 34 invasive ductal carcinoma of no special type (IDC-NST), 6 apocrine carcinomas, 2 spindle cell carcinomas, 2 medullary carcinomas, and 2 adenoid-cystic carcinomas. Both PET/CT and MRI were performed in 40 cases. Higher SUVmax values were significantly associated with IDC-NST and spindle cell carcinoma (p=0.02). Intratumoural necrosis was only seen in IDC-NST or spindle cell carcinoma. Multivariate analysis showed that the SUVmax was the only independent predictor of IDC-NST or spindle cell carcinoma (p=0.03).
Conclusion: There is a possibility that the sub-classification of TNBCs can be performed based on imaging findings.

B-0945 11:10

Does MRI background enhancement correlate with breast cancer risk? A systematic review and meta-analysis

B. Bennani-Baiti, P.A.T. Baltzer; *Vienna/AT*
(barbara.bennani-baiti@meduniwien.ac.at)

Purpose: Assess the possible correlation between MRI Background Parenchymal Enhancement and breast cancer risk.
Methods and Materials: Two investigators independently performed a systematic review using predefined search terms. Studies that applied contrast enhanced MRI for assessment of lesions rated BI-RADS 3-6 in patients that had not previously undergone chemo- or hormonal therapy were eligible. Standard of reference had to be established by histopathology or clinical follow-up. Study design, technical parameters, and level of BPE with regard to outcome, were extracted from the original publications, and possible bias was determined using the QUADAS 2 applet. Statistical analysis included data pooling, forest plot construction, and heterogeneity testing.
Results: Six eligible studies comprising 1933 lesions (959 benign and 974 malignant) were identified. Dichotomized assessment (minimal/mild vs. moderate/marked BPE) revealed a pooled OR of 1.06 for lesions associated with moderate/marked BPE and significant heterogeneity (I^2=88%,P<0.001). Subgroup analysis displayed a pooled OR of 0.46 (I^2=0%,P<0.5) in non-high risk cohorts, a pooled OR of 0.94 (I^2=0%,P<0.6) for mixed cohorts (30-50% high risk) and a pooled OR of 4.77 (I^2=0%,P<0.5) for high-risk cohorts.
Conclusion: Our analysis based on a limited number of studies shows that the discrepant findings in the literature on BPE in regard to breast cancer risk could be explained by the different patient cohorts that were investigated. High levels of BPE in high risk patients seem to be associated with an increased risk of malignancy while high levels of BPE in non-high risk patients are not. Further studies are needed to confirm this finding.

B-0946 11:18

Correlation between background parenchymal enhancement (BPE) and whole breast vascularisation of the breast at contrast-enhanced MRI

C.G. Monaco[1], N. Berger[2], G. Lo Bue[1], L.A. Carbonaro[3], F. Sardanelli[3];
[1]*Milan/IT*, [2]*Zurich/CH*, [3]*San Donato Milanese/IT*
(cristianmonaco87@gmail.com)

Purpose: A positive correlation between BPE and breast cancer risk was suggested by literature. Our aim was to investigate the association among the breast vascularization with BPE, fibro-glandular tissue(FGT) and breast size at MRI.
Methods and Materials: 46 women with intermediate risk for breast cancer (dense breasts or lifetime risk 15-20%), who underwent dynamic contrast-enhanced MRI from Sep/2013 to Nov/2015, were evaluated. Vascularization was scored 0 to 3, based on the number of vessels per breast ≥3cm-long and with a diameter ≥2mm-large; BPE and FGT were evaluated with BI-RADS classifications; breast size(nipple-pectoral distance) was measured. Statistical analysis was performed on per-breast basis. χ^2-test for categorical variables or Student's t test and ANOVA evaluation for continuous variables were used.
Results: 92 breasts were evaluated. Vascularization showed a score 0 in 42 breasts (46%), 1 in 20 breasts (22%), 2 in 28 breasts (30%) and 3 in 2 breasts(2%). Low breast vascularization(score 0) showed 17% (7/42) of BPE 3 and 4 while high breast vascularization (score 2-3) showed 63% (19/30) of BPE 3 and 4 (P < .001). Breast vascularization showed a negative correlation with FGT and a positive correlation with breast size (P<0.001); FGT showed a negative correlation with breast size (P<0.001). BPE and FGT did not showed a statistically significant correlation (P=0.552)
Conclusion: High values of BPE were significantly rarer in presence of low whole breast vascularization at MRI. When high BPE was evaluated as a risk factor, a potential difference in breast cancer risk between women with high or low breast vascularization at MRI might be considered.

B-0947 11:26

Quantitative assessment of residual fibroglandular breast parenchyma after mastectomy on MRI

R. Woitek, G. Pfeiler, A. Farr, P. Kapetas, J. Furtner, M. Bernathova, P.A.T. Baltzer, T.H. Helbich; *Vienna/AT (ramona.woitek@meduniwien.ac.at)*

Purpose: Skin-sparing and nipple-sparing mastectomies (SSM/NSM) are performed to remove the breast's fibroglandular tissue, thereby reducing the risk of new breast cancer or cancer relapse. The postoperative presence of residual fibroglandular parenchyma (RFGP) is associated with remaining cancer risk. This study evaluated the role of MRI for the quantitative assessment of RFGP and skin envelope thickness after NSM and SSM.
Methods and Materials: The postoperative MRI scans (in accordance with EUSOMA recommendations, including T2-TSE and T1 GRE sequences) of 58 patients (85 breasts) who had undergone mastectomies with immediate reconstructions, between 2003 and 2013, were retrospectively evaluated. Skin envelope thickness was measured and volumetry of hypointensities that were suggestive of RFGP was performed using standard software (ImageJ). Hypointensities >1cm³ were considered positive for RFGP.
Results: Of 58 patients, nine had NSM and 49 SSM. RFGP was found in 16 patients (27.6%; volume range = 1.1 - 14.5cm³). Retromamillary RFGP ($RFGP_{rm}$) was found only after NSM (mean volume = 2.8 ± 1.7cm³). RFGP in other locations ($RFGP_{other}$) was found in 24.2% (mean volume = 4.2 ± 3.6 cm³). The volumes of both $RFGP_{other}$ and $RFGP_{rm}$ were significantly higher after NSM than SSM (p = .023; p <.001). Skin envelope thickness correlated significantly with $RFGP_{other}$ in left-sided breasts (p = .018).
Conclusion: In almost 25% of patients, MRI showed $RFGP_{other}$ after SSM and NSM, apart from $RFGP_{rm}$ after NSM. Preoperative MRI is recommended to improve preoperative planning to avoid RFGP and the associated cancer risk.

B-0948 11:34

Correlation of quantitative multiparametric ultrasound with immunohistochemical expression of breast tumours

P. Kapetas, R. Woitek, P. Clauser, K. Pinker, M. Bernathova, T.H. Helbich, P.A.T. Baltzer; *Vienna/AT (panagiotis.kapetas@meduniwien.ac.at)*

Purpose: To evaluate the correlation of quantitative ultrasound (US) parameters with immunohistochemical expression of breast cancer.
Methods and Materials: 64 patients, each with one malignant, biopsy-proven breast lesion were included in this prospective, IRB-approved study. Each lesion was examined with B-mode US, elastography (acoustic radiation force impulse (ARFI)), Doppler US and contrast-enhanced US (CEUS). Quantitative indices were recorded for each modality as follows: shear wave velocity (SWV) for ARFI, pulsatility (PI) and resistive index (RI) for Doppler US, and peak enhancement (PE), wash-in area under the curve (WiAUC), rise time (RT), mean transit time (local) (mTTl), time to peak (TTP), wash-in rate (WiR), wash-in perfusion index (WiPI), wash-out AUC (WoAUC), fall time (FT) and wash-out rate (WoR) for CEUS. For each lesion, histologic study determined tumour grade, oestrogen (ER) and progesterone receptor (PR), human epidermal growth factor receptor 2 (HER2), Ki67 proliferation index and tumour protein p53. Paired and unpaired nonparametric statistics were applied for comparisons as appropriate. Spearman's correlation coefficient was used to evaluate the correlation of sonographic quantitative indices with immunohistochemical parameters.
Results: There was a significant yet weak negative correlation between ER positivity and PE (r_s=-0.258,p<0.05), WiAUC (r_s=-0.329,p<0.01), WiWoAUC (r_s=-0.309,p<0.05) and WoAUC (r_s=-0.294,p<0.05) as well as PR and PE (r_s=-0.248,p=0.05), WiWoAUC (r_s=-0.279,p<0.05) and WoR (r_s=-0.294,p<0.05). A significant but weak correlation was shown between tumour grade and RI (r_s=0.314,p<0.05).
Conclusion: Several quantitative US indices show significant (yet weak) correlation to immunohistochemical parameters of breast tumours. The clinical relevance of this finding has yet to be explored.

B-0949 11:42

3D quantitative ultrasound analysis of breast carcinoma can non-invasively detect important pathological prognostic factors

A.S.S. Meel-van den Abeelen, G. Weijers, J.C.M. van Zelst, J.M. Thijssen, R.M. Mann, C.L. de Korte; *Nijmegen/NL*
(aisha.vandenabeelen@radboudumc.nl)

Purpose: In breast cancer, tumour grade and biological markers (oestrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2)) are predictive factors for medical treatment response and important for patient prognosis. 3D quantitative breast ultrasound (3DQBUS) may be used to guide histological biopsy. We investigated the correlation of 3DQBUS features with tumour grade and receptor status and assessed its predictive value.
Methods and Materials: 3D US examinations of 81 breast tumours were included. Per tumour, 3 regions of interest were defined: LES (ellipsoid

covering the hypoechoic part of the LESion), PER (PERitumoural border: 0.5mm around LES, capturing the halo), and POS (POSterior-tumoural region, capturing the posterior acoustic effect). Mean and variance of the echo level within the regions was calculated, and for LES and POS, the attenuation coefficient was calculated. Logistic regression was used to test the associations of 3DQBUS with receptor status and tumour grade. Additionally ROC-analysis was performed.
Results: Of 81 IDCs, 58 were ER- or PR-positive and 23 were ER- and PR negative, of which 16 were also HER2 negative. 37 were low-grade and 32 were high-grade tumours (unknown in 12). 3DQBUS provided good discrimination between tumours that were ER or PR positive versus ER/PR- (AUC=0.86) and triple negative tumours (AUC=0.89) and also allowed separation of low- and high-grade tumours (AUC=0.84).
Conclusion: 3DQBUS allows non-invasive separation of breast cancers with a different prognosis. This may be used to target the most aggressive part of a tumour during biopsy.

B-0950 11:50

Upgraded malignancy from high-risk and borderline lesions: correlated with immunohistochemical and clinical findings
J.-H. Choi[1], B. Kang[2], S. Kim[2]; [1]*Gyeonggi-do/KR*, [2]*Seoul/KR*
(mchjjh2@naver.com)

Purpose: We investigated the immuohistochemical characteristics of upgraded malignancy from high-risk and borderline lesions and correlated with clinical and imaging findings.
Methods and Materials: We reviewed the image-guided biopsy record retrospectively. We included all women with high-risk and borderline lesions and followed them for later breast cancers. We evaluated the clinical and imaging findings and we correlated the clinical and imaging factors with upgrade to malignancy. After surgery, the pathologic results were reviewed. When the lesion was updated to malignancy, the immuohistochemical characteristics were analysed.
Results: From January 2011 to July 2015, 340 high risk or borderline lesions confirmed by image-guided biopsy were included. Of the total 340, 81.2% (n=276) was not upgraded, 13.5% (n=46) was upgraded to carcinoma in situ, and 5.3% (n=18) was upgraded to invasive cancer. The upgrade rates were higher in patients with older age, larger lesion size, and with ADH than with other pathologic type (p<0.05). In the surgical proven malignancy (n=64), there was no lymph node metastasis (0%). ER positive (93.9%), PR positive (87.5%), HER2 negative (90.6%), Ki-67 negative (82.8%), EGFR negative (84.4%) were more frequent. Luminal A (76.6%) was most frequent, and then there were luminal B (17.2%), HER2 positive (1.6%), basal type of triple negative (1.6%), and non-basal type of triple negative (0.6%).
Conclusion: This immunohistochemical approach may form a useful addition to the clinical and imaging evaluation of high-risk and borderline lesion of the breast.

3D-x-ray-tomographies of lumbar spine performed with twin robotic x-ray: quantitative results of lumbar neural foramens in supine and upright position
A.L. Falkowski, R.M. Benz, S. Schön, L. Rizzo, E. Sommer, A. Hirschmann;
Basle/CH

Purpose: Tomographic examinations of lumbar spine are generally performed in supine non-weight-bearing position. This position is unphysiologic and might underestimate pathologies due to lack of body-weight. Evaluation of changes of lumbar neural foramina in supine non-weight-bearing and upright weight-bearing position using 3D-x-ray-tomography.
Methods and Materials: Lumbar spines of 48 patients (14 male; 34 female) with a mean age of 67.8±13.0 years were examined in upright weight-bearing position using a twin robotic x-ray unit (Multitom Rax, Siemens Healthineers). Supine non-weight-bearing scan was either performed using x-ray unit or CT. All patients were prospectively enrolled after IRB-approval. Images were reformatted according to intervertebral disc and axis of the spine at each lumbar level. Sizes of neural foramina (area and cranio-caudal diameter) were measured by two readers independently on sagittal reformats. Wilcoxon signed rank test (P<0.05) was used and interreader reliability was defined by intraclass correlation coefficient.
Results: Area of neural foramina significantly decreased at nearly all levels for both readers from supine (reader 1; L5: 1.20±0.36cm^2) to upright (1.15±0.41cm^2; P=.005) position, except for L4. Cranio-caudal diameter of neural foramina decreased in all levels L1-3 and at left L5-level for both readers. Interreader reliability for area was fair to excellent (0.504-0.894) and showed a wide range of variability for cranio-caudal distance (0.322-0.744).
Conclusion: Upright weight-bearing position decreases size of neural foramina causing potential risk factors for neural nerve compression that might be not evident on routine supine examinations. Thus, more specific diagnoses in unclear cases might be made using 3D-tomography.

Can listhesis on upright radiographs predict the Schizas grade of lumbar spinal canal stenosis assessed on MRI?
T. Finkenstaedt[1], N. Bolog[2], J. Burgstaller[1], F. Del Grande[3], F. Del Grande[3], N. Ulrich[1], J. Steurer[1], G. Andreisek[1], S. Winklhofer[1]; [1]*Zurich/CH*, [2]*Bucharest/RO*, [3]*Lugano/CH (tim.finkenstaedt@usz.ch)*

Purpose: To assess the correlation between the grade of degenerative listhesis on upright radiographs with the grade of central spinal stenosis on supine magnetic resonance imaging (MRI) in patients with lumbar spinal stenosis (LSS).
Methods and Materials: Conventional radiographs and MR images of 141 consecutive patients (77 female, mean age 73) were retrospectively evaluated in this IRB-approved study. The grade of listhesis (in millimeter [mm]) was assessed on upright radiographs and on supine MRI of the lumbar vertebral segment 4/5. In addition, the grade of central spinal stenosis of the same segment was evaluated according to the classification of Schizas and correlated to the listhesis severity in radiographs. Kappa and ICC statistics were performed.
Results: Listhesis was detected in significantly more patients in radiographs (n = 53; 38 %) compared to MRI (n = 27; 19 %), p < 0.001. Pairwise comparison demonstrated a significant larger extension of listhesis in radiographs (mean 8.6 ± 2.8 mm) compared to MRI (mean 5.6 ± 1.9 mm), p < 0.001, each. A significant positive correlation was found regarding the grade of listhesis measured in radiographs and the grade of stenosis in MRI (Pearson correlation 0.48, p < 0.001). The interreader agreement was excellent for the presence of listhesis (Kappa = 0.938) and for the grading of listhesis (ICC = 0.913).
Conclusion: The grade of listhesis on radiographs is highly correlated with the grade of central LSS on MRI.

B-0953 10:46

Intravoxel incoherent motion (IVIM) analysis of vertebral bone marrow changes after radiation exposure from diagnostic imaging and interventional procedures
M. Yoon[1], S.-J. Hong[1], C. Kang[1], K.-S. Ahn[1], B. Kim[2]; [1]*Seoul/KR*, [2]*Gyeonggi-do/KR (mina11360@gmail.com)*

Purpose: To assess changes in vertebral bone marrow diffusion and perfusion using intravoxel incoherent motion diffusion-weighted magnetic resonance imaging (IVIM-DW MRI) after exposure to ionizing radiation from diagnostic imaging and interventional procedures in hepatocellular carcinoma (HCC) patients.
Methods and Materials: A total of 21 IVIM-DW MRI sets in 20 HCC patients, consisting of baseline and follow-up liver MRI with an interval less than 100 days were reviewed, after varying levels of radiation exposure from transarterial chemoembolisation (TACE), dynamic computed tomography (CT) of the liver, and plain radiography of the abdomen. IVIM parameters (apparent diffusion coefficient (ADC), true diffusion coefficient (D), pseudodiffusion coefficient (D*), and perfusion fraction (PF)) of the lower thoracic and lumbar vertebral bone marrow were analysed for significant differences between baseline and follow-up MRI using Wilcoxon signed-rank test, and for correlations with cumulative effective dose, as well as time interval between the last radiation exposure and follow-up MRI using Spearman's correlation.
Results: Compared to baseline MRI, ADC, D* and PF values decreased on follow-up MRI with statistical significance (p<0.05). Cumulative effective dose was moderately correlated with decrease in D* (r=0.434). In addition, longer intervals between the last exposure and follow-up MRI were moderately and negatively correlated with changes in D and ADC (r=-0.352 and -0.333, respectively).
Conclusion: Vertebral bone marrow diffusion and perfusion parameters were significantly changed after exposure to medical radiation.

B-0954 10:54

Evaluation of sclerosis in modic changes of the spine using susceptibilityweighted magnetic resonance imaging

S.M. Böker, Y.Y. Bender, L. Adams, M. Wagner, E.M. Fallenberg, B. Hamm, M. Makowski; *Berlin/DE (Sarah-maria.boeker@charite.de)*

Purpose: Evaluation of the diagnostic performance of susceptibility-weighted magnetic resonance imaging (SWMR) to differentiate between sclerotic and non-sclerotic Modic changes (MC) of the spine compared to computed tomography (CT) and radiographs.
Methods and Materials: SWMR and standard T1/T2 MR of the cervical (n=21) and/or lumbar spine (n=34) were performed in 54 patients. 21 subjects served as control. CT was performed in 18 patients; in all other patients radiographs were available. 67 Modic changes were identified on T1/T2 MR. On SWMR changes were classified as sclerotic and non-sclerotic based on signal intensity measurements. Sensitivity and specificity of SWMR and T1/T2 MR for differentiating between sclerotic and non-sclerotic Modic changes were determined. CT and radiographs were used as reference standard.
Results: Signal measurements between sclerotic and non-sclerotic Modic changes differed significantly ($p<0.01$) on SWMR. In contrast on T1- and T2-weighted MR no significant difference ($p>0.05$) was measured. Using a specific cut-off value on SWMR, a reliable differentiation between sclerotic and nonsclerotic Modic changes could be achieved, with a sensitivity of 98% and specificity of 95%. T1-/T2-weighted MR yielded a significantly lower sensitivity to detect sclerosis (20 %).
Conclusion: Using CT and radiographs as reference standard, SWMR allows a reliable detection of sclerosis in Modic changes with a higher accuracy compared to standard spine MR sequences.

Facet joint effusion on supine MRI in patients with lumbar spinal stenosis: correlation with listhesis on upright radiographs

N.V. Bolog[1], T. Finkenstaedt[1], G. Andreisek[1], J. Burgstaller[1], J. Steurer[1], F. Del Grande[2], A.F. Mannion[1], S. Winklhofer[1]; [1]*Zurich/CH*, [2]*Lugano/CH (nbolog@phoenixswissmed.com)*

Purpose: To asses the correlation between facet joints effusion in MRI and grade of listhesis on upright conventional radiographs in patients with clinically suspected lumbar spinal stenosis (LSS)
Methods and Materials: MR images and upright conventional radiographs of 50 consecutive patients (31 female, 19 male, mean age 73 years) with LSS were retrospectively evaluated in this institutional review board-approved study. The grade of listhesis was assessed on upright radiographs and was measured in millimetres (mm). The facet joint effusion (in mm) was evaluated in the corresponding segment of the listhesis in axial T2-weighted images. Intraclass correlation coefficient statistics were performed to investigate into the inter-reader agreement. Pearson analysis was conducted to assess the correlation between facet joint fluid in MRI and grade of listhesis in upright radiographs.
Results: The mean listhesis in radiographs was 6.6 +/- 3mm. The mean facet joint effusion was 1.4 +/- 1.4 mm (range 0-5mm). A significant positive correlation was found regarding the amount of fluid in the facet joints in MRI and the grade of listhesis measured on radiographs (p less than 0.005). ICC values demonstrated an excellent inter-reader agreement for listhesis (ICC=0.91) and substantial agreement (0.55) for inter-reader agreement regarding joint fluid.
Conclusion: Lumbar fact joint effusion on supine MRI correlates with listhesis on the upright radiographs in patients with clinically lumbar spinal stenosis. Thus, the thickness of the fluid within the facet joints may be an indicator for the extent of listhesis on upright position.

Feasibility of ADC value in lumbar disc degeneration at 1.5T

C. Kim; *Sungnam-si/KR (hello.hello.chohee@gmail.com)*

Purpose: Grading of disc degeneration based on T2-weighted image has some ambiguity. To evaluate feasibility of ADC value in lumbar disc degeneration is introduced based on the both Pfirrmann and modified Pfirrmann grading systems.
Methods and Materials: Lumbar spine T2-weighted and diffusion-weighted with b-value 0 and 500 1.5T MR imaging scans in our single institution from March 2014 to December 2014 were retrospectively reviewed. A total of 210 lumbar discs of 70 patients were analyzed. Severity of lumbar disc degeneration was graded by two independent observers using Pfirrmann's and modified Pfirrmann's scales, and the weighted value of kappa is calculated to measure the degree of disagreement between two readers. ADC values were recorded by the third observer for each disc within the center of disc in midsagittal plane. ADC values of disc were tested by correlation with visual grading systems, age, and gender.
Results: Intervertebral disc degeneration was negatively correlated with ADC values at lumbar levels except between grade 4 and 5 in Pfirrmann's scale and except above grade 5 in modified Pfirrmann's scale. Inter-observer agreements were good (κ_P=0.74, κ_{mP}=0.76) in both grading systems. And intra-observer agreements were very good in both grading systems (κ_P=0.92, κ_{mP}=0.84). Multiple linear regression analysis revealed ADC value had statistically correlation with grading systems, not age and gender.
Conclusion: Using ADC values to evaluate degenerative lumbar disc can be alternative approach supplementing visual grading system and while directly quantifying subtle changes.

B-0957 11:18

Role of fractional anisotropy (FA) in diffusion tensor imaging (DTI) for assessing degenerative lumbar disc disease: a preliminary study in 75 patients

M. Perri[1], R. Balzano[1], R. Izzo[2], G. Guglielmi[1], T. Popolizio[1]; [1]*San Giovanni Rotondo/IT*, [2]*Naples/IT (ro.balzano@gmail.com)*

Purpose: To evaluate the imaging features of the lumbar disc degenerative disease using FA in DTI imaging and comparing them with those obtained by standard MR protocol.
Methods and Materials: Medical Ethical Committee approval and informed consent were obtained. We selected 75 patients (mean age 42,3) composed by 20 healthy volunteers and 55 patients with already documented pathology whose 16 with extrusion, 19 with protrusion and 20 with bulging disc. All patients underwent MRI 1,5 T scanner examinations . Axial DTI images were performed using b value =600 s/mm^2 and diffusion directions = 30. FA values and corresponding images were extraced from the axial DTI images. Disc levels were also studied using standard MR protocol. Two expert radiologists evaluated MRI exams according to the recommended Nomenclature of the combined task forces of the ASSR, ASNR, and NASS. Chi-Square Test was performed for statistical analysis.
Results: All 20 healthy volunteers showed no significant alterations of the annulus fibers as on MR standard protocol as on FA ($p>.01$). Twelve out of 20 patients with documented bulging disc, showed on FA annulus fissures and were classified as intraannular herniation ($p<.01$). In 10 out of 19 patients, classified as protrusions showed on FA no annulus fissures ($p<.01$). All 16 patients with extrusions showed annulus fissures on both standard sequences and FA ($p>.01$).
Conclusion: The FA could demonstrate the integrity or rupture of the annulus fibers and could be added to the standard MRI protocol for obtaining more information on the disc structure.

Lumbar plexus neuropathy in diabetic patients: an MRI evaluation study

F.I. Rozalli, N. Mohd. Ramli, K. Rahmat, F. Fadzli, N. Sulaiman, N. Shahrizaila, F.N. Zulkilpully; *Kuala Lumpur/MY (izzrozalli@aol.com)*

Purpose: There is a high prevalence of peripheral neuropathy among diabetics in Malaysia. This is usually assessed clinically and via nerve conduction study. Our goal is to assess the feasibility of utilising Diffusion Tensor Imaging (DTI) to assess severity of peripheral neuropathy and to predict concurrent muscle atrophy.
Methods and Materials: 30 diabetic patients and 10 age-matched healthy controls were prospectively recruited. The neuropathy was classified using the Toronto Clinical Scoring System (TCSS). MRI 3-Tesla with DTI was performed on the dominant leg to evaluate sciatic and peroneal nerves. Fractional anisotropy (FA) values were obtained for each nerve. Axial in-out-phase of the calf was used to determine the presence of muscle atrophy and is classified into severity by using Goutallier classification on the lateral gastrocnemius muscle.
Results: Spearman correlation test on neuropathy severity level with sciatic nerve and peroneal nerve was done and proved that the neuropathy severity (TCSS) had strong negative correlation with sciatic FA (r^2=-0.61, $p<0.05$) and poor negative correlation with peroneal FA (r^2=-0.39, $p<0.05$). This concludes that the worse the neuropathy severity, the worse the FA values for both nerves. There is no association between medial gastrocnemius atrophy severity with neuropathy severity level ($p<0.05$). There is no significant association between the mean FA values for both nerves with HbA1c control, age and duration of diabetes.

Conclusion: DTI is a good predictive tool to assess peripheral neuropathy severity among diabetic patient as it correlates well with TCSS severity. However, muscle atrophy is not directly related to neuropathy severity.

Stir and diffusion MR neurography of the lumbar and sacral plexus: findings in asymptomatic individuals
M.L. Zanatta, M.R. Abreu, W. Ezequiel Neto; *Porto Alegre/BR (matheuszanatta@gmail.com)*

Purpose: Evaluate and compare image quality of lumbar and sacral plexus anatomy with DW (diffusion weighted) and STIR (short tau inversion recovery) magnetic resonance (MR) neurography sequences.
Methods and Materials: MR neurography of the spine and hip were performed in 30 asymptomatic individuals (20-60 y) utilising DW and STIR sequences on a 1,5 tesla siemens MAGNETOM espree. Nerve and ganglia morphology analysis and measurements were performed by two musculoskeletal radiologists employing MPR (multiplanar reconstruction) and MIP (maximum intensity projection) on an advanced workstation.
Results: The visualisation of nerve roots and ganglia was possible in all patients through DW sequences with and without MIP reconstructions, meanwhile were only demonstrated in 80% of STIR sequence images without MIP and in 90% with MIP. The neural structures on DW images were easier to read than STIR sequences, whereas the surrounding vessels appeared on the same intensity as some nerve roots. DW also had a higher concordance ratio between the observers in comparison with STIR (Pearson 0.8).
Conclusion: Lower lumbar and sacral nerve roots and its ganglia were successfully assessed using DW neurography, specially after using the MIP technique, and surpassed STIR imaging on evaluation of the nerves anatomy and surrounding structures.

Dual-layer spectral CT: reduction of metallic artefacts from posterior spinal fusions
J. Dangelmaier, B.J. Schwaiger, M. Renz, A. Sauter, I. Riederer, D. Münzel, A. Fingerle, E.J. Rummeny, P.B. Noël; *Munich/DE (julia.dangelmaier@gmx.de)*

Purpose: To evaluate the clinical potential of virtual monoenergetic images (monoE) generated with a dual-layer spectral Computed Tomography (CT) system and determine the optimal settings for reduction of metal artifacts from posterior spinal fusions of diverse extent and different spine levels.
Methods and Materials: Twenty patients with posterior spinal fusion who underwent a spectral CT scan (IQon Spectral CT, Philips Healthcare, USA) for various clinical indications were included into this study. Two independent readers evaluated axial 0.9 mm slides with a window center of 50 HU and width of 380 HU. Image quality of the conventional scan was compared with monoE images at 40, 60, 80, 100, 120, 140, 160, 180 and 200 keV. A four point Likert-scale was used to document subjective impression of diagnostic image quality and the Hounsfield unit of the area with the most pronounced streak artefact was documented for every keV-setting. Additionally, the optimal monoE (OPTkeV) setting for all patients was determined.
Results: Quantitative and qualitative analysis showed statistically significant artefact reduction for higher monoE levels and especially for the OPTkeV compared to conventional images. Optimal keV-settings ranged from 120 to 140 keV. Our results reveal high inter-reader agreement for quantitative and qualitative evaluations.
Conclusion: Virtual monoenergetic images of higher energy levels (120-140 keV) provide significant reduction of metallic artefacts from posterior spinal fusions compared to conventional scans. Compared to previous results, with dual-layer spectral CT our findings can be applied to the whole field-of-view and to all patients without any compromises.

Value of dedicated iterative metal artefact reduction algorithms in CT following spinal instrumentation
J. Aissa, C. Thomas, L. Sawicki, J. Caspers, P. Kröpil, G. Antoch, J. Boos; *Düsseldorf/DE (patric.kroepil@med.uni-duesseldorf.de)*

Purpose: To investigate the value of CT iterative metal artifact reduction (MAR) algorithms in patients after spinal instrumentation.
Methods and Materials: Twenty-four patients (13 male, 11 female; age 60.1±16.6) with post-surgical spinal CT between March 2015 and July 2016 were retrospectively included. CT Images were reconstructed with weighted filtered back projection (WFBP) and with two iterative MAR algorithms (MAR-Algo1, adjusted to spinal instrumentations and MAR-Algo2, adjusted to large metallic implants). A medium smooth kernel (B30f) and a sharp kernel (B70f) were used for image reconstruction. Frequencies of density changes were measured to assess quantitative artefact strength. Two independent readers rated visibility of anatomic structures including the central canal, the spinal cord, neural foramina and vertebral bone (0 = structure not identifiable to 5 = structure visible with high diagnostic confidence).
Results: Both algorithms quantitatively reduced artefacts compared with WFBP (MAR-Algo1: 59527.2±70182.6; MAR-Algo2: 89593.3±41590.5, WFBP: 123273.4±104734.9, $p < 0.001$). Subjectively, both algorithms improved visualization of bone (median MAR-Algo1: 3; inter quartile range (IQR): 3-4; MAR-Algo2: 4; IQR: 4-5) and soft tissue structures (median MARAlgo1: 3; IQR: 1.5-3; MAR-Algo2: 4; IQR: 3.5-4) compared with WFBP (bone structures: median 2; IQR: 1-3; soft tissue: median 2; IQR: 0.5-2) ($p<0.001$). Compared with MAR-Algo1, quantitative artefact reduction and visualization of soft tissue and bone structures was improved with MAR-Algo2 ($p<0.001$).
Conclusion: Both iterative MAR algorithms improved image quality and reduced artefacts compared with WFBP, however, the algorithm with dedicated settings for large metallic implants was superior to the algorithm specifically adjusted to spinal implants.

Fat quantification in MRI and MRS - an in vitro validation
N.P. Linder, T. Rakete, A. Schaudinn, T. Kahn, H. Busse; *Leipzig/DE (linder@uniklinik-leipzig.de)*

Purpose: MR is a well established technique for quantification of adipose tissue (fat). Current techniques involve MR imaging, mainly based on the Dixon technique and MR spectroscopy. There is little evidence on the exactness of this fat quantification, which is addressed in this project.
Methods and Materials: Two separate sets of fat emulsions (E1 and E2) were generated by two independent pharmaceutical laboratories. Concentrations ranged from zero (water only) to 100% in steps of 10%. Using a standard 1.5 T MR scanner (Archieva, Philipps, Best, NL) MR sequences performed were 2 (slice thickness 10 mm, FOV 530 x 530 mm, TE1 3.45 ms, delta TE 1.44 ms) and 11-point Dixon (10 mm, 384 x 288 mm, 0.93 ms, 0.77 ms), stimulated echo acquisition mode (STEAM) proton spectroscopy (VOI 20 x 20 x 20 mm, TE 10 ms, TR 4000 ms) and point resolved spectroscopy (PRESS) (30 x 30 x 30 mm, 29 ms, 3500 ms). Results were blotted and compared by a linear regression true the origin by the resulting coefficient of determination (R2) and Bland Altman Blots.
Results: Overall Performance of the MR techniques was moderate to good with best results shown in the 11-point Dixon technique: R^2 values for 2p Dixon, 11p Dixon, STEAM and PRESS were 0.7479, 0,9831, 0.340 and 0.9823 for E1 and 0.8065, 0.9853, 0.342 and 0.9267 for E2, respectively.
Conclusion: Both 11 point Dixon and PRESS techniques are a reliable choice for fat quantification over a wide range of fat concentration.

B-0963 10:38

Estimation and correction of susceptibility-related distortions in MRI
I. Seimenis[1], E.P. Pappas[2], A. Moutsatsos[2], E. Georgiou[2], P. Karaiskos[2]; [1]*Alexandroupoli/GR*, [2]*Athens/GR (iseimen@med.duth.gr)*

Purpose: To propose and implement a methodological approach for the differentiation, evaluation and correction of susceptibility-related distortions in MR images.
Methods and Materials: A custom-made, head-sized, CT- and MR-compatible phantom, encompassing 947 control points (CPs) and two inserts, was constructed. CT provided the reference locations for inserts and CPs. Following 1.5T imaging, distortions were estimated with either the read gradient reversal or phase difference mapping technique. Distortions related to Bo inhomogeneity were estimated with phantom and inserts filled with copper sulphate solution, whilst susceptibility effects were evaluated with air or gadolinium (Gd) solution (5-10 mmol/ml herein) within the inserts. Correction schemes were based on the average-image and phase unwrapping techniques.
Results: Read gradient reversal effortlessly highlights areas of increased distortion, although CPs analysis is required to quantitatively assess distortion. The phase difference method proves excellent at high-signal regions but lack of phase information at low-signal areas, often encountered in patient images, results in unwrapping errors. For the protocol employed and volume scanned, Bo inhomogeneity distortion reaches 1 mm. The presence of air or Gd within

the inserts results in approximately 0.5 mm disposition which is read gradient direction dependent.
Conclusion: The presented methodology employing a prototype phantom effectively untangles complex distortion phenomena present in patient images. Under specific conditions applied, Bo inhomogeneity constitutes the predominant source of sequence-dependent distortion compared with susceptibility effects. A correction approach employing the average-image method is the simplest and most efficient method to improve geometric accuracy in demanding applications.

X-ray dark-field imaging to monitor the development of acute lung injury in mice

K. Hellbach[1], F. Meinel[1], T. Conlon[2], A. Yaroshenko[3], S. Auweter[1], M.F. Reiser[1], O. Eickelberg[2], F. Pfeiffer[3], A.Ö. Yildirim[2]; [1]*Munich/DE*, [2]*Oberschleißheim/DE*, [3]*Garching/DE*
(katharina.hellbach@med.uni-muenchen.de)

Purpose: The aim of this study was to evaluate the assessment of acute lung injury (ALI) in a murine model of pulmonary emphysema with grating-based x-ray dark-field imaging in vivo.
Methods and Materials: ALI was induced in female, 8-10 week old C57Bl/6N mice by orotracheal instillation of porcine pancreatic elastase (80 U/kg BW) (n=11). Control mice (n=10) received orotracheal instillation of PBS. Mice were imaged immediately before and 1 day after the application of elastase or PBS to assess acute changes in pulmonary structure due to ALI. Subsequently, 6 mice from each group were sacrificed and their lungs were lavaged and explanted for histological analysis. 7, 14 and 21 days later the remaining mice were imaged to assess the development of acute lung injury as well as emphysema progression. All images were acquired with a prototype grating-based small-animal scanner. At day 21, lungs were lavaged and obtained for histopathological analysis.
Results: Lavage confirmed that mice had developed ALI one day after administration of elastase. Additionally, lungs showed signs of early pulmonary emphysema, which continuously worsened until the end of the experiment. ALI was visible as a striking decrease in signal intensity of the pulmonary parenchyma on dark-field images at day 1. Quantitative analysis confirmed that dark-field signal intensity at day 1 was significantly lower than signal intensities measured at the remaining timepoints. There was no significant alteration in median transmission signal intensity.
Conclusion: The development of ALI in vivo can be monitored with dark-field radiography.

B-0965 10:54

X-ray dark-field radiography for the depiction of pneumothoraces in living pigs

K. Hellbach[1], A. Bähr[2], J. Herzen[3], P.B. Noël[1], A. Yaroshenko[4], T. Köhler[4], J. Mohr[5], M.F. Reiser[1], F. Pfeiffer[3]; [1]*Munich/DE*, [2]*Oberschleißheim/DE*, [3]*Garching/DE*, [4]*Hamburg/DE*, [5]*Eggenstein-Leopoldshafen/DE*
(katharina.hellbach@med.uni-muenchen.de)

Purpose: The aim of this study was to investigate whether pneumothorax diagnosis in a large animal model can be facilitated using x-ray dark-field radiography.
Methods and Materials: Experiments were performed using 2.5 months old, wild-type German landrace pigs (n=8). The animals were anesthetized, intubated, and mechanically ventilated during the experiments. All pigs were imaged with an experimental grating-based large animal scanner to acquire x-ray transmission and dark-field radiographs before and after induction of a unilateral pneumothorax. All scans were performed in abdominal position and posterior-anterior (p.a.) direction under respiratory arrest. Image contrast-to-noise ratios (CNR) between lung tissue and the air filled pleural cavity were quantified for both, transmission and dark-field radiograms.
Results: Lateral pneumothoraces were clearly visible as areas with no dark-field signal next to the adjacent lung parenchyma, which generated a strong dark-field signal. CNR between the air filled pleural cavity and the adjacent lung tissue was significantly higher in dark-field (3.65 ± 0.9) than in transmission images (1.14 ± 1.1; $p < 0.01$). Due to abdominal positioning of the pigs some of the animals developed a dorsal pneumothorax, which was also visible in dark-field images.
Conclusion: This study shows increased contrast between lung parenchyma and air in the pleural space in x-ray dark-field radiography as compared to conventional chest x-ray in a large animal model in p.a. images. This makes this technique a promising tool for facilitated diagnosis of pneumothoraces.

B-0966 11:02

Channel data recycling in CEUS imaging

G. McLaughlin, D. Napolitano, R. Steins, J. Baun; *Mountain View, CA/US (glen@zonare.com)*

Purpose: Investigate CEUS performance enhancement possibilities through the use of Channel Data Recycling (CDR), and Synthetic Steered Continuous Transmit/Receive Focusing (SSCTRF), to extracting and compound multiple minimally correlated images from a single CEUS transmit/receive sequence for the purpose of improving contrast resolution, improving SNR, minimising microbubble destruction, and enhancing temporal resolution. For example, 9 minimally correlated CEUS images can be generated from a 4-pulse sequence set, along with 3 B-mode reference images for compounding.
Methods and Materials: CEUS loops were collected from a ZONARE ZS3 system using two different transducers (C9-3&L14-5w). These loops were then processed with traditional methods, where single cubic-fundamental and single B-mode images were extracted. They were also processed to extract up to 6 cubic-fundamental images and 3 harmonic images along with 3 B-mode images. The 6 cubic-fundamental images consisted of 2 images that were constructed by weighting and adding combinations of the pulse sequence, and 4 images that were than constructed through SSCTRF techniques to generate 2 steered left and 2 steered right images. The same technique was used to generate the 3 harmonic and 3 B-mode images.
Results: The CEUS loops generated from the CDR data sets utilising SSCTRF showed improved contrast resolution, improved SNR, and improved border delineation while maintaining tissue perfusion kinetics along with no additional bubble destruction. This resulted in enhanced visualisation and higher diagnostic confidence.
Conclusion: CDR with SSCTRF is a viable technology to improve SNR and contrast resolution in CEUS imaging while maintaining temporal resolution with no additional bubble destruction.

Conventional ultrasound speed of 1540 m/s is inappropriate for examinations of obese patients at second trimester of pregnancy

B. Chauveau[1], C. Auclair[1], A. Legrand[1], H. Laurichesse[1], R. Mangione[2], L. Gerbaud[1], F. Venditelli[1], L. Boyer[1], D. Lémery[1]; [1]*Clermont-Ferrand/FR*, [2]*Bordeaux/FR (benoitchauveauaconf@gmail.com)*

Purpose: Obesity impairs the quality of ultrasound images. All ultrasound scanners are calibrated for an ultrasound propagation speed of 1540 m/s, although the speed in fatty tissue is only 1450 m/s. Our objectives were to compare the quality of mid-trimester foetal scans set at different ultrasound propagation velocities and to see whether patient characteristics affected this choice.
Methods and Materials: This cross-sectional study collected image triplets of four recommended scanning planes from 32 obese pregnant women at their mid-trimester foetal scan. Each of them was obtained at three different speeds (1540 m/s, 1480 m/s, and 1420 m/s). A panel of 114 experts assessed the quality of 100 triplets (online, with the speed settings masked), grading them from A to C. The grades were converted to a score (10, 5, 0). The analysis used Kappa coefficients, ANOVA, Chi^2, Student's t, and non-parametric Mann-Whitney tests, with the Bonferroni correction.
Results: The experts had a mean of 18.1 (±10.2) years of experience. The grade distribution (A, B, C) differed significantly between the three propagation velocities tested ($P<0.0001$), with 1480 m/s ranked highest (5.6±1.0), followed by 1420 m/s (4.9±1.1); the conventional speed of 1540 m/s (4.5±1.0; $P<0.0001$) was rated worst. Regardless of the scanning plane, the thicker the abdominal wall, the lower the preferred speed ($P<0.0001$).
Conclusion: Image construction set for ultrasound propagation velocities lower than 1540 m/s significantly improves image quality for mid-trimester fetal scans of obese patients.

B-0968 11:18

A platform to investigate photon counting detectors for dedicated spectral breast CT imaging

M. Tornai, D. Coccarelli, J. Greenberg, M. Gehm; *Durham, NC/US (martin.tornai@duke.edu)*

Purpose: Photon counting detectors promise low dose, spectroscopic, in vivo x-ray CT imaging. A prototype platform is investigated which could be incorporated for theranostic purposes into our existing fully-3D dedicated breast SPECT-CT imaging system.
Methods and Materials: Six 128-element x-ray detector modules having 800micron CdZnTe pixels with 64 energy-channels (MultiX ME100) form a 60cm linear array. This array is irradiated by a 1.2mm focal-spot tungsten

anode tube (Aerosino SAXG1701). With 3mm slat collimation through 5cm lead bricks, this system creates a fan beam geometry on a 145cm SID. Material phantoms imaged for 720 projections on the rotation stage at the center-of-rotation include: low/high scatter rods/tubes (1.1-4.7mm diameters), 6 materials (2cm diameter delrin, acrylic, breast glandular- and fat-equivalent plastics, polyethylene, and oil cylinders), and a cadaveric human breast supported in a 12cm diameter breast cup. Various source filtration conditions including heavy-K-edge Ce-filtration yielding a quasi-monochromatic x-ray beam and detector-energy windowing are investigated. Data is reconstructed using fan-beam filtered back-projection, and compared with an ordered subsets iterative method.
Results: Measured energy spectra from 70-120kVp without/with filtration were representative of those in the literature. For both low/high scatter phantoms, rods greater than 1.5mm were easily visualised. For the cylinders, measured attenuation coefficients were within 6% of true narrow-beam values, and were easily separable in histograms of reconstructions. Reconstructions of breast slices yield glandular, adipose tissues along with skin boundaries.
Conclusion: With optimisation, linear arrays of photon counting detectors could be used to distinguish tissue composition in low-dose dedicated breast CT.

High-pitch emergency CT of the abdomen in obese patients in third generation dual-source CT: a radiation dose pilot study
R. Forbrig[1], F. Schwarz[2], M. Ingrisch[1], R. Stahl[1], M.F. Reiser[1], C. Trumm[1]; [1]*Munich/DE*, [2]*Augsburg/DE (robert.forbrig@med.uni-muenchen.de)*

Purpose: In the field of radiation dose reduction in 3rd generation dual-source computed tomography (DSCT) several modern techniques have been introduced recently. However, only little practical data exist in obese patients. We therefore investigated radiation dose in selected patients with a high body mass index (BMI) referred to our university hospital emergency unit undergoing high-pitch CT of the abdomen on a 3rd generation DSCT scanner.
Methods and Materials: 18 patients (11 female, mean age 52 years) with a BMI ≥ 30 kg/m^2 were examined between October 2014 and June 2016 on a 3rd generation DSCT scanner (SOMATOM Force, Siemens Healthcare, Forchheim, Germany). The standard CT protocol comprised the following parameters: Rotation time 0.25 s, pitch 1.55, slice collimation 192 x 0.6 mm, slice width 0.75 mm, increment 0.3 mm, kernel Br36, flow rate 2.5 mL/s, start delay 95 s and scan direction cranio-caudal. Radiation dose optimization was performed with automated tube current and voltage modulation. Radiation dose indices (volumetric CT dose index [$CTDI_{vol}$] and dose-length product [DLP]) were recorded.
Results: Mean BMI was 40.1 kg/m^2 (range, 30.0 - 50.3 kg/m^2). Mean tube current time product was 256 mAs (range, 95 - 410 mAs). Tube voltage ranged between 90 and 130 kV (mean 110 kV). Mean $CTDI_{vol}$ was 13.4 mGy (range, 6.4 - 23.6 mGy) and mean DLP was 659.2 mGy*cm (range, 264.1 - 1338.3 mGy*cm).
Conclusion: In 3rd generation DSCT high-pitch CT of the abdomen provides tolerable radiation dose in obese patients.

B-0970 11:34

Automatic tube voltage selection on a 320-slice CT-scan: a strategy to reduce the iodine load in routine contrast-enhanced CT? - a retrospective and a phantom study
P. Leyendecker[1], A. Labani[1], V. Noblet[2], M. Riou[1], A. Lallement[2], K. Haioun[3], M. Ohana[1], C. Roy[1]; [1]*Strasbourg/FR*, [2]*Illkirch/FR*, [3]*Puteaux/FR (pierre.leyendecker@chru-strasbourg.fr)*

Purpose: Retrospective study and phantom assessment of automatic tube voltage selection (ATVS) in iodine load reduction. To develop individualised low-volume contrast media (CM) protocols adapted to tube voltage in patients undergoing routine portal venous phase contrast-enhanced computed tomographic (CT) scan.
Methods and Materials: 70 patients underwent a 320-slice CT scan, without ATVS (group 1), and with ATVS (group 2). A quantitative analysis was performed in thoracic and abdominal aorta. A modified CM protocol based on these results was designed with the aim to obtain a homogeneous vascular attenuation across tube voltages. Secondly, an ex-vivo experiment in a phantom was performed to confirm the results of the clinical study by determining iodine attenuation curves for each selected tube voltages.
Results: Linear regression was used to test in objective image quality between the automatically selected tube voltages. Thus, in group 2, a CM dose saving of 20% could be achieve at 100 kV (p=0.002) with a constant contrast in the ascendant thoracic aorta compared with 120 kV. Phantom experiments revealed tube voltage-dependent iodine attenuation curves. Mean iodine attenuation in terms of CM concentration follows these equations respectively at 120 kV, y=70x-200 (R^2=0.97) and at 100 kV, y=92x-226 (R^2=0.95). A CM dose saving of 23.9% could be obtained at 100 kV (p=0.001) compared to 120 kV protocol.
Conclusion: The use of an individualised low-volume CM protocol adapted to the tube voltage enables significant iodine load reduction compared with a standard weight-based CM protocol for routine enhanced CT-scan using ATVS.

B-0971 11:42

Feasibility of very low volume of low iodine concentration contrast media and 80-kVp protocol at CT angiography of renal arteries
Y. Choi, J. Kim, J. Choi, E.-S. Cho; *Seoul/KR (mirr0412@gmail.com)*

Purpose: To investigate the feasibility of 80-kVp protocol using low volume of low iodine concentration contrast media (LC-CM) for CT angiography (CTA) of the renal arteries by comparison with a 120-kVp protocol using low volume of high-concentration contrast media (HC-CM). In addition, we tried to further reduce the volume of LC-CM in 80-kVp setting.
Methods and Materials: 36 volunteers underwent CTA of the renal arteries using one of three protocols: Group A, 120-kVp and 48mL of HC-CM (350mgI/mL-CM); group B, 80-kVp and 48mL of LC-CM (270mgI/mL-CM); group C, 80-kVp and 32mL of LC-CM. The attenuation and contrast-to-noise ratio (CNR) of the renal arteries, image qualities, and radiation dose were compared among three groups.
Results: Among three groups, mean attenuations, CNR and image quality in group B (303.3 ± 73.6 HU and 29.4 ± 13.7, respectively) were significantly higher than those in group A (226.2 ± 70.4 HU, 13.8 ± 7.7) or group C (266.4 ± 84.8 HU and 23.2 ± 16.5). There was no significant difference in the mean attenuations, CNR and image quality between groups A and C. Radiation dose of groups B or C was significantly lower than group A by 22.0%.
Conclusion: The use of 80-kVp with LC-CM (group B) could improve arterial enhancement and CNR and provide superior image quality with a smaller amount of iodine administration and a lower radiation dose, compared with 120-kVp with HC-CM (group A). Furthermore, it enables to reduce the volume of LC-CM by 28.9% while maintaining arterial attenuation and CNR.

B-0972 11:50

CT protocolmanagement: from the perspective of a large-scale cancer institution
X. Liu, D. Cody, W. Stefan, J. Rong; *Houston, TX/US (xliu@mdanderson.org)*

Purpose: To develop a data-base core CT protocol management system and maintain CT protocol parameters effectively in a large-scale cancer institution.
Methods and Materials: The number of 21 CT scanners of different models and approximately 300 protocols on each scanner combine to produce over a half-million of parameters to manage in our routine operation. A data-base core software program was developed and running on a Dell PowerEdge R720 server to retrieve protocol files, scanned protocols, and dose Notification Value log from each scanner daily. It allows for editing/viewing permissions to be controlled and keeps track of protocol changes with time stamps.
Results: Managing and implementing the protocol changes becomes more challenging than assembling the protocol itself. The web-based protocol management interface allows for the flexibility of editing and reviewing process. It provides a powerful tool to compare/monitor protocol changes between scanners of different model/vendor, or when several regional imaging facilities are expected to produce exams with the same quality. Protocol changes are notified daily to minimise the potential mistakes in scan parameters. NV notifications are triggered within an hour of the event so investigation and action can be taken timely. As one measure of the success, the number of CT Image Quality reports generated that were protocol parameter specific has reduced substantially in recent 5-years compared with prior to the implementation of this new program.
Conclusion: The data-base core CT protocol management approach has resulted in more reliable imaging outcomes and facilitated a vast improvement in our overall CT operation.

Do radiographers find evidence-based practice (EBP) a suitable tool for developing guidelines or protocols in imaging departments?
L. Hammerstrøm; *Oslo/NO (linda.hammerstrom@hioa.no)*

Purpose: To investigate if radiographers find EBP suitable for developing guidelines or protocols in imaging departments in Norway.
Methods and Materials: The study has a qualitative inductive design with phenomenological approach. Data collection took place in individual, semi-structured interviews. Inclusion criteria: Radiographers with experience in developing guidelines or protocols in imaging departments. Managers in eight imaging departments received information about the study and inclusion criteria by email, to help in recruitment by suggesting participants. Fourteen suggested participants received information about the study by email. Seven radiographers in five different imaging departments who met the inclusion criteria choose to participate in the study. The author transcribed and analysed all interviews.
Results: The study reveals shortcomings and certain misunderstandings regarding EBP. It suggests that brief encounters with patients and complex high-tech equipment stands out as factors that can complicate the use of EBP in imaging diagnostics. Few respondents have had training or courses in EBP. Radiographers who have, believes that the method is suitable for developing guidelines and protocols. Radiographers that has little knowledge regarding EBP has the perception that the method is unnecessary and complicated. There seems to be a clear connection between the extent of knowledge radiographers have about the method, and to what extent they find EBP suitable for developing guidelines and protocols.
Conclusion: The findings in this study suggests that further focus on EBP, education-courses and time to search for research articles is needed in order to fully utilize EBP in developing guidelines and protocols.

B-0974 10:47

Radiographer and elderly people in x-ray examinations: is there a need for radiographers' further education?
A. Henner[1], L. Karhumaa[1], E. Riippi[2], H. Kiuttu[3]; [1]*Oulu/FI*, [2]*Pori/FI*, [3]*Rovaniemi/FI (anja.henner@oamk.fi)*

Purpose: Population in developed countries is ageing strongly. Increased life expectancy results increase in chronic illnesses. Number of elderly people using health services is increasing and more than half of all elderly patients are daily patients in many hospitals. The purpose of this study was to find out radiographer's opinions towards elderly people who are coming to radiological examinations and to find out further education needs of radiographers.
Methods and Materials: Radiographers working in magnetic resonance imaging, computer tomography, mammography, ultrasound and x-ray imaging were included in this survey. A link to questionnaire was sent by Webropol to radiographers (N=152) and data was analysed with Webropol data analysis and survey tools programme. The open questions were analysed using textual analysing methods.
Results: Radiographers want more information about physiological and physical changes following ageing. Radiographers felt that they know how to work with elderly patients and how to change procedures to fit better to patient's needs, but agree that some procedures are harder with elderly. Most difficult modalities are magnetic resonance and x-ray imaging. There is enough knowledge about elderly, but radiographers are still open for information and further education. Radiographers felt that the knowledge about elderly and co-operation with them was learnt more through practice than in academic lectures during the basic education.
Conclusion: Radiographers are aware of the needs of elderly patients but there is still need for further education to deepen knowledge, e.g. in physiological senescence.

B-0975 10:55

Effect of training and experience on quality of radio stereometric analysis (RSA) examinations
O. Muharemovic[1], A. Troelsen[1], M.G. Thomsen[1], H.R. Siebner[1], K.K. Gosvig[2]; [1]*Hvidovre/DK*, [2]*Herlev/DK (omarradiograf@hotmail.com)*

Purpose: Producing x-ray images for the purpose of Radio Stereometric Analysis (RSA) is a demanding radiography technic resulting in high percentage of exposure repetition. The aim of this study is to investigate if RSA focused training and experience in performing RSA examinations, have effect on development of radiographers' skills and improvement on quality of RSA x-ray images.
Methods and Materials: Four radiographers are selected for the study group. Assessment of radiographers' performance is divided in two phases in this project identified as cyclus1 and cyclus2. Each cycle includes 20 examinations on phantom followed by 10 patient examinations. The quality of all x-ray images performed during the two cycles will be measured by number of beads visible (NB) and the centre position of prosthesis (CP) compared to centre of calibration field (CCF). The number of re-exposures used to obtain a usable image during patient examinations will be recorded
Results: After a workshop training on phantom and gaining experience on the patient examinations radiographers projecting images where CP is in average 36,1mm closer to the CCF ($p<0,001$), NB visible increase significantly with 3,1 ($p<0,001$) and radiographers use between 2, 1 and 2, 9 exposures less to obtain a usable images during patient examinations in cyclus2 ($p<0,001$).
Conclusion: Experience and training implemented in this project have significant effect on development of radiographers' skills and improvement on quality of RSA x-ray images. This improvement will results in decreasing of radiation dose delivering to the RSA patients.

B-0976 11:03

The impact of innovative technological change on employee motivation: a case study of radiographers working in the public healthcare in Malta
D. Chetcuti; *Msida/MT (chetcutidaniella@gmail.com)*

Purpose: Explores how innovative technological change has an impact on the level of motivation in radiographers and develop useful strategies to overcome innovation resistance and increase user acceptance of technology.
Methods and Materials: The impact of innovative technological change on employee motivation was identified using a cross-sectional, non-experimental research design. 70 radiographers participated in an online questionnaire survey, which enquired about employees' motivation factors, use of technology, sources of occupational stress and resistance to change.
Results: This study reveals which factors motivate radiographers and the causes for employee dissatisfaction. It also demonstrates that innovative technology improves quality of their work and enables a more efficient service. Although radiographers are prepared for the challenges brought about by innovative change, they are uncertain and under-confident on the introduction of an innovative technology in their work. This research establishes which employees are more likely to resist an innovation, and identifies the factors contributing to resistance to change.
Conclusion: Based on the findings of the study, it was concluded that there is a significant association between innovative technological change and employee motivation in radiography. The author has put forward a number of conclusions and recommendations which offer effective means of improving innovative change in radiography, with the aim of increasing employee motivation and user acceptance of technology, while reducing dissatisfaction and resistance to change.

B-0977 11:11

Small group facilitation: reflections of inexperienced tutors
L. Robinson[1], C. Mercer[1], J. Coward[1], S. Labouchere[2], P. Tavakol[3], C. Palmqvist[3], J. Lowe[4]; [1]*Salford/UK*, [2]*Lausanne/CH*, [3]*Huddinge/SE*, [4]*Dublin/IE (l.robinson@salford.ac.uk)*

Purpose: The 3-week OPTIMAX summer school involves approximately 50 international students working in facilitated groups. As well as being pedagogically valuable for students, OPTIMAX provides tutor learners (TLs) with an opportunity to develop facilitation skills. We aimed to provide TLs with a structured learning framework involving peer observation. We report our method and findings
Methods and Materials: Following a preparatory tutorial on observation and facilitation, TLs observed their allocated facilitator using a template developed for the project until data had been saturated (typically 3 hours). Post-observation, TLs and the facilitator being observed, reflected together on observations to clarify and verify interpretation. TLs then wrote up these reflections. TLs attended a consensus meeting to develop a thematic framework related to themes grounded in the reflective observations. This framework was then circulated along with all the reflective reports for detailed analysis and framework refinement.

Results: 6 TLs observed 7 facilitators in a variety of permutations: paired, singly, and over the length of Optimax. This allowed us to consider intra- and inter-observer differences, group dynamics, and changes in facilitator behaviour over time. **Key themes:** (i) tutor emotion/ personality heavily influenced group dynamic and development; (ii) experience in facilitating learning was more important than topic knowledge; (iii) effective facilitation engaged students in demonstrating their understanding rather than just stating it; (iv) group configuration is important.
Conclusion: Facilitators strongly influence group development so should be adequately prepared for their role. Experienced tutors and TLs found peer-observation informative for professional development.

B-0978 11:19

Can motion capture technologies enhance radiography skills development?

M. Hardy, H. Ugail, K. Fenemore, A. Al-Dahoud, Z. Sayed; *Bradford/UK (M.L.Hardy1@bradford.ac.uk)*

Purpose: Radiographic practice encompasses knowledge of imaging technologies, radiation safety, anatomy and patient care in order to produce images of diagnostic quality. While computer programmes can enhance simulated learning of the image acquisition process, the practice of positioning patients and reviewing anatomical appearances on resultant images has required clinical placement experience and supervised exposure of patients to x-radiation. This proof of concept study explores whether motion capture technologies might be developed to simulate real life clinical radiographic practice.
Methods and Materials: Using an XSENS MVN motion capture suit and configured hardware, we developed a purposeful coding programme to link body position of suit wearer to CT and radiographic image data of a chest phantom to simulate varying degrees of sagittal rotation.
Results: The motion capture technology permitted students to practice chest radiography within the university simulation suite and allowed real time evaluation of the relationship between patient position and chest image appearances without exposure to x-rays. The technology also enabled students to discuss image acceptability and repeat imaging thresholds as well as develop confidence in 'touching' patients during positioning and appreciate patient experience in a meaningful way.
Conclusion: Motion capture technologies are well established within the film and media industry and could be developed to create a simulated radiography education environment that reflects actual practice. This is the first study to explore this concept and consider the potential of motion capture technologies to enhance the development of radiography practical skills and reduce the risks associated with 'learning on patients'.

An evaluation of the educational requirements to practise radiography in the European Union

J.G. Couto[1], C. Hughes[2], S. McFadden[2], P. McClure[2], P. Bezzina[1]; [1]*Msida/MT*, [2]*Newtownabbey/UK (jose.g.couto@um.edu.mt)*

Purpose: The aim of this research was to compare the requirements to practise radiography across the EU. As a health-care profession that uses ionising radiation, this profession has a great impact on the health and safety of the population. Due to the free movement of professionals across borders (Directive 2005/36/EC), it is important to explore the education and competencies required of staff across the EU to ensure this health and safety is maintained.
Methods and Materials: A descriptive, non-experimental, qualitative methodology was used. Competent authorities were identified through the Regulated Profession Database (RPD) of the European Commission and the requirements to practise the profession were requested. Inductive analysis of the data was performed using thematic analysis.
Results: Twenty-seven out of the 28 EU member states have the profession regulated and although most countries require some level of education they vary considerably in level, subjects covered and branches/specialisms. Fourteen different English titles were identified in the RPD under the generic name of “Radiographer/Radiotherapist”, indicating different branches and levels of autonomy.
Conclusion: There is no uniformity in the title and requirements to practise radiography in the EU, leading to a lack of uniformity in education. This limits free movement of professionals since the level and subjects covered by the professional are verified prior to registration in the host country. It is, therefore, important to identify and close the educational gaps between countries to ensure that feasibility of professional movement and patient safety are not compromised.

B-0980 11:35

Subsequent publication of orally presented original studies within five years presented at the European Congress of Radiology 2010

M. Dollinger[1], F. Zeman[2], L.P. Beyer[2], C. Stroszczynski[2], T. Bley[1], P. Wiggermann[2]; [1]*Würzburg/DE*, [2]*Regensburg/DE (marco.dollinger01@gmail.com)*

Purpose: To determine the rate at which original studies that were presented orally at the European Congress of Radiology (ECR) 2010 were published in Medline-indexed journals and to identify factors predictive of publication.
Methods and Materials: The Scientific Program of ECR 2010 was reviewed by one reader. A total of 869 abstracts were included in the study. A Medline search of articles published between March 2010 through February 2015 was conducted to identify articles written by the first, second, and/or last authors of all abstracts published in the Scientific Program of ECR 2010. The year of publication, journal, country origin of the abstract, subspecialty, and nature of the research (i.e., human, animal, or technical) were recorded.
Results: 450 abstracts were expanded into manuscripts that were subsequently published in Medline-indexed journals (overall publication rate, 52%). Subspecialty molecular imaging and cardiac radiology studies had the highest publication rates (75% and 62%, respectively), whereas computer applications studies had the lowest (28%). The publication rate also differed substantially according to the nature of research. The articles were published in a total of 125 journals, most of them in radiology journals (317/450, 70%), and chiefly in European Radiology (50 cases, 11% of published studies). Of all published manuscripts 87% (393/450) were published within a 3 year time Frame.
Conclusion: More than half of original studies presented orally at the ECR 2010 were subsequently published in Medline-indexed journals. More articles were published in the journal European Radiology than in any other identified journal.

B-0981 11:43

A tool to supervise the radiographer clinical placement

L.P.V. Ribeiro, A.F. Abrantes, L. Guerra, R.P.P. Almeida, K. Azevedo, J. Guerreiro, J.P. Pinheiro, A.M. Ribeiro; *Faro/PT (luispedroribeiro@hotmail.com)*

Purpose: Radiographer trainee supervisors have a permanent need to communicate and exchange information between the hospital and the university. The aim of this work was to develop a tool to help the monitoring and assess the trainees in different clinical placement locations.
Methods and Materials: Recurring to Google sites, we have developed a multi-profiled site, based on user authentication permissions, where the supervisor can consult information regarding the place of internship and trainees, and fill out trainee's individual assessments. The evaluation form with the criteria is provided for all supervisors. The supervisors from the university as administrators can consult and compile all of the information available in a daily basis.
Results: The trial version is functional and answering the initial needs requested by the hospital supervisors. Trainees monitoring and assessment is simplified, reducing the number of dislocations between hospitals and the university.
Conclusion: This tool provides clearly written up-to-date learning outcomes/objectives (the learning outcomes are reviewed and assessed) appropriate to the practice placement environment.

B-0982 11:51

E-learning tool in students ultrasound education: increase stable perception of organic structures

B. Kraus, H.T. Zipko, M. Schratter, W. Wadsak, M. Kundi; *Vienna/AT (barbara.kraus@fh-campuswien.ac.at)*

Purpose: Ultrasound examiners are medical doctors from different areas like radiologists, internists, gynaecologists and also radiographers, physiotherapists and biomedical scientists. Optimal training procedures for all groups involved in medical imaging is of real importance. Medical ultrasound examinations are a powerful alternative to more expensive and/or invasive imaging modalities. Worldwide, different training procedures are in place, but little is known about the cognitive processes that lead to the transformation of the visual information provided by the ultrasound image into an anatomical and pathological assessment.
Methods and Materials: A prospective quasi-experimental study design was applied to compare the visualization performance of radiographer students in Ultrasound imaging, evaluating two groups, one with traditional method, the other with augmented e-Learning method. Overall 97 of 6th Semester Bachelor degree radiographer students at University of Applied Sciences FH Campus Wien participated in this descriptive-statistical evaluation, 41 assigned to the traditional group and 56 to the augmented e-Learning group.

Results: The e-Learning group had a faster increase of correct visualizations. But the difference declined during follow-up. Greatest problems in correct assignment of anatomical structures were detected for middle upper epigastric region (pancreas-region, vessels), retroperitoneal-region as well as for the correct orientation during three-dimensional dynamic measurements.
Conclusion: E-Learning tools may have advantages in early stages of ultrasound examiner education. Training of three-dimensional dynamic measured procedures should be forced due to the difficulty to maintain stable perception of organic structures.

Adenosine and adenosine triphosphate (ATP) have a similar stress effect in patients undergoing stress/rest perfusion cardiac magnetic resonance examinations

P. Bartolomé Leal, A. Quilez Larragan, A. García Baizán, M. Millor Muruzábal, J. Pueyo Villoslada, G. Bastarrika Alemañ; *Pamplona/ES (pbartolome@unav.es)*

Purpose: Adenosine is generally employed in stress perfusion cardiac magnetic resonance (CMR) examinations. Little is known about usefulness of adenosine triphosphate (ATP), a cheaper adenosine analogue. This study was conducted to evaluate the stress effect of ATP compared with adenosine in routine perfusion CMR examinations.
Methods and Materials: Thirty patients (15 in each group) prospectively underwent a clinically indicated CMR examination with a conventional stress/rest perfusion protocol following intravenous contrast injection of a total dose of 0.2 mmol/kg of gadobutrol. Individuals were randomly assigned to ATP (160 mckg/kg/min) or adenosine (140, 180 or 210 mckg/kg/min, as necessary). The vasodilator effect of both drugs was analyzed by comparing differences in heart rate, symptoms during the stress, and myocardial and splenic perfusion values, including time to peak, signal intensity, area under the curve of each sector, tissue perfusion values, splenic and myocardial signal intensity ratios and the splenic-to-myocardial signal intensity ratio.
Results: No statistically significant differences were found in heart rate variation (26.1±19.1 bpm vs 21.7±17.3 bpm, p=0.68) and myocardial perfusion reserve index between the two stress agents (1.81±0.61 and 2.29±0.89 for ATP and adenosine, respectively, p=0.11). Spleen to myocardium ratio was also similar (ATP=0.90±0.39 vs adenosine=0.71±0.24, p=0.202). During pharmacologically induced stress, patients receiving ATP referred less pronounced clinical symptoms compared with those receiving adenosine.
Conclusion: ATP and adenosine have similar stress effect based on patients vital signs, myocardial blood flow reserve and splenic switch-off and can be safely employed in patients undergoing stress/rest CMR perfusion examinations.

B-0984 10:38

Role of T1 mapping on the evaluation of cardiac perfusion during adenosine stress CMR in CAD patients

E. Cannizzaro, P. Palumbo, L. Panebianco, F. Bruno, L. Patriarca, V. Vellucci, R. Masi, E. Di Cesare, C. Masciocchi; *L'Aquila/IT (estercannizzaro@hotmail.it)*

Purpose: The aim of this study was to evaluate the capability of T1 mapping at rest and during adenosine stress in identifying cardiac involvement in coronary artery disease (CAD) patients.
Methods and Materials: We retrospectively analysed 44 CAD patients who underwent stress CMR (3.0-T). CMR protocol included MOLLI, first-pass perfusion imaging during adenosine stress, cineMR sequences, STIR T2w and LGE after administration of a bolus of 0.2mmol/kg gadoterate dimeglumine (Gd-DOTA). MOLLI images were acquired before and during adenosine injection and were analysed with a dedicated software (Cvi42, Circle). Results are expressed on mean±SD and compared with Student's t test, Pearson correlation and Wilcoxon test.
Results: A total of 44 patients with CAD was analyzed. 20 patients showed infartuated or ischaemic myocardium, with high value of T1 mapping at rest (1306.62±68.36ms) and no significant response during adenosine infusion (p vale:0,305). 24 patients showed normal myocardial perfusion and no LGE. 16 of these had high value of T1 mapping at rest (1243±184ms) and no significant modification during stress (p value:0,21). The remaining 8 had lower T1 mapping value at rest (1138±112ms) with significant modification during adenosine infusion (p value: 0.0167; r: 0.844).
Conclusion: T1 mapping during adenosine infusion can help to identify an early myocardial involvement also in CAD patients without other MRI signs of cardiac disease. Therefore, T1 mapping alterations are earlier than other MRI sign.

B-0985 10:46

Value of transluminal attenuation gradient of stress CCTA for diagnosis of haemodynamically significant coronary artery stenosis - comparison with stress perfusion CMR

J. Lee, H. Yong, H.-Y. Kim, E.-Y. Kang; *Seoul/KR (ljw2000e@naver.com)*

Purpose: This study aimed to evaluate the value of the transluminal attenuation gradient (TAG) of stress coronary computed tomography angiography (CCTA) using a wide detector in patients with coronary artery disease comparing to stress perfusion cardiac magnetic resonance (CMR).
Methods and Materials: From May 2012 to January 2015, 21 patients with moderate coronary stenosis on invasive coronary angiography were prospectively included. All patients underwent adenosine stress single-shot CCTA with a rest CCTA scan using a wide area detector CT. Coronary artery stenosis was evaluated on both stress and rest CCTA images, and TAG was manually obtained for all vessels. Stress perfusion CMR using a 3.0T scanner was used as a reference standard. A TAG cut off value of 15.1 HU/10 mm was considered significant. The diagnostic accuracies of TAG and CMR were estimated and compared.
Results: TAG of stress CCTA in all coronary arteries had a sensitivity, specificity, PPV, and NPV of 90.5%, 90.0%, 86.4%, and 93.1%, respectively. Corresponding values for TAG of rest CCTA in all coronary arteries were 42.9%, 83.3%, 64.3%, and 67.6%, respectively, whereas those for TAG of coronary arteries with moderate stenosis on stress CCTA were 93.3%, 100%, 100%, and 92.3%, respectively. Mean effective radiation doses for stress and rest CCTA were 10.6 ± 2.6 mSv and 2.3 ± 1.3 mSv, respectively.
Conclusion: TAG of CCTA provides high diagnostic accuracy for detecting haemodynamically significant coronary artery stenosis. TAG of stress CCTA was more diagnostically accurate than rest CCTA, especially in coronary arteries with moderate stenosis.

B-0986 10:54

A multiple regression analysis of determinants of myocardial perfusion as measured by CT

T. Rienmüller[1], V.N. Makarenko[2], O.L. Bockeria[2], I.E. Rychina[2], V. Bereznitsky[2], C. Baumgartner[1], L.A. Bockeria[2], P. Ourednicek[3], R. Rienmüller[1]; [1]*Graz/AT*, [2]*Moscow/RU*, [3]*Brno/CZ (theresa.rienmueller@tugraz.at)*

Purpose: To assess the relationship between global myocardial perfusion (MP) values and of some of its (possible) determinants using multiple regression analysis.
Methods and Materials: 34 patients (25 male) with known/suspected coronary heart disease underwent dynamic CT perfusion measurements with ECG-gating, i.v. contrast agent and 80/100/120kV (weight dependent). All patients signed informed consent (study NCT02361996). Functional determinants as heart rate (HR), systolic/diastolic blood pressure (SBP/DBP), left ventricular muscle mass (LVMM), and stroke volume (SV) were registered together with potential risk factors for decreased perfusion (calcium score, stenotic lesions, high body mass index (BMI)). Descriptive statistics are provided as mean±standard deviation/percentages, respectively. Mean MP values were compared for different risk factors (Wilcoxon rank-sum test and Kruskal-Wallis test (more than two groups)). A multivariate model was computed using a stepwise regression algorithm (all statistics at 0.05 level of significance).
Results: Age: 62.4±11.1 years, BMI: 27.9±4.3 kg/m^2, HR: 66.2±11.8 bpm, SBP: 134.7±20 mmHg, DBP: 81.7±8.7mmHg, LVMM: 170.3±42.2g, SV: 92.3±22.6ml, stenoses: no: 21%, <50%: 11%, >50%: 26%, >85%: 42%, overweight: 35%, MP: 78±17ml/100g/min. Overweight led to a (not significant) decrease of 4ml/100g/min, stenotic lesions >50% to a (not significant) decrease of 9ml/100g/min, stepwise regression provided a statistically significant model including age, BMI, sex, HR, SBP, SV, LVMM, calcium score, severity of stenosis (p<5e-04, average relative error: 0.04).
Conclusion: Our results confirm the close relationship between functional determinants and MP and demonstrate the effectiveness of the studied risk factors in reducing MP implying the need to consider the MP-values and its determinants in clinical settings simultaneously.

Fractal analysis of the transition region in perfusion imaging to characterise the pathophysiology of perfusion defects - application in chronic myocardial ischaemia

F. Michallek, M. Dewey; *Berlin/DE (florian.michallek@charite.de)*

Purpose: The introduced concept of fractal analysis (FA) will allow characterisation of the pathophysiology in abnormally perfused tissue by addressing the transition region in perfusion imaging. This study establishes a method to differentiate the pathophysiological composition in chronic myocardial ischaemia regarding its macrovascular (coronary artery disease, CAD) and microvascular (coronary microvascular dysfunction, CMD) components and to evaluate severity of ischaemia.
Methods and Materials: The ischaemic transition region was studied with FA using specifically developed software ("FraktalWandler"). Fractal dimensions (FD) were calculated in dynamic, contrast-enhanced magnetic resonance imaging data acquired from 26 patients. FD values during first-pass ($FD_{first\text{-}pass}$) and recirculation ($FD_{recirculation}$) were evaluated to conclude on the predominating pathophysiology or severity of ischaemia, respectively. Percent diameter stenosis on coronary angiography (ICA) was used as reference standard. Receiver operating characteristics (ROC), univariate and bivariate analysis were performed.
Results: 108 ischaemic myocardial segments were studied. ROC analysis demonstrated $FD_{first\text{-}pass}$=2.358 as optimal operating point for pathophysiological classification. Mean±standard deviation of $FD_{first\text{-}pass}$ or $FD_{recirculation}$, respectively, was 2.449±0.035 or 2.215±0.085 in classified CAD lesions, and 2.280±0.039 or 2.127±0.044 in classified CMD lesions. A linear correlation was found between $FD_{recirculation}$ and percent diameter stenosis in ICA in classified CAD (r=0.472, p=0.001) but, as expected, not in classified CMD lesions (r=0.082, p=0.6).
Conclusion: This novel pathophysiology-driven, modality-independent concept was successfully applied in chronic myocardial ischaemia to delineate CAD and CMD and evaluate severity of ischaemia, which have been clinical challenges. The approach can be extended to study a variety of perfusion abnormalities.

Iodine quantification using dual energy CT in first generation dual layer CT and third generation dual source CT

G. Pelgrim[1], R.W. Van Hamersvelt[2], M.J. Willemink[2], M. Oudkerk[1], T. Leiner[2], R. Vliegenthart[1]; [1]*Groningen/NL*, [2]*Utrecht/NL (g.j.pelgrim@umcg.nl)*

Purpose: To investigate the accuracy of quantification of iodine concentration using dual energy CT (DECT) on two high-end CT systems: third generation dual source CT (DSCT) and first generation dual layer CT (DLCT).
Methods and Materials: Five tubes with increasing iodine concentrations (0, 5, 10, 15 and 20 mg/mL) were inserted in an anthropomorphic phantom. Small, medium and large patient sizes were simulated using two fat-equivalent rings. Tube voltage combinations of 150Sn with 70, 80, 90 or 100 kVp, and 140/80kVp were used to acquire DSCT data. DLCT data were acquired at 120 and 140kVp. Images were reconstructed using four iterative reconstruction levels (ADMIRE 0,1,3,5 for DSCT and Spectral 0,2,4,6 for DLCT); all scans were repeated 3 times. Vendor-specific iodine quantification software was used to calculate iodine concentrations based on the DECT scan data. Median normalized differences between CT-measured and known iodine concentrations, and absolute differences were compared for the different imaging protocols.
Results: Iodine concentration quantification was not influenced by iterative reconstruction level. For DSCT, median measurement error was lowest for the 150Sn/70kVp combination, -0.5%(interquartile range [IQR]: -2.0-2.0%) and highest for the 140/80kVp combination, 4.5% (IQR:1.3-6.5%). For DLCT, median measurement error was -3.3% (IQR:-4.9 - -1.5%) for 140kVp, and -4.6% (IQR:-6.0 - -3.6%) for 120 kVp. Increase in simulated patient size resulted in higher variation of iodine measurements.
Conclusion: Quantification of iodine concentration was accurate for both high-end CT systems with different spectral imaging approaches. Images acquired with larger energy separation resulted in the most accurate iodine concentration calculation for both systems.

B-0989 11:18

Pixel-wise quantification of myocardial blood flow from dynamic contrast-enhanced magnetic resonance imaging: the impact of deconvolution method

C. Kräuter, U. Reiter, C. Reiter, A. Schmidt, M. Fuchsjäger, R. Stollberger, G. Reiter; *Graz/AT (corina.kraeuter@gmx.at)*

Purpose: To study the impact of different commonly employed deconvolution methods on pixel-wise quantification of myocardial blood flow (MBF) from dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI).
Methods and Materials: Eight patients with coronary heart disease underwent 3T pre-contrast T1 mapping and cardiac DCE-MRI at rest using a saturation recovery fast low angle shot sequence. Gadolinium-based contrast agent was administered as bolus at a dose of 0.05 mmol/kg. After coil sensitivity and motion correction of DCE series as well as T1-mapping-based conversion of signal intensity to contrast agent concentration, MBF was calculated pixel-wise by deconvolution using three different methods: Fermi modelling, Tikhonov regularisation with B-splines and autoregressive moving average (ARMA) modelling. The relationships between different pixel-wise evaluated MBFs and between resulting global MBFs were analysed by correlation analysis; mean global MBFs were compared with paired t-test.
Results: Mean global MBFs determined by deconvolution using Fermi modelling (0.72±0.13 ml/min/g), Tikhonov regularisation (0.67±0.10 ml/min/g) and ARMA modelling (0.84±0.16 ml/min/g) differed ($p<0.02$ for all comparisons). The MBFs correlated strongly, both pixel-wise (r=0.95, 0.86, and 0.83 for Fermi modelling vs Tikhonov regularisation, Fermi modelling vs ARMA modelling, and Tikhonov regularisation vs ARMA modelling, respectively) and globally (r=0.93, 0.86, and 0.85 for Fermi modelling vs Tikhonov regularisation, Fermi modelling vs ARMA modelling, and Tikhonov regularisation vs ARMA modelling, respectively).
Conclusion: There is a close relationship between pixel-wise myocardial blood flows determined by different commonly employed deconvolution methods, especially between Fermi modelling and Tikhonov regularisation with B-splines. Absolute values of myocardial blood flow, however, differ.

Quantitative assessment of salvaged myocardial zone and intramyocardial haemorrhage by 7T MRI

Y. Zhang[1], L. Yang[2], F. Gao[3]; [1]*Guizhou/CN*, [2]*Beijing/CN*, [3]*Sichuan/CN (102651873@qq.com)*

Purpose: To determine the myocardial area at risk (AAR), infarction-core size (IS) and the salvaged myocardial zone (SMZ), and to evaluate the imaging and histological characteristics of intramyocardial haemorrhage (IMH) after myocardial infarction using non-contrast T2-mapping on 7T MRI.
Methods and Materials: Twenty Sprague-Dawley (SD) rats were randomly divided into the sham and model groups (n=10 for either group). In the model group, myocardial infarction models were established by left anterior descending branch ligation. All animals were imaged on a 7.0 Tesla system with cine spiral imaging, T2-mapping LGE after 24 h. Then, the rats were sacrificed for measurement of the IS and AAR using TTC and HE staining. T2-mapping revealed the AAR in the model group was significantly higher than sham group.
Results: No remarkable T2 value was noted in the entire heart of the sham group. LGE and TTC staining demonstrated similar IS. T2-mapping and HE staining revealed similar AAR as well. T2 mapping characterized the IMH as a phenomenon resulting from the area of hypointensity in the hyperintensity involving infarct-core zone and corresponding T2 value (28.6±1.52) ms with IMH vs. (35.8±2.61) ms without IMH: n=3 with 18 slices, P=0.032). Non-contrast T2-mapping was a reliable approach to quantitatively evaluate the SMZ and IMH.
Conclusion: This present study was designed to establish a stable and reliable platform using a non-invasive technique to assess the SMZ and IMH in a rat model despite a high heart rate.

B-0991 11:34

Identification of the best CMR technique for quantitative assessment of myocardial salvage using a systematic comparison

J. Kihlberg[1], V. Gupta[1], H. Haraldsson[2], A. Sigfridsson[3], S.I. Sarvari[4], T. Ebbers[1], J. Engvall[1]; [1]*Linköping/SE*, [2]*San Francisco, CA/US*, [3]*Stockholm/SE*, [4]*Oslo/NO (johan.kihlberg@regionostergotland.se)*

Purpose: Several cardiac magnetic resonance (CMR) techniques exist for the quantitative assessment of myocardial salvage that is vital in planning coronary revascularisation. The purpose of the current study is to identify the best technique for this assessment by systematic comparison with late gadolinium enhancement (LGE).

Methods and Materials: Data from 81 patients (mean age: 66 ± 6 years; 58 men) with suspect coronary artery disease were analysed. Analysis were performed using three commonly used CMR techniques, cine steady state free precession (SSFP) imaging for feature tracking (FT), tagging (current gold standard), and Displacement Encoded Stimulated Echoes (DENSE). The data were analysed using Tomtec software, Harmonic Phase Imaging (HARP), and an in-house algorithm, respectively. SSFP was included in standard CMR protocols while tagging and DENSE required separate acquisitions. The comparison was performed using circumferential strain in the myocardial segments with transmurality ≥ 50% LGE.
Results: 23 patients were identified with transmurality ≥ 50% LGE (49 segments). The area-under curve (AUC) value from the receiver-operating curve (ROC) for detecting transmurality ≥50% LGE was 0.87 for DENSE, 0.74 for FT and 0.66 for HARP. The Pearson Correlation between global circumferential strain and left ventricle end systolic volume was 0.76 (DENSE) and 0.73 (FT) at a significance level of 0.01, and 0.27 (HARP) at a significance level of 0.05.
Conclusion: DENSE outperformed FT and tagging in detecting regional dysfunction caused by coronary artery disease.

How to assess haemodynamic aspect of not-evaluable plaques by cardiac CT? Use of CCO and role of stress CMR

P. Palumbo, E. Cannizzaro, L. Panebianco, F. Bruno, L. Patriarca, V. Vellucci, R. Masi, E. Di Cesare, C. Masciocchi; *L'Aquila/IT*
(palumbopierpaolo89@gmail.com)

Purpose: Stress myocardial perfusion imaging by cardiac magnetic resonance (CMR) and corrected coronary opacification (CCO) can help to assess calcified plaques not correctly evaluable by standardised method of cardiac-CT analysis.
Methods and Materials: We retrospectively analysed 26 patients who had undergone cardiac-CT and stress CMR, with match of calcified plaques not certainly evaluable at cardiac-CT. Evidence of stress myocardial perfusion imaging by CMR was compared with attenuation values in coronary lumen (CCO). The CCO difference across the calcified plaque was measured proximally and distally to the calcified plaque, in an axial plane, and normalised to the descending aorta at same slice.
Results: A total of 30 calcified plaques were assessed. Eight calcified plaques were not haemodynamically significant, and showed a low CCO difference (0.062). Ten calcified plaques determined reversible perfusion alteration under stress, with a significant correlation with an intermediate CCO difference (0.20; r: 0.7530; p value: 0.0012). Twelve calcified plaques determined irreversible perfusion alterations under stress with a significant correlation with a high CCO difference (0.364; r: 0.8152; p value: 0.0002).
Conclusion: Stress myocardial perfusion imaging by CMR and CCO analysis by cardiac-CT, offers interesting similar information about haemodynamic significance of calcified plaques not evaluable due to "blooming effect". Correlation of these two methods permits an effective management of patients with not-evaluable calcified plaques.

Myocardial texture analysis for the detection of ischaemic heart disease on routine non-contrast cardiac MRI sequences

P. Talarczyk, J. Weir-McCall, S. Waugh, P. Guntur Ramkumar, G. Houston; *Dundee/UK*

Purpose: Texture analysis allows quantification of tissue heterogeneity and has been proven to provide powerful diagnostic and prognostic data in oncological imaging. However to date this technique has not been applied to the assessment of the myocardium. The hypothesis of the current study was that those with ischaemic heart disease (IHD+) have a more heterogenous myocardial texture than those without (IHD-).
Methods and Materials: Cardiac MRI was performed in 52 study participants on a 3T scanner, with routine bSSFP and late gadolinium enhancement sequences. 23 IHD+ patients with myocardial scarring confirmed on late gadolinium enhancement images were compared with 29 IHD- volunteers with no cardiovascular disease and absence of myocardial scarring. Image analysis was performed on a pre-contrast bSSFP short axis mid-ventricular slice at end systole. Texture features were measured using MazDa software, with co-occurrence matrix and run-length matrix.
Results: IHD+ had significantly increased measures of myocardial heterogeneity compared to the IHD- group. On a forward condition entry binary logistic regression model Grey Level Variance (IHD+ 3.2±1.3 vs IHD- 4.3±2.1, p=0.035), Grey Level Non-uniformity (IHD+ 4.8±1.2 vs IHD- 3.8±0.8, p=0.001) and Mean signal intensity (IHD+ 164±34 vs IHD- 206±54, p=0.002) were the strongest predictors for the presence of IHD showing 73% accuracy (ROC 0.84). When all 29 measures of texture were applied in the same model, there was 100% accuracy (ROC 1.0).
Conclusion: Myocardial heterogeneity on routine non-contrast sequences can predict the presence of myocardial fibrosis in those with ischaemic heart disease potentially obviating the need for contrast sequences.

Evaluating a new objective indicator of idiopathic intracranial hypertension (IIH) on routine paediatric brain CT scan

T. Bartsikhovsky, S. Tal, S. Nagieva, M. Vaiman, P. Gottlieb, I. Bekerman; *Tzrifin/IL (hatul.ratz@gmail.com)*

Purpose: The aim of this study was to establish optic nerve sheath diameter (ONSD) to eyeball transverse diameter (ETD) index value as sign of elevated ICP on brain CT scan in paediatric patients and correlate this data with papilloedema on ophthalmologic examination.
Methods and Materials: We retrospectively reviewed brain CT studies and medical files of paediatric patients for a period 2014-2015 years, selecting patients who had normal CT scans. Total study population included 153 patients (75 male, 78 female, mean age 11.1±5.2). Patients who were admitted to the emergency department with complaints of headache and/or one of the signs of elevated ICP and underwent ophthalmological evaluation were selected and stratified into two groups: with no signs of papilloedema and with papilloedema. The control group included subjects who underwent brain CT studies for various reasons not related to elevated ICP and are unlikely to have papilloedema. All measurements were held manually on axial images of routine brain CT scans obtained by the 256-slice CT scanner.
Results: ONSD/ETD index had significantly higher values ($p<0.001$) in patients with papilloedema (median 0.24, IQR=0.22-0.25) compared to patients with no signs of papilloedema (median 0.18, IQR=0.16-0.19) and control group (median 0.17, IQR=0.15-0.18). The ONSD/ETD index of 0.21 is 82% sensitive and 93% specific for papilloedema and therefore increased ICP in paediatric patients with with headache.
Conclusion: A strong correlation between papilloedema on ophthalmologic examination and elevated values of the ONSD/ETD index was established making it a simple and reliable sign of elevated ICP in paediatric patients.

B-0995 10:38

Mechanical thrombectomy for acute ischaemic stroke: what about children, should we include them?

C. Parra-Fariñas, I. Delgado Álvarez, Á. Sánchez-Montanez, M. Ribó Jacobí, A. Tomasello Weitz, P. Coscojuela Santaliestra, A. Macaya Ruiz, C. Hernández Giraldo, É. Vazquez Mendez; *Barcelona/ES*
(carmenparrafarinas@gmail.com)

Purpose: Acute ischaemic stroke in children is difficult to diagnose and manage due to atypical presentation and imaging challenge. Recent trials have demonstrated mechanical thrombectomy success in adults, but there is a lack of evidence-based data concerning children. This study aimed to analyse the safeness and effectiveness of endovascular approach in paediatric intracranial recanalisation.
Methods and Materials: From October 2012 to October 2016, a prospective study of four patients younger than the age of 18 who underwent mechanical thrombectomy was performed. Baseline characteristics, successful recanalisation (TICI grade ≥2b), procedural time, dramatic neurological improvement (≥10 points decrease in NIHSS score at 24 hours), and independent functional outcome (mRS ≤2) at three months were recorded.
Results: Mean age at treatment was 14±1.2, all female. Patients presented with hemiparesis (n=2) and aphasia (n=1). Median NIHSS score was 13 (7-19) on arrival and 4 (1-5) at 24 hours. Two patients needed general anaesthesia. Occlusion site was middle cerebral artery (n=3) and basilar artery (n=1). All four patients achieved successful recanalisation. Procedural time was 62.3±23.9 min. We combined stent-retriever technology plus distal aspiration in three patients (median number of passes: 2) and direct aspiration first pass technique in one (duration of aspiration: 30 s). All procedures resulted in good early response and functional independence at three months. No complications were reported.
Conclusion: The current four patients treated with modern devices reported that children presenting with acute large-vessel embolic occlusion should be considered for mechanical thrombectomy to allow safe, effective, and prompt recanalisation to improved outcomes.

B-0996 10:46

Feasibility of T1-weighted dynamic contrast-enhanced MR imaging in paediatric neuroradiology in a 1.5T MRI

B.-B. Rochetams, J.-P. Cottier, L. Morales, C. Sembely-Taveau, J. Buraschi, H. Daurel, D. Sirinelli, B. Morel; *Tours/FR*

Purpose: The aim of this study is to evaluate the feasibility of T1-weighted dynamic contrast enhanced (DCE) MR imaging in paediatric patients at 1.5T with a low peripheral intravenous gadoteric acid injection rate of 1 ml/s.
Methods and Materials: Children with neurological symptoms underwent prospectively conventional MRI and T1-weighted DCE MR imaging. An MR perfusion analysis method (syngo MR Tissue 4D, Siemens Healthcare GmbH, Erlangen, Germany) was used to obtain time-concentration curves (persistent pattern, type-I; plateau pattern, type-II; washout pattern, type-III) and to calculate pharmacokinetic parameters. Two radiologists manually defined ROIs in the greatest enhancement part of the tissular lesion and in the surrounding or contralateral tissue. Tissular lesion/surrounding or contralateral tissue pharmacokinetic parameter ratios were calculated. Tumours were categorised by grade (I-IV) by using the WHO Grade. Mann-Whitney testing was performed.
Results: 9 boys and 9 girls (mean age 10.5 years) were included. Lesions consisted of 10 brain tumours, 3 inflammatory diseases, 3 arteriovenous malformations and 2 strokes. We obtained analysable concentration time curves for all patients (6 type-I, 9 type-II, 3 type-III). Ktrans between tumoural tissue and surrounding or contralateral tissue was significantly different (p=0.034). Tissular lesion/surrounding or contralateral tissue Ktrans ratios were significantly different between Grade I tumours and Grade IV tumours (p = 0.027).
Conclusion: The results establish the feasibility of paediatric T1-weighted DCE MR imaging at 1.5T with an intravenous injection rate of 1 ml/s. The proposed procedure allows obtaining quantitative concentration time curves which could be of great value for differentiating brain tumour grades.

B-0997 10:54

Gadolinium deposition in paediatric brain: findings after multiple exposures to gadobenate dimeglumine

G. Schneider, P. Raczeck, A. Bücker; *Homburg/DE (dr.guenther.schneider@uks.eu)*

Purpose: The possibility of gadolinium (Gd) deposition in the paediatric brain following Gd-based contrast agents (GBCA) is a potentially serious issue. We determined if T1-signal changes potentially indicative of Gd-deposition occur in paediatric brain structures after multiple exposures to gadobenate dimeglumine (MultiHance; Bracco).
Methods and Materials: 34 patients (Group 1; 17M/17F; mean age: 7.18 years; range: 9 months-17 years; mainly oncologic patients) that received between 5 and 15 injections (mean: 7.8 injections; each at 0.05 mmol/kg bw) of gadobenate over a mean of 2.24 years (range: 9 months-7 years) were compared with 24 control patients (Group 2; 16M/8F; mean age: 8.78 years; range: 7 months-17 years) never exposed to any GBCA. Five blinded readers independently determined the SI at regions-of-interest placed in the dentate nucleus (DN), globus pallidus (GP), pons, and thalamus on unenhanced T1-w images. Unpaired t tests were used to compare SI values.
Results: Mean SI in the DN, GP, pons and thalamus of patients exposed to gadobenate ranged 366.4-389.2, 360.5-392.9, 370.5-374.9, and 356.9-371.0, respectively. Corresponding values in control subjects were not significantly different (p>0.05), ranging from 368.3-374.3, 377.0-383.4, 364.4-385.4, 363.2-376.8, respectively. Similarly, no significant differences were noted by any reader for comparisons of mean DN-to-pons and GP-to-thalamus SI ratios.
Conclusion: SI increases in the DN, GP, pons and thalamus that are potentially indicative of Gd-deposition are not seen in paediatric patients after multiple exposures to gadobenate dimeglumine, even in patients with 15 injections over a time interval of 6 years.

Arterial spin labelling performance in rhombencephalitis diagnosis in children: a study over the last year at Necker Hospital in Paris

I. Cosmina Dana; *Paris/FR (ianc.cosmina.dana@gmail.com)*

Purpose: The aim of our study was to highlight the arterial spin labelling performance in imaging features of rhombencephalitis of the brain and spinal cord.
Methods and Materials: Retrospective and observational study reviewing records of patients hospitalized in neurology department at Necker Hospital between November 2015 and September 2016. MRI was performed with a 1.5-T and a 3-T units in 76 patients with suspected rhombencephalitis within maximum 4 hours after the onset of symptoms. The sequences consisted of spin-echo T1-weighted images, T2-weighted images , enhanced T1-weighted images with the intravenous injection , DWI and ASL.
Results: Between the 76 children suspected with rhombencephalitis, 28 were diagnosed with the infection . Clinical check-up showed respiratory and gastroenterological signs, supratentorial and cranial nerves damage brainstem dysfunction , signs of myelitis .MRI showed FLAIR and T2 hyperintensities in the brainstem in 36% of the children, in the cerebellum in 25.5%, at the supratentorial level in 28% , in the bone marrow in 36% . 36% had hyperintensities in combined territories. ASL was positive in 66% of the cases and was the only positive sign in 33% of the entire confirmed group.
Conclusion: Arterial spin labelling a non-invasive technique that provides absolute cerebral blood flow information within a brief period. It has been increasingly used in our department especially in diagnosis of SNC infections .Our results demonstrate the accuracy of ASL in imagining diagnosis of rhombencephalitis and its performance compared to techniques that relay only to T1, T2, DWI and contrast enhanced imaging.

B-0999 11:10

Robustness of kurtosis acquisition via multi-slice EPI: a test-retest study in children

A. Napolitano[1], C. Carducci[1], L. Filograna[1], V. Cannata[1], T. Beck[2], G. Colafati[1]; [1]*Rome/IT*, [2]*Erlangen/DE (gstefania.colafati@opbg.net)*

Purpose: Diffusion kurtosis imaging is an emerging technique based on non-Gaussian diffusion of water in biologic systems. The method provides complementary information to the traditional diffusion. Unfortunately, diffusion kurtosis suffers from long acquisition times. However, a recent technique, named simultaneous multi-slice (SMS) acquisition, allows simultaneous acquisition of multiple slices and thus reducing the acquisition time. The purpose of this work is then to investigate the robustness of diffusion kurtosis in children when using SMS.
Methods and Materials: Ten 6-10-year-old children were recruited. Two DTI acquisitions at the beginning and the end of scanning were acquired. The DTI protocol was acquired using a prototyping sequence from Siemens (acceleration factor =2). Diffusion images were preprocessed in matlab to account for eddy current and movement artefact. The actual kurtosis processing was performed on DKE toolbox. FA, kFA, kmean maps were calculated. ROIs were placed in anterior (AWM) and posterior (PWM) white matter, right (RSC) and left (LSC) semiovale centre. The absolute difference (AD) between the first and last scan scaled by the mean was used to evaluate the variability of the measure.
Results: The AD FA was AWM: 4.0+/-2.0%; PWM: 7.0+/-3.0%; RSC: 6.7+/-3.1%; RSC: 7.8+/-5.9%. The AD kFA was AWM: 6.0+/-4.0%; PWM: 12.8+/-9.0%; RSC: 9.5+/-5.4%; RSC: 9.7+/-6.9%. The AD kmean was AWM: 3.3+/-1.8%; PWM: 3.0+/-1.6%; RSC: 3.9+/-3.6%; RSC: 2.9+/-1.4%.
Conclusion: The AD estimates for FA, kFA and kmean are around 7% of the mean values of each measurements and the AD kurtosis estimates are also comparable to the more stable measurement of FA.

B-1000 11:18

Role of proton MR spectroscopy of the brain in neonatal hyperbilirubinemia

R.H. Hashem, I. El Hawary, W. Shaarawy, M. Elsayed.; *Cairo/EG (rania.hachem@yahoo.com)*

Purpose: The purpose of this study was to analyse proton ((1)H) MR spectroscopic data of infants with severe hyperbilirubinemia ,and wether it can be used to differentiate bilirubin encephalopathy from just severe hyperbilirubinemia in neonates, to compare the MRS findings with that of conventional MRI.
Methods and Materials: 10 patients aged 3 days to 2 weeks, with severe hyperbilirubinemia (indirect NH more than 20 mg/d) divided into 2 equal groups based on wether or not having clinical encephalopathy . All the patients underwent MR imaging and proton MR spectroscopy with a single-voxel point-resolved spectroscopic sequence. The voxel of interest was centered in the basal ganglia. metabolite ratios relative to creatine were evaluated. The ratios were compared to normal ratios for age in former studies. We compare their clinical , laboratory and radiological data.
Results: 3 out of the 10 patients had abnormal MR signal in the globi pallidi and the subthalamic nuclei. All the 5 Patients with clinical encephalopathy were having an abnormal MRS findings.3 out of the 5 with no clinical encephalopathy were having an abnormal MRS findings .2 out of the group with no clinical encephalopathy were free on MRI and MRS basis. The most frequently encountered MRS abnormality was a decrease in the Ch /Cr ,decrease in the NAA/Cr, then increase Glx /Cr ratio.
Conclusion: Neonatal hyperbilirubinemia with encephalopathy has a characteristic detectable (1)H-MR spectroscopic changes. Proton MRS could be used for early detection of bilirubin encephalopathy in neonates.

B-1001 11:26

SMI of the neonatal brain: assessment of feasibility and morphological features

K. Göral, A. Hojreh, G. Kasprian, K. Klebermass-Schrehof, K. Vergesslich-Rothschild, M. Weber, J.M. Patsch; *Vienna/AT (janina.patsch@meduniwien.ac.at)*

Purpose: Superb microvascular imaging (SMI) is a novel ultrasound application capable of depicting micro-vasculature throughout the body. To the best of our knowledge, there are no systematic reports on feasibility and morphologic features of brain SMI in healthy neonates.
Methods and Materials: Following study approval by institutional review and written informed consent, we performed transcranial ultrasound in healthy term-born neonates (n=19; Toshiba Applio 4000). Routine examinations (including Doppler) were performed and documented according to national standards. SMI ultrasound was performed according to a structured examination protocol, using two linear 18mHz and 14mHz transducers: superficial and deep scans were acquired in the coronal and parasagittal plane, using the left and right superior frontal gyrus as anatomical landmarks. All SMI views were imaged by monochrome and colour SMI and documented as video sequences. Videos were batch-read by a board-certified radiologist.
Results: On superficial coronal scans, cortical micro-vessels were identifiable in 89.5-100%(depending on region and scan mode). Medullary micro-vessels were visible in 94.7-100%. SMI performance was better on coronal views than on sagittal views (cortical in sagittal: 29.4-73.7%; medullary in sagittal: 82.4-89.5%). Color SMI improved overall SMI performance in only one of eight superficial assessment regions. On deep scans, cortical and medullary micro-vessels were visible in all cases. Periventricular micro-vessels were seen in 88.2% of cases. Thalamic micro-vessels were identifiable in 70.6% of cases.
Conclusion: SMI ultrasound of the neonatal brain is feasible and captures cortical, medullary, periventricular, and thalamic micro-vessels without the use of contrast.

B-1002 11:34

Malformations of cortical development associated with corpus callosum dysgenesis (CCD): diagnostic value of foetal MRI in prenatal counseling

A. Antonelli, S. Bernardo, E. Marchionni, V. Vinci, M. Saldari, A. Pizzuti, C. Catalano, L. Manganaro; *Rome/IT (amanda.antonelli@hotmail.it)*

Purpose: To define the diagnostic role of foetal MRI in the assessment of cortical dysplasias and other malformations of the developing cerebral cortex, in foetuses with different forms of Agenesis of the Corpus Callosum (ACC).
Methods and Materials: 104 MR images of foetal CNS with a US suspicion of ACC were retrospectively reviewed. Foetal MRI was performed at 1.5 T Magnetom Avanto (Siemens, Erlangen, Germany) without mother-foetal sedation. Polymicrogyria, lissencephaly, schizencephaly, subependymal heterotopias and migration disorders were evaluated. Cortical findings were compared to three types of ACC (complete agenesis, partial agenesis and hypoplasia). Genetic tests were collected. Post-natal MRI or foetopsy for diagnostic confirmation were collected.
Results: On 104 foetuses, fetal MRI was able to detect cortical malformations in 32 cases even in early gestational ages (<24GW). The mean Gestational Weeks (GW) at MR diagnosis was 26 (range: 22-36GW). MR imaging found 13/32 polymicrogyria, 7/32 lissencephaly, 5/32 schizencephaly, 4/32 subependymal heterotopias and 3/32 neuronal migration disorders. 22/32 had complete ACC, 4/32 had partial ACC and 6/32 had CC hypoplasia. Statistically significant correlations ($p<0.005$) between complete ACC, focal polymicrogyria and cortical dysmorphism affecting frontal lobes were found.
Conclusion: Fetal CNS MRI can detect cortical development malformations in complex ACC, providing further information for the clinician to assess the severity of perinatal outcome. MRI is a useful tool in improving obstetrical genetic prenatal counselling to predict pregnancy and foetal prognosis.

B-1003 11:42

Real-time virtual sonography: a new integrated approach for the evaluation of foetal CNS pathologies?

S. Bernardo, A. Antonelli, M. Saldari, V. Vinci, C. Catalano, L. Manganaro; *Rome/IT (silviabernardo@live.it)*

Purpose: The aim of this prospective study is to evaluate the feasibility and ability of foetal MRI-US real-time fusion imaging (RVS: real-time virtual sonography) in the assessment of the main cerebral pathologies, on foetuses with a US suspicion of CNS anomalies.
Methods and Materials: Fusion imaging (Hitachi HI Vision Ascendus) was offered to 35 patients who had undergone foetal MRI for a US suspicion of cerebral anomaly. Acquired MRI were loaded into the fusion system using a CD support and images were displayed together in real time with US images. Both sets of acquisition were then manually synchronised and images were recorded: this allowed the possibility to retrospectively re-evaluate examinations.
Results: RVS was technically possible in all cases. Data registration, matching and fusion imaging were performed in 25 minutes at the beginning and in less than 15-20 minutes after practice. The ability of RVS imaging to assess the main foetal CNS anatomy and anomalies was evaluated and compared with standard US and MRI. The principal application of RVS was the study of midline, cerebral gyration and vascular malformations because it also allowed adding a real-time Doppler signal on MRI images. Fusion imaging helped the diagnosis in 25%. In 25/35 cases of encephalic pathology, fusion imaging improved the diagnosis; in 10/35 MRI was superior to US even using RVS.
Conclusion: Both techniques are complementary but still independent and the retrospective synthesis of these exams allows optimal analysis of foetal cerebral anomalies. However, RVS is currently limited to the research area.

B-1004 11:50

Can foetal MRI predict the need for neonatal emergency procedures in cases of head and neck congenital masses?

M. Saldari, A. Antonelli, V. Vinci, C. Catalano, L. Manganaro; *Rome/IT (matteo.saldari@gmail.com)*

Purpose: To evaluate the role of foetal MRI in predicting the need and helping the planning of neonatal emergency procedures in cases of congenital head and neck masses.
Methods and Materials: In this prospective study we enrolled 24 consecutive pregnant women with ultrasound detection of foetal head and neck masses possibly requiring a post-partum surgical procedure or anaesthetic management and referred to our department of radiology for a foetal MRI. Foetal MRI protocol included T1 and T2-weighted, TrueFISP and DWI sequences on a 1.5 T unit. A Radiologist with more than 10 years of experience in foetal MRI, reviewed the images in order to detect the presence of findings suggestive for the necessity of a neonatal surgical or anaesthetic intervention.
Results: Foetal MRI confirmed the US suspicion of: cystic hygroma (n=8), lymphangioma (n=9) and cervical teratoma (n=7). All prenatal diagnoses were confirmed surgical or pathological findings. In 7 cases Foetal MRI highlighted the need for emergency neonatal surgery, whereas in 10 cases excluded it, suggesting a medical management until respiratory and cardiovascular status were stabilized. In 7 cases Foetal MRI suggested the necessity of an emergency EXIT procedure.
Conclusion: Foetal MRI provides useful information for a proper neonatal intervention to prevent a fatal outcome in cases of head and neck congenital masses.

Correlation of manual and semi-automated evaluation of aortic root in TAVI candidates

B. Horehledova[1], C. Mihl[1], C. Schwemmer[2], B.M.F. Hendriks[1], N. Eisvoogel[1], B.L.J.H. Kietselaer[1], J.E. Wildberger[1], M. Das[1]; [1]*Maastricht/NL*, [2]*Forchheim/DE (barbora.horehledova@mumc.nl)*

Purpose: Preprocedural TAVI planning requires highly sophisticated and time-consuming manual measurements performed by experienced readers. Semi-automatic software may assist with partial automation of assessment of multiple parameters. The aim was to evaluate differences between manual and semi-automated measurements, also in the light of the time needed for this assessment.
Methods and Materials: 120 pre-TAVI candidates referred for retrospectively ECG-gated CTA (Somatom Force/Flash, Siemens Healthcare GmbH, Forchheim, Germany) were evaluated. Fully manual and semi-automated measurements of aortic root dimensions were assessed in the 20%phase of the R-R interval. Semi-automated assessment was performed with a prototype version of dedicated software (Valve Pilot, syngo.CT Cardiac Planning, Syngo.via™VB20A, Siemens). Inter-software agreement was calculated using the Intraclass correlation coefficient (ICC) in a 2-way mixed effects model. Reading time was compared using paired samples t-test.
Results: Mean values (manual;semi-automated assessment) are stated in mm: aortic annulus (AA) short axis (21.9±2.2;22.2±2.3), AA long axis (27.7±2.7;27.7±3.0), AA area (469.1±85.8;486.3±92.1), AA perimeter (79.1±6.8;79.5±7.5), AA effective diameter derived from cross-sectional area

(24.3±2.3;24.8±2.3), AA effective diameter derived from perimeter (25.2±2.2;25.3±2.4), long axis at left coronary ostium (35.7±4.4;34.1±4.0), long axis at right coronary ostium (33.0±4.6;33.0±4.0), widest portion of coronary sinuses (36.6±4.3;35.1±4.1), long axis at sinotubular junction (31.0±4.6;31.8±4.0). Excellent inter-software agreement was found (ICC=0.84±0.1; range:0.64-0.95). Time needed for aortic root evaluation using semi-automated assessment (3min 24sec±1min 7sec) was significantly lower (p<0.001) compared to a fully manual approach (6min 31sec±1min 1sec).
Conclusion: Use of semi-automatic software in pre-TAVI evaluation results in comparable results in respect of measurements, while necessary reading time is significantly lower.

Calcifications of the aortic arch: angio-CT quantification and correlation with cerebrovascular events in patients undergoing TAVI
M. Muca, M.G. Belgrano, J. De Groodt, A. De Luca, M.A. Cova; *Triest/IT (matilda02@hotmail.it)*

Purpose: To assess accuracy of Angio-CT in quantification of calcium amount on aortic arch and valve and to establish how this impact the occurrence of Cerebrovascular events (CVEs) in patients that undergo trans-catheter aortic valve implantation (TAVI), during six months of follow up.
Methods and Materials: We retrospectively measured on Angio-CT examination the calcium amount on aortic arch and valve of 98 patients who underwent TAVI with trans-femoral o trans-aortic approach, using dedicated software. The quantification was made with three different attenuation threshold (AT: 500-1500 HU, 700-1500 HU, 800-1500 HU).
Results: 6 of 98 (6,12%) patients had a CVE, 3 patients had TIA and 3 ischemic ictus. In all 98 patients the average of calcium amount in the aortic valve was 0,72 cm³ with AT 500-1500 HU, 0,17 cm³ with AT 700-1500 HU, 0,09 cm³ with AT 800-1500 HU; in the aortic arch was 5,7 cm³ with AT 500-1500 HU, 1,02 cm³ with AT 700-1500 HU, 0,45 cm³ 800-1500 HU. In patients who have had CVEs we measured a calcium amount in the aortic valve of 3,06 cm³ with AT 500-1500 HU, 0,57 cm³ with AT 700-1500 HU, 0,13 cm³ with AT 800-1500 HU; in the aortic arch an amount of 16,77 cm³, 1,8 cm³ and 0,78 cm³ respectively with the three different attenuation threshold.
Conclusion: We observed a significant correlation (P<0.001) between Angio-CT's evidence of high calcium burden in aortic arch and occurrence of CVEs. We identified the AT with lower limit higher than 700 HU more accurate.

B-1007 10:46

Diagnostic accuracy of third generation Dual Source CT with FLASH protocol for the detection of significant coronary artery stenosis in patients candidates for TAVI procedure
P. Toia[1], E. Maffei[2], C. Mantini[3], S. Seitun[4], A. Clemente[5], C. Lario[6], L. La Grutta[1], M. Midiri[1], F. Cademartiri[2]; [1]*Palermo/IT*, [2]*Montreal, QC/CA*, [3]*Chieti/IT*, [4]*Genoa/IT*, [5]*Massa/IT*, [6]*Turin/IT (toiapatrizia@gmail.com)*

Purpose: To evaluate the performance in the assessment of coronary arteries of high-pitch spiral acquisition, using 3rd generation dual-source CT equipment, in a selected patients' population candidate for TAVI and undergoing thoraco-abdominal CT angiography screening.
Methods and Materials: High-pitch thoraco-abdominal CT angiography was performed in 120 consecutive patients (mean age 80.2±11.5yrs); using a dual-source system (2x192 0.6mm sections, 0.25s rotation time, 66 ms temporal resolution). Tube settings were automatically modulated both for kV and mAs (CARE-kV and CARE-Dose). Data acquisition was prospectively electrocardiographically-triggered at 60% of the RR interval using a pitch of 3.2, corresponding to a table feed of 737 mm/s. Diagnostic accuracy was assessed using conventional coronary angiography as the reference standard. Image quality was evaluated using a three-point scale (1=excellent; 2=moderate; 3=poor).
Results: Image quality was of diagnostic value in 55% of the segments. In 30% of the patients diagnostic image quality was observed for all segments. Diagnostic accuracy was: sensitivity 95%, specificity 83%, PPV 78%, NPV 99%. Average heart rate was significantly (p<.001) higher in patients with at least one non-diagnostic coronary segment compared to those without. All patients with an average heart rate <65 bpm had diagnostic image quality in all coronary segments. Radiation dose was always <3mSv and contrast material volume was always below 70ml.
Conclusion: High-pitch thoraco-abdominal CT angiography for non-coronary purposes enables simultaneous diagnostic evaluation of the coronary arteries at a low contrast material dose and low radiation dose in patients candidate for TAVI.

B-1008 10:54

Reduction of metal artifacts after transcatheter aortic valve implantation in cardiac CT: value of iterative metal artifact reduction
K. Higashigaito, M. Mannil, H. Alkadhi; *Zurich/CH (Kai.Higashigaito@usz.ch)*

Purpose: To assess metal artifact reduction (MAR) capabilities of iterative metal artifact reduction (iMAR) in patients after transcatheter aortic valve implantation (TAVI) in cardiac CT.
Methods and Materials: First, MAR capabilities of three different prototype iMAR settings were evaluated in a phantom study by placing four different TAVI devices in a commercially available human chest phantom. Second, the best iMAR setting was then selected and tested in patients after TAVI which were scanned on a third generation dual source CT. Images were reconstructed with and without iMAR. Two blinded readers independently assessed qualitative image quality in three locations (center, anterior and lateral of TAVI device) by using a 5-point Likert scale (5=excellent, no artifacts, 1=non diagnostic, severe artifacts). Quantitative image quality was assessed on the same regions by measuring image noise. Intraclass correlation coefficients (ICCs) and Cohen's κ were calculated to evaluate interreader agreements. Wilcoxon signed-rank test and the student's T-test were used to compare qualitative and quantitative image quality.
Results: Agreements between both readers were good to perfect (all, κ ≥ 0.683) for qualitative and high (ICC ≥ 0.98) for quantitative image quality. As compared to images reconstructed without iMAR, images reconstructed with iMAR achieved significant higher qualitative (average image score: 4.1 vs. 3.2) and quantitative (average image noise: 37±9 HU vs. 52±17 HU) image quality in all three locations and all TAVI systems (all p>0.05).
Conclusion: iMAR significantly improves qualitative and quantitative image quality by reducing metal artifacts produced by TAVI devices.

B-1009 11:02

Comparison of aortic root dimensions by multimodal measurement before transcatheter aortic valve implantation
R. Qi; *Hangzhou/CN (tsirea@163.com)*

Purpose: We sought to compare 3 methods(TTE, TEE, and MSCT)of measurements of aortic root in patients of severe aortic stenosis, and to evaluate their potential clinical impact on TAVI strategy.
Methods and Materials: Aortic root dimensions were measured using 3 methods within 1 month in 138 consecutive patients referred for TAVI. The difference among the measurements of aortic annulus diameter was compared. The accuracy of the multimodal measurement before TAVI was evaluated with postoperative follow-up.
Results: Mean aortic annulus diameter was 24.9 ± 2.03mm using TTE and 25.3 ± 1.92mm using TEE (p = 0.21) and correlation between TTE and TEE was excellent (r = 0.86). The mean of long-and short-axis diameters (24.7 ± 2.01mm) using MSCT did not differ from the TTE and TEE measurements (p = 0.05, p = 0.08). Correlations between the diameter derived from the circumference (25.8 ± 2.23mm) and the diameter derived from the cross-sectional area (25.4 ± 2.19mm) were good in comparison with the measurements using TTE (r = 0.77, r = 0.79) or TEE (r = 0.81, r = 0.85). Implantation, performed in 118 patients (85.5%) based on MSCT measurements, was successful in all but 3 patients with worse than moderate paravalvular leakage and 1 patient with valve-in-valve implantation because of prosthetic valve restenosis.
Conclusion: In patients referred for TAVI, measurements of the aortic root using TTE, TEE, and MSCT were close but not interchangeable. In the absence of a gold standard, a strategy based on comprehensive consideration would provide good clinical results.

B-1010 11:10

Pressure recovery determination by cine MRI is feasible and leads to significant re-classification of aortic stenosis severity
F. Sagmeister[1], S. Herrmann[2], M. Weininger[3], T. Bley[2], H. Köstler[2], D. Hahn[2], F. Weidemann[4], M. Beer[1]; [1]*Ulm/DE*, [2]*Würzburg/DE*, [3]*Mutlangen/DE*, [4]*Unna/DE (florian.sagmeister@gmail.com)*

Purpose: Pressure recovery (PR) is an essential haemodynamic process to maintain the energy of forward flow distal the aortic valve. We tested the feasibility of cine-MRI for estimation of PR in AS and its potential clinical impact.
Methods and Materials: Twenty-five patients with severe aortic stenosis (AS) according to echocardiography were re-evaluated by cine MRI measurements (mean age 68±10 years). The echocardiographic AS-severity parameters were corrected for pressure recovery by MRI-measurements of ascending aorta in three chamber view. Pressure recovery, indexed pressure recovery and energy

loss index were calculated. The values were compared between different measurement positions of aorta and measurements at the beginning and end of systole.
Results: Measurements of sinotubular junction in three chamber view (3CV) at the beginning of systole resulted in a PR of 18±7.3 mmHg, indexed PR (iPR) of 25±9.2% and energy loss index of 0.56±0.24 cm^2/m^2. Severe AS using indexed effective orifice area was found in 22/25 (88%) of patients. After PR-correction and using energy loss index as parameter severe AS was only found in 16/25 (64%) of patients. This corresponds to a downward classification of AS-severity in 6/25 (24%) of patients There were only small variations of PR and iPR depending on measurement position in ascending aorta and depending of time point of measurements.
Conclusion: The estimation of PR is feasible by CINE-MRI. The estimation of PR by MRI resulted in a downward classification from severe to moderate AS-severity in up to 24% of patients.

Impact of pulmonary valve replacement (PVR) and right ventricular (RV) remodelling on global and regional left ventricular (LV) mechanics in repaired tetralogy of Fallot (rTOF)

L. D'Errico, R. Wald, K. Hanneman, C. Silversides, M. Farkouh, B.J. Wintersperger; *Toronto, ON/CA (luigia.derrico@uhn.ca)*

Purpose: To evaluate the impact of PVR and consecutive RV remodelling on global/regional LV function assessed by cine MRI in patients with rTOF.
Methods and Materials: 44 patients (28m/16f;32.7±11.7y) with rTOF underwent cardiac MRI pre/post-PVR with standard short and long axes cine SSFP (6-8mm/2mm; TR less than 50ms) as well as cardiopulmonary exercise testing. RV/LV end-diastolic volume (EDV) and ejection fraction (EF) were assessed according to standard approaches. LV global longitudinal strain (GLS) and global circumferential strain (GCS) were performed using deformable registration algorithms (DRA). Analysis included assessment of global RV and LV remodelling post-PVR and changes in LV strain. ANOVA was performed to assess for possible predictors of LV functional recovery after PVR.
Results: In addition to LV EF (n=20; 45%) peak LV strain assessment identified additional patients with abnormal LV (n=10; 23%). Pre-PVR LV GLS significantly correlated to indexed RV EDV(P=0.029) while LV EF (P=0.18) and LV GCS (P=0.35) did not. Patients with impaired LV EF pre-PVR demonstrated no significant post-PVR improvement of global function (48.5±5.8% vs 46.9±7.2%;P=NS) or GLS (-13.0±2.2 vs -12.2±2.7%; P=NS) while GCS demonstrated significant improvement (-15.0±2.3 vs -13.0±3.1%;P=0.008). Post-PVR improvement of peak vO_2 correlated significantly to the improvement in RV EF (P=0.0008) while changes in any of the global or regional LV parameters did not correlate with peak vO_2 changes.
Conclusion: Cine MR-based LV strain analysis provides additional insight into LV dysfunction in patients with rTOF scheduled for PVR. Post-PVR changes of the LV do not correlate to improved exercise testing.

B-1012 11:26

Mitral valve prolapse: diagnostic value of MRI

S. Pradella, G. Grazzini, M. Brandani, L. Calistri, V. Miele, S. Colagrande; *Florence/IT (pradella3@yahoo.it)*

Purpose: Mitral valve prolapse (MVP) is a common valvulopathy affecting 2-3% of population. MVP has been associated with an increased risk of arrhythmic complications including atrial/ventricular arrhythmias and sudden cardiac death. Echocardiography is the first-line imaging modality for MVP. Cardiac magnetic resonance (CMR) represents an ideal, non-invasive diagnostic tool as an alternative or complementary modality to echocardiography providing systolic function, ventricular volume, regurgitant fraction and presence of fibrosis.
Methods and Materials: In 2015-16, consecutive patients with MVP underwent a comprehensive CMR examination at 1.5T with multiplanar cine imaging, phase-contrast flow acquisitions (at mitral annulus, proximal aorta and pulmonary valve), T1 mapping pre- and post-gadolinium administration. Expert readers independently and blindly analysed CMR and echocardiographic data. Inter-rater comparison was made by concordance correlation coefficient (CCC) with 95% confidence intervals.
Results: 32 patients mean age 56.8 ± 6.3, male 18 (56%). LGE was present in 13 (40%). CMR regurgitant fraction reproducibility was excellent (CCC 0.95, 0.86-0.98). Severity grading by CMR had good inter-observer agreement (CCC 0.85, 0.62-0.95). T1 mapping was significant in confirming LGE and more sensitive in identifying alterations.
Conclusion: CMR performs very well in MVP, with excellent reproducibility. A further unique strength of the exam is its ability to characterize myocardial tissue changes (LGE), which has further expanded with the implementation of T1 mapping techniques (relevant information regarding the amount and distribution of replacement fibrosis; over conventional LGE to identify diffuse interstitial fibrosis). The information derived from CMR may be the optimal key towards personalised therapy in MVP.

B-1013 11:34

Assessment of anatomic substrates for electrical instability in mitral valve prolapse (MVP) patients: a cardiac magnetic resonance (CMR) study

D. Palumbo[1], M. Cava[2], A. Esposito[1], S. Ravelli[1], G. La Canna[1], A. Del Maschio[1], F. De Cobelli[1]; [1]*Milan/IT*, [2]*Alessandria/IT (palumbo.diego@hsr.it)*

Purpose: MVP is a common condition due to improper leaflets atrial prolapse; often asymptomatic, it may be complicated by insidious conditions, as ventricular arrhythmias. Our aim was to investigate the CMR role in the evaluation of potential anatomic substrates for arrhythmogenic risk in MVP.
Methods and Materials: We enrolled 33 patients (47.4±17.8yrs, 21F, 12M); CMR protocol included evaluation of ventricular (LV and RV) function, myocardial oedema (T2-STIR) and late gadolinium enhancement (LGE). In order to assess MVP we measured prolapsed distance of posterior valve leaflet (maximum leaflet excursion beyond the mitral annular plane during systole, MVPE).
Results: All patients showed systolic mitral valve leaflets excursion towards left atrium >2mm, with mean MVPE of 8.5±5mm. Mean mitral indexed annular diameter (MADi) was 23.7±5.1mm; MADi and MVPE were directly related (p=0.008, r=0.473). 22 patients showed a bulging of LV inferior wall near mitral valve annulus during systole and higher values of MVPE (10.6±4.6 vs 4.2±2mm p<0.001) and MADi (25.5±4.3 vs 19.5±4.4mm p=0.004). 20 patients showed LGE, in 6 cases involving the posterior papillary muscle (PP), in 7 cases the infero-lateral LVwall, in 7 cases both. Patients with LGE in PP demonstrated systolic bulging in 92.3% of cases (p=0.044) and had greater MVPE (11.9±4.5 vs 6.2±3.8mm p<0.001). In 20 cases patients complained about arrhythmic events (2 VF, 11 NSVT, 6 LBBB, 1 AVblock); these events were significantly associated with presence of ventricular LGE (p=0.010).
Conclusion: In patients with MVP, CMR may characterise structural alterations of myocardium, probably representing a potential arrhythmogenic risk substrate.

B-1014 11:42

Coronary stent image subtraction using monochromatic CCTA derived from a dual-layer spectral CT

W. Yang, L. Qin, F. Yan, Y. Jiang, Q. Han; *Shanghai/CN (yanjiangcs@hotmail.com)*

Purpose: To investigate the coronary stent image subtraction using spectral tools derived from a dual-layer spectral CT as well as to compare the image quality among subtracted images and routine images.
Methods and Materials: 15 patients with 21 stents underwent CCTA using a dual-layer spectral CT (IQon Spectral CT, Philips Healthcare). Conventional, monochromatic and virtual non-contrast (VNC) images were reconstructed from the raw data of one scan in the same cardiac phase. Stent subtraction images were acquired by subtracting stent on VNC images from monochromatic (100keV) and conventional images ($Mono_{sub}$ and $Conv_{sub}$). Mean in-stent lumen diameter and reader confidence were assessed and compared among both subtraction images, monochromatic images and conventional images. One-way ANOVA and Friedman M test were used for statistical analysis.
Results: Significant difference were found in in-stent lumen diameter for all comparison combinations among different image sets ($Mono_{sub}$ > $Conv_{sub}$> Monochromatic > Conventional, all p<0.05). Higher reader confidence were found in $Mono_{sub}$, $Conv_{sub}$, monochromatic images compared to conventional images. No difference was found in reader confidence among two subtracted images sets and monochromatic images.
Conclusion: Subtracted images derived from monochromatic images exhibited largest in-stent diameter and better reader confidence, which indicated that stent subtraction using dual-layer spectral CT helps to improve in stent luminal visualisation and reader confidence.

B-1015 11:50

Image quality study of monochromatic coronary stent imaging with a dual-layer spectral CT: initial experience of optimal mono-energy exploration

W. Yang, F. Yan, L. Qin, Y. Jiang, Q. Han; *Shanghai/CN (yanjiangcs@hotmail.com)*

Purpose: To investigate the image quality of coronary stent imaging using a dual-layer spectral CT. Additionally, to explore the optimal monochromatic energy for coronary stent imaging.
Methods and Materials: 15 patients with 21 stents underwent CCTA using a dual-layer spectral CT (IQon Spectral CT, Philips Healthcare). Conventional series and monochromatic series (40-200keV, with an interval of 10keV) were reconstructed from the raw data of one scan. CT attenuation in both coronary artery near stents and aorta root for all series were measured. Difference between coronary luminal and aortic attenuation was calculated as an indicator for blooming artefacts. In-stent lumen diameter and subjective image quality were recorded.
Results: An increase in monochromatic energy was associated a decrease in luminal attenuation and blooming artefacts indicator. In-stent lumen diameter in 90keV and 100keV series was larger compared to other series, while series below 80keV as well as conventional series exhibited significant reduced lumen diameter due to severe blooming artefacts. Subjective image quality scores were higher in 90keV, 100keV and 110keV compared to other series.
Conclusion: Monochromatic CCTA using a dual-layer spectral CT improved image quality of stent imaging compared to conventional CCTA. 90keV and 100keV may be the optimal monochromatic energy for coronary stent imaging.

The ratio of coronary artery diameters predicts left main diameter and coronary dominance

M. Kolossváry, B. Szilveszter, K. Júlia, Á. Jermendy, M. Károlyi, A. Bartykowszki, A. Panajotu, B. Merkely, P. Maurovich-Horvat; *Budapest/HU (marton.kolossvary@cirg.hu)*

Purpose: Coronary artery stenosis is defined as the percent of maximal diameter stenosis compared to an adjacent normal segment. In cases of diffuse left main(LM) stenosis, such reference does not exist. Our goal was to assess how the LM diameter could be predicted from the left anterior descending(LAD) and the left circumflex(LCX) aretries' diameters. Furthermore, we sought to assess the diagnostic accuracy of the ratio of the LM and the right coronary artery(RCA) diameters for determining coronary dominance.
Methods and Materials: We included 952 consecutive patients (age:59.8±11.7; women:43.3%) who underwent 256-slice coronary CT angiography. We measured coronary artery ostium diameters on curved multiplanar reconstruction views on dedicated cardiac workstations.
Results: Coronary artery diameters were as following: LM:4.7±0.7mm; LAD:3.8±0.6mm; LCX:3.5±0.7mm; RCA:3.9±0.8mm. There was a significant difference between the diameters of the LM, LCX, RCA between left and right dominant coronary systems ($p<0.001$ for all), while there was no significant difference between LAD diameters ($p=0.24$). The ratio of the LM diameter as compared to the average of LAD and LCX was: 0.61±0.1, with no significant differece between right and left coronary systems ($p=0.88$). The ratio of the LM and RCA could predict coronary dominance with high diagnostic accuracy (AUC=0.95).
Conclusion: The average of the LAD and LCX ostium diameters can be used to estimate LM diameters (LM=1.64* (LAD+LCX) /2) both in right and left coronary systems. The ratio of the LM and RCA defines coronary dominance. These simple ratios might support clinical decision making especially in patients with severe coronary artery disease or unusual coronary anatomy.

B-1018 14:08

Diagnostic accuracy of coronary CT angiography performed in 100 consecutive patients with coronary stents using a novel whole organ high-definition CT scanner

D. Andreini, G. Pontone, S. Mushtaq, A. Annoni, A. Formenti, M. Mancini, C. Fiorentini, A. Bartorelli, M. Pepi; *Milan/IT (daniele.andreini@ccfm.it)*

Purpose: To evaluate image quality, interpretability, diagnostic accuracy and radiation exposure of coronary CT angiography (CCTA) using a new generation CT scanner in consecutive patients with coronary stents, including those with high heart rate (HR) and atrial fibrillation (AF).
Methods and Materials: We enrolled 100 consecutive patients (85 males, mean age 65±10 years) with previous coronary stent implantation scheduled for clinically indicated non-emergent invasive coronary angiography (ICA). A novel whole organ high-definition CT scanner was used. Image quality score, using a 4-point Likert scale on a per-stent level, coronary interpretability and diagnostic accuracy vs ICA were evaluated and the effective dose (ED) was recorded.
Results: Mean HR during the scan was 67±13 bpm. Twenty-six patients had >65 bpm HR during scanning and 13 patients had AF. Overall, image quality was high (Likert=3.2±0.9). Stent interpretability was 95.8% (184/192 stents). Among 192 stented segments, CCTA correctly identified 32 out of 33 with >50% in-stent restenosis (ISR) at ICA (sensitivity 97%). In the stented-based analysis, specificity, positive and negative predictive values and diagnostic accuracy for ISR detection were 97%, 86%, 99% and 97%, respectively. Overall, mean ED was 2.4±1.2 mSv.
Conclusion: A new whole organ high-definition CT scanner was able to evaluate coronary stents with high image quality, stent interpretability, diagnostic accuracy and low radiation exposure, also in the presence of unfavourable HR and heart rhythm.

B-1019 14:16

Standardized description of coronary artery disease by means of CAD-RADS: a better method?

G. Tabacco, G. Finetto, M. Poletti, M. Vettori, R. Malagò, R. Pozzi-Mucelli; *Verona/IT (giuliatabacco23@gmail.com)*

Purpose: CA-CTMS is a procedure of considerable usefulness in the study of cardiovascular diseases, particularly those resulting from coronary artery disease. To maximize the clinical impact of coronary CTA, CAD-RADS, a standardized reporting system for coronary CTA results was recently introduced. We analysed the data collected at our institute, classifying coronary artery lesions according to this system.
Methods and Materials: 1565 patients (953 M, 612 F, average age 63 years) underwent CA-CTMS, from April 2008 to April 2016, with a 64-slice CT scanner (Brilliance 64, Philips, Best, The Netherlands). We reconstructed and analysed each exam using a Philips workstation, classifying the detected lesions and plaques according to the CAD-RADS system.
Results: 470/1565 (30.5%) patients resulted free of plaques or stenosis (CAD-RADS 0). 156/1565 (10%) patients were classified as CAD-RADS 1, 579/1565 (37%) as CAD-RADS 2, 234/1565 (15%) as CAD-RADS 3, 78/1565 (5%) as CAD-RADS 4, 8/1565 (0,5%) as CAD-RADS 5, 40/1565 (2%) as CAD-RADS N, 313/1565 (20%) patients had CAD-RADS S as modifier, 6/1565 (0,4%) CAD-RADS G and 175/1565 (11%) CAD-RADS V.
Conclusion: The CAD-RADS classification allowed us to group our patients into a uniform, updated and evidence-based way, according to their risk profile. Through it we can provide to the patients a better follow-up and therapeutic approach.

B-1020 14:24

Diagnosticefficacy of coronary artery three-dimensional steady-state free precessionmagnetic resonance angiography in comparison with invasive coronaryangiography for detection of coronary artery disease

A. Mohammadzadeh[1], F. Faeghi[1], N. Sahraee[1], H. Pouraliakbar[1], R. Kiani[1], M. Mohammadzadeh[1], P. Entezari[1], A. Borhani[1], V. Mohammadzadeh[1], S. Kadivar[2]; [1]*Tehran/IR*, [2]*Rasht/IR (mralimohammadzadeh@yahoo.com)*

Purpose: To assess the diagnostic value of three-dimensional steady-state free precession magnetic resonance angiography (3D-SSFP MRA) for detecting coronary artery disease (CAD).
Methods and Materials: Patients, suspected of CAD based on clinical evaluation, underwent invasive coronary angiography (CAG) and cardiac MRA (CMRA). Collected data in favour of any CAD findings in CMRA were compared to ICA results as the standard diagnostic method in CAD detection. Analysis was performed on per-patient, per-vessel and per-segment basis.
Results: A total of 30 patients (mean age: 43±10 years, 19 male) enrolled in the analysis. On per-patient analysis, sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and area under receiver operator characteristic (ROC) curve of CMRA for detection of coronary artery stenosis were as follows, respectively: 100% (CI95%: 75%-100%), 50% (CI95%: 18%-

81%), 73.33% (CI95%: 46%-90%), 100% (CI95%: 47%-100%) and 0.827. On per-vessel analysis, CMRA had a sensitivity of 89.29% (CI95%: 71%-97%), specificity of 80.56% (CI95%: 63%-91%), PPV of 78.13% (CI95%: 60%-90%), NPV of 90.63% (CI95%: 74%-98%) and area under ROC curve of 0.845. On per-segment analysis sensitivity, specificity, PPV and NPV of CMRA for segmental stenosis detection were as follows, respectively: 77.78% (CI95%: 60-89%), 87% (CI95%: 81%-92%), 62% (CI95%: 46%-76%), 93.89% (CI95%: 88%-97%). Area under ROC curve was 0.835 on per-segment analysis.
Conclusion: 3D SSFP CMRA provides a promising non-invasive diagnostic tool in the assessment of coronary artery disease.

B-1021 14:32

Monochromatic imaging improving accuracy of coronary stenosis with heavy calcification compared with conventional imaging and invasive coronary angiography

Y. Yi, R.-Z. Wu, S. Yan, X.-M. Zhao, S.-H. Yu, M. Wang, Y. Wang, Z.-Y. Jin, Y.-N. Wang; *Beijing/CN (xy_yiyan@sina.com)*

Purpose: To investigate the performance of monochromatic imaging in assessing the stenosis with heavy calcification by coronary CT angiography (CCTA), compared with conventional 120 kVp image and invasive coronary angiography (ICA) as reference.
Methods and Materials: Seventeen patients (9 men and 8 women; 63.7±13.1 years) underwent CCTA and ICA. CCTA images were acquired on a dual-layer spectral detector CT. The conventional and monochromatic image were acquired within one scan. Monochromatic images from 50 to 150 keV with 10 keV increment were reconstructed. The degree of each coronary stenosis was quantitatively measured at all keV levels. The best keV is defined at which the stenosis degree is close to the result of ICA. The degree of stenosis on the best keV and conventional 120 kVp images was recorded.
Results: Forty-three stenosis were included in analysis. The keV images were selected at 80 and 90 keV in 35% and 53% cases. When using the best keV image, the mean and standard deviation for the difference of stenosis grade between monochromatic image and ICA is 0.35% ± 1.60%. While using the conventional images, the mean and standard deviation for the difference of stenosis grade between conventional image and ICA is 7.9% ± 5.4%. The difference of conventional image is significantly larger than that of the best keV images using ICA as the reference ($p < 0.001$).
Conclusion: The monochromatic images (e.g. 80 and 90keV) improve the accuracy of the stenosis evaluation in heavily calcified coronary artery, compared with the conventional images in CCTA.

B-1022 14:40

Cardiac allograft vasculopathy assessment with coronary computed tomography in heart transplanted patients

M. Károlyi, M. Kolossváry, A. Bartykowszki, I. Kocsmar, B. Szilveszter, Á. Jermendy, J. Karády, B. Merkely, P. Maurovich-Horvat; *Budapest/HU (karolyimisi@gmail.com)*

Purpose: Cardiac allograft vasculopathy (CAV) affects >50% of the heart transplanted (HTX) patients within 10-years of transplantation and has poor prognosis. Coronary CT angiography (CTA) has been proposed for the routine annual assessment of CAV. We sought to assess the feasibility of quantitative assessment and follow-up of CAV with coronary CTA in HTX patients.
Methods and Materials: 20 patients (12 males, age 54 [IQR:47;58] years) underwent 256-slice coronary CTA one year after HTX and an additional coronary CTA as part of the routine yearly follow up. We quantified the total vessel wall volume in all coronaries up to 2 mm luminal diameter using a semi-automated software. Fixed threshold settings were used to assess various vessel wall components: calcified lesions (>350HU), non-calcified lesions (75-350HU) and low-attenuation non-calcified lesions (<75HU).
Results: The average time between the baseline and follow-up scans was 368 [IQR:359;394] days. Total lumen volume did not change between baseline and follow-up studies (p=0.39). The total vessel wall volume showed significant progression during the follow-up period (464 [IQR:318;600] vs. 486 [IQR:359;600] mm^3, p=0.01). The volume of non-calcified and low-attenuation noncalcified components showed progression (401 [IQR:249;502] vs. 416 [IQR: 265;498] mm^3, p=0.05 and 11 [IQR: 7;17] vs. 16 [IQR: 9;34] mm^3, p=0.01, respectively), while the calcified volume did not change between baseline and followup CTAs (63 [IQR: 12;103]) vs. 49 [IQR: 16;88] mm^3, p=0.53).
Conclusion: Quantitative CAV assessment is feasible with coronary CTA in HTX patients. CAV progression within the first years after HTX is mainly attributable to noncalcified lesions.

B-1023 14:48

Predictors of clinical significance of moderate coronary stenosis in multiple lesions of culprit arteries in 256 multi-detector coronary CT angiography one-beat acquisitio

J.-L. Sablayrolles, P. Guyon, L. Macron, J. Feignoux, I. Timofeeva; *Saint-Denis/FR (dr.irina.timofeeva@gmail.com)*

Purpose: To identify morphological coronary CT angiography (CCTA) predictors for the clinical significance of moderate coronary artery stenosis using the fractional flow reserve (FFR) studying by quantitative coronary angiography (QCA).
Methods and Materials: A total of 61 arteries (43 consecutive patients) underwent CCTA and QCA associated with a lesion-specific FFR measurement were retrospectively analyzed. CCTA was performed on a 256-MDCT one-beat acquisition, three-phase injection protocol by using smart shot dual injector. Stenosis from 50-69% considered as moderate. FFR ≤0,80 was considered as functionally significant. The degree and length of stenosis was evaluated on CCTA and QCA.
Results: The mean age was 67,9±10,1, BMI 27,3±4,4 kg/m^2 and 75% were males. No difference between coronary stenosis degree and length measured by CCTA and QCA (p=0,10 and p=0,94 respectively) were observed.
29% patients (18 arteries) have clinically significant moderate stenosis with FFR ≤0,8; 23% (n=14) have moderate but not clinically significant stenosis and 48% (n=29) were presented by 30-49% stenosis.
All of stenosis <50% by CCTA were functionally non significant with FFR>0,8 (p<0,05, 100% negative predictive value (NPV)).
As CT-predictors for the clinical significance of moderate coronary stenosis (FFR≤0,8) were revealed: stenosis length ≥16 mm (sensitivity (ss) 78%, specificity (sp) 79%, PPV 82%, NPV 73%, p=0,004) and multiple stenosis in calcified arteries with the stenosis's length ≥16 mm (sp 86%, PPV 85%, p=0,012).
Conclusion: Moderate coronary artery stenosis evaluated by CCTA are clinically significant (FFR≤0,8) if their length is more than 16 mm in calcified arteries, particularly in culprit arteries with multiple stenosis.

B-1024 14:56

CT angiography for the diagnosis and subcategorisation of unroofed coronary sinus syndrome

A. Zhi[1], Z. Pei[1], D. Ruping[1], M. Weiguo[2], L. Bin[1], J. Shiliang[1]; [1]*Beijing/CN*, [2]*New Haven, CT/US (Zhiah@163.com)*

Purpose: To evaluate the role of CT angiographic (CTA) in diagnosis and classification of unroofed coronary sinus syndrome (URCSS).
Methods and Materials: We retrospectively analyzed 46 URCSS patients diagnosed by CTA from 2005-2015. Based on defect location and size, URCSS were divided into 4 types: complete defect as type I, partial defect of proximal coronary sinus (CS)as type II, partial defect of distal CS as type III, partial defect in which a communication occurs between CS and left atrial as type IV. In accordance with or without persistent left superior vena cava (LSVC), all types were divided into two subtypes as a and b.
Results: Based on CTA findings, URCSS type I was observed in 23 cases (Ia 7, Ib 16), type II in 10 cases (IIa 3, IIb 7), type III in 12 (IIIa 3, IIIb 9), and type IV in 1 case classified as IVb subtype. In type I patients, CS diameter was larger than other types (P <0.05). The CS diameter between type I, II and III, IV were significantly different (p <0.05). In these 46 cases, 21 were detected by echocardiography correctly as URCSS (46%). 22 patients were treated successfully by surgery and confirmed diagnosis of URCSS, types I, II and IIIa differs significantly from patients with types IIIb and IV ($p < 0.05$).
Conclusion: CT imaging can provide excellent anatomical structure and precise diagnosis of URCSS. URCSS classification in this paper is simple and easy to practice and very important for clinical diagnosis and treatment.

B-1025 15:04

Accuracy of CT for selecting revascularisation method based on mortality predictions: combined with the SYNTAX II score

S. Lee, B. Choi, Y. Suh, K. Han; *Seoul/KR (sieun@yuhs.ac)*

Purpose: To investigate the diagnostic performance of coronary CT angiography for selecting revasclarisation method based on mortality predictions according to combination of the 2011 American College of Cardiology Foundation (ACCF) and American Heart Association (AHA) guidelines for CABG surgery and SYNTAX score II, which enables individulised approach with clinical charcteristics.
Methods and Materials: From January to May 2011, a total of 160 patients who underwent both coronary CT angiography and invasive coronary angiography within 30 interval days were included. We reviewed coronary CT angiography and invasive coronary angiography for selecting CABG cadidates and calculated SYNTAX score. Diagnostic performances of coronary CT angiography, coronary CT angiography plus CT-SYNTAX score I and plus CT-SYNTAX score II were analyzed by using invasive angiography counterparts

as references. We suggested a method to dichomotise the results of the SYNTAX score II and investigated the added value of SYNTAX score II over I.
Results: The overall sensitivity, specificity, positive predictive value (PPV), and negative predictive value of coronary CT angiography for selecting CABG surgery candidates were 89.3%, 84.6%, 75.8%, and 93.6%, respectively. Combined coronary CT angiography with a CT-SYNTAX score I had higher specificity and PPV (94.3% and 65.2%, respectively) than did coronary CT angiography alone (67.1% and 30.3%, respectively; P<.0001). CT-SYNTAX score II showed high accuracy (94.4%) using ICA-SYNTAX II as reference.
Conclusion: Coronary CT angiography combining with a CT-based SYNTAX score II can be reliable method for selecting CABG surgery candidates.

B-1026 15:12

Prognostic implications of coronary CT angiography-derived quantitative markers for the prediction of major adverse cardiac events

C. Tesche, F. Plank, C.N. De Cecco, T.M. Duguay, M.H. Albrecht, A. Varga-Szemes, J. Yang, I.L. Jacks, U.J. Schoepf; *Charleston, SC/US (tesche.christian@gmail.com)*

Purpose: To evaluate quantitative markers derived from coronary CT angiography (CCTA) as predictors of major adverse cardiac events (MACE).
Methods and Materials: Datasets from two centers were retrospectively analyzed. 46 patients (65.5±8.1 years, 62% male) with suspected coronary artery disease (CAD) who underwent dual-source CCTA and experienced a MACE within 12 months were included and compared to a Framingham risk score matched cohort (*n*=46) without MACE. CCTA-derived quantitative markers were compared between both groups: total plaque volume (TPV), calcified and non-calcified plaque volumes (CPV and NCPV), plaque burden (PB), remodelling index (RI), lesion length (LL), presence of Napkin-ring sign, segment involvement score (SIS), and segment stenosis score (SSS).
Results: Patients suffering MACE had significantly more obstructive CAD with higher PB, SSS, and SIS (all $p<0.05$) compared to controls. MACE lesions showed more TPV, NCPV, LL, PB, and Napkin-ring sign (all $p<0.05$). On multivariate analysis, odds ratios (OR) for MACE on a per-patient level were 1.07 for PB ($p=0.0002$) and 1.13 for SSS ($p=0.049$). On a per-lesion basis OR for LL was 1.05 ($p=0.042$), 1.03 for PB ($p=0.018$), 1.28 for RI ($p=0.026$), and 1.68 for the Napkin-ring sign ($p=0.031$). A receiver operating characteristics analysis showed a combination of markers (Framingham risk score, Napkin-ring sign, LL, RI) showed the highest predictive value for MACE (AUC 0.92, $p=0.013$).
Conclusion: CCTA-derived markers portend predictive value for MACE on a per-patient (PB, SSS) and per-lesion level (LL, PB, RI, Napkin-ring sign). A combination of markers with the Framingham risk score has the highest predictive power.

Wrist angle measurements: are they applicable to the paediatric population in the trauma setting?

E.A. Joyce, T. Farrell, J. McMorrow, A. Snow; *Dublin/IE (joyceea@tcd.ie)*

Purpose: The purpose of this study is to assess the reliability of standard adult carpal angle measurements, specifically the scapholunate and capitolunate angles, in the assessment of the paediatric wrist in the trauma setting.
Methods and Materials: The study cohort comprised of male and female children who underwent a wrist radiograph for the evaluation of suspected wrist or forearm injuries post trauma. In order to ensure an accurate technique of carpal angle measurement, only individuals with a sufficiently ossified carpus and an adequately positioned lateral wrist radiograph were included. In addition, we determined wrist angle measurements on a gender matched adult population in order to assess if the two groups were comparable. Adults between the ages of 18-40 who underwent wrist radiographs for evaluation of suspected injury post trauma were included and similar exclusion criteria were applied.
Results: Carpal angle measurements were performed on the lateral wrist radiographs of 256 individuals between the ages of 5 and 17 years (mean 11.2 years , SD± 2.5 years). The mean scapholunate angle was 48°(SD± 7). The mean capitolunate angle was 10°(SD± 6). The mean scapholunate and capitolunate angles of the adult cohort were 49°(SD± 8°) and 11°(SD± 6°) respectively. No statistically significant difference was observed between the scapholunate or capitolunate angle measurements in the two groups (p=0.57 and p=0.92 respectively).
Conclusion: The data suggests that standard adult assessment techniques and values for scapholunate and capitolunate angle radiographic measurements are applicable to the paediatric population provided the carpus is sufficiently ossified.

B-1028 14:08

Pertinence of the micro-dose biplanar radiographs in children's pangonometry

C. Tillaux, H. Lerisson, E. Amzallag-Bellenger, A. Cebulski-Delebarre, L. Deruyter, E. Nectoux, F. Avni, B. Herbaux, N. Boutry; *Lille/FR (c.tillaux@outlook.com)*

Purpose: To evaluate the dose and reliability of micro-dose biplanar radiographs (BPR) in children's pangonometry.
Methods and Materials: From September 2015 to February 2016, children aged 6-18 years followed up for lower limb malalignment were prospectively included. Body mass index (BMI) was calculated for each patient. Morphotype was selected according to hip width: M1 (< 25cm), M2 (25 to 35cm), M3 (> 35cm). For each patient, standing full-length lower limb BPR were acquired using randomly either a standard low-dose protocol or a micro-dose protocol. Pangonometry was performed independently by two observers. Reliability of measured parameters was compared for each protocol and morphotype subgroups, using the intraclass correlation coefficient (ICC). For each patient, dose area product (DAP) and skin dose using two thermoluminescent dosimeters were registered.
Results: We studied 260 consecutive children (100 girls and 160 boys).The mean age was 12 years (SD: 3 yo); 74 children in M1 (mean BMI: 15.7 kg/m²), 149 in M2 (BMI: 19.8 kg/m²) and 40 in M3 (BMI: 30,2 kg/m²). In micro-dose protocol, reliability was excellent for lower limb lengths (ICC = 0.99), good for alignment (ICC = 0.85), comparable to low dose (ICC = 0.99 and 0.89). No correlation was found between BMI and measurements reliability in both protocols. DAP and skin dose was significantly lower ($p < 0.001$) in micro-dose protocol for all morphotypes (0.21 mGy vs 1.13 mGy).
Conclusion: Micro-dose BPR can be reliably used in pangonometry and allows a significant dose reduction in paediatric lower limb examinations.

B-1029 14:16

Conventional radiography in juvenile idiopathic arthritis: joined recommendations from the French societies for rheumatology, radiology, paediatric radiology

P. Marteau[1], C. Adamsbaum[2], L. Rossi-Semerano[2], M. De Bandt[3], I. Lemelle[4], C. Deslandre[2], T. Tran[5], A. Lohse[6], E. Solau-Gervais[7], C. Sordet[8], P. Pillet[9], B. Bader-Meunier[2], J. Wipff[2], C. Gaujoux-Viala[5], S. Breton[2], V. Devauchelle-Pensec[1]; [1]*Brest/FR*, [2]*Paris/FR*, [3]*Fort-de-France/FR*, [4]*Nancy/FR*, [5]*Nîmes/FR*, [6]*Belfort/FR*, [7]*Poitiers/FR*, [8]*Strasbourg/FR*, [9]*Bordeaux/FR (pa.marteau@hotmail.fr)*

Purpose: To provide guidelines concerning conventional radiography (CR), in every subtype of juvenile idiopathic arthritis (JIA) (let alone systemic JIA)
Methods and Materials: A multidisciplinary task force of 15 French rheumatologists, paediatricians, radiologists and two patients representatives was convened. Following the GRADE method for recommendations, they expressed a series of research questions. Systemic JIA was ruled out. An exhaustive literature review was performed. Articles in English describing structural damage (joint space narrowing, erosions, growth abnormalities) were considered. Several assessments were proposed, based on literature data and expert opinion when evidence-based medicine was lacking. This first draft was sent to a group of 14 independent French-speaking reviewers. It was then reconsidered by the authors, and accordingly modified. A final version was submitted for evaluation to each author and reviewer, for evaluation by a Delphi process.
Results: 72 articles were included in the literature review. Often, radiographic course was a secondary outcome. Four general statements and 28 recommendations were produced. Agreement between experts was high, ranking from 8.05 to 9.70. Grades of recommendations were mostly C and D, due to lack of power of the studies. We recommend systematic CR of hands, wrists and feet at diagnosis and follow-up when the structural threat is high. In oligoarticular JIA, CR should be performed in specific situations guided by clinical apprecation. CR is not the best imagery for axial skeletton.
Conclusion: This is the first work providing practical guidelines concerning CR in JIA - when to, and when not to, perform them.

B-1030 14:24

Femoral torsion assessment with MRI in children and adolescents: should we use the bony or cartilaginous contours?

A.B. Rosskopf, C.A. Agten, L.E. Ramseier, C.W.A. Pfirrmann, F.M. Buck; *Zurich/CH (andrea.rosskopf@balgrist.ch)*

Purpose: To assess whether the use of cartilaginous contours at the femoral condyles instead of bony contours significantly changes femoral torsion measurements in children and adolescents.
Methods and Materials: Femoral torsion was measured in 32 girls (mean age 10.1 years ±2.3 standard deviation) and 42 boys (10.9 years ±2.5) by two independent readers (R1,R2). The femoral condyle angle was measured twice using once the cartilaginous and once the bony contours of the distal femur. Cartilage thickness at femoral condyles was assessed. Intraclass-correlation-coefficient (ICC) and Pearson`s correlation were used for statistical Analysis.
Results: Mean difference between cartilaginous and bony femoral torsion in girls was -1.1°±1.75 (range, -5.4° to 3.1°) for R1 and -1.64°±1.67 (-6.3° to 2.1°) for R2, in boys -1.5°±1.87(-8.4° to 1.1°) for R1 and -2.28°±1.48 (-4.3° to 9.7°) for R2. Weak-to-moderate correlations between difference of cartilaginous-versus-bony measurements and cartilage thickness (r=-0.15 to -0.55,P<0.001-0.46) or age (r=-0.33 to 0.46,P<0.001-0.006) were found for both genders. Intermethod-ICC for cartilaginous versus bony femoral torsion measurements was 0.99/0.99 for R1/R2 in girls, and 0.99/0.98 in boys.
Conclusion: There is no benefit in the use of cartilaginous condyle contours instead of bony contours for femoral torsion assessment in children and adolescents, since measurement results are interchangeable.

B-1031 14:32

Human long bone development in intrauterine growth restriction: in vivo analysis of the distal femoral epimetaphysis on prenatal MR imaging

U. Nemec, S. Nemec, P. Brugger, D. Prayer; *Vienna/AT (ursula.nemec@meduniwien.ac.at)*

Purpose: To investigate human long bone development in fetuses with intrauterine growth restriction (IUGR) by analyzing distal femoral epimetaphyseal structures and bone morphometrics on prenatal MR imaging.
Methods and Materials: This retrospective study included 14 fetuses (mean gestational age, 26 weeks 2 days; range, 21 weeks 3 days to 33 weeks) with IUGR caused by placental insufficiency, without other brain or body abnormalities, as well as a total of 192 age-matched normal fetuses. On 1.5-T echo-planar MR images, diaphyseal and epiphyseal morphometric measurements were assessed, and, using a grading system, the cartilaginous epiphyseal and metaphyseal shape, secondary ossification, and the perichondrium were qualitatively analyzed. Student's t-testing was used to compare the morphometric measurements of IUGR fetuses with normal fetuses, and descriptive statistics were used to compare the qualitative bone characteristics.
Results: The morphometric measurements of the IUGR fetuses did not exceed the minimum normative measurements at any gestational age (diaphyseal length: p <0.0001 - 0.0053; epiphyseal length: p <0.0001 - 0.0022; epiphyseal width: p <0.0001 - 0.0032). Overall, the same grading for cartilaginous epiphyseal shape as observed in IUGR fetuses was found in 28.6% - 100% of normal fetuses, for the metaphyseal shape in 7.1% - 94.4%, for secondary ossification in 16.7% - 100%, and for the perichondrium in 12.5%- 91.7%.
Conclusion: On prenatal MR imaging, fetuses with placental-based IUGR exhibit long bone shortening, whereas their qualitative bone characteristics appear within normal limits. Consequently, the presence of qualitative bone abnormalities should include the differential diagnosis of various fetal skeletal disorders.

B-1032 14:40

Role of MRI to assess skeletal age in paediatric celiac disease

S. Bernardo, E. Tomei, M. Martino, A. Laghi; *Rome/IT (silviabernardo@live.it)*

Purpose: Coeliac children are often subject to weight loss and lower somatic growth rate, compared to healthy children of the same age. The purpose of this study was to asses the feasibility of magnetic resonance imaging (MRI) of the hand and the wrist to assess skeletal age and growth delay.
Methods and Materials: We enrolled in our study 39 coeliac children (13 males and 26 females) affected by histological proven coeliac disease, with a chronological age ranged between 5 years and 1 month and 16 years and 4 months (mean age of 10years, +/- 3 years and 8 months standard deviation). A single MRI sequence (T13D SE, acquisition time: 1 minute 31 seconds) of the hand and wrist in coronal plane was performed of each patient to estimate the skeletal age. Patients' data were compared with a population of normal subjects.
Results: The preliminary results showed a delay in skeletal age in children affected by coeliac disease in 85,7% of the simple study, with a delay of maturity of 0.83 years (+/- 2,2 years of SD). Only 3 children showed advance MRI skeletal age when compared to normal subjects.
Conclusion: MRI of hand/wrist to assess skeletal age may be considered as a reliable indicator of somatic growth. MRI, without radiation exposure, can be an used as a diagnostic tool in skeletal delay. It could play an important role in the follow up of coeliac children, after glutenfree diet.

B-1033 14:48

MRI T2* mapping for bone marrow iron overload assessment in patients with beta-thalassemia

E. Nazarova, G. Tereshchenko, A. Gvozdev, D. Ibragimova; *Moscow/RU (evelina.nazarova@fccho-moscow.ru)*

Purpose: To estimate iron distribution in the bone marrow of vertebrae according to the grade of liver siderosis.
Methods and Materials: MRI T2* mapping followed by liver biopsy was performed in 43 children with beta-thalassemia (mean age - 9 years). According to the grade of liver siderosis, patients were divided into 4 groups: group 1 - without iron overload (N=8); group 2 - mild iron overload (N=8); group 3 - moderate iron overload (N=10); group 4 - severe iron overload (N=17). Quantitative estimation was conducted by Phillips Achieva 3T with T2* - mapping using Multi echo GRE pulse sequence (TR=350 ms, TE=0.9 ms, ΔTE=0.9 ms, Breath Hold).
Results: From the perspective of regression analysis, we found correlations between the values of T2* signal intensity from liver and bone marrow. 1 group - LIC (Liver iron concentration) > 2.5 ms (0.1 - 2 mg/g dry weight), VIC (Vertebrae iron concentration) > 2.5 ms, r= 0.82 (R^2=0.67); 2 group - LIC of 1.5 - 2.5 ms (2-7 mg/g dw), VIC of 1.3-2.9 ms, r=0.47 (R^2=0.22); 3 group - LIC of 1.0 -1.5 ms (7-15 mg/g dw), VIC of 1.0-2.8 ms, r=0.67 (R^2=0.45); 4 group - LIC of 0.6-1.0 ms (>15 mg/g dw), VIC of 0.6-1.0 ms, r= 0.91 (R^2=0.83).
Conclusion: VIC is an indication of severe liver iron overload in children with beta-thalassemia.

B-1034 14:56

Diffusion-weighted MRI and FDG-PET in children with mediastinal lymphoma: does the apparent diffusion coefficient (ADC) discriminate between benign and malignant masses?

M.A. Stoffels, J. Herrmann, M. Groth, C. Berliner, S. Klutmann, G. Adam, M. Regier; *Hamburg/DE (m.stoffels@uke.de)*

Purpose: To intraindividually evaluate the role of diffusion weighted MRI (DWI) with ADC measurement as a marker of malignancy in children with mediastinal lymphoma in comparison to standardized uptake values (SUV) calculated by positron emission tomography computed tomography (PET-CT).
Methods and Materials: DWI-MRI and PET-CT were performed in 16 consecutive patients with histologically proven Hodgkin's and Non-Hodgkin's lymphoma before initiation of chemotherapy, comprising a total amount of 104 malignant nodes. DWI was performed at 3T with the following imaging parameters: TR/TE 2000/66ms; FOV 425mm; slice thickness 4mm; b-values 0, 25, 50, 75, 150, 500 and 900. By placing a region of interest (ROI) encovering the entire tumour manifestation, the minimum (ADC_{min}), mean (ADC_{mean}) and maximum (ADC_{max}) ADC as well as the mean and maximum SUV (SUV_{mean} and SUV_{max}) were determined by two independent radiologists. The results of DWI and PET-CT were statistically compared on a per-node base applying Pearson's correlation coefficient.
Results: The comparison of the ADC_{min} and SUV_{max} indicated a statistically significant inverse correlation (r=0.91; p=0.02). In contrast, no correlation was found between ADC_{mean} and SUV_{mean} (r=0.37; p=0.51). Higher tracer uptake at PET-CT and lower ADC were determined in Hodgkin's lymphoma compared to Non-Hodgkin's lymphoma.
Conclusion: The minimum ADC values demonstrate a higher tumour metabolism, as confirmed by SUV measurements, and allows the discrimination of benign and malignant mediastinal masses. In paediatric patients, DWI with ADC measurement should be considered as a powerful, radiation-free complementary tool in the diagnostic workup of mediastinal lymphoma.

B-1035 15:04

Vessel wall changes after radiochemotherapy in former paediatric medulloblastoma patients: a high-resolution MRI

Y. Tanyildizi, S. Keweloh, M.-A. Neu, A. Russo, A. Wingerter, A. Tropine, J. Faber, M.A. Brockmann; *Mainz/DE*

Purpose: High-resolution MRI (HR-MRI), including vessel wall imaging (VWI), is an emerging tool for evaluating intracranial vessel disease. Going along with the improved survival of medulloblastoma (MB) patients, an increasing number of long-term MB survivors experiences cerebrovascular late sequelae of the applied radiochemotherapy (RCT), including early occurrence of atherosclerotic lesions. This study evaluates radiation-induced intracranial vascular changes, imaged through HR-MRI.
Methods and Materials: In this prospective study, 22 former MB patients were enrolled (range 10-53 years, mean age 25.8 years). The internal carotid artery (ICA) and the basilar artery (BA) were analysed. Following MR sequences

were performed: precontrast 3D TOF-MRA, precontrast 2D T1- and 2D T2-VWI sequences and postcontrast 2D T1-VWI sequences. Vessel wall thickening, postcontrast enhancement (CE) and luminal narrowing were analysed in every image.
Results: In 7 (31%) and 5 (22%) out of 22 patients vessel wall alterations in the right and left ICA, respectively, were found. Alterations in the BA vessel wall were found in 13 (59%) patients. In total, 59% of the patients presented vessel wall changes. TOF-MRA did not reveal any alteration of the ICA or BA, respectively.
Conclusion: Cerebrovascular changes after RCT gain importance, as treatment and overall survival for MB patients is improving. In this study, vessel wall alterations were imaged with high-resolution MRI. In more than 50% vessel wall alterations were identified. Further studies are needed to image the progression of sequelae after RCT and to determine the time for preventive treatment, regarding vessel stenosis.

B-1036 15:12

MR imaging of post-treatment local bone marrow alterations in paediatric soft tissue sarcomas of the extremities
G. Pasquotti[1], G. Bisogno[1], G. Cecchetto[1], R. Stramare[1], M. Weber[2], T. Toffolutti[1], C. Giraudo[2]; [1]*Padua/IT*, [2]*Vienna/AT*
(giulio.pasquotti@sanita.padova.it)

Purpose: To retrospectively assess, by MRI, post-treatment local bone marrow abnormalities (BMA) occurring in paediatric patients affected by soft tissue sarcomas of the extremities (eSTS).
Methods and Materials: Paediatric patients with histologically proven eSTS, a follow-up of at least two years from diagnosis, and both pre- and post-treatment MRI scans of the affected limb were included.Two radiologists independently reviewed for BMA all available restaging examinations.Size, pattern, contrast-enhancement and site of involvement, as long as the risk (10 points-scale) for each BMA to be a metastasis (BMM), were assessed;intraclass correlation coefficient (ICC) and 95% confidence interval were calculated.
Results: Twenty-nine patients (age-range 1mo-20 yrs) met the inclusion criteria.Histology showed 12 alveolar and 4 embrional rhabdomyosarcomas, 3 fibromyxoid and Ewing sarcoma, 2 synovial sarcomas;angiosarcoma, extraskeletal osteosarcoma, epitelioid, fibrosarcoma and liposarcoma, in one patient each.Two patients were treated only with surgical excision, 2 only with chemotherapy, 6 only with radiotherapy and 19 with radio and chemotherapy.Seventeen BMA were diagnosed in nine patients.Most of the BMA were nodular or patchy (*n=5*) and smaller than 3 cm (*n=11*);all, except one, showed contrast-enhancement.The mean rate for BMM's risk was 2.12, with a high ICC (0.890;95%CI 0.721-0.959).Only one BMA (later on, histologically proven metastases in a patient with known wide-spread disease) showed a significant risk of 7. At the latest available follow-up, all other BMA solved.
Conclusion: To optimally assist the clinicians and avoid the risk of overrating,radiologists should carefully interpret BMAs occurring at local restaging in children treated for eSTS, which rarely represent malignant dissemination.

Clinical impact of delayed enhancement in brain MRI for patients with AIDS
A.A. Drozdov, V.M. Cheremisin, I.G. Kamishanskaya, A.A. Yakovlev, V.B. Musatov, I.P. Fedunyak, O.I. Fedunyak, M.N. Artem'eva;
St. Petersburg/RU (a_a_drozdov@mail.ru)

Purpose: To compare early and delayed enhancement in routine brain MRI for patients with AIDS; to identify optimal postcontrast delay.
Methods and Materials: 42 patients with profound AIDS with mean CD4+ 42±14/ml prospectively underwent brain MRI after intravenous Gd-DTPA group contrast injection (0.2mmol/kg body weight). MR scanning (1.5T) was performed immediately and in 20 minutes after the contrast administration. Two experienced radiologists independently compared early and delayed postcontrast images and rated by 0 (no new findings identified) or 1 (when new findings were identified). Those studies where new findings were identified were discussed with 2 experienced infectiologists, who rated them by 0 (for findings not implying change of treatment) or 1 (for findings implying change of treatment).
Results: Areas of pathological contrast enhancement were identified in 20 (47,6%) of the 42 cases. New findings at images after late enhancement were identified in 8 (40%) of the 20 cases with no areas of pathologic enhancement at early images in 3 cases. Among 8 cases 4 were associated with toxoplasmosis, 2 with tuberculomas and for 2 cases etiology of contrast enhancement was not identified. In 4 cases (9.5%) out of 42 changing in treatment was indicated. Two patients with toxoplasmosis and 2 patients with intracranial tuberculomas underwent imaging at multiple time points to identify the optimal postcontrast delay. Optimal postcontrast delay was between 10-15 minutes for toxoplasmosis and between 15-20 min for tuberculomas.
Conclusion: Optimal imaging protocol with delayed enhancement scanning is crucial for appropriate treatment in patents with profound AIDS.

B-1038 14:08

Conventional brain MRI data as an indicator to perform a HIV test
A.A. Drozdov, V.M. Cheremisin, I.G. Kamishanskaya, A.A. Yakovlev, I.P. Fedunyak, V.B. Musatov, O.I. Fedunyak, M.N. Artemjeva;
St. Petersburg/RU (a_a_drozdov@mail.ru)

Purpose: Evaluate the ability of conventional brain MRI to serve as an indicator to perform HIV-testing by working out MR-scoring system.
Methods and Materials: In our retrospective study we enrolled 21 patients (mean age 38,99±3,13) with AIDS (CD4+<200) and without signs of opportunistic or mass lesions based on conventional brain MRI. Control group included 12 healthy volunteers with negative HIV test (age 37,49±4,24). Brain MR images were reviewed with series of different structures measurements and with reporting features, that are usually low yield. Data for two groups of patients have been compared with One-way ANOVA or Chi-square methods ($p<0.05$) to identify features and measurements that were statistically significant and score 0-2 was given to significant findings with 0 being more common for non-HIV infected and 1-2 for finding associated with HIV infection.
Results: Six findings had statistical significance: ratio of maximal transverse length of the skull to distance between external margins of bodies of the lateral ventricles (score 0-2), number of focal white matter hyperintensities (0-2), effusion in the mastoid air cells (0-1), edema of mucosal lining of the paranasal sinuses (0-1), distention of perivascular spaces in the basal ganglia (0-1), distention of perivascular spaces in the centrum semiovale (0-1). The average score for HIV-infected patients was 4.1 while in the control group the average score was 1.75. Using 3 as a cut of criteria it had a 85% sensitivity, 67% specificity.
Conclusion: Conventional brain MRI is an effective diagnostic tool that might serve as a strong indication for HIV-testing.

Role of diffusion-weighted imaging and magnetic resonance imaging in differentiation of intracranial abscess and neoplasms with necrosis
A.A. Jain, N. Bahri, H. Parekh, S. Chudasama; *Jamnagar/IN*
(a.jain56@yahoo.com)

Purpose: The aim of our study was to determine the utility of dffusion-weighted imaging (DWI) with calculated apparent diffusion coefficient (ADC) and MR spectroscopy (MRS), to distinguish brain abscess from necrotic tumour in patients presenting with an intracranial mass.
Methods and Materials: We studied patients referred for an MRI of the brain for evaluation of an intracranial mass. All patients underwent an MRI study on a 1. 5T Siemens Magnetom essenza. DWI was obtained with single-shot echo planner imaging spin echo sequences. Multi-voxel MR spectroscopy was performed. Imaging findings were compared with the histopathological diagnosis.
Results: We enrolled a total of 30 patients. 16 (53%) patients had glioblastoma multiforme (GBM), 12 (40%) patients of cerebral abscess, 2 (6%) patients of lymphoma. The ADC of abscesses was significantly lower than that of necrotic tumours, consistent with restricted diffusion in abscesses vs free diffusion in tumours. On spectroscopic evaluation, the lipid lactate peak with an absent choline peak was observed in 100% of abscesses. While necrotic neoplasms demonstrated an absent lipid lactate peak in most of the cases, an elevated choline peak and decreased NAA.
Conclusion: DWI and MRS can be used to differentiate between intracranial abscess and necrotic neoplasms. Abscesses demonstrate a much lower ADC value than GBM or metastasis, whereas specific MRS findings with selective peak and spectral pattern are seen with abscess vs necrotic neoplasms.

B-1040 14:24

Can new interferon-free therapy lead to white matter tracts recovery in HCV-infected patients?

J. Bladowska, K. Fleischer-Stepniewska, B. Knysz, A. Zimny, M. Inglot, W. Rymer, M. Waliszewska-Prosol, M. Ejma, M. Sasiadek; *Wroclaw/PL (asia.bladowska@gmail.com)*

Purpose: The aim of the study was to evaluate the selected white matter tracts using diffusion tensor imaging (DTI) in HCV-positive patients before and after 24 weeks after completion of interferon-free therapy.
Methods and Materials: Ten HCV-positive patients (mean age 50.1) treated with ombitasvir/paritaprevir/r and dasabuvir ± ribavirin and 17 control subjects were enrolled in the study. DTI examinations were performed with 1.5T MR scanner. Fractional anisotropy (FA) and average diffusion coefficient (ADC) values were obtained with a small ROI method in middle cerebellar peduncles (MCP), inferior longitudinal fasciculi (ILF), inferior frontooccipital fasciculi (IFOF), genu (GCC) and splenium (SCC) of the corpus callosum, posterior limbs of the internal capsules (PLIC), superior longitudinal fasciculi (SLF) and posterior cingula (CG). Sustained viral response as well as liver fibrosis using elastography and APRI (AST to Platelet Ratio Index) were analysed.
Results: Significant increase of FA values ($p<0.05$) after therapy compared to values obtained before treatment was found in almost all white matter tracts apart from the right SLF and right CG. Significant decrease of ADC values ($p<0.05$) after treatment was observed in the right IFOF, SCC, left PLIC, left SLF, left CG. Compared to controls, HCV-positive patients showed significantly higher FA value in both MCP and the left CG after treatment. All patients achieved a sustained viral response. Liver fibrosis regression was also observed.
Conclusion: Efficient interferon-free therapy leads to white matter tracts recovery. This is the first report on impact of interferon-free therapy on microstructural cerebral changes in chronic hepatitis C patients.

B-1041 14:32

Diffusion kurtosis imaging in diffuse axonal injury: a novel diagnostic approach

N. Zakharova, G. Danilov, A. Potapov, I. Pronin, E. Alexandrova, A. Tonoyan, L. Fadeeva, A. Sichev, E. Pogosbekian; *Moscow/RU (nzakharova@nsi.ru)*

Purpose: Diffusion kurtosis imaging (DKI) is an advanced tool for non-Gaussian water diffusion detection. The aim of this study was to evaluate DKI in patients with diffuse axonal injury (DAI) compared to healthy controls.
Methods and Materials: DTI and DKI data for 12 patients with acute severe DAI and 8 healthy volunteers were compared. The main group consisted of 8 males and 4 females (29±11 y.o.). We assessed mean, axial, radial diffusivities (MD, AD, RD), mean, axial, radial kurtosis (MK, AK, RK), kurtosis anisotropy (KA) for white and grey matter, fractional and relative anisotropy (FA, RA), axonal water fraction (AWF), axial and radial extra-axonal diffusion (AxEAD, RadEAD) and tortuosity (TORT) parameters for white matter in bilateral regions of interest (ROI): centrum semiovale, internal capsules, thalami, putamen, corpus callosum and brain stem.
Results: We revealed a statistically significant KA reduction in the right (0.31 vs 0.45, p=0.003) and left (0.30 vs 0.43, p=0.0001) cerebral peduncles versus controls. AWF was reduced in several white matter ROIs (>.05). TORT showed similar tendency with the most pronounced changes in genu (3.02 vs 4.18, p=0.002) and splenium (2.42 vs 4.12, p=0.0002) of corpus callosum. AK in DAI tended to increase not only in white matter (centrum semiovale and cerebral peduncles), but also notably in right (0.65 vs 0.56, p=0.02) and left (0.67 vs 0.57, p=0.01) putamen.
Conclusion: Significant changes of DKI parameters reflected brain structure disintegration, demyelination and loss of axons in DAI.

B-1042 14:40

The effect of early MRI in the management of children with traumatic brain injury admitted to the PICU

P.A. Caruso; *Boston, MA/US (pcaruso@partners.org)*

Purpose: While CT is used most commonly for assessing head injury, MRI provides increased sensitivity for many traumatic lesions without radiation dose. We sought to determine the effect on management of early MRI in paediatric traumatic brain injury by analysing a consecutive series of 79 children requiring paediatric intensive care (PICU) admission who underwent MRI within days of injury.
Methods and Materials: The medical records were reviewed for each patient to determine the indications, MR imaging findings, and whether the study had influenced decisions to escalate, de-escalate, or redirect care. The images were reviewed by two neuroradiologists, a paediatric neurosurgeon, and a paediatric intensivist, using the NIH common data elements definitions dictionary.
Results: Different lesion patterns influenced management in different ways. Mass lesions including haemorrhages and evolving contusions, seen readily on T2 and FLAIR images, led to continued aggressive medical and/or surgical interventions. Findings of diffuse axonal injury with open cisterns led to de-escalation of sedation and monitoring. Early widespread diffusion abnormality or evidence of brainstem herniation or infarction was correlated with redirection of care.
Conclusion: Early MRI can play an important role in the targeted management of severe traumatic brain injury in children, allowing for prompt understanding of injury type and pathophysiology with acceptable reliability and reduced radiation. Cost-effectiveness analyses also will be needed to fully analyse this management approach.

B-1043 14:48

Sonographic texture analysis for neonatal white matter injury: focused on change according to follow-up cranial ultrasonography

A. Pak, S.-i. Suh, S. Chae, K. Cheol, I. Ryoo, H.-Y. Seol; *Seoul/KR (csyloo@naver.com)*

Purpose: In neonatal serial screening cranial ultrasound (cUS), diagnosis whether periventricular echogenicity (PVE) is progressed to periventricular leukomalacia (PVL) or not is difficult because of different ultrasound acquisition settings and interobserver variability. For early and objective diagnosis of PVL, we assess pattern of echotexture of PVE during follow-up cUS through quantitative texture analysis.
Methods and Materials: We included preterm neonates born between 25 and 34 weeks of gestation showed parietooccipital PVE on initial cUS within 1 week of birth (1st cUS), and underwent follow-up cUS on 2-3 weeks (2nd cUS) and 4-6 weeks (3rd cUS) of life respectively. Patients was diagnosed as PVL (n=10) or normal (n=10) from brain MRI or cUS after term-equivalent age. Texture analysis was performed with region of interest on PVE in coronal sections. Histogram, gradient, run-length matrix, co-occurrence matrix, autoregressive model and wavelet-derived parameters were analysed.
Results: Total 57 of 308 texture features showed statistically significant difference during follow-up cUS. The PVE texture features of 1st cUS showed no significant difference between two groups. The variance was significantly changed between 1st cUS and 2nd cUS in both two groups, which was decreased in normal (p=0.009) and increased in PVL (p=0.017) group. There was no significant difference of texture parameter change between PVL and PVE groups during 2nd cUS to 3rd cUS.
Conclusion: Assessment of change of PVE echotexture during serial cUS based on quantitative texture analysis may be important clue for early PVL diagnosis of preterm neonate within the first 2-3 weeks of life.

B-1044 14:56

The value of susceptibility-weighted imaging and T2-weighted gradient echo in imaging in assessment of mild traumatic brain injury

A. Brakus, M. Karan, J. Ostojic, S. Stojanovic, P. Vulekovic, S. Pena Karan, K. Petrovic; *Novi Sad/RS (alma.brakus@gmail.com)*

Purpose: Our aim was to analyse sensitivity of GRE-T2* sequences and SWI in detecting lesions in patients with symptoms of mild traumatic brain injury and normal CT findings.
Methods and Materials: We analysed clinical data and MRI findings in 34 patients suffering from mTBI and admitted at clinic for neurosurgery clinical centre of Vojvodina in two-year period. All patients had initial CT examination without signs of trauma. MRI examination including GRE-T2*w and SW sequence was performed in all patients in first 72 hours from trauma. Neuropsychological assessment was performed at 1 month and 6-9 months after injury.
Results: Evidence of axonal pathology reflected as signal change on T2w FLAIR was present in 44% (15p). On SWI: 61% (21p) had haemorrhagic lesions, 18 patients (53%) had lesion visible both on GRE T2* and SWI. One patient (3%) had lesions visible only on T2w (pure oedematous lesions), 30% (10p) had pure haemorrhagic lesions ; 31% (11p) had mixed lesions. We failed to establish connection between any clinical findings, such as GCS score, duration of amnesia or presence of vegetative disturbances and MRI detected signs of trauma.
Conclusion: Unusually high percentage of positive MRI findings can be explained with selection bias because analysed patients had more pronounced clinical presentation of mTBI that led to admission to hospital. SWI proves itself as the most sensitive sequence in detection of haemorrhagic lesions. MRI should be considered as diagnostic tool in patients with more severe clinical presentation.

B-1045 15:04

Limbic encephalitis, diagnostic pitfall in MR-imaging

A.-H. Schievelkamp, A. Jurcoane, B. Mädler, T. Rüber, L. Ernst, H. Schild, C. Elger, E. Hattingen; *Bonn/DE*
(Arndt-Hendrik.Schievelkamp@ukb.uni-bonn.de)

Purpose: Asymmetric high signal intensity (SI) of the amygdala on T2-weigthed (T2-w) images is typical for the limbic encephalitis (LE). These changes are often only discrete or can be absent. We investigated if these SI changes are measurable and if there is an increase of T2-relaxation time (T2).
Methods and Materials: 24 patients with clinical diagnosis of LE and 21 age-matched healthy controls were measured on a 3T-scanner. T2-Mapping was based on temporal-angulated, 2mm-coronar sequences with increasing TE (15,30,45,60,75,105,120ms). ROIs were manually drawn in the left and right amygdala. SI on respective T2-w (TE=105ms) and PD-w images (TE=15ms), as well as quantitative T2-values (qT2) were analysed. Laterally Index was used to analyse if there is an asymmetric involvement of the amygdala.
Results: There was no significant left-to-right difference of the amygdala in controls and in LE patients, neither for SI nor for qT2. qT2 was higher in LE patients (left 97±8ms (mean±SD) and right 98±9ms) compared to controls (left 90±5ms and right 89±6ms) with $p<0.01$. No significant differences were for found for SI in T2-w images between both groups. The SI in PD-w images was by trend lower in LE patients.
Conclusion: Patients with LE have elevated qT2-values in the amygdala. However, the expected SI increase in T2-w images was not found, and there were no left-to-right differences. The reason for this discrepancy might be explained by lower PD-values which can also reduce the T2-SI. This could explain the difficulty to recognize LE, despite the pathologic changes of the amygdala.

B-1046 15:12

Imaging features of neurocysticercosis, a radiologic-clinical correlation

M. Campos[1], S. Rivadeneira[2], D. Páez[3], R. Salinas[1]; [1]*Quito/EC*,
[2]*Buenos Aires/AR*, [3]*Murcia/ES (rr.sebastian@icloud.com)*

Purpose: To illustrate the most common radiological features of human neurocysticercosis, describing the recurrent locations and stages of the parasite in the CNS in order to help us launch the possible clinical manifestations.
Methods and Materials: Twenty two patients with NCC from the General Hospital Eugenio Espejo in Quito-Ecuador were initially referred to the Neurology department. The study focused on CNS imaging features. MR and CT imaging examinations were grouped based on the pathological stage (Escobar's classification: vesicular, colloidal, granular and nodular calcified), anatomical location and the clinical symptoms of each patient.
Results: Location: parenchymal cysticerci were commonly located in the cortical- juxtacortical junction (68%), basal ganglia (18%) and ventricular cysticerci were relatively rare with an incidence of 14% of our neurocysticercosis cases. Escobar's stages: the first group of 45% was found in the vesicular stage, most of them located in the cortico-subcortical interface, 59% had scolexes with an average size 13-17 mm. Secondly, 27% was in a colloidal stage and 9.5% were found in glanular stage and 18.5% was calcified nodular was better detected by CT.
Conclusion: Current strategies for diagnosis of NCC must include neuroimaging studies due to a wide variety of neurologic disorders can be associated with the disease. As in this study, the most common symptoms were headaches, followed by seizures and focal neurological deficits. We must learn the different radiological findings of the disease and take it into account the differential diagnosis of multiple intracranial lesions, particularly in patients from endemic areas.

B-1047 15:20

Brain MRI characteristics of anti-N-methyl-D-aspartate receptor encephalitis

T. Zhang; *Beijing/CN (zhangtian822@163.com)*

Purpose: To investigate the brain MRI characteristics of anti-N-methyl-D-aspartate (NMDA) Receptor Encephalitis and their associations with clinical disability at one-year follow-up.
Methods and Materials: We retrospectively enrolled 45 clinically defined anti-NMDA encephalitis patients. Brain MRI were acquired for all patients at onset phase including T1WI, T2WI and FLAIR. The brain MRI were categorised as normal and abnormal. We further classified the abnormal brain MRI as hippocampal lesion, non-hippocampal lesion, and lesions involving hippocampus and other brain areas. The modified Ranking Scale (mRS) at 1 year follow-up was assessed. The association between MRI characteristics at baseline and one-year follow-up mRS was evaluated.
Results: Twenty-six (26/45; 57.8%) NMDA patients had normal MRI at onset phase, while nineteen patients(19/45; 42.2%)presented abnormal MRI. Among brain MRI abnormalities, thirteen patients showed hippocampal lesions (13/19; 68%). Lesions were only located in hippocampus in 5 patients, and 8 patients showed lesions in brain areas besides hippocampus such as insula, thalamus,basal ganglia,and frontal, temporal, parietal lobes. Six patients (6/19, 31.6%) showed lesions in frontal lobe, thalamus, cerebellum and white matter lesions in corpus callosum. Abnormal MRI was observed more frequently in female patients (17/22) than male patients (9/23) ($p=0.025$). The patients with hippocampus lesions had higher mRS at one-year follow-up than patients without hippocampal lesions ($P=0.04$).
Conclusion: Hippocampal lesions were the most common lesions in NMDA encephalitis patients, but nearly one-third patients can have lesions in other brain areas without hippocampus involvement. The NMDA encephalitis patients with hippocampal lesions had worse prognosis than patients without hippocampus involvement.

(kachulove@hanmail.net)

Purpose: To investigate clinical feasibility of free-breathing multi-arterial phase using Cartesian sampling and added value of motion resolved reconstruction in gadoxetic acid-enhanced liver magnetic resonance imaging (MRI).
Methods and Materials: This retrospective study was approved by IRB and the requirement of informed consent was waved. A total of 37 patients were included who underwent iterative three-dimensional gradient echo sequence for precontrast, early arterial, late arterial and portal venous phases of T1-weighted image (T1WI) in free-breathing manner. Timing, motion artifact, image quality were evaluation by four radiologists on a 4-point scale. In addition, respiratory motion-resolved reconstruction was performed for patients with below average score (score <3) of late arterial phase and reviewed in the same manner.
Results: Overall image quality of free-breathing T1WI was 3.30±0.59 on precontrast, 2.68±0.70, 2.93±0.65 and 3.30±0.49 on early arterial, late arterial and portal venous phases, respectively. Image quality of early and late arterial phase was significantly lower than precontrast and portal venous phase (P<0.0001~0.001). Eleven patients showed late arterial phase with below than average image quality (<3), but image quality of late arterial phase was significantly improved on motion-resolved reconstruction images using the same MRI data (P=0.007). In addition, none of the patients missed adequate arterial phase timing on multiarterial phase acquired in free-breathing manner.
Conclusion: Dynamic phase with acceptable image quality at gadoxetic acid-enhanced liver MRI can be achieved using Cartesian reconstruction in free-breathing manner.

Virtual monochromatic image of detector-based spectral CT: improved image quality as compared with that obtained with conventional CT
H.-J. Kang, J. Lee, S. Lee, H. Yang, R. Kim, J. Nam, J. Han; *Seoul/KR*
(dr.kanghj@gmail.com)

Purpose: To compare image quality obtained in phantom with virtual monochromatic image of detector-based spectral CT (VMS) with that performed with conventional CT on various body size and dose right index (DRI) values.
Methods and Materials: Three different size of body phantoms with 8 FLLs were scanned with two conventional mode (80 and 120kVp) by detector-based spectral CT with iDose (level 4) reconstruction. The VMS is reconstructed from 120kVp iDose (level 4) image basis and displayed on vendor specific workstation. The noise and CNR in different body size, and subjective image quality and FLL conspicuity in small phantom were analysed with different DRI values (16, 19, 22 and 25).
Results: Image noise on VMS is always lower than that of 80kVp with higher CNR in low KeV ranges (from 40 to 69~73KeV) regardless of DRI values. Also comparing 120kVp, CNR of VMS is improved in low KeV ranges (from 40 to 75~81KeV) on each DRI values. On the qualitative analysis, diagnostic acceptability (p=0.015) and subjective noise (p<0.01) is significantly higher in VMS. Lesion conspicuity of low-contrast FLLs are significantly improved in VMS (all p<0.05) than 120kVp CT. Also, VMS present lesser stiff noise increment with higher CNR than those of 120 kVp as body size increases.
Conclusion: VMS of detector-based spectral CT, the up-to-date VMS technique, is presenting improved CNR, noise and subjective image quality, and it is especially valuable in large phantom and low-contrast FLLs.

Respiratory motion artefacts during arterial phase imaging with gadoxetic acid: how can we minimise this drawback?
S. Polanec[1], H. Bickel[1], P.A.T. Baltzer[1], P. Thurner[1], F. Gittler[1], J. Hodge[1], M. Bashir[2], A. Ba-Ssalamah[1]; [1]*Vienna/AT*, [2]*Durham, NC/US*
(stephan.polanec@meduniwien.ac.at)

Purpose: To determine which of three gadoxetic-acid injection techniques, performed serially in the same patient, could produce liver MRI with fewer contrast-related arterial-phase motion artefacts.
Methods and Materials: This IRB-approved, retrospective study included a cohort of 78 consecutive patients. Each patient had serial gadoxetic acid-enhanced MRI of the liver performed with at least two of three injection techniques: M1-test bolus undiluted, power-injected; M2-test bolus, diluted 50% with saline, power-injected; M3-fixed delay, undiluted, manually injected. The injection dose was 0.025mmol/kg body weight in all three methods. Three readers independently rated the images for motion artifacts, timing, and lesion detectability based upon a four-point Likert scale.
Results: Respiratory artefacts related to gadoxetic-acid arterial phase images obtained by M3 were superior to M1 (p=0.0001). M2 was rated significantly better than M1 (p=0.012). The difference between M3 and M2 scores was not statistically significant (p=0.49). Arterial-phase timing was significantly better for M1 compared to M3 (p<0.0001). The AUC was 0.59-0.68. M2 significantly outperformed M3 in arterial phase timing (p<0.0001). There was no significant difference between M1 and M2 (p=0.35). With regard to lesion detectability, there was no significant difference in the ratings for all three-injection techniques (p>0.05).Inter-reader agreement was moderate to substantial (0.41-0.62).
Conclusion: There were significantly fewer contrast-related-motion-artefacts in the arterial phase when gadoxetic acid was administered undiluted manually (M3), or diluted power-injected (M2), compared to undiluted power injection (M1).The arterial phase timing was significantly better with test-bolus, power injection of contrast media, however the diagnostic performance for all three methods was not significantly different.

B-1051 11:03
Free-breathing undersampled radial VIBE as a salvage strategy for liver dynamics in patients unable to suspend respiration
B. Kaltenbach, A. Roman, T.J. Vogl, S. Zangos; *Frankfurt a. Main/DE*
(benjamin.kaltenbach@kgu.de)

Purpose: Respiratory motion artifacts are a frequent source for image degradation in abdominal MRI. The introduced free-breathing sequence can be used as a salvage strategy in patients with limited breath-holding capacity for dynamic liver imaging.
Methods and Materials: Twenty-seven consecutive patients with known liver metastases underwent dynamic liver MR imaging using a free-breathing undersampled radial sequence. Patients were eligible for the free-breathing protocol due to severe respiratory artifacts at the precontrast sequences. The introduced free-breathing sequence was compared to a standard dynamic breathhold VIBE. Overall image quality, liver edge sharpness, liver lesion conspicuity, hepatic vessel clarity, respiratory motion artifacts and streaking artifacts were independently, retrospectively and blindly scored by four experienced readers using a 5-point Likert scale. Contrast-enhancement ratio (CER) between native and arterial phases was measured to assess temporal resolution.
Results: Free-breathing VIBE received lower image quality scores than breathhold VIBE but presented with generally good image quality. Regarding patients with severe respiratory artifacts already at breathhold VIBE, free-breathing VIBE received significantly higher scores for overall image quality (4.1 vs 3.8, p=0.01) and hepatic lesion conspicuity (4.2 vs 3.8, p=0.02). There were generally more respiratory artifacts in breathhold VIBE (p<0.0001), whereas streaking was characteristic for the undersampled radial acquisition (p<0.0001). Temporal resolution assessed with CER showed higher values for free-breathing VIBE sequence (p=0.028).
Conclusion: The introduced free-breathing sequence is a promising alternative for liver dynamics in challenging patients. Accurate temporal resolution, low motion artifact susceptibility and good image quality qualify this sequence for daily routine.

B-1052 11:11

Accuracy of new real-time shear wave elastography for assessing liver fibrosis in chronic viral hepatitis patients

J. Han, S. Yeom, I. Choi, S. Lee, H. Chung, S. Cha, S. Suh, Y. Jung, H. Yim; *Ansan-si, Gyeonggi-do/KR*

Purpose: Recently, new real-time shear wave elastography (SWE, Aplio500®, Toshiba) has been released. In this study, the diagnostic performance of SWE and TE (transient elastography) in assessing liver fibrosis in chronic viral hepatitis was investigated. Differences in diagnostic performance of SWE were evaluated according to the obesity.
Methods and Materials: 53 chronic viral hepatitis patients who underwent liver biopsy were prospectively enrolled (23 with HBV, 30 with HCV). For each patient, liver stiffness was assessed by SWE and liver biopsy was performed in the same session (METAVIR score). TE was performed within two weeks of liver biopsy. AUROCs were performed and compared for each degree of liver fibrosis. Differences in AUROCs were investigated according to body mass index (BMI ≥25, and BMI≥ 30).
Results: Among 52 patients, 16 belonged to F0-F1 stage, 12 were F2, 16 were F3 and 9 were F4. TE was significantly more accurate for prediction of F ≥2 than SWE (AUC: SWE=0.630, TE = 0.810, P=0.02). However, there were no significant differences between SWE and TE in prediction of F≥3(AUC: SWE = 0.800, TE = 0.883, P = 0.20). In overweight patients(BMI ≥25), SWE showed good diagnostic performance (AUC:0.808 with cutoff value 18.9kPa with 69.23% sensitivity and 87.5% specificity) in prediction of F≥3. However, in obese patients (BMI ≥30), SWE showed poor diagnostic performance (AUC:0.667).
Conclusion: New SWE seems to be good method for assessing advanced liver fibrosis with similar predictive value to TE. SWE showed poor diagnostic performance for assessing advanced liver fibrosis in obese patients.

Diffusion-weighted MRI in liver fibrosis staging: added value of normalised ADC using spleen and renal cortex as reference organs

T.F.T. Ali, M.A. El-Hariri; *Zagazig/EG (tamerfathi2008@yahoo.com)*

Purpose: To evaluate the potential value of the spleen and renal cortex as reference organs to improve the performance of DWI in the assessment of liver fibrosis.
Methods and Materials: 30 patients with chronic viral hepatitis and 14 volunteers were subjected to DWI. Liver ADC, normalised ADC (ratio between ADC of liver to spleen (S-ADC) and renal cortex (R-ADC) was calculated. Data was analysed to evaluate the performance of ADC, S-ADC and R-ADC.
Results: The mean S-ADC value was significantly lower in patients with different hepatic fibrosis stages in comparison to control group (P<0.001). Significant negative correlation was noted between S-ADC value and fibrosis stage (r=-0.75, p<0.001). It had significant difference between stage 0 compared to stage 2, 3, and 4 as well as between stage 4 in comparison to stage 1, 2 and 3. Significant negative correlation was noted between R-ADC value and fibrosis stage (r=-0.68, p<0.001). The mean R-ADC value was lower in patients with liver fibrosis compared to volunteers with significant difference between stage 0 and 3 and between stage 0 and 4 (P <0.001). It had significant difference between stage 0 compared to stage 3, and 4 as well as in stage 4 in comparison to stage 1 and 2. ROC curve showed higher performance using S-ADC in comparison to liver ADC and R-ADC while R-ADC had higher performance in comparison to liver ADC.
Conclusion: Normalised liver ADC increases the ADC performance of ADC in the evaluation of liver fibrosis which is highest in S-ADC.

B-1054 11:27

Evaluation of virtual monoenergetic images computed by new dual-layer CT in assessing hypervascularised liver lesions

N. Große Hokamp, A. Höink, T. Persigehl, D. Maintz, S. Haneder; *Cologne/DE (nils@grossehokamp.de)*

Purpose: Evaluation of both objective and subjective image quality of virtual monoenergetic (vME) images for assessment of arterially hypervascularized liver lesions in dual-layer CT (e.g. haemangiomas, metastases).
Methods and Materials: 50 liver lesions in 20 contrast enhanced CT examinations, acquired at dual-layer CT (IQon, Philips Healthcare) in arterial contrast phase, were identified and retrospectively analysed in vME (40-200 keV; 10 keV intervals) and in conventional images, respectively. Image noise was represented by standard deviation of liver parenchyma; signal- (SNR) and contrast-to-noise ratio (CNR) of lesions and liver parenchyma were calculated. To assess subjective image quality, vME-images (40-110 keV) were rated by two readers with regard to lesion delineation and overall image quality, compared to conventional images, on a 5-point-scale.
Results: SNR of liver parenchyma was significantly higher in 40- and 50-keV-vME-images as compared to conventional images (3.8, 2.8 vs 1.3; p≤0.001). SNR and CNR of lesions were significantly higher in 40/50/60-keV-vME-images, compared to conventional images (SNR: 17.8, 12.4, 8.8 vs 5.0; CNR: 14.2, 10.5, 7.7 vs 4.4; p≤0.001). Image noise was significantly lower in vME-images (50-200keV), while 40-keV-vME-images exhibited similar image noise as conventional images (12.1 vs 13.8). Subjective lesion delineation received best rating at 50-keV-vME-images, while overall image quality was rated inferior to equal at all vME-intervals, compared to conventional reconstructions.
Conclusion: Both objective image quality and subjective assessment of hypervascularised liver lesions are superior at vME images of 40-60 keV. However, improved CNR at low-keV-vME-images impairs overall image quality.Thus, vME-images of low-keV may be useful as screening reconstructions.

B-1055 11:35

Comparison between the conventional Couinaud method vs a semiautomatic software (Syngo.CT. liver analysis, Siemens) in the precise localisation of liver metastases

P. Bartolomé, A. Quilez, I. Gonzalez de la Huebra, A. García Baizán, I. Gonzalez, I. Vivas; *Pamplona/ES (pbartolome@unav.es)*

Purpose: To analyse the variability in the location of CT detected liver metastases using the conventional method of Couinaud (CM) or a semiautomatic software (SAS) for liver segmentation (Syngo.CT-*liver Analysis*©, Siemens Healthcare, Germany).
Methods and Materials: Two expert radiologists in abdominal imaging consecutively studied 25 oncologic patients with a total of 70 liver metastases detected on abdominal CT. Lesions were distributed by segments, following either the Couinaud method based on anatomical landmarks or the semiautomatic software *liver Analysis*©, which relies on the ramifications of portal branches. The global agreement between the two methods was calculated, as well as the Kappa agreement values for each segment.
Results: The kappa values for each segment were: I(1.0), II(0.79), III(0.9), IV(0.68), V(0.42), VI(0.65), VII(0.49), VIII(0.4). The global agreement between methods was of 62%. There agreement was only moderate for lesions localised on the segments V, VII and VIII. With CM it is difficult to differentiate the V-VI boundaries because the right hepatic vein is not well recognised in the inferior segments. Between segments VII-VIII at the dome the middle hepatic vein trajectory is not well depicted.
Conclusion: The Couinaud method alone, based on indirect anatomical landmarks is not reliable enough for the precise localisation of hepatic metastases, especially for the lesions located below the liver dome (segments V-VI, VII-VII) Software tools that are able to demarcate the liver segments using a more anatomical approach, based on the portal ramifications, are essential for an accurate localisation of liver metastases, especially in patients undergoing surgery.

B-1056 11:43

Volumetric iodine-uptake measurement for early assessment of therapy response after microwave ablation in rabbit model with intrahepatic VX2 tumour

L. Zhang, X. Liu, B. Feng; *Shenyang/CN (270973226@163.com)*

Purpose: To investigate the diagnostic value of volumetric iodine-uptake (VIU) in assessing early therapy response after microwave ablation in rabbit model with intrahepatic VX2 tumour.
Methods and Materials: Our institutional animal care committee approved all experiments. VX2 tumours were implanted into the livers of 14 rabbits. Dual-source CT (DSCT) was performed at baseline and 7 days after microwave ablation. 23 lesions were treated and evaluated for tumour response according to VIU, adapted Choi and standard AALSD measurement criteria. Disease control was defined as the sum of complete response (CR), partial response (PR) and stable disease (SD). Lesions were collected 8 days after microwave ablation for histological examination to verify the assessment result.
Results: According to Choi and VIU assessment, more lesions were considered as disease control (56% and 47%, respectively) than that with AASLD (13%) (p<0.05). 10/20 and 8/20 progression disease (PD) lesions assessment by AASLD were classified as PR by Choi and VIU, respectively. For disease control group, change in mean VIU ranges from 3.43 ± 1.504 mg/ccm to 1.88 ± 1.268 mg/ccm (decreased 51.47± 29.56%). For progressive disease group, change in mean VIU ranges from 2.33 ± 1.127 mg/ccm to 2.85 ± 1.140 mg/ccm (increased 36 .03±70.26%). VIU has moderate consistency with Choi (kappa = 0.574, p<0.05).
Conclusion: VIU measurement by DSCT can make an early assessment of therapy response after microwave ablation. VIU has the potential to reflect vital tumour burden, therefore, it is likely to be applied as an optimal tumour response biomarker for HCC treatment.

B-1057 11:51

Differentiation of malignant thrombus from bland thrombus of the portal vein in patients with cirrhosis: application of intravoxel incoherent motion diffusion-weighted MR imaging

J. Choi, E.-S. Cho, J. Kim, Y. Choi; *Seoul/KR (justice-cjm@yuhs.ac)*

Purpose: Our purpose of this study was to demonstrate the presence of blood flow within the malignant thrombus using intravoxel incoherent motion (IVIM) diffusion-weighted (DW) MR imaging and investigate the utility of IVIM in distinguishing bland thrombus from malignant tumour thrombus of the PV in patients with cirrhosis or hepatocellular carcinoma.
Methods and Materials: Forty three patients with PV thrombosis (malignant thrombus n=29 and bland thrombus n=14) examined with gadoxetic acid-enhanced MR imaging including IVIM were enrolled. IVIM DW imaging was acquired with free-breathing axial single-shot echo-planar two-dimensional imaging sequence and the following eight b values: 0,25,50,75,100,200, 500 and 800 sec/mm^2. Diffusion coefficient (D), pseudo-diffusion coefficient (D*), and perfusion fraction (f) were calculated with bi-exponential model using Matlab software and were compared between malignant and bland thrombi using unpaired t-test.
Results: D* of malignant thrombus (mean=67.51 x 10^{-3}mm^2/sec) was significantly higher than that of bland thrombus (9.31 x 10^{-3}mm^2/sec, $p < 0.001$). However, there was no significant difference in f between malignant (18.47 %) and bland thrombi (18.46 %). D of bland thrombus (1.35 x 10^{-3}mm^2/sec) was significantly higher than that of malignant thrombus (1.03 x 10^{-3}mm^2/sec, p=0.014). However, the mean D difference between the two thrombi was relatively small.
Conclusion: Increased pseudo-diffusion coefficient (D*) of malignant thrombus suggests higher intra-thrombus micro-perfusion, which might be due to blood flow by arterial neovascularisation within the malignant thrombus. Therefore, IVIM DW imaging appears to be a promising method for the discrimination between bland and malignant PV thrombi.

Voxel-wise bone and plaque subtracted datasets calculated from dynamic lower limb CT angiography - image quality compared to conventional datasets

N. Vogler, S. Sudarski, M. Meyer, H. Haubenreisser, S.O. Schönberg, T. Henzler; *Mannheim/DE (nils.vogler@medma.uni-heidelberg.de)*

Purpose: Static CT angiography of the lower limb (sCTA) and dynamic CT angiography of the calf (dCTA) are routinely used in patients with peripheral artery disease. However extensive calcification provides a diagnostic challenge and impairs image quality, especially in the calf. The aim of this study was to evaluate the diagnostic image quality of voxel-wise bone and plaque subtracted datasets calculated from dCTA in comparison to sCTA and the best-contrast phase from dCTA.
Methods and Materials: 15 patients were retrospectively included. The CT acquisition consisted of a sCTA (Dataset 1) and a 14-phase dCTA of the calf. The dCTA images were corrected for motion and noise and the best-contrast phase (Dataset 2) was selected. Subsequently the first non-contrast-enhanced phase was subtracted from the corresponding best-contrast phase generating a voxel-wise bone and plaque subtracted dataset (Dataset 3). Two independent readers evaluated all three Datasets on a per-segment basis for diagnostic confidence and overall image quality using a 5-point Likert scale.
Results: Dataset 3 showed significantly higher overall image quality then Dataset 1 and Dataset 2 ($p<0.0001$). Dataset 3 showed significantly higher diagnostic confidence then Dataset 1 and Dataset 2 ($p<0.0001$). Reader 1/2 reported good or excellent diagnostic confidence in 20.2/20.0%, 33.5/47.8% and 70.1/95.8% for Datasets 1, Datasets 2 and Datasets 3, respectively.
Conclusion: Voxel-wise bone and plaque-subtracted datasets calculated from motion and noise-corrected dCTA datasets are superior in terms of overall image quality and diagnostic confidence to sCTA and non-subtracted dCTA of the calf.

Clinical utility of quiescent interval single-shot (QISS) non-contrast MRA at 3 Tesla for the diagnosis of chronic lower limb arterial disease

Y. Ragab, K. Alhusseiny, A. Almarakby; *Cairo/EG (yragab61@hotmail.com)*

Purpose: To assess the diagnostic performance of ECG-gated non-contrast enhanced quiescent interval single-shot (QISS) magnetic resonance angiography at a magnetic field strength of 3 Tesla in patients with peripheral arterial occlusive disease (PAOD).
Methods and Materials: 19 patients with advanced PAOD Rutherford classification (stage 3 and higher) referred for peripheral magnetic resonance angiography (MRA) were included. Imaging was performed on a 3T whole body MR. Image quality and stenoses diameters were compared to contrast-enhanced MRA (CE-MRA) as standard of reference. Two blinded readers rated the image quality and the degree of stenosis for both ECG gated HR-QISS and CE-MRA in 26 predefined arterial vessel segments on 5-point Likert scales.
Results: Compared with CE-MRA, HR-QISS technique showed high sensitivity (93%), specificity (95%), positive (95.1%), and negative predictive value (96%) for the detection of significant (≥50%) stenosis. Interreader agreement for stenosis assessment of both HR-QISS and CE-MRA was excellent (κ-values of 0.94 and 0.95, respectively). As compared to CR-MRA, image quality of HR-QISS was significantly lower for the distal aorta, the femoral and iliac arteries (each with $p<0.01$), while no significant difference was found in the popliteal ($p=0.07$) and lower leg arteries ($p=0.9$).
Conclusion: Non-contrast QISS MRA has been shown to be technically comparable to CE MRA. QISS provides good early results for the detection of significant peripheral arterial stenotic disease. Accordingly, QISS MRA may prove valuable in patients with renal dysfunction by avoiding the use of gadolinium-based contrast agents in peripheral MRA.

B-1060 10:46

Popliteal artery aneurysm (PAA) surveillance: a 5-year retrospective cohort study

H. Shiwani, E. Taylor, J. Scott; *Leeds/UK (hshiwani@gmail.com)*

Purpose: Popliteal artery aneurysms (PAA) comprise up to 85% of all peripheral aneurysms. There are, however, no longitudinal studies tracking the progression of PAA size, which is the determinant of intervention. In this study, we aimed to track the progression of asymptomatic PAAs.
Methods and Materials: A retrospective single-group cohort study included patients who had a PAA of any size on arterial duplex ultrasound (USS) between the 1st of January 2011 and 1st of January 2016. Progression of PAA size and progression to event or intervention were the primary outcome measures.
Results: 3217 records were screened and a total of 22 patients (males = 15, females = 7) with PAA were identified (9 had bilateral PAAs) with a median age of 77 (IQR = 10.3). Eight had a previous open repair of an AAA or previous EVAR and five had an AAA under surveillance. The median size of PAA at diagnosis was 13.0mm (IQR = 5mm). Six limbs eventually proceeded to intervention. Median size at the time of intervention was 30mm (IQR = 13.5mm). The median time to event duration was 2.74 years. Seventeen patients with a growth rate of their PAA slower than 1mm a year were asymptomatic irrespective of initial size.
Conclusion: PAAs were frequently bilateral (40%) and were associated with AAA (59%). We recommend that all those with PAA should undergo screening for AAA and vice versa. We also recommend initial yearly surveillance for asymptomatic PAAs until there is a stable growth rate of <1mm per year.

B-1061 10:54

Image quality assessment of lower extremity quiescent-interval single-shot (QISS) MR angiography: comparison with CT angiography

A. Varga-Szemes[1], G. Muscogiuri[1], C.N. De Cecco[1], P. Suranyi[1], J.L. Wichmann[1], P.M. Cannao[1], S. Giri[2], U.J. Schoepf[1], T.M. Todoran[1]; [1]*Charleston, SC/US*, [2]*Chicago, IL/US (vargaasz@musc.edu)*

Purpose: To evaluate the qualitative image quality of non-contrast quiescent-interval single-shot (QISS) MRA in patients with peripheral artery disease (PAD).
Methods and Materials: Thirty patients (66±7 years, 16 male) with PAD referred for a clinically indicated lower extremity CTA underwent non-contrast lower extremity MRA on a 1.5T scanner using an investigational prototype QISS sequence (FOV 400x260mm^2, TR/TE 3.5/1.4ms, flip-angle 90°). Image evaluation was performed on a per-segment basis according to an 18-segment model. The overall image quality was subjectively rated by two observers according to a 3-point scale: (1) vascular segment not assessable due to severe image artifacts; (2) acceptable image quality with minor artifacts, marginal reader confidence; (3) excellent image quality, high reader confidence. Quality scores 2 and 3 were considered acceptable for diagnostic purposes.

Results: A total of 540 segments were evaluated. Overall subjective image quality was rated similarly with QISS-MRA (2.52 [2.46-2.57]) and CTA (2.49 [2.43-2.55], P=0.5062). Excellent inter-reader agreement was found in image quality ratings (κ>0.8). Forty-two segments (7.8%) in CTA were excluded from the analysis due to stent artifacts (11), heavy calcification (8), or suboptimal opacification (23), while 15 segments (2.8%) were non-diagnostic in MRA due to major image artifacts.
Conclusion: Image quality of QISS-MRA was comparable to that of contrast enhanced CTA. In certain circumstances, such as in heavily calcified segments or suboptimal opacification (i.e. the scanner outruns the contrast bolus), QISS-MRA provides superior vascular visualization compared to CTA. Such a non-contrast technique may have potential advantage in patients with contraindication to contrast media.

Reference values of vessel diameters and stenosis prevalence of the lower limb arteries using MR angiography - a population-based approach
B. Mensel[1], A. Grotz[1], H. Völzke[1], W. Lieb[2], M. Dörr[1], J.-P. Kühn[1], R. Lorbeer[3]; [1]*Greifswald/DE*, [2]*Kiel/DE*, [3]*Munich/DE (menselb@uni-greifswald.de)*

Purpose: This study aims to determine reference values of vessel diameters and to assess the prevalence of stenosis of the lower limb arteries in a population-based sample.
Methods and Materials: Magnetic resonance angiography at 1.5 Tesla was performed in 756 male participants (median age=52 years, range=21-82 years) of the population-based Study of Health in Pomerania. Vessel diameters were measured in 9 predefined segments of the pelvic and leg arteries on both sides.
Results: Reference values of vascular diameters decreased from proximal to distal arteries: common iliac=1.18cm; internal iliac=0.75cm; external iliac=1.03cm; proximal femoral=1.02cm; distal femoral=0.77cm; popliteal=0.69cm; anterior tibial=0.42cm; posterior tibial=0.38cm; fibular=0.40cm. Body-surface area indexed reference values increased with age in all segments. A number of 53 subjects (7.0%) had at least one stenosis, mainly in the lower leg arteries anterior tibial (n=28, 3.7%), posterior tibial (n=18, 2.4%) and fibular (n=20, 2.6%). The risk of stenosis increased considerably with age (odds ratio=1.08; p<0.001).
Conclusion: We present reference values for different pelvic and leg artery segment diameters in men that decrease from proximal to distal and increase with age. Stenoses were most prevalent in lower leg arteries.
Author Disclosures:

CT angiography in peripheral artery disease - feasibility of low-contrast media volume protocol
B. Horehledova, C. Mihl, R. Brans, N.G. Eijsvoogel, B.M.F. Hendriks, J.E. Wildberger, M. Das; *Maastricht/NL (barbora.horehledova@mumc.nl)*

Purpose: This study evaluated image quality (IQ) of low-contrast media (CM) volume computed tomographic angiography (CTA) of the peripheral arteries in patients with peripheral artery disease (PAD).
Methods and Materials: 50 patients were scanned on 3rd generation DSCT scanner (Somatom FORCE, Siemens Healthcare, Germany) with the following scan characteristics: tube voltage 70kV, tube current 90mAs, collimation 0.6, pitch 0.6 from diaphragm to forefoot; images were reconstructed with a slice thickness 2/1.4mm and kernel Bf40. CM injection protocol consisted of 15ml test bolus and 30ml main bolus (Iopromide 300mgI/ml, Ultravist, Bayer), at an injection rate of 5ml/s (Iodine delivery rate:1.5gI/l, respectively), followed by a 40ml saline chaser at the same flow rate. Aorto-popliteal bolus transit times were used to calculate the overall acquisition time and delay. Objective (attenuation;contrast-to-noise (CNR)) and subjective IQ (4-point Likert score:1=non-diagnostic, 2=diagnostic, 3=good, 4=excellent) were assessed at the infrarenal aorta and five levels of peripheral arteries: common iliac artery (CIA), superficial femoral artery (SFA), popliteal artery (PA), anterior tibial artery (ATA), dorsalis pedis artery (DPA).
Results: Objective IQ mean attenuation values/CNR (HU±SD) at aorta: 383±89/21±9, and peripheral arteries were: left: CIA 410±100/23±13, SFA 414±93/24±13, PA 316±89/17±8, ATA 249±71/12±6, DPA 166±65/7±5 right: CIA 401±80/22±9,SFA 413±101/24±13, PA 329±88/18±10, ATA 272±76/14±7, DPA 199±89/9±5. Subjective IQ median Likert score value was: 4 at aorta, in peripheral arteries (left/right): CIA 4/4, SFA 4/4, PA 4/4, ATA 3/3, DPA 3/3.
Conclusion: CM volume can be reduced using 70kV protocols using the transit time approach, while maintaining sufficient IQ for evaluation of PAD.

B-1064 11:18

Multipath curved planar reformations of peripheral CT angiography: higher diagnostic accuracy and time-savings for vascular radiologists and radiology residents
M. Schreiner, H. Platzgummer, C. Loewe, S. Unterhumer, G. Mistelbauer, E. Groeller, M. Sramek, R.E. Schernthaner; *Vienna/AT (markus.schreiner@meduniwien.ac.at)*

Purpose: To compare diagnostic performance and time efficiency between multipath curved planar reformations (mpCPRs) and axial images of CT angiography for the assessment of peripheral arterial disease (PAD).
Methods and Materials: Forty patients (10 female, mean age: 72 years) were prospectively included and underwent peripheral CT angiography. A semi-automated toolbox was used to render mpCPRs. Twenty-one arterial segments were defined in each leg; for each segment, the presence of stenosis > 70% was assessed by two independent readers (one expert vascular radiologist, one resident), once on mpCPRs and once on axial images, with digital subtraction angiography as gold standard.
Results: Both readers reached lower sensitivity (Reader 1: 89% vs 93%, p = 0.03; Reader 2: 91% vs 94%, p = 0.08) but significantly higher specificity (Reader 1: 96% vs 95%, p = 0.01; Reader 2: 94% vs 89%, p < 0.01) with mpCPRs than with axial images. Whereas the expert vascular radiologist had similar overall accuracy in both evaluations (94% vs 94%, p = 0.96) the resident achieved even higher accuracy with mpCPRs (93% vs 91%, p = 0.02). Both readers read mpCPRs significantly faster than axial images (p < 0.01).
Conclusion: The assessment of PAD based exclusively on mpCPRs is time-saving, yields high diagnostic performance and should be considered an alternative to time-consuming axial image reading. In particular less experienced readers might benefit from the assessment of mpCPRs. However, further confirmation of these initial results is required.

B-1065 11:26

Lower limb angiography: utilising dynamic datasets to optimise contrast and radiation dose
H. Haubenreisser, M. Meyer, N. Vogler, S. Sudarski, S.O. Schönberg, T. Henzler; *Mannheim/DE (Holger.Haubenreisser@medma.uni-heidelberg.de)*

Purpose: To investigate the impact of the additional information from time-resolved CT angiography examinations with a 3rd generation DSCT on standard CTA protocols.
Methods and Materials: 80 patients with suspected lower limb arterial occlusive disease underwent a combined CTA protocol consisting of a high-pitch-CTA run-off study starting from the abdominal aorta as well as a time-resolved-CTA of the lower limbs over 80cm (10 sec delay, 72sec scan time (8x3sec, 8x6sec); 70kV; 40ml iomeprol400). Quantitative information was gathered in the 3 popliteal segments over the 16 scan phases. In addition, two radiologists and one vascular surgeon assessed the time-resolved examination regarding additional information leading to changes in patient management.
Results: Peak contrast enhancement of the P1 segment was found in Phase 6 (430HU 28s post contrast), in Phase 7 for P2 (388HU 31s post contrast) and in Phase 7 for P3 (366HU 31s post contrast). Diagnostic CNR values (>6) were found in Phases 4-9 (22-40s) in Segment P1, Phases 4-9 (22-40s) in Segment P2 and Phases 5-9 (25-40s) in Segment P3.
Conclusion: Using the gathered information in combination with scanner parameters for static CTA of the lower limbs, it is possible to optimise the protocols for optimal contrast. For example, if a scan time of 20s is chosen, a delay of 21s (31-20/2s) is suitable. Similarly, for a high pitch scan of 2s a delay of 30s should be used.

Low dose whole aorta angio CT in the evaluation of Takayasu vasculitis: a prospective study analysing anatomic classification and identification of disease activity criteria

A. Habouchi, A. Habba, C. Aimeur, M. Tabouche, D. Hakem, N. Slimani, A. Berrah, B. Mansouri; *Algiers/DZ (aminehabouchi@gmail.com)*

Purpose: Takayasu disease is an inflammatory periaortitis involving large and medium size vessels. By the absence of a standardised medical imaging protocol, we propose by this study, the evaluation of a reproducible and exhaustive angio-CT protocol in the statement and the follow-up of the disease.
Methods and Materials: We report the results of a prospective study, realised from January 2013 to December 2015, involving the evaluation by a triphasic angio-CT (non-contrast, arterial and late phase at 5mn), with ECG triggering, low dose protocol (80kv, automatic adaptation of mAs, post treatment with AIDR 3D), and ordinary protocol (120kv, 100mAs) on a 320 rows CT, patients responding to the 1990 ACR criteria of Takayasu disease. Quality of vascular enhancement, irradiation dose, classification of anatomic lesions and correlation of radiologic findings with biologic inflammatory status were recorded.
Results: We have explored 31 patients, 11 patients at active phase and 20 at late phase of the disease. Vascular enhancement quality was at mean 3.8/4, with a mean DLP measured at 1257.3mGy.cm for a low dose protocol and at 3003mGY.cm for a standard protocol. Patients' classification was different according if we integrated or not vascular wall thickening to the anatomic modifications. Late double ring enhancement, blurring and densification of perivascular environment, also densification of the anterior mediastinal fat presented a significant statistic correlation with the biological inflammatory status (p<0.001).
Conclusion: Aortic angio-CT is a reliable and relevant technique with an acceptable irradiation dose in the evaluation of Takayasu disease.

Abdominal large vessel vasculitis: diagnostic value of T1 3D mVISTA-MRI

S. Maurus[1], N.N. Sommer[1], H. Kooijman[2], E. Coppenrath[1], J. Bock[1], T. Saam[1], K.M. Treitl[1]; [1]*Munich/DE*, [2]*Hamburg/DE (karlamaria.treitl@med.uni-muenchen.de)*

Purpose: To assess the value of a high-resolution T1-3D black-blood TSE sequence for the diagnosis of abdominal large vessel vasculitis (aLVV).
Methods and Materials: The mono centric study included 20 patients (51.9 yrs.) with aLVV diagnosed according to the diagnostic reference standard and 17 controls (44.1 yrs.), who underwent a 3.0T MRI scan using a navigated T1-3D modified Volumetric Isotropic TSE Acquisition (T1-mVISTA) sequence with peripheral pulse-unit triggering and a segmented T1 3D turbo-field-echo sequence (T1-3D eThrive). Two radiologists analysed the abdominal aorta and its main branches for concentric contrast enhancement and wall thickening (CCE/CWT), image quality, flow artefact intensity and diagnostic confidence (IQ/FAI/DCL). T1-mVISTA findings were compared to T1-eThrive using accuracy parameters and inter-reader agreement. The average aortic wall thickness was analyzed in post contrast T1-mVISTA and compared for both groups.
Results: The scan time of T1-mVISTA was 4:10min. at an average heart rate of 80bpm. IQ was rated good to excellent in 91.5% of 282 evaluated segments with no or minor FAI present in 85.4%. The inter-observer reproducibility and the DCL for CCE and CWT were high (0.92/0.93; P<0.001; 3.54±0.52/3.50±0.63). The distribution of segmental inflammation in T1-mVISTA significantly correlated with T1-eThrive (CCE/CWT: k=0.740/0.702; P<0.001), resulting in a sensitivity of 87.8%, a specificity of 83.3%, an accuracy of 85.2%, positive and negative predictive value of 79.6% and 90.2%. The supra- and infrarenal aortic wall thickness significantly differed between both groups (3.60±0.65/3.04±0.85mm vs 2.32±0.44/2.18±0.44mm; P<0.001).
Conclusion: Navigated T1-mVISTA allows the detection of aLVV with a high IQ.

B-1068 11:50

Fibromuscular dysplasia of renal arteries: comparison of computed tomography angiography with digital subtraction angiography

E. Charpentier[1], F. Thony[2], E. Mousseaux[1], P.-F. PLOUIN[1], L. Boyer[3], A. Azarine[1]; [1]*Paris/FR*, [2]*Grenoble/FR*, [3]*Clermont-Ferrand/FR (etienne.charpentier88@gmail.com)*

Purpose: To evaluate the accuracy of computed tomography angiography [CTA] with submillimeter section slice compared to digital subtraction angiography [DSA] to diagnose and evaluate stenosis severity in patients with renal artery fibromuscular dysplasia [FMD].
Methods and Materials: Datasets from prospective study ARCADIA including 500 patients with FMD from November 2009 to December 2014, were analysed. A total of 43 patients [6 male and 37 women; mean age: 49 +/- 18 years; age range: 19-89 years] who underwent both renal artery CTA and DSA within 3 months without angioplasty prior to the CTA were included. For each artery, the angiographic phenotype, the stenosis severity were reviewed by 2 blinded radiologists for CTA and one radiologist for DSA. Stenosis severity greater-than-or-equal 70% was evaluated in terms of Se, Spe, PPV, NPV by comparing CTA results to DSA.
Results: DFM was diagnosed in 41/43 patients and 49/103 RA (48%), 67% multifocal, 33% unifocal. Among 41 FMD patients, 10 (24%) had bilateral FMD with multifocal FMD in 8/10 (80%). Interobserver agreement for the diagnosis of FMD using CTA was 0.84 with an overall Se 91% and 98,5% Spe compared to DSA. For stenosis greater-than-or-equal 70% Se, Spe, PPV & NPV of CTA were respectively 73%, 93%,62%,96% for the experimented and 55% ,94%, 60% and 93% for the junior radiologist.
Conclusion: CTA is an accurate tool for the diagnosis of FMD per patient with good reproducibility. DSA technique with selective catheterisation still remains the gold standard.

Preoperative splenic artery embolisation in patients who underwent splenectomy for hypersplenism

M. Zaitoun, S.B. Elsayed, A.A. Elsammak, T. Rushdy; *Zagazig/EG (zaitoun2015@gmail.com)*

Purpose: To identify the role of preoperative splenic artery embolisation in reduction of blood transfusion after splenectomy and compare the results with splenectomy without prior embolisation in patients with hypersplenism
Methods and Materials: During 2 years, 100 consecutive patients with hypersplenism were divided into 2 groups; group (1) 50 patients with hypersplenism underwent preoperative splenic artery embolisation with Polyvinyl alcohol (PVA) and group (2) 50 patients with hypersplenism underwent splenectomy without prior splenic artery embolisation. Mean age was 35.6 years, 57 (57%) were males.
Results: Mortality rate was zero in both groups. Significant difference was detected between the two groups concerning the postoperative blood transfusion as there was no need for blood transfusion in group (1) in 100 % of patients as the platelets count rose from mean 8500 u/µl before the embolisation of the splenic artery to 70000 u/µl after embolisation of the splenic artery with PVA while 45 (90%) of the patients in group (2) received blood transfusion post-splenectomy.
Conclusion: Preoperative embolisation of the splenic artery in patients who undergo splenectomy for hypersplenism significantly reduces blood transfusion in comparison to splenectomy without prior embolisation. Preoperative SAE is a safe procedure with neither morbidity nor mortality.

B-1070 10:47

Percutaneous endovascular aortic repair (PEVAR) in the radiological suite: a paradigm shift?

R. Thomas, T. Kowald, B. Schmuck, O. Eldergash, M. Book, V. Dikov, P. Dohmen, A. Chavan; *Oldenburg/DE (kowald.tobias@klinikum-oldenburg.de)*

Purpose: To evaluate the efficacy of percutaneous femoral access closure in endovascular aortic repair (PEVAR) in the radiological angiography suite.
Methods and Materials: All patients undergoing percutaneous endovascular aortic repair (PEVAR) using the Prostar XL device from January 2010 to May 2016 were retrospectively analysed for incidence of complications and their relationship to various access site characteristics which included artery size, degree of vessel calcification, skin to artery distance and sheath to artery ratio.
Results: Indications for PEVAR in altogether 92 patients (142 access sites) included thoracic and abdominal aortic aneurysms and dissections. Mean follow-up was 32.39 ± 21.66 months. Introducer system sizes ranged from 12F to 25F. The endograft implantation was successful in 91 patients. Primary haemostasis was achieved in 97.1% (138/142) of the access sites. Four access sites (2.8 %) had to be closed surgically due to inadequate haemostasis; in all four cases the introducer systems was ≥18F. Late complications including inguinal / scrotal haematoma (n=8), wound infection

(n=1), pseudoaneurysm (n=4) and late bleeding (n=4), occurred in 17 access sites (11.9%), of which 13 were managed conservatively. On account of the low complication rate, no correlation between the evaluated variables and observed complications could be established.
Conclusion: PEVAR is feasible and safe irrespective of sheath size and nature of aorto-iliac pathology. The technical success rate is high and the incidence of complications is low. Failed haemostasis occurs most often with sheath sizes ≥ 18 F. The majority of late complications can be treated conservatively.

B-1071 10:55

Endovascular aneurysmal repair in octogenarians: is it justified?
V.M. Vishwanath[1], J. Soares[1], A. Burahee[2], S. Latif[3], R. Pathak[3];
[1]*Manchester/UK*, [2]*Birmingham/UK*, [3]*Dudley/UK*
(doctorveenavishwanath@gmail.com)

Purpose: The use of endovascular aneurysmal repair (EVAR) is favoured in the ageing population.[1] Despite the results of the recent EVAR II Trial showing survival advantage with intervention, further studies are needed to show the questionable survival advantage in patients with limited life expectancy.[2] In this study, we report an institution's experience with octogenarians undergoing EVAR over an 8 year period. We analysed mortality rate, complications, rate of re-intervention, outcomes on perioperative renal function and overall reduction in aneurysmal size.
Methods and Materials: All patients who had undergone EVAR for infrarenal aneurysms between 2006-2014 were identified using an electronic patient database. Patients were stratified by the age of 80 years and above. Demographics, comorbidities, imaging and perioperative blood results were analysed.
Results: Of 129 octogenarians, mean age was 84 years. Mean preoperative aneurysmal sac size was 6.35cm. Of 129 patients, 30 day mortality rate was 1.6%. We established 1 year mortality in 103 patients which was 7.8%. We established 2 year mortality in 70 patients which was 12.9%. The incidence of perioperative acute kidney injury was 3.9%. Mean reduction measured in postoperative aneurysmal sac size was 0.84cm.
Conclusion: This study shows a high success rate for EVARs in octogenarians with 87.1% surviving greater than 2 years and 3.1% rate of re-intervention. There is minimal effect on perioperative renal function and a good reduction in aneurysmal sac size. Factors relating to a short perioperative survival period were a significant number of co-morbidities (>3) and emergency repair.

B-1072 11:03

Importance of angiosome-targeted vascular bed identification using DSA and MR techniques for endovascular treatment in patients with critical limb ischaemia
A. Chahal, S. Sharma, P. Jagia, A. Dhar; *New Delhi/IN*
(anuragchahal18@gmail.com)

Purpose: Angiosome targeted vessel bed localisation by DSA, CEMRA (3 station bolus chase) and T-MRA (dedicated BTK time resolved CEMRA) in patients with Critical limb ischaemia.
Methods and Materials: 41 patients with 43 affected limbs with chronic CLI (Rutherford category IV-VI) underwent MRA on 1.5 T and Intra-Arterial DSA with additional T-MRA in 31 patients with BTK disease. Images obtained by each of the modalities were analysed by 2-blinded radiologists. Quality of MRA and T-MRA in BTK station was compared and accuracy of all modalities in localising the affected angiosome was assessed taking affected clinical angiosome as the gold standard.
Results: MRA had excellent sensitivity, 87.1% (95% CI 84-90%) and specificity, 98.04% (95% CI, 98.4-99.2%) taking DSA as gold standard. MRA was non-diagnostic in BTK station in 30% (13/43) limbs. Primary factors deteriorating quality of MRA were venous overlay in 19(44.2%) and motion artifact in 10(23.2%) limbs. Overall, quality of T-MRA was excellent in 22(70.9%), adequate for diagnosis in 8(25.8%) and non-diagnostic in only 1 (3.2%) limb by avoiding venous overlay or motion artifact. TMRA (87.9%, 93.5%) was able to detect 15.5 % more cases of ATA disease and 10.6 % more cases of PTA disease as compared to MRA alone (72.2%, 82.9%). Peroneal disease has poor accuracy (72.7-76.9%) for all the modalities probably due to multiple collaterals for this territory.
Conclusion: Dedicated BTK time resolved MRA proved to be an essential addition to the routine 3 station bolus chase MRA for angiosomal localisation in patients with critical limb ischaemia.

B-1073 11:11

Single-centre experience of endovascular treatment of visceral artery aneurysms (VAAs) and pseudoaneurysms with Viabahn stent graft in 30 patients
M. Colombo, M. Venturini, P. Marra, M. Alparone, F. De Cobelli,
A. Del Maschio; *Milan/IT (colombo.michele@hsr.it)*

Purpose: In endovascular treatment of VAAs, covered stenting, when feasible, can be preferred to trans-catheter embolisation and considered first therapeutic option. Our aim was to retrospectively assess technical aspects, complications, technical/clinical success, mid-term follow-up of covered stenting with stent graft in 30 patients.
Methods and Materials: From 2000 to 2015, 30 patients affected by VAAs were treated with peripheral self-expandable stents. Following data were recorded: aneurysms vs pseudoaneurysms number, involved artery, emergent vs elective procedure, trans-femoral vs trans-axillary approach, one vs more than one stent, proximal vs middle vs distal position, and stent placement modality: remodelling the affected artery vs occluding the affected artery. Follow-up was based on clinical monitoring and contrast-enhanced MDCT. Complications, technical success and clinical success after the procedure and at 6 months were evaluated.
Results: 15 VAAs and 15 pseudoaneurysms (10 splenic, 8 hepatic, 6 renal, 5 gastroduodenal, 1 superior mesenteric arteries) were treated with stents. The procedures were performed via trans-femoral in 27 cases, via trans-axillary in 3 cases. Stents (one in 23 cases, more than one in 7 cases) were placed in proximal (n=15), middle (n=10), distal (n=5) position and remodelling the affected artery in 22 cases, occluding the affected artery in 8 cases. No complications were recorded. At mid-term technical and clinical success were and 91%, respectively.
Conclusion: Covered stenting is a safe and effective treatment for VAAs and VAPAs. In our experience, VSG showed high rates of technical and clinical success, especially in elective procedures, with good clinical outcome in terms of aneurysm exclusion.

B-1074 11:19

Clinical outcome of transarterial embolisation for postgastrectomy arterial bleeding
J. Yoon, K. Han, M.D. Kim, J.Y. Won, D.Y. Lee, G.M. Kim, J.H. Kwon,
S.H. Noh, W.J. Hyung; *Seoul/KR (jkyoon87@yuhs.ac)*

Purpose: To retrospectively investigate the feasibility and safety of transcatheter arterial embolisation in the management of postgastrectomy arterial bleeding.
Methods and Materials: Between January 2004 and July 2015, 13,246 patients underwent total or subtotal gastrectomy at our institution. 24 patients (18 men; mean age, 66.8 years; range, 42-80 years) received transcatheter arterial embolisation for postoperative arterial bleeding identified on angiography.
Results: Postgastrectomy arterial bleeding occurred after subtotal gastrectomy in 14 patients (58%) and after total gastrectomy in 10 patients (42%), after a mean of 17 days (range, 1-57 days). It manifested as luminal bleeding in 10 patients and as abdominal bleeding in 14 patients. Technical success was achieved in all 24 patients (100%). The clinical success rate was 79% (19/24); there were three transcatheter arterial embolisation-related major complications resulting in 30-day mortality (12%), one recurrent bleeding, and one persistent bleeding. The most common bleeding focus was the gastroduodenal artery (46%, 11 patients), followed by the splenic artery (29%, 7 patients). By surgery type, the gastroduodenal artery was the most common site of bleeding in subtotal gastrectomy (64%, 9/14) and the splenic artery in total gastrectomy (50%, 5/10).
Conclusion: Transcatheter arterial embolisation demonstrated high technical and clinical success rates with an acceptable complication rate in the management of postgastrectomy arterial bleeding. However, transcatheter arterial embolisation may not be the best treatment option in patients who underwent subtotal gastrectomy and bled from the splenic artery owing to the high risk of infarctions of the remnant stomach and the spleen.

B-1075 11:27

Stent graft implantation in visceral arteries in acute life-threatening haemorrhage after upper abdominal surgery: a single center experience
B.M. Schaarschmidt, C. Buchbender, J. Boos, P. Kröpil, F. Kröpil,
R.S. Lanzmann, G. Fürst, G. Antoch, C. Thomas; *Düsseldorf/DE*,

Purpose: Haemorrhage due to hepatic or mesenteric artery arrosion following pancreatic fistula and bile leakage ("sentinel bleed") is a rare but severe complication after pancreatic surgery. Endovascular management of these cases is challenging as it is necessary to preserve the blood supply of the upper abdominal organs. The purpose of this study was to evaluate technical success, complications and short-term outcome after implantation of endovascular stent grafts in these patients.

Methods and Materials: Twenty-nine consecutive patients (22 male, 7 female, mean age: 66.4y) that underwent stent graft implantation (Gore Viabahn®) after pancreatic (n=26) or hepatic (n=3) surgery between 2009 and 2016 were retrospectively analyzed. Explorative data analysis for technical success, complications and short-term survival after 30 days was performed.
Results: Initial technical success (stent graft placement, complete sealing and patent outflow) was obtained in 24 patients (83%), with a surgical conversion rate of 17% (n=5). Peri-interventional complications were observed in 6 patients (21%), including severe reversible vasospasms (n=4), aneurysm rupture (n=1) and reversible stent graft occlusion (n=1). In eleven patients stent-related complications (38%) occurred within the follow-up interval (recurrence of bleeding, n=7; stent thrombosis, n=4); access-related complications due to transbrachial access were observed in three patients (10%). Short-term survival was 72%, while eight patients died due to mulitorgan failure (n=4), fatal abdominal haemorrhage (n=2), sepsis and a cardiac event (n=1, respectively).
Conclusion: Emergency endovascular stent-graft implantation in patients with life-threatening upper abdominal bleeding after major abdominal surgery is feasible but prone to a high complication rate.

B-1076 11:35

Imipenem/cilastatin sodium (IPM/CS) as a temporary embolic agent for non-tumoural acute abdominal haemorrhage: our promising experience
J. Valcarcel, J. Joudanin, D. León, E. Alba, E. Escalante, Q. Ordi, A. Sotomayor, P. Naval; *Barcelona/ES (j.valcarcel89@gmail.com)*

Purpose: To evaluate IPM/CS effectiveness as a temporary embolic agent for abdominal bleeding of non-tumoural origin, and its safety in minimizing the risk of distal ischaemia.
Methods and Materials: In a 4 month period we performed 28 embolisations for abdominal haemorrhage of non-tumoural origin. 8 upper and 1 lower-gastrointestinal bleeding were embolised with IPM/CS. This agent was used in cases that required proximal large vessel embolisation, which comprises a high risk of distal ischaemia.An IPM/CS-isosmolar contrast mixture was used (1:1 dilution). IPM/CS was used alone in 3 cases, while a “sandwich” technique was performed in another 3, and in conjunction with proximal coiling in the rest. A retrospective study was performed, analysing technical success (angiographic cessation of bleeding) and clinical success (blood haemoglobin, blood transfusion needs within 7 days, and reintervention within 14 days).
Results: The technical success rate was 100%, with an angiographic cessation of bleeding in all cases. Clinical success was satisfactory, with an improvement/non-worsening of haemorrhagic parameters in 8. None of the cases required reintervention within 14 days. In three patients a computed tomography was performed for other reasons, and no rebleeding or signs of ischaemia were evident in any of them. In the follow-up no clinical and laboratory signs suggestive of ischaemia were objectified.
Conclusion: This study’s promising results, though preliminary, suggest the effectiveness and safety of intravascular embolisation with IPM/CS for abdominal haemorrhage. The authors consider this agent of great potential use in cases that require proximal embolisation, with high risk of tissue ischaemia.

Dual contrast agent-based spectral photon-counting computed tomography for detection of endoleaks following EVAR
J. Dangelmaier[1], D. Bar-Ness[2], D. Münzel[1], H. Daerr[3], F. Pfeiffer[4], R. Proksa[3], E.J. Rummeny[1], P. Douek[2], P.B. Noël[1]; [1]*Munich/DE*, [2]*Bron/FR*, [3]*Hamburg/DE*, [4]*Garching/DE (julia.dangelmaier@gmx.de)*

Purpose: After endovascular aortic repair (EVAR) discrimination of leaking contrast media and calcifications of similar attenuation within the aneurysm sac is challenging and often requires multiple CT acquisitions. Dual contrast agent based spectral photon-counting CT may provide reliable detection of endoleaks with a single CT acquisition.
Methods and Materials: To experimentally evaluate the potential of spectral photon-counting computed tomography (SPCCT), an aortic phantom was in-house designed and produced. A centrally located stent lined compartment was filled with water as well as iodine and gadolinium mimicking enhanced blood within the aortic lumen. Representing the endoleak, adjacent compartments contained either one of the contrast agents or calcium chlorine to mimic calcifications. After data acquisition with a modified clinical base, small field-of-view SPCCT prototype scanner with multi-energy bins, material decomposition was performed to generate iodine, gadolinium and calcium maps.
Results: In a conventional CT slice, Hounsfield Units of the different compartments were similar ranging from about 145 HU up 170 HU. Material specific maps clearly differentiate the distributions, within the compartments filled with iodine, gadolinium or calcium.
Conclusion: A single dual contrast agent based spectral photon-counting CT scan may replace conventional CT scans in native, arterial and delayed phase to detect endoleaks of different flow rates without interference from existing calcifications after endovascular aortic repair. It is a unique feature of our method to capture different contrast media dynamics in a single scan. Additionally, a significant reduction of radiation exposure is enabled.

Neointimal coverage in polymer coated stents with and without antiproliferating agent
W. Hundt, M. Burbelko, D. Jones, M. Kalinowski; *Marburg/DE (hundt@med.uni-marburg.de)*

Purpose: Investigation of the development of restenosis and neointimal coverage in passive coated stents compared to active and passive coated stents.
Methods and Materials: The passive coated stent (Camouflage®-Stent) is in clinical use, however no data exist using this stent with an active antiproliferative component. Arteriosclerotic plaques with stenosis were induced in the common iliac arteries of 10 rabbits by induction of endothelium lesions. Four weeks later, percutaneous intervention was performed by implanting a passive coated stent (Camouflage®-Stent) in one common iliac artery and an active and passive coated stent (Sirolimus+ Camouflage®-Stent) in the other. After further four weeks, the animals were euthanized and the vessels were removed. Microscopic evaluation of neointimal proliferation was performed and analysed statistically.
Results: The passive coated stents showed more neointimal proliferation (86.6±4.0 µm per section) than the active and passive coated stents (74.1±2.6 µm per section; p = 0.008). In both groups, a significant restenosis rate was noted at the stent edges and in the middle of the stent. In the active and passive covered stents naked stent struts were found in 26.8% and extended overgrowth in 3.3%. In the passive covered stents missing stent coverage and an extended overgrowth was seen in 41.6% and 11.6%, respectively .
Conclusion: The active and passive coated stents showed lesser induction of in-stent restenosis because of lesser intimal proliferation than the passive coated stents.

Pulmonary nodules: diagnostic accuracy of MRI
O. Solyanik, K. Hellbach, M. Bonert, D. Bondesson, T. Gaaß, N. Thäns, M.F. Reiser, J. Dinkel; *Munich/DE (olga_solyanik@hotmail.com)*

Purpose: To evaluate the sensitivity of modern MR sequences for the detection of pulmonary nodules using a dedicated porcine chest phantom.
Methods and Materials: Four porcine lungs containing a total of 131 variable sized nodules made of agar were inflated inside a phantom. Two three-dimensional (3D) gradient-echo (GRE) and one steady-state free precession (SSFP) MR sequences were acquired with optimised short TE (0.01-0.6ms). Spiral computed tomography served as the standard of reference. Two blinded readers (with 2 (reader 1) and 4 (reader 2) years experience in chest radiology) analysed the MR images independently and recorded the size and location of the nodules.
Results: Pulmonary nodules were divided into four groups depending on the nodules' size: A: 1.0-1.9 mm (n=57); B: 2.0-2.9 mm (n=50); C: 3.0-3.9 mm (n=14); D: 4.0-4.9 mm (n=10). Interobserver agreement was excellent (k=0.9) for D nodules with a sensitivity of 0.95 for SSFP sequence and 0.75 for GRE sequences. The interobserver agreement decreased (k=0.46) with smaller nodules. Reader 1 showed a sensitivity of 0.60 (all nodules), 0.58 (A), 0.56 (B), 0.67 (C) for SSFP sequence and of - 0.54 (all nodules), 0.50 (A), 0.53 (B), 0.60 (C), 0.65 (D) for 3D-GRE sequences. Reader 2 showed a sensitivity of 0.77 (all nodules), 0.70 (A), 0.83 (B), 0.71 (C) for SSFP sequence and - 0.65 (all nodules), 0.58 (A), 0.68 (B), 0.71 (C), 0.80 (D) for 3D-GRE sequences.

Conclusion: MRI showed a high to good sensitivity for the detection of pulmonary nodules depending on the readers' experience and nodule size. The SSFP sequence showed higher sensitivity than 3D-GRE sequences reaching sensitivity of 0.95 in nodules bigger than 4mm.

Lung cancer screening with MRI compared to low-dose CT: initial results after one year of screening

M. Meier-Schroers[1], R. Homsi[1], D. Dabir[1], D. Kütting[1], A. Feißt[1], J. Gieseke[2], H.H. Schild[1], D. Thomas[1]; [1]*Bonn/DE*, [2]*Hamburg/DE*

Purpose: To evaluate the suitability of non-enhanced MRI for lung cancer screening.
Methods and Materials: 224 participants of a lung cancer screening program were examined with low-dose CT and MRI, both without contrast media. Acquired MRI sequences were T2w MultiVane XD, steady-state free precession, T1w GRE, and DWI with a maximum examination time of 20 minutes. MRI was analyzed regarding focal lesions blinded to CT. Lesions with a minimum size of 6 mm were assessed, since these require further investigation according to LungRADS criteria to determine their dignity. In these cases, participants underwent follow up after three or six months, PET/CT, biopsy, or surgery. The other participants were scheduled for regular controls after twelve months.
Results: By CT/MRI, the following lesions were detected: 17/16 lesions 6-7 mm, 12/12 lesions 8-14 mm, and 4/4 lesions ≥ 15 mm. Seven lesions were histologically confirmed carcinomas, five of them underwent curative resection. The 6 mm lesion missed by MRI was fat containing and located in between hypoventilated lung parenchyma. There was size discrepancy in two 7 mm lesions, which were measured as 8 respectively 9 mm on MRI. When only MRI had been available, these lesions would have been controlled after three instead of six months. Sensitivity/specificity of MRI was 94%/100% for 6-7 mm, and 100%/100% for ≥ 8 mm. There were no false-positive results for MRI concerning lesions ≥ 6 mm.
Conclusion: Non-enhanced MRI has very high sensitivity/specificity for lesions ≥ 6 mm and is therefore suitable for lung cancer screening.

B-1081 10:55

MRI detection of pulmonary nodules: comparison between true FISP and contrast-enhanced VIBE

S.B. Barlas, O.L. Ulusoy, S. Server, A. Öz, B. Koyuncu Sökmen, N. İnan, N.C. Balcı; *Istanbul/TR (sezgibarlas@gmail.com)*

Purpose: To evaluate the diagnostic performance of true FISP and contrast-enhanced VIBE (CE VIBE) sequences for the detection of pulmonary nodules.
Methods and Materials: Ninety patients with 300 pulmonary nodules (211 nodules were <5 mm; 89 nodules were ≥5 mm) diagnosed by CT underwent lung MRI. MRI examination were performed on 1.5 T scanner. CT and MRI data were analysed independently by two radiologists. The detection rate of pulmonary nodules was calculated for whole MRI and for individual MRI sequence. In addition, subgroup analysis have been done as <5 mm, ≥5mm and sensitivities of each sequences were calculated.
Results: The overall sensitivity of MRI for the detection of pulmonary nodules was 35.33% and according to nodule size: 21.80% for nodules <5 mm; 67.41% for nodules ≥5 mm. MRI sequences yielded following sensitivities according to nodul size: 12.79% (true FISP), 21.80% (CE VIBE) for nodules <5 mm; 44.94% (true FISP), 67.41% (CE VIBE) for nodules ≥5 mm.
Conclusion: Contrast-enhanced VIBE sequence is more sensitive for lung nodule detection than true FISP sequence.

B-1082 11:03

Non-contrast MR imaging of the lung: differentiation of infective and malignant lesions

S.N. Nagel, D. Kim, T. Penzkofer, I.G. Steffen, B. Hamm, S. Wyschkon, S. Schwartz, T. Elgeti; *Berlin/DE (thomas.elgeti@charite.de)*

Purpose: To investigate non-contrast MR imaging of the lung at 3T for characterisation of solid pulmonary lesions in immunocompromised patients to differentiate infectious from malignant findings.
Methods and Materials: 17 immunocompromised patients (11 infections, 6 lymphomas) and 12 immunocompetent patients (4 pneumonias, 8 solid tumours) were imaged using fast breath hold T2-weighted turbo spin echo sequences and T1-weighted gradient echo sequences at 3T. Signal intensities (SI) were measured in the lesion (L), chest wall muscle (M) and subcutaneous fat (F). A scaled signal intensity ratio was calculated using the mean T2 SI: ssiT2 = (SI_L - SI_M) / (SI_F - SI_M) * 100. Furthermore, the lesion SI in T1-weighted images was normalised against muscle SI. Wilcoxon's signed rank test and ROC analysis were used as statistical methods.
Results: Infectious pulmonary lesions showed a higher ssiT2 (40.1 [14.6-56.0] vs 20.9 [2.4-30.1], $p < 0.05$). T1-ratio differed significantly between infectious and malignant findings with higher values in the latter (0.85 [0.68-0.94] vs 0.93 [0.87-1.09], $p < 0.05$). The optimal cutoff value to differentiate infectious from malignant lesions was 43 for ssiT2 (YI 0.61, sensitivity 0.71, specificity 0.91). Combining ssiT2 and T1-ratio using binary regression increased sensitivity (YI 0.72, sensitivity 0.77, specificity 0.95).
Conclusion: ssiT2 allows differentiation of acute infectious from malignant pulmonary lesions with high specificity. Adding T1-ratio further increases overall performance, especially regarding sensitivity.

Assessment of contrast-enhancement in the lung parenchyma using 3D ultra-fast steady-state free precession MRI

G. Sommer, O. Pusterla, M. Wiese, F. Santini, D. Lardinois, J. Bremerich, G. Bauman, O. Bieri; *Basle/CH (gregor.sommer@usb.ch)*

Purpose: To investigate the signal intensity enhancement in the lung parenchyma in 3D ufSSFP MRI after administration of gadolinium-based contrast agents in healthy subjects and patients with lung cancer and chronic obstructive pulmonary disease (COPD).
Methods and Materials: Eight healthy subjects and three patients with lung cancer and/or COPD underwent ufSSFP and VIBE imaging at 1.5 T before and 3 min after i.v. injection of Gadobenate-Dimeglumine. Quality of images and contrast enhancement (CE) maps was compared for the two sequences. In the patients, CE-mapping was set against recent ^{99m}Tc-MAA-SPECT/CT.
Results: The acquisitions were successful and provided diagnostic image quality in all subjects. The signal enhancement seen with 3D ufSSFP after contrast agent injection was significantly higher in the lung parenchyma (101%±8%) than in other tissues (fat: 2%±4%, muscle: 26%±6%, liver: 33%±9%) and in the blood pool (83%±9%). The relative signal enhancement of the lung parenchyma seen after contrast agent injection was more than twice as high for ufSSFP than for VIBE (47%±13%) providing homogeneous CE-maps of the lung parenchyma in all healthy subjects. The CE-maps acquired in the three patients showed characteristic changes due to the underlying diseases. There was good visual agreement between ufSSFP-based CE-mapping and SPECT/CT.
Conclusion: 3D ufSSFP CE-mapping allows for a selective depiction of the contrast enhancement in the lung parenchyma. The method is feasible in healthy subjects and in lung cancer and COPD patients. It may be used as a simple, fast and radiation-free alternative to lung perfusion SPECT/CT for patients with pulmonary perfusion abnormalities.

B-1084 11:19

Self-gated non-contrast-enhanced functional lung (SENCEFUL) MRI for quantitative ventilation assessment in patients with cystic fibrosis

S. Veldhoen[1], A. Weng[1], A.S. Kunz[1], D. Stäb[2], C. Wirth[1], H.U. Hebestreit[1], U. Malzahn[1], H. Köstler[1], T.A. Bley[1]; [1]*Würzburg/DE*, [2]*Brisbande/AU (veldhoen_s@ukw.de)*

Purpose: To assess the clinical feasibility of SElf-gated Non-Contrast-Enhanced FUnctional Lung (SENCEFUL) MRI for quantitative ventilation imaging in patients with cystic fibrosis (CF).
Methods and Materials: Twenty patients with CF and 20 matched healthy volunteers underwent unenhanced functional 1.5-T lung MRI in free-breathing using the SENCEFUL approach. The lungs were manually segmented from ventilation-weighted images to obtain quantitative ventilation (QV) measurements, which were compared between groups. QV values of the patients were correlated with results of pulmonary function testing. Three radiologists rated the functional images for presence of ventilation deficits.

Results: QV of the lungs was lower for CF patients (0.09 vs. 0.11 ml/ml, p<0.01). QV ratios of upper to lower lung quadrants were lower in CF patients expressing less ventilation of upper parts (right, 0.84 vs. 1.16, p<0.001; left, 0.88 vs. 1.11, p=0.02). Accordingly, ventilation differences between the groups were larger in the upper quadrants (mean difference, 0.04 ml/ml,p<0.01). Mean breathing frequency was higher in CF patients with 20 respiratory cycles per minute vs. 16 in the controls (p<0.01). QV values of CF patients correlated with vital capacity (r=0.7, p=0.01), residual volume (marker for static hyperinflation, r =-0.8, p<0.01) and FEV1 (marker for airway obstruction, r=0.7,p=0.02). A pattern of widely distributed small ventilation deficits was found in 40% of the patients vs. 8% of the volunteers (p<0.001).
Conclusion: SENCEFUL-MRI is feasible for contrast-free quantitative ventilation assessment. CF patients show less ventilation of upper lung parts and lower overall QV values, which correlate with vital capacity and with markers for hyperinflation and airway obstruction.

B-1085 11:27

SENCEFUL MRI for detection of lung perfusion deficits in CF patients
A.S. Kunz, A.M. Weng, C. Wirth, C. Kestler, F. Segerer, H. Hebestreit, H. Köstler, T.A. Bley, S. Veldhoen; *Würzburg/DE (kunz_a@ukw.de)*

Purpose: To identify lung perfusion deficits in CF-patients using SElf-gated non-contrast-enhanced functional lung (SENCEFUL)-MRI.
Methods and Materials: Unenhanced Fourier decomposition-based SENCEFUL-MRI at 1.5T was performed in free breathing on 38 participants, i.e. 19 patients with known Cystic Fibrosis (CF) and 19 healthy volunteers. Color-coded lung maps indicating semiquantitative lung perfusion and lung perfusion phase (i.e. temporal pulmonary distribution of blood flow) were reconstructed. Four readers blinded to all clinical aspects rated 1644 coronal lung maps (10 mm slice thickness). Lungs in each map were rated per quadrant using a 4-point Likert scale (1=healthy, 2=defect <25% quadrant area, 3=defect <50% quadrant area, 4=defect >50% quadrant area). Readers rated perfusion and phase maps separately followed by simultaneous assessment thereof. Phase data was plotted in histograms with subsequent Gaussian fit. Peak-to-offset ratio was determined as the maximum of the fitted curve divided by the mean outer 10%. Ratios were compared between groups and to the reader's scoring.
Results: In perfusion maps, readers attributed pathological/conspicuous scores to 25.3% of quadrants (controls) vs 56.5% (CF-patients;p<0.05). Phase maps were rated conspicuous in 20.9% vs 56.1% (p<0.05). Simultaneous assessment was scored with 15.1% vs 53.6% (p<0.05). ICC-analysis for Inter-Reader-Agreement regarding the 4-point scale showed excellent agreement (perfusion: 0.851, phase: 0.805, combined: 0.822). Objective assessment of peak-to-offset ratios showed a median of 63.8 in controls vs 15.3 in CF-patients (p<0.05).
Conclusion: SENCEFUL-MRI detects impairments of lung perfusion and phase distribution with good spatial resolution. Analysis revealed distinct differences between CF-patients and controls, plausibly attributed to Euler-Liljestrand-Mechanism/hypoxic vasoconstriction.
Author Disclosures:
H. Köstler: Grant Recipient; Siemens Healthcare. **T.A. Bley:** Consultant; GSK, MSK. Equipment Support Recipient; Noras, Rapid. Grant Recipient; Deutsche Forschungsgemeinschaft. B-1086 11:35

Non-contrast enhanced ventilation and perfusion magnetic resonance imaging in early cystic fibrosis lung disease
M.O. Wielpütz[1], S. Gehlen[1], P. Leutz[1], M.U. Puderbach[1], M. Eichinger[1], Y. Ohno[2], G. Bauman[3], H.-U. Kauczor[1], M.A. Mall[1]; [1]*Heidelberg/DE*, [2]*Kobe/JP*, [3]*Basle/CH (mark.wielpuetz@me.com)*

Purpose: Previous studies demonstrated that morpho-functional magnetic resonance imaging (MRI) detects structural and perfusion abnormalities in lungs of cystic fibrosis (CF) patients. With the present study we evaluate Fourier decomposition (FD-)MRI to detect ventilation and perfusion defects in infants and preschool children with CF without the need for exogenous contrast materials.
Methods and Materials: In total, 30 children with CF (age 1.8±2.0y range 0-6y at first exam) contributed 85 MRI studies. Balanced steady-state free-precession imaging was performed in free breathing in three coronary slices through the central lung for FD-MRI, in addition to a standardized T1- and T2-weighted protocol including contrast-enhanced perfusion imaging. For FD-MRI lungs were segmented manually, and percent of ventilation and perfusion defects calculated by custom software. The remaining MRI protocol was assessed using the MRI score as previously evaluated.
Results: Ventilation-weighted images could be generated from 81 (95%) and perfusion-weighted images from all 85 (100%) datasets. Ventilation correlated substantially with perfusion defects (r=0.67, p<0.001). Mean ventilation and perfusion defects tended to be higher in older patients with 20.8±9.7% and 26.8±3.3% at 6y compared to 10.9±6.9% and 21.6±4.4% in newborns, respectively. Ventilation defects moderately correlated with overall disease severity documented by the MRI score (r=0.56, p<0.001), but perfusion defects did not (r=0.21).
Conclusion: FD-MRI is feasible and detects ventilation and perfusion defects already in newborns, infants and preschool children with CF. These results support the development of FD-MRI for non-invasive functional lung imaging in this age group, and may render application of exogenous contrast materials unnecessary.

MR imaging of airway mucus contrasts as a tool to diagnose allergic bronchopulmonary aspergillosis in cystic fibrosis
G. Dournes, J. Refait, A. Rispal, F. Laurent; *Bordeaux/FR (snek60@gmail.com)*

Purpose: Allergic broncho-pulmonary aspergillosis (ABPA) is a fungal complication of cystic fibrosis (CF) associated with acute and chronic respiratory function loss that requires specific antifungal therapy. We hypothesised that MR characterisation of mucus contrasts could diagnose ABPA in CF and be a tool for treatment response.
Methods and Materials: The study was approved by the local Ethic Committee and all patients gave written informed consent. 110 consecutive CF patients were screened between January 2014 and July 2015 were included. All patients underwent a non-contrast-enhanced MR protocol including routine T1-weighted and T2-weighted sequences. The presence of mucus of both high T1 and low T2 signal, that we call the IMIS (Inverted Mucoid Impaction Signal) sign was qualitatively and quantitatively assessed by 2 physicians blinded from any other data. The Gold Standard to diagnose ABPA was the Cystic Fibrosis Foundation Consensus Conference criteria. ABPA status was followed-up during 1 year.
Results: 108 CF patients were included, 18 with and 90 without ABPA. At lobar scale, inter and intra-reader reproducibility was excellent (kappa>0.90). IMIS had a 94% [73;99] sensitivity and 100% specificity [96;100] to diagnose ABPA. After 3-months of specific ABPA treatment, complete resolution of IMIS was observed in ABPA patients and was significantly correlated with a decrease in total IgE blood levels (rho=0.47;p=0.04).
Conclusion: IMIS sign appeared both highly specific and sensitive to diagnose ABPA in CF. Allergic fungal inflammation induces characteristic modifications of mucus properties which are quickly and easily assessable using a non-invasive, contrast-free and radiation-free chest MRI.

MR pulmonary angiography: can it be used as an alternative to CT angiography in diagnosis of major pulmonary thrombosis
A.M. Osman, E.H. Abdeldayem, N.M. Osman; *Cairo/EG (DR_osman80@yahoo.com)*

Purpose: A comparative study between the non-contrast magnetic resonance pulmonary angiography and the computed tomography angiography in diagnosis of pulmonary embolism.
Methods and Materials: Fifty patients were included in our study. All patients admitted and/or referred to Chest Department with moderate to high clinical suspicious of pulmonary embolism. All patients underwent CT angiography and non contrast MR pulmonary angiography in the same day or within two consecutive days after written consents. The radiological examinations were interpreted by two different radiologists. The results were compared and statistically analyzed.
Results: The mean age of the selected patients was about 55 years old. Thirty one cases showed positive pulmonary embolism in both MR and CT. Four cases showed positive pulmonary embolism only in CT with two cases showed positive pulmonary embolism only in MR. The rest of cases showed negative results in both. The sensitivity of non contrast MR angiography was 88.5% with 86.6% specificity. The sensitivity and specificity also calculated per vessel and was 87.2% and 99.3% respectively.
Conclusion: The non-contrast MR pulmonary angiography has a reasonable sensitivity and specificity in diagnosis of pulmonary embolism especially in major branches. So, it can be used as an alternative to the CT angiography especially when the use of CT and gadolinium are contraindicated.

Comprehensiveness of EHSRGE/ESGE classification of female genital tract anomalies: systematic review of cases by MRI

P. Yadav; *Pune/IN (yadavpratiksha@hotmail.com)*

Purpose: To find the comprehensiveness of the EHSRGE/ESGE classification in uterovaginal congenital anomalies on MR imaging. Comparison of the EHSRGE/ESGE classification with AFS classification in systematic review of cases.
Methods and Materials: Retrospective study included the 45 cases of congenital anomalies of female genital tract,detected on MRI pelvis.MRI performed on 1.5 Tesla Siemen's Avonto). Images were observed to evaluate the uterine contour,endometrium and vagina.Each case was classify according to AFS as well as EHSRGE /ESGE.
Results: Study included 45 cases of the uterovaginal anomalies.Observation of the uteus, cervix and vagina done on MR imaging.Uterus was the most frequently involved organ in 82% followed by cervix (20%) and vagina (17.7%). Single organ anomalies seen in 57.8% cases and multiple organ,complex anomalies in 42.2% cases. Ipsilateral renal agenesis seen in 8.8% cases and contralateral in 1 case.There was no separate class in the AFS for the bicornuate uterus with septum,in ESHRE/ESGE it is classified as U3c.One case of duplication vagina with agenesis of uterus and cervix can not be classified in any of the class in the AFS,in ESHRE/ESGE it is classified class VI.
Conclusion: Uterovaginal congenital anomalies can involve single or multiple organ. AFS classification has limitation in systematic categorization of uterovaginal anomalies EHSRGE system may provide an effective and comprehensive categorization of uterovaginal anomalies,with cervix and vaginal anomalies in the subclasses.ESHRGE system may overcome the limitation of the AFS in classification.It includes a separate class VI for few complex uterovaginal anomalies,subtle changes,duplication defects and ectopic mullerian tissue,which was not in the AFS classification.

B-1090 10:38

Evaluation of Mayer-Rokitansky-Küster-Hauser syndrome with magnetic resonance imaging: variable findings of uterine remnants, ovaries and related clinical settings

Y. Wang, J. Lu, L. Zhu, B. Jiang; *Beijing/CN (yuewang9203@sina.com)*

Purpose: To summarise the magnetic resonance imaging (MRI) features of Mayer-Rokitansky-Küster-Hauser (MRKH) syndrome.
Methods and Materials: Eighty-one females with MRKH syndrome consecutively attended our institution between July 2014 and Aug 2016 and all underwent MRI of the pelvic cavity. One case was excluded for poor image quality; images of the rest 80 cases were retrospectively reviewed by two experienced gynaecological radiologists in consensus. Characteristics including the volume of uterine remnants, endometrium, haematometra, ovarian location and endometriosis were assessed. Basic demographic and clinical information were acquired by reviewing electronic records. The Chi-square and U tests were used to test for differences.
Results: The unilateral uterine rudiments were significantly larger (68.4±19.0ml vs 6.5±3.2ml, P=0.000) than those in patients with bilateral uterine rudiments. And the incidence of endometrium (100% vs 21%, P=0.000), haematometra (64% vs 2%, P=0.000), ovarian endometriosis (43% vs 2%, P=0.000) were significantly higher in patients with unilateral rudimentary uterus as compared with those who showed bilateral uterine rudiments.Twenty-six patients (33%) showed abnormally located ovaries. Abdomen pain was more common (P=0.000) in patients with unilateral rudimentary uterus (64%) as compared with those who had no (12%) or bilateral uterine remnants (16%).
Conclusion: Unilateral rudimentary uteri were more voluble. The incidence of endometrium, haematometra and ovarian endometriosis were significantly increased in patients with unilateral uterine remnants. Pelvic pain was more common in patients with unilateral rudimentary uterus. Ectopic ovary was not rare. Knowledge of such disparities can facilitate the adjuvant diagnosis and subsequent optimal treatment option.

B-1091 10:46

3D and 2D ultrasound-based foetal weight estimation a single center experience

M.F. Farghaly Amin, L.A.M.S. Mohsen; *Minya/EG (dr.laila.adel77@gmail.com)*

Purpose: To evaluate two new 3D and two new 2D ultrasound formulae for foetal weight estimation against the modified Hadlock formula and compare their estimation to the actual foetal weight.
Methods and Materials: Fifty pregnant females were included. Inclusion criteria: singleton pregnancy, within five days of delivery and normal or IUGR pregnancy. 3D evaluation of the foetal thigh and arm was done to calculate mid-thigh and mid-arm volumes. The actual foetal weight was recorded at delivery and compared to the estimated weights.
Results: Modified Hadlock formula had higher accuracy, whereas fractional limb volume method had higher precision. Systematic errors for the modified Hadlock formula, Model 6 of fractional limb volume and the original mid-thigh soft tissue thickness methods were 2.3%, 4.8% and 11%, respectively, whereas the random errors were 7.7%, 6.2% and 13.8%, respectively. The percentage of cases estimated within 5%, 10% and 15% of actual foetal weight were 48%, 86%and 92%, respectively, for the modified Hadlock method, whereas for the fractional limb volume method, these were 40%, 78% and 98%, respectively.
Conclusion: Fractional limb volume method is a very promising method for foetal weight estimation. Its performance is not significantly different from the modified Hadlock method.

B-1092 10:54

Assessment of endothelial function in postpartum preeclamptic women using flow mediated dilation of brachial artery

P. Tripathy, M. Sahu, M. Singh, P. Mishra, J. Mohanty; *Cuttack/IN (dr.priyadarshini.tripathy@gmail.com)*

Purpose: Preeclampsia is associated with inflammation and dysfunction of the maternal vascular endothelium. However, it is unclear whether this problem persists postpartum, and whether it also predisposes patients to increased cardiovascular risk. Hence, we aimed to compare the vascular profile of postpartum preeclamptic women with that of normal postpartum women.
Methods and Materials: Forty-five women with previous preeclampsia and 40 age-matched normotensive controls were enrolled in this study, all within 6 months to 2 years postpartum status. The brachial artery was identified though colour Doppler in cubital fossa, and its baseline diameter was measured. It was occluded for 5 minutes with an inflated cuff, and a measurement was repeated 1 minute after initial occlusion. Flow mediated dilation (FMD) of the brachial artery was calculated as a diameter percentage change after baseline occlusion. We determined ambulatory blood pressure measurement (ABPM) and serum high sensitivity C-reactive protein (hs-CRP) levels. Parameters were compared across groups, adjusting for potential confounders.
Results: FMD was significantly reduced in women with preeclampsia compared to controls (3.47±6% versus 8.75±6%; $p < 0.05$). Serum hs-CRP levels were slightly higher in the preeclamptic group than controls, while ABPM showed higher mean arterial blood pressures in the preeclamptic group than controls (98±7 mmHg versus 91±4 mmHg, $p < 0.05$).
Conclusion: Endothelial dysfunction in women with previous preeclampsia is persistent for up to 2 years postpartum. As a result, brachial artery FMD might be a useful noninvasive tool to assess the risk of future vascular disease in postpartum preeclamptic women.

B-1093 11:02

MRI evaluation of invasive placentation in high-risk patients: accuracy and reproducibility in comparison with the reference standard

F. Monelli, F. Fiocchi, G. Besutti, A. Pecchi, E. Petrella, E. Bertucci, F. Fachinetti, P. Torricelli; *Modena/IT (mofilippo@hotmail.it)*

Purpose: The aim of this study was to assess accuracy and reproducibility of MRI in the diagnosis of invasive placentation (IP) in high risk patients, using histologic findings or clinical evaluation as the reference standard.
Methods and Materials: Sixteen patients with placenta previa and other risk factors for IP (mean age 36 yrs, 62.5% with previous uterine surgery) underwent 1.5 T MR examination including T2-weighted Turbo-Spin-Echo, Balanced Turbo-Field-Echo and THRIVE sequences acquired on the three uterine planes. Images were reviewed by two readers, who evaluated specific MRI signs of IP. The reference standard was histology in 7 patients who underwent hysterectomy, and clinical diagnosis in the remaining 9 patients. Sensitivity and specificity of MRI findings were calculated, reproducibility was estimated by using Cohen's K test.
Results: The prevalence of IP was 56.25%, placenta percreta was found in two patients (12.5%). MRI had sensitivity and specificity of 100% and 85.7%, respectively. MRI findings with higher sensitivity were placental heterogeneity (PH), uterine bulging, dark intraplacental bands (DIB), myometrial interruption (MI), and thinning of the uterine-placental interface; those with higher

specificity were uterine scarring from previous caesarean delivery (US), PH, MI and tenting of the bladder wall. MRI reproducibility was high (K=1); US, DIB, and MI were the most reproducible MRI findings.
Conclusion: MRI is an accurate and reproducible tool in the evaluation of IP. Placental heterogeneity and myometrial interruption are the most accurate MRI findings.

B-1094 11:10

Quantitative and qualitative analysis of DWI of gestational trophoblastic disease: can it predict progression of molar pregnancy to persistent disease?

F. Hosseini; *Shiraz/IR (f.hoseini88@gmail.com)*

Purpose: To describe diffusion-weighted imaging (DWI) appearance of gestational trophoblastic disease (GTD) and to determine and compare apparent diffusion coefficient (ADC) values of hydatidiform mole (HM), persistent trophoblastic neoplasia and non-molar early pregnancy bleeding.
Methods and Materials: During a period of 6 months, women with preliminary diagnosis of GTD based on ultrasound and ßhCG levels underwent 1.5T MRI (T2 high resolution and DWI; b values 50,400,800; sagittal and perpendicular to endometrium, and T1, T2 Turbo Spin Echo (TSE) axial images). Patients underwent 6-12 months follow-up for progression to persistent form of disease. ADC values and image characteristics were compared between HM and persistent neoplasia and also between GTD and non molar pregnancy using Mann Whitney U and Fissure`s exact tests respectively.
Results: among 23 patients, 19 (83%) were classified as molar and 5(17%) as non-molar base on pathology reports. After 6-12 months follow up 5 (26%) cases progressed to persistent disease and 14(74%) were benign HM. There was no significant difference between ADC values of HM and persistent neoplasia, ($1.93\pm0.33*10^{-3}$ mm²/sec) and ($2.03\pm0.28*10^{-3}$ mm²/sec) respectively (P=0.69). ADC of non molar pregnancy was ($0.96\pm0.46*10^{-3}$ mm²/sec) with significant difference with GTD ($1.96\pm0.32*10^{-3}$ mm²/sec) (p=0.001). Heterogeneous snowstorm appearance, focal intratumoural haemorrhage, myometrial contraction and prominent myometrial vascularity were more common in GTD compared to non-molar pregnancy ($p<0.05$).
Conclusion: Heterogeneous snowstorm appearance, focal intratumoural haemorrhage, myometrial contraction and prominent myometrial vascularity are imaging characteristics of GTD. We cannot use ADC values to predict progression to persistent disease.

The added value of DWI for appreciating the degree of placental invasion of the myometrum: do the results depend on observer's experience?

D. Costachescu, D. Malita; *Timişoara/RO (dan_costachescu@yahoo.com)*

Purpose: To evaluate the added value of DWI in the diagnosis of placental invasion of the myometrium as well as the depth of invasion both for senior radiologists as well as junior radiologists.
Methods and Materials: We included 21 pregnant women investigated by prenatal MRI (T1, T2 and DWI sequences without i.v. contrast); among them 12 had histopathologically proven placental invasion and 9 women without placental invasion used as control group.Two senior and two junior radiologists blindly and independently reviewed MR-examinations in two separate reporting sessions indicating the presence and degree of placental invasion (placenta increta, accreta or percreta). In the first session only T1 and T2 sequences were evaluated, while in the second session DWI sequence was also evaluated among T1 and T2.For each reader the sensibility, specificity, and receiver operating curve (ROC) were calculated for both of the two reporting sessions.
Results: Sensitivity and specificity for placental invasion without the DWI sequence was 86.9% and 74% for seniors and 72.8% and 61.8% for juniors, respectively. In the second reporting session which included DWI sequence the sensitivity and specificity where improved, both for the Seniors (92,3%/85,6%) and juniors alike (91,2%/83,2%). Seniors detected placental invasion and depth of infiltration with significantly higher diagnostic certitude than juniors ($p = 0.0010$ and $p = 0.0262$, respectively). The use of DWI significantly reduced the diagnostic discrepancies between seniors and juniors.
Conclusion: DWI can clearly define the border between the placenta and myometrium making it an excellent tool in the assessment of placental invasion of the myometrium.

B-1096 11:26

Contribution of diffusion-weighted MRI to conventional MRI in ovarian torsion: a prospective study for the detection of haemorrhagic infarction

O. Ozdemir, Y. Metin, N. Orhan Metin, M. Kadioğlu, E. Zengin, Ö. Şahin; *Rize/TR (droguzrad@hotmail.com)*

Purpose: The objective of this study was to assess the role of DWI in differentiation haemorrhagic ovary infarction from non-haemorrhagic one. To our knowledge, this is the first prospective study regarding preoperative DWI diagnosis of haemorrhagic infarction in ovary torsion.
Methods and Materials: For this prospectively designed study, of 117 female patients who presented with acute lower quadrant pain and underwent MRI for suspicion of ovary torsion, results of only 29 patients (mean age, 24.7; SD, ±5.7; age range, 18-37), with surgical and pathological confirmation of adnexial torsion, were included to the study. All patients underwent DWI after conventional MRI. Quantitative and qualitative analysis of both the torsed and contralateral normal ovary were performed. Results of conventional MRI and DWI were noted.
Results: At operation 15 patients were found to have haemorrhagic infarction while 14 had non-haemorrhagic infarction. Of the 29 patients, 16 torsed ovaries could be salvaged in a viable state. We found statistically significant correlation of the ADC values, between haemorrhagic and non-haemorrhagic ovary infarction. The ADC values were significantly lower in patients with haemorrhagic infarction than non-haemorrhagic ones ($p<0.001$). Using an ADC threshold of 1.27, the sensitivity of DWI for haemorrhagic infarction was 0.93 and specificity 0.85.
Conclusion: DWI may be used with a significant success for the preoperative diagnosis of haemorrhagic infarction. This may be useful for preemptive surgery in preserving ovarian viability.

B-1097 11:34

Endometriosis as an underestimated foe: can MRI help?

W.R.A. Abdel Hamid, Y. Abbas; *Cairo/EG (w.gforever@yahoo.com)*

Purpose: The current days have shown an increased concern about endometriosis attributed to its significant morbidity rates. Our study aims to assess the ability of MRI to detect solid endometriotic implants and verify active from quiescent lesions.
Methods and Materials: 30 female patients with clinically proven endometriosis were included in this study to verify their endometriotic load through a dedicated MR protocol covering the lower abdomen and pelvis (including T1W images with and without fat suppression, T2W images, DWI (diffusion-weighted Images), IVIM (intravoxel incoherent motion) and T1W post-contrast images with fat suppression) followed by laparoscopic correlation.
Results: In these 30 patients, 108 lesions were detected including 18 ovarian endometriomas, 37 lesions at uterosacral ligaments, 22 parametrial lesions, 3 mural bladder lesions (2 serosal and 1 full thickness mural involvement), 4 serosal bowel lining lesions, 13 anterior abdominal wall serosal lining lesions, 3 vesicovaginal pouch lesions and 8 uterine serosal lining lesions. MR results were correlated with laparoscopic results with a sensitivity of 95.29%, specificity of 75%, PPV 93.1% and NPV 81.8%.
Conclusion: Preliminary results have revealed a promising role of DWI and IVIM as an asset in the detection of solid endometriotic implants and furthermore differentiating between active and quiescent lesions with which we can reliably exclude contrast reducing both time and cost of the MR studies together with acting as a road map to point out lesions and highlight blind spots for laparoscopic planning.

B-1098 11:42

Rectal and vaginal opacification MRI in the diagnosis of deep pelvic endometriosis

C. Saracin, D. Malita, F. Birsasteanu, D. Costachescu; *Timişoara/RO (oana.cristina.voicu@gmail.com)*

Purpose: The paper's objective was to establish the sensitivity of MRI using vaginal and rectal opacification with ultrasound gel in the detection of deep pelvic endometriosis as well as to appreciate the need of an experienced radiologist for reporting this pathology.
Methods and Materials: Prospective, single-centre study. All patients with symptoms of endometriosis were included. Axial T2-weighted imaging was performed before and after gel opacification of the vaginum and rectum. Four blinded radiologists (2 experienced and 2 unexperienced) reported the images. MRI performance was evaluated without vaginal and rectal opacification (C-) and with opacification (C+) by calculating sensitivity, specificity and both positive and negative predictive values.
Results: Sensitivity and specificity for C- and C+ scans were calculated for all the 4 reviewers.Sensitivity and specificity increased after opacification for all the reviewers ($p<0.0001$). Although before opacification there was a significant difference between the experienced and unexperienced readers, after

opacification, there were no notable differences between readers.The interpretation time for all of the 4 reviewers was calculated for each scan. The mean reporting time without opacification dropped from 8.8 minutes to 6.9 minutes when the rectum and vaginum were opacified. Moreover, the mean reporting time between the experienced and unexperienced radiologists became almost equivalent.
Conclusion: Our study was intended to evaluate the use of ultrasound gel to opacify the rectum and vaginum in diagnosing deep pelvic endometriosis.The results show that this technique is generally accepted by patients, the sensitivity and specificity are extremely high and the differences in reporting between experienced and unexperienced radiologists are almost none.

Uro colon CT in the diagnosis of pelvic deep infiltrating endometriosis
S. Zanardi, F. Coppola, D. Papadopoulos, D. Valerio, A. Di Vincenzo, L. Zannoni, R. Seracchioli, R. Golfieri; *Bologna/IT (sara.zanardi10@gmail.com)*

Purpose: To evaluate the diagnostic accuracy (DA) of the uro-colon-CT (U-CCT) with dose-reduction dedicated protocol in preoperative study of deep infiltrating endometriosis of the anterior and posterior compartments (aDIE and/or pDIE).
Methods and Materials: 73 patients with clinical suspicion of aDIE and/or pDIE were analysed retrospectively, undergone U-CCT between January 2012 and December 2014 before laparoscopic surgery, and imaging data were compared with the surgical and histological reports. We calculated sensitivity, specificity, PPV, NPV of U-CCT and evaluated the utility of this technique to select patients who need a more detailed presurgical planning.
Results: 74 surgical interventions were performed on 73 patients (one patient was exposed to surgery twice due to DIE relapse after two years). In 4/74 surgical interventions U-CCT with dose-reduction dedicated protocol was negative for DIE. The urologists were properly involved when DIE nodules concerning ureters and bladder (p=0,042); The colorectal surgeons were more often involved when DIE nodules concerning sigmoid colon, particularly in case of bowel stenosis >50% (p=0,031%). U-CCT attested better results in the evaluation of DIE nodules involving digestive tract (DA 81%; p=0,000) and bladder (DA 87,8%; p=0,000).
Conclusion: U-CCT with dose-reduction dedicated protocol proved to be a valid alternative to barium-enema x-ray and urography or in absence of MRI with targeted protocol, to elaborate a detailed presurgical planning in selected patients with DIE; in particular this method is very helpful to individuate DIE nodules involving digestive tract or bladder and to evaluate the correct involvement of the urologist and/or the colorectal surgeon.

Radiogenomics: evaluation of CT imaging features of melanoma metastases compared with genomic expression
E. Khodak, M. Lotem, J. DiPoce, S. Goldberg, J. Sosna; *Jerusalem/IL (Jkhodak@gmail.com)*

Purpose: Imaging features and the distribution of metastases could serve as surrogates predictive of molecular genotype, contributing to the diagnosis, prognosis, and BRAF-dependent treatment response in melanoma. We aimed to identify imaging biomarkers for metastatic melanoma.
Methods and Materials: A database of 142 patients with metastatic melanoma, previously genotyped for BRAF mutation status, was retrospectively reviewed. Patients >18 years with imaging evidence of metastases prior to treatment (including radiation), with no other neoplastic disease, were included. CT and PET-CT were assessed for 182 imaging features, including distribution (10 organs) and characteristics (border, shape, calcifications, central necrosis, vascularity, size) of metastases with blinding to BRAF status. Associations between imaging characteristics and BRAF status were assessed (T-test of proportion, Bayesian analysis).
Results: 30 BRAF-positive (BRAF-POS) and 34 BRAF-negative (BRAF-WT) patients (total 64) met inclusion criteria. There were significant differences between groups in the distribution of 54 imaging features, which were merged into 16 clusters. There was a strong correlation for spread to the adrenals, soft tissue, and lymph nodes for the BRAF-POS genotype (adrenals 10% vs 0%; soft tissues 47% vs 15%, lymph nodes 70% vs 38%, for BRAF-POS and BRAF-WT, respectively, p<0.01), and spread to the liver for the BRAF-WT genotype (26% vs 10% for BRAF-WT and BRAF-POS, respectively, p<0.01).
Conclusion: The pattern of metastatic spread in melanoma varies with BRAF genotype. BRAF-positive patients tend to present adrenal, lymph node, and soft tissue metastases; BRAF-negative patients tend to present liver metastases. Future studies assessing prognostic implications of these findings are warranted.

B-1101 10:38

Reduced dose CT for staging in patients with melanoma: evaluation of radiation dose and diagnostic confidence in comparison to standard dose dual-energy CT
D. Zinsser, A. Othman, T. Eigentler, C. Garbe, K. Nikolaou, B.D. Klumpp; *Tübingen/DE*

Purpose: To compare reduced dose intermediate tube voltage CT to standard dose dual-energy CT (DECT) for staging in melanoma patients regarding radiation dose, image quality and diagnostic confidence.
Methods and Materials: We retrospectively included 118 melanoma patients (53 females, mean age 60.2±14.5) who underwent whole-body DECT with 100/150 kVp (Tube A/B). Two datasets were reconstructed: 100 kVp (reduced dose, Tube A) and mixed series (standard dose, 80 % Tube A/20 % Tube B). Image quality and diagnostic confidence using a 4-point Likert scale (1=poor, 4=excellent) and presence/absence of tumour were assessed. Target lesions according RECIST1.1 were recorded. SNR values of skeletal muscles of neck, thorax and abdomen were calculated.
Results: Based on fixed combination of both tubes, 100 kVp acquisition instead of mixed DE acquisition renders 27% dose reduction. Diagnostic confidence was rated equal for both datasets (3.29±0.66 vs. 3.30±0.66, p=0.317). For standard dose, we observed better subjective and objective image quality for thorax (3.78±0.44 vs. 3.65±0.5, p≤0.001, SNR 6.69±1.02 vs. 6.5±1.34, p=0.032) and better subjective image quality for abdomen (3.81±0.45 vs. 3.41±0.57, p≤0.001). There was nearly perfect accordance in size and number of metastases (102 target lesions, mean diameter 33.7±35.1 mm/33.3±34.8 mm, p=0.022, correlation r≥0.999, p≤0.001).
Conclusion: Reduced dose intermediate tube voltage CT provides a comparable diagnostic confidence regarding presence and extent of metastases at 27% dose reduction compared to standard dose DECT for staging of melanoma.

B-1102 10:46

Automated tube potential selection in cancer staging on a third-generation dual-source CT: comparison to second generation dual-source CT
M. Beeres, C. Park, C. Frellesen, J.L. Wichmann, J.E. Scholtz, M. Albrecht, A.M. Bucher, B. Bodelle, T.J. Vogl; *Frankfurt a. Main/DE (beeres@gmx.net)*

Purpose: Evaluation of latest generation automated attenuation-based tube potential selection (ATPS) impact on image quality and radiation dose in contrast-enhanced chest-abdomen-pelvis CT examinations for gynaecological cancer staging.
Methods and Materials: This IRB approved single-centre, retrospective study included a total of 100 patients with contrast-enhanced chest-abdomen-pelvis CT for gynaecological cancer staging. All patients were examined with ATPS for adaption of tube voltage to body habitus. 50 patients on a third-generation dual-source CT (DSCT), and another 50 patients on a second-generation DSCT. Predefined image quality setting remained stable between both groups at 120 kV and a current of 210 Reference mAs. Subjective image quality assessment was performed by two blinded readers independently. Attenuation and image noise were measured in several anatomic structures. Signal-to-noise ratio (SNR) was calculated. For the evaluation of radiation exposure, CT dose index ($CTDI_{vol}$) values were compared.
Results: Diagnostic image quality was obtained in all patients. The median $CTDI_{vol}$ (6.1 mGy, range 3.9-22 mGy) was 40% lower when using the algorithm compared with the previous ATCM protocol (median 10.2 mGy·cm, range 5.8-22.8 mGy). A reduction in potential to 90 kV occurred in 19 cases, a reduction to 100 kV in 23 patients and a reduction to 110 kV in 3 patients of our experimental cohort. These patients received significantly lower radiation exposure compared to the former protocol.
Conclusion: Latest generation automated ATPS on third-generation DSCT provides good diagnostic image quality in chest-abdomen-pelvis CT while average radiation dose is reduced by 40% compared to former ATPS protocol on second-generation DSCT.

B-1103 10:54

Radiation dose reduction with venous-arterial MDCT in breast cancer patients

A. Meldo, I. Burovik; *St. Petersburg/RU (anna.meldo@yandex.ru)*

Purpose: Traditionally in oncology biphasic CT (arterial and venous phases) is used. The new approach in MDCT - venous-arterial phase (VAP) in breast cancer patients is presented.
Methods and Materials: Venous-arterial MDCT is a technique, which composes characteristics of arterial and venous phases in one scanning - venous-arterial phase (VAP). To obtain VAP we divided contrast bolus is 2 parts (2:1). Next we programmed scanning protocol so that the end of the second bolus part corresponded to the 60th sec from the beginning of the first one. ROI of "bolus tracking" was set to the aorta. It started scanning according to the second part of the bolus. Thus, the first part of the bolus provides a venous phase image, the second one provides an arterial phase image. 50 patients with primary breast cancer were examined. We compared the density of the tumour, pulmonary artery, thoracic aorta in the native, arterial phases and VAP.
Results: CT density of the tumour in arterial and native phases was equal (36±9 HU and 33±8 HU, $p>0.05$). We find a statistically significant increase of breast tumour density in VAP (69±14 HU, $p<0.05$). Enhancement of pulmonary artery and aorta in VAP and in arterial phase was identical (PA: 270±58 HU and 272±47 HU, $p>0.05$; A: 234±46 HU and 249±40 HU, $p>0,05$). Method was patented in Russia (№ 2556619).
Conclusion: The venous-arterial MDCT is effective method for visualization of breast cancer and mediastinal vessels. Radiation dose is reduced in comparison with traditional biphasic scanning.

B-1104 11:02

Added value of the virtual non-calcium technique for the detection of bone metastases with computed tomography in breast cancer patients

L.J. Claeys, J. Alexiou, J. Moreau, S.-L. Chao, M. Lemort; *Brussels/BE (lionel.claeys@gmail.com)*

Purpose: To evaluate the added value of the virtual non calcium technique (VNC) on the diagnostic performance of conventional Computed Tomography (CT) for the detection of bone metastases (BM).
Methods and Materials: This single-center study approved by the institutional ethics committee was based on retrospective interpretation of prospectively acquired data. Fifty patients with known breast cancer who underwent dual-energy CT (DECT) and whole-spine MRI (the standard of reference) were included after signing informed consent. The presence of BM was assessed on MR images with a vertebra-based and patient-based analysis by one blinded independent reader. Sensitivity, specificity and matched pair analyses for reading CT images alone and when combining CT with VNC were determined based on the results of 2 readings sessions, separated by a 4 weeks interval, with 2 independent blinded readers. Cohen's kappa coefficient was used for interobserver agreement evaluation.
Results: Twenty-nine patients and 381 vertebrae showed BM at MRI. The impact of VNC images on the diagnostic performance of the readers was contradictory but no statistically significant difference was shown by the matched pair analyses but for the greater specificity of CT alone for the vertebra-based analysis for one of the readers. The interobserver agreement was excellent for both CT and CT with VNC images (kappa=0.85 and kappa=0.82 respectively) but was moderate for VNC-only images (kappa=0.51).
Conclusion: In our study, the VNC technique showed no added value to the detection of bone metastases in breast cancer patients.

B-1105 11:10

Diffusion whole-body MRI (DWB) in the management of metastatic breast cancer patients

F. Zugni, P. Pricolo, P.E. Summers, M. Iorfida, M.A. Colleoni, M. Bellomi, G. Petralia; *Milan/IT (fabio.zugni@unimi.it)*

Purpose: To compare the clinical impact of diffusion whole-body MRI (DWB) in the management of patients with metastatic breast cancer (BC), with computed tomography (CT) and CT with ^{18}F-FDG positron emission tomography (PET/CT).
Methods and Materials: A retrospective audit was performed of all DWB examinations performed on patients with BC between 2012 and 2015, who had undergone CT or PET/CT (control examination). All DWB were acquired on the same 1.5 T scanner (Avanto Siemens, Erlangen). Clinical records were consulted to assess whether the findings on DWB and on the control examination determined a therapeutic change.
Results: 472 DWB examinations were identified, of which 51 had a control examination (median time between examinations = 35 days). In 34/51 examinations, DWB and the control examination had comparable findings, leading to concordant disease assessments and therapeutic management. In 17/51 examinations, DWB and the control examination had discordant findings: one PET/CT showed disease undetected by DWB, with a subsequent therapeutic change, and 16 DWB showed metastatic disease undetected by the control examination, leading to a therapeutic change in 12 cases (12/51 cases, 23%). Notably, 7/12 of these were in a subgroup of 20 DWB performed in patients with invasive lobular BC.
Conclusion: DWB increased the detection of metastatic disease over CT and PET/CT, leading to therapeutic changes for nearly one fifth of all cases. This initial observation encourages us to implement DWB in the management of patients with BC, and draws interest in the dedicated use of DWB for invasive lobular BC patients.

B-1106 11:18

Oncological staging of 30 pregnant patients with diffusion whole-body MRI (DWB)

F. Zugni, P. Pricolo, S. Alessi, P.E. Summers, F.A. Peccatori, M. Bellomi, G. Petralia; *Milan/IT (fabio.zugni@unimi.it)*

Purpose: To evaluate the feasibility of diffusion whole-body MRI (DWB) for the systemic staging of tumours in pregnant women.
Methods and Materials: Between 2011 and 2015, 30 patients with a tumour diagnosed during pregnancy underwent DWB examination for staging on a 1.5 Tesla scanner (Avanto, Siemens, Erlangen) without administration of contrast agent, by means of both morphological and diffusion-weighted sequences. All images were prospectively reviewed by an expert oncological radiologist and by one in training. Data regarding tumour histology, pregnancy history and tumour treatment were collected. Suspicious findings were reassessed through either histopathology or further imaging studies.
Results: The patients (median age = 34 years, median gestational age = 22.5 weeks) had histories of breast carcinoma (22 cases), lymphoma (5 cases), and one case each of lung adenocarcinoma, colon adenocarcinoma and melanoma. All DWB examinations were completed successfully and were readable. DWB led to a diagnosis of metastatic disease in 13 patients, distributed as follows: 8 breast cancer patients (regional lymph-nodes confirmed at pathology, and in 2 cases bone metastases confirmed at follow-up DWB), 4 lymphoma (supra-diaphragmatic lymph-nodes confirmed by postpartum CT or PET/CT) and one lung adenocarcinoma (brain, skeleton, abdomen and chest metastases confirmed at a follow-up MRI). In one patient, the DWB finding was not confirmed (breast nodule benign at biopsy). In the remaining 16 patients DWB revealed no suspicious findings.
Conclusion: DWB was feasible for the staging of patients with tumour during pregnancy, thus providing a systemic staging without contrast agent administration and exposure to ionizing radiation.

B-1107 11:26

Whole-body MRI as the method of choice during oncologic follow-up at 3T: outcome after 400 examinations

A. Malich, D. Wiech, A. Kott; *Nordhausen/DE (ansgar.malich@shk-ndh.de)*

Purpose: Whole-body MRI might be a beneficial diagnostic option in the oncological follow-up, providing information beyond the detection of bone metastatic lesions. However, it has been criticised due costs, scanning times, number of incidental co-findings, triggering inevitable but frequently unnecessary additional imaging causing raise of follow-up-costs. In the current study we investigated the impact of 400 3T-based MR-examinations at 380 patients.
Methods and Materials: 400 whole-body-MRI scans: mDixon:T1w +/-contrast uptake; whole-body STIR:3mm slice thickness; 3T:Philips-Ingenia were analysed (exclusively oncologic patients) comparing diagnostic outcome to clinical data (follow up +1y), other diagnostics (ultrasound, x-ray, scintigraphy), incidental findings requiring additional investigation and its relevance.
Results: The average scanning time was 64min. In 135cases osseous metastases were described, in 64 cases scintigraphy was performed matching with MRI in 84%. Overall 126 patients underwent additional MRI within 1year after whole-body-MRI, just 39 cases (9.7%) in order to clarify findings of whole-body MRI. In 45 cases an additional tumour like finding was reported; in 50 cases other surgically or orthopaedically relevant findings were described. Other than bone metastases were found in 88 cases.
Conclusion: Total body MRI is a sensitive, precise and reliable tool in the oncological follow-up routine, sufficient to replace current standards-of-care such as basic ultrasound, bone scintigraphy or conventional imaging. Increased sensitivity in detection of metastatic and other tumour-like lesions sufficiently counteracts cost of incidental findings, which are within acceptable limits. The realistic limitations remain the scanning time and MR-availability.

B-1108 11:34

Assessment of informativity between static scintigraphy and full-body magnetic resonance imaging examinations in children with metastatic bone disease at Riga, Latvia

J. Baronenko, L. Štelce, I. Apine; *Riga/LV (jevgenijs.baronenko@gmail.com)*

Purpose: To evaluate retrospectively all the paediatric patients with primary malignant tumours examined at Children's Clinical University Hospital, Riga, Latvia, with both static bone scintigraphy and whole-body MRI (DWIBS) with proven cancer for assessment presence of bone metastases (MTS). To compare informativity of bone MTS identification in children with malignant tumours between full-body MRI DWIBS and the static scintigraphy.
Methods and Materials: A retrospective study was conducted based on data from clinical history and radiology reports from the hospital and radiology information systems from January 2013 till September 2016.
Results: The analysis of totally 61 patients under the age of 18 with histologically confirmed cancer was performed. Only patients who underwent both SC and MRI DWIBS examinations were studied. Bone metastases were found in 12 cases. Of them: 5 cases included multiple bone MTS in both SC and MRI DWIBS, 2 cases included multiple MTS in SC whereas MRI DWIBS did not show MTS, in 4 cases MTS were detected in MRI DWIBS whereas SC did not show MTS, in 1 case MRI DWIBS revealed multiple MTS whereas SC showed only 1 metastasis.
Conclusion: According to our study data, both investigation methods finding metastases in bones had the same results in less than half of the patients. When the results differed, MRI DWIBS was more accurate in diagnosing bone MTS. The sensitivity of both radiological investigation methods is most likely to depend on the histological type of cancer. A further cohort with increased number of participants is necessary.

Diffusion-weighted MRI of solid bone tumours of the spine: the diagnostic value of the apparent diffusion coefficient

G. Pozzi, C. Messina, G. Cannella, J. Almolla, A. Zerbi, L.M. Sconfienza; *Milan/IT (carmelomessina.md@gmail.com)*

Purpose: To evaluate the utility of the mean apparent diffusion coefficient value (m-ADC) in differentiating between benign and malignant solid bone tumours of the spine.
Methods and Materials: We reviewed MRI images of 107 patients with biopsy-proven spinal tumours (ST) who underwent 1.5 T MRI with T1, T2 and DWI (b values: 0 and 1000 s/mm²) sequences between January 2010 and June 2015. Two radiologists independently measured m-ADC by placing region of interest in both pathologic and normal bone, and findings were compared to histology (reference standard). ST were classified into three groups: malignant primary tumours (MPT), bone metastases (BM) and benign primary tumours (BPT).
Results: M-ADC values of MPT (N=30), BM (N=63) and BPT (N=14) were: 0.99 (0.59-1.47) x 10^{-3} mm^2/sec, 1.05 (0.73-1.96) x 10^{-3} mm^2/sec and 1.34 (0.83-2.14) x 10^{-3} mm^2/sec, respectively. M-ADC showed significant difference between benign and all malignant lesions (p=0.008), between BM and BPT (p=0.04) and between MPT and BPT (p=0.02). No statistical difference was found between BM and MPT (p=0.09). Normal bone showed ADC values lower than those of bone lesions (m-ADC = 0,33 x 10^{-3} mm2/sec). ADC measurements had almost perfect interobserver correlation (average intraclass correlation coefficient = 0.97).
Conclusion: M-ADC values of BPT showed to be higher than malignant ST with almost perfect interobserver correlation. In association with conventional MRI sequences, ADC values can be a useful tool in differentiating between benign and malignant bone tumours of the spine.

B-1110 11:50

Added diagnostic value of complementary gadoxetic acid-enhanced MRI to ^{18}F-DOPA-PET/CT for liver staging in medullary thyroid carcinoma

P.M. Kazmierczak, A. Rominger, M. Brendel, W. Kunz, R. Stahl, J. Sargsyan-Bergmann, C. Spitzweg, M.F. Reiser, C.C. Cyran; *Munich/DE (Philipp.Kazmierczak@med.uni-muenchen.de)*

Purpose: To investigate the added diagnostic value of complementary gadoxetic acid-enhanced MRI to ^{18}F-DOPA-PET/CT for liver staging in medullary thyroid carcinoma (MTC).
Methods and Materials: 29 consecutive Patients (n=17 f, n=12 m, median age 58 years) with histologically confirmed MTC undergoing gadoxetic acid-enhanced liver MRI within one month of matching contrast-enhanced ^{18}F-DOPA-PET/CT between 2010 and 2015 were selected for retrospective analysis. ^{18}F-DOPA-PET/CT and multiparametric MRI data sets were read consecutively and liver lesions were categorized on a 5-point scale analogously to the LI-RADS criteria (1-definitely benign; 2-probably benign; 3-intermediate risk for metastasis; 4-probably metastasis; 5-definitely metastasis). It was noted if gadoxetic acid-enhanced MRI detected additional, ^{18}F-DOPA-PET/CT-occult metastases (category 5) or if gadoxetic acid-enhanced MRI allowed for a definite classification (categories 1 and 5) of lesions for which ^{18}F-DOPA-PET/CT remained inconclusive (categories 2-4).
Results: A total of n=141 liver lesions (^{18}F-DOPA-PET/CT n=107, MRI n=141; n=99 metastases, n=27 benign cysts, n=15 hemangiomas) were analyzed. N=34 additional lesions were detected by MRI, of which n=30 were additional metastases (median diameter 0.5 cm [0.4 - 1.9 cm]) occult on ^{18}F-DOPA-PET/CT. MRI allowed for a definite lesion classification (categories 1 and 5) in 89 % (125/141) (^{18}F-DOPA-PET/CT 69 %, n=74/107). MRI lead to a change in lesion categorization in n=17 cases (from category 2 to 1: n=10; from category 3 to 1: n=3; from category 4 to 5: n=4).
Conclusion: Gadoxetic acid-enhanced MRI allows for a more accurate liver staging in MTC patients compared to ^{18}F-DOPA-PET/CT alone, particularly for ^{18}F-DOPA-negative metastases and lesions <1 cm.

Motion vector field upsampling for precise respiratory motion compensation with cone-beam CT of the thorax region

S. Sauppe[1], C.M. Rank[1], M. Brehm[2], P. Paysan[2], D. Seghers[2], M. Kachelrieß[1]; [1]*Heidelberg/DE*, [2]*Baden-Dättwil/CH (Sebastian.Sauppe@dkfz.de)*

Purpose: To improve the accuracy of motion vector fields (MVFs) required for motion-compensated (MoCo) CT image reconstruction.
Methods and Materials: On-board CBCT images for radiation therapy suffer from patient respiratory motion artefacts. However, accurate information about patient motion is useful for precise radiation therapy. While respiratory gating improves the temporal resolution it leads to sparse view sampling artefacts. MoCo image reconstruction is able to significantly reduce motion artefacts while utilising 100% of the acquired data. In some cases, however, the MVF accuracy is still to be improved. We developed an approach to upsample MVFs (estimated by the our acMoCo algorithm) and thereby to double the temporal samples without increasing the reconstruction time. Our upsampling strategy interpolates the original MVFs by incorporating respiratory amplitude to drive the interpolation weights. For validation we use an artificially deformed clinical CT scan and patient data. We varied the upsampling factor (UF) from 2 up to higher values. The entropy and total variation (TV) are used as an image quality measure.
Results: For both phantom and patient data, in-phase motion blurring was considerably decreased when using MVF upsampling. This is visible in the reconstructed images and is reflected in an improved entropy (10.1%) and TV value (6.5%). It turns out that UF=2 produces the most significant improvement regarding image quality and is the optimal choice in terms computation time.
Conclusion: Upsampling the MVFs can improve the quality of the MoCo reconstruction substantially without increasing acquisition time, patient dose, streak, or noise artefacts.

B-1112 10:38

Inflow effect correction in fast gradient-echo dynamic contrast-enhanced imaging in vitro and in vivo

F. Bidault[1], H. Wang[2], B. Asselain[1], K. Rachid[2], D. Rodríguez[2], X. Maître[2], N. Lassau[1]; [1]*Villejuif/FR*, [2]*Orsay/FR (francois.bidault@gustaveroussy.fr)*

Purpose: The inflow effect in the arteries (flow-related enhancement (FRE)) leads to a biased assessment on the Arterial Input Function (AIF) and further on the perfusion quantification. Here, the goal was to develop a correction method based on pre-saturation pulses in flow apparatus and applied to measure the AIF in the carotid of patients.

Methods and Materials: MR-compatible flow apparatus [CardioFlow 5000MR] generated a closed-circuit, mimicking-blood flow of glycerol-water to determine FRE versus velocity (0-50 cm/s). MRI was performed on 3T PET-MR [GE SIGNA] with head-neck coil using multi-phases Fast-SPGR and LAVA sequences with clinical practice-based parameters. Spatially-selective saturation bands (1-4 cm) were applied at imaging slab upstream to suppress FRE. To assess FRE with contrast agent (CA), MR injection system [Bayer MEDRAD] generated continuous flow (10 mL/s) of Gd-DOTA solution (0, 2.5mM) into an open-circuit. Same sequences were performed without and with pre-saturation (4cm). All acquisitions were repeated 5 times. The method was further applied to patients (n=4).
Results: FRE increased with velocity without pre-saturation. Saturation bands of 3 or 4cm allowed suppressing significantly FRE (6-fold FRE for SPGR and 17-fold for LAVA with v=20cm/s). In presence of CA, significant increase (one-way ANOVA, $p<0.01$) was observed in SI without pre-saturation compared to static reference, while pre-saturated SI was comparable to reference. The correction allowed obtaining more precise AIF in the carotid of patients with both sequences, compared to flat curves without pre-saturation.
Conclusion: The proposed method corrects efficiently FRE and provides a better precision on the AIF measurement.

Reanimating patients using motion transfer: a cardiorespiratory motion ground truth based on clinical CT patient data

J. Mayer, S. Sauppe, C.M. Rank, M. Kachelrieß; *Heidelberg/DE (johannes.mayer@dkfz.de)*

Purpose: Respiratory and cardiac motion often leads to artefacts in CT, e.g. in cone-beam CT (CBCT) scans in radiation therapy or during interventional imaging. Our aim is to provide volumetric cardiac and respiratory motion ground truth (GT) patient data to optimize imaging protocols or to evaluate image reconstruction algorithms.
Methods and Materials: We developed a method that transfers motion extracted from a 4D CT scan of a source patient onto the anatomy of a motion-free destination patient. For the motion transfer (MT) the cardiac or respiratory motion vector fields (MVFs) of a source patient are determined. These are warped onto the destination anatomy with a deformable map describing the geometric relation between source and destination patient. The resulting MVFs serve as the motion information GT in the destination anatomy. Thereby 4D or 5D volumes without motion artefacts can be generated. We evaluated our recently developed motion compensation (acMoCo) algorithm, simulating a CT scan with gantry rotation speeds of 3° and 6°/s with the reanimated destination patient serving as the GT.
Results: MT was used to generate 4D cardiac CT and 4D respiratory MR data. By definition the transferred motion is correct in the destination anatomy. The evaluation of the acMoCo algorithm indicated an accuracy of about 1 mm in MVF estimation on average.
Conclusion: The MVF ground truth based on patient data provides an improved framework to quantify MoCo algorithms and to design optimised imaging protocols. It may thus help to bring these algorithms and scan modes into clinical routine.

Diffusion coefficient and perfusion fraction parameters correlate with gestational age in normal human in vivo placenta: a preliminary study

A. Antonelli, M. Guerreri, A. Di Paolo, S. Bernardo, S. Capuani, C. Catalano, L. Manganaro; *Rome/IT (amanda.antonelli@hotmail.it)*

Purpose: To investigate the potential of diffusion parameters derived from a bi-exponential analysis as marker to evaluate the perfusion quality of normal in vivo placenta.
Methods and Materials: 18 normal pregnancies, fulfilling the study inclusion criteria, have been analysed at 1.5 T Magnetom Avanto (Siemens, Erlangen, Germany) without mother-foetal sedation. DW imaging was collected using seven b values: 0, 50, 100, 150, 400, 700, 1000 (s/mm²). Three regions of interest (ROIs) have been considered - central (C), peripheral (P) and umbilical (U) regions. A bi-exponential model was used to obtain perfusion fraction (f), pseudo-perfusion (D*) and apparent diffusion (D) coefficients. Pearson test was performed to investigate correlation between diffusion parameters and gestation weeks (GW), body mass index (BMI) and basal glycaemia (bG).
Results: The average values on all ROIs were $D=1.41\pm0.16\cdot10^{-3}$ (mm²/s), $D^*=1.81\pm1.28\cdot10^{-2}$ (mm²/s), $f=3.28\pm0.18\cdot10^{-1}$, in good agreement with the literature. In the C ROI, a positive correlation ($p<0.04$) was observed between f and GW. After 30 GW in the P ROI a positive correlation between f and GW ($p<0.05$) and a negative correlation between D and GW ($p<0.0001$) were found. No correlation was found between D, D*, f, BMI and bG.
Conclusion: The f increase reflects normal placenta perfusion physiology. On the other hand, the decrease of D highlights placental parenchyma maturation becoming more fibrotic during late gestational age. Bi-exponential model provides more and useful information about placental morphological changes compared to mono-exponential diffusion model.

B-1115 11:02

Detection rates of simulated microcalcifications in FFDM, Synthetic-2D and DBT using an antropromorphic phantom model

K. Krug[1], S. Peters[2], M. Hellmich[1], M. Püsken[1], O. Grinstein[1], L. Stahlhut[1], A. Storck[3], J. Kemper[1], D. Maintz[1]; [1]*Cologne/DE*, [2]*Wennigsen/DE*, [3]*Düsseldorf/DE (Barbara.krug@uk-koeln.de)*

Purpose: To compare the microcalcification detectability in an anthropomorphic phantom model in full-field digital mammography (FFDM), synthetically reconstructed two-dimensional images (Synthetic-2D) and digital breast tomosynthesis (DBT).
Methods and Materials: Simulated microcalcifications of different numbers, sizes and shapes were randomly scattered on 50 film phantoms each divided in 4 quadrants. FFDM and DBT x-rays were taken of each film with both x-ray mammography systems (SenoClaire, GE, Selenia Dimensions, Hologic) using an anthropomorphic scattering body and automatic exposure control. The exposure factors were similar to a clinical setting. Synthetic 2D-images were generated automatically on both systems. All FFDM, Sythetic-2D and DBT images were interpreted in randomised order and independently of each other by 6 radiologists using a structured questionnaire.
Results: The number categories of simulated microcalcifications were correctly evaluated in 55.3% of instances in FFDM, 50.9% in Synthetic-2D and 59.5% in DBT, summarised for 200 quadrants per reader for each device. FFDM was superior to Synthetic-2D (mean difference 4%, 95% CI 2-7%, $p<0.001$) and DBT was superior to both FFDM (4%, 2-7%, $p = 0.002$) and Synthetic-2D (9%, 6-11%, $p<0.001$). This trend was consistent in all subgroup analyses. The number of the smallest microcalcifications (100-399µm) was correctly evaluated in 25.2% of the FFDM, in 14.2% for Synthetic-2D and in 28.3% of the DBT images.
Conclusion: In the presented in-vitro environment standard FFDM was superior to Synthetic-2D in the detection of simulated microcalcifications. Further investigations are needed to assess the clinical impact of the in-vitro results.

B-1116 11:10

Model observer approach applied to an innovative method for LCD assessment in mammography: comparison with CDMAM evaluation including psychometric correction

R. Villa[1], N. Paruccini[1], N. Oberhofer[2], C. Spadavecchia[1], A. Baglivi[1], A. Crespi[1]; [1]*Monza/IT*, [2]*Bolzano/IT (raffaele.vill@gmail.com)*

Purpose: In mammography image quality assessment is usually carried out by automated low contrast detectability (LCD) evaluation of the CDMAM phantom (Artinis, The Netherlands) with psychometric correction for human observer. The current study proposes a different approach where human detection performance was evaluated with a Model Observer.
Methods and Materials: LCD, expressed in terms of mmAl and contrast, was estimated by means of a homemade phantom and a dedicated MATLAB software exploiting a statistical approach requiring only single images. The effect of human perception was considered through a NPWE model observer. The internal eye noise was introduced with a response degradation factor while the eye response function was evaluated for different distances between the observer and the screen. Method parameters were derived from 2D mammography images acquired on five equipment of different manufacturers with different exposure parameters and phantom thickness. Human detection of 95% was considered. A comparison with CDMAM results associated with the same acquisition parameters was carried out.
Results: The conversion curve produced by the model observer resulted to be independent from both the acquisition parameters and the equipment (percent error 4,5%). For each equipment the agreement with the psychometric corrected CDMAM analysis was very good, with a mean difference of 9% (1% to 19%).
Conclusion: The statistical approach with model observer correction resulted in accordance with the psychometric corrected automatic readout of CDMAM images, being less time-consuming compared to CDMAM analysis . Thus, the current method could be applied in image quality assurance protocols.

B-1117 11:18

Radiation dose comparison between photon counting and selenium mammography technology

R. Salvador Tarrason, K. Piccotti, X. Salvador Izquierdo, M. Vallespi, N. Riquel; *Barcelona/ES (rafasalvador@imaginebarcelona.com)*

Purpose: To compare the radiation dose received by patients during a screening mammography exam for breast cancer with a photon counting detector (PhC) and a selenium detector (Se).
Methods and Materials: This study includes patients who had mammography exam between June 2013 and December 2014, with the PhC (Philips MicroDose SI) and an exam with the Se (Fujifilm Amulet) within a two years period. Patients with missing paired organ radiation dose data were excluded

from this study. The exposure was compared between both examinations for each patient, by age group (<40, 40-49, 50-59 and >60), and breast density groups (A, B, C and D). Linear mixed models were used to compare radiation dose. Least square means (LSM) and 95% confidence intervals (CI) were estimated. The hypothesis of no differences in mean radiation exposure was evaluated using an F-test. All analyses were conducted using SAS version 9.3.
Results: 2286 women were included. The mean age 57 years. LSM estimates and CI for overall mean radiation dose for the Se and PhC showed a difference of 0.88mGy (0.84 - 0.92), p<0.0001 . Higher radiation was observed for Se in all the subgroups evaluated; 0.44 mGy (0.42 - 0.46). The dose differences by age subgroups were: 1.33; 1.06; 0.84; and 0.77 mGy. And for A to D breast density subgroups were: 0.75mGy, 0.64 mGy, 1.04 mGy and 1.68 mGy.
Conclusion: The use of PhC resulted in a significant radiation reduction. Most benefit was observed in younger patients and in patients with dense breast.

B-1118 11:26

Dose data in mammography: what a dose management software can tell us?

C. Heilmaier, E. Kummer, N. Zuber, D. Weishaupt; *Zurich/CH (christina.heilmaier@triemli.zuerich.ch)*

Purpose: Mammography is a frequently performed screening examination, thus, radiation protection is essential. The purpose of the present study was to establish local diagnostic reference levels (DRLs) for mammography with a dose management software, taking into account the differences in breast types.
Methods and Materials: Dose data of full-field digital mammographies (FFDM) conducted in a 6-month-period was analyzed with a dose management software (DoseWatch®, GE Healthcare). Analysis was carried out separately for cranio-caudal (CC)- and medio-lateral-oblique (MLO)-views, which were further subdivided concerning compressed breast thickness (CBT; <4 cm, ≥4-6 cm, ≥6 cm), glandular fraction (≤50 %, >50 %) and compression force applied (low, standard, high). Analysis focused on entrance surface air kerma (ESAK), average glandular dose (AGD), compression force, and CBT and included descriptive statistics, Mann-Whitney U tests and Spearman rank correlation coefficients.
Results: Analysis of n = 3,454 mammographic images revealed mean values ± standard deviation (ESAK/AGD/CBT/compression force) as follows: 7.07±3.19 mGy/1.55±0.48 mGy/4.87±0.96 cm/100.8±37.0 Newton (N), respectively. ESAK, AGD and CBT was considerably higher in MLO-compared to CC-views, in which higher compression force was seen (for all, P<0.001). Compared to smaller breast, CBT and ESAK/AGD correlated stronger in larger breasts with CBT ≥6 cm. In breasts with the same CBT, ESAK- and AGD-values were higher in the group with glandular fraction >50 %.
Conclusion: A dose management software in mammography allows obtaining local DRLs, which are specific for several breast types. As proven in the present study, CBT is the strongest indicator to predict radiation exposure to the breasts.

B-1119 11:34

Performance characterisation of digital breast tomosynthesis systems: the need for a standardisation

M. Chevalier, M. Castillo-García, A. Rodríguez-Ruiz, D. García-Pinto; *Madrid/ES (chevalier@med.ucm.es)*

Purpose: To evaluate possible dependencies on material, size, and position of test objects used in performance characterization and quality control (QC) of digital breast tomosynthesis (DBT) systems.
Methods and Materials: Four different DBT systems (A,B,C,D) underwent the same testing procedure, with testing objects of different size and material, placed at different locations. Modulation transfer function (MTF) of the projections was measured with a steel edge (1mm thick), positioned at different heights above the table. In-plane MTF of the reconstructed planes was estimated with an aluminium (Al) edge (0.1mm thick) and tungsten (W) wires of different diameters (25, 50, 100µm), at fixed height. Similar wires (but tilted) were used to calculate the in-depth PSF. Artefact spread function (ASF) was computed with 1 mm diameter W and Al beads, placed at different (x,y,z) locations.
Results: Projections' MTF on the tube-travel direction depends on height for systems that use a continuous tube motion (-42% averaged decrease in $MTF_{50\%}$ frequency from 0mm to 70mm). In-plane MTF in the anode-cathode direction improves with decreasing wire diameter (a factor 1.7 in average), but the 25µm wire often splits. In-plane MTF results from edge and wires are compatible. In-depth PSF does not differ with wire diameter. ASF values and their reproducibility change randomly across the bead (x,y) position, but are independent of height and material.
Conclusion: DBT performance parameters show a different dependency on material, size, and position of test objects to be taken into account when developing phantoms for QC of DBT systems.

B-1120 11:42

Adjustment of x-ray measuring instruments for a new x-ray beam quality for mammography

R. Klausz, F. Mattana, Y. Popova, A. Guerin, F. Jeunehomme Patoureaux; *Buc/FR (remy.klausz@ge.com)*

Purpose: Currently available semi-conductor based x-ray beam measuring instruments (air-kerma, kVp) may not be operating per specifications when used with a newly introduced mammography x-ray beam quality. The process and results of introducing new adjustments are described.
Methods and Materials: One year before the planned introduction of a mammographic equipment featuring a new beam quality (rhodium anode, 30 µm silver filter) three leaders in x-ray measuring instruments were contacted, and detailed characteristics of the new beam quality shared with them. When needed they designed new adjustments for measuring air-kerma, single-shot Half-Value-Layer (HVL), and High Voltage (HV) for their respective measuring instruments. Measurements with adjusted instruments were compared with reference measurements performed on prototype mammographic equipment, using mammography-dedicated ionisation chamber dosemeters, high accuracy aluminium sheets, and invasive voltage dividers.
Results: Depending on manufacturers the final adjustments were obtained 12 to 16 months after initial contacts. The current uncertainty specifications were extended to the new beam quality. Maximum measured deviations vs. references between 27 and 40 kV for the three instruments were respectively 1%, 0,7% and 2% for HV, 0,2%, 0,5% and 3% for air-kerma, and 4%, 0.6% and 4% for one-shot HVL.
Conclusion: It was possible to synchronize the availability of satisfactory x-ray measuring instruments with the first installations of the mammographic equipment featuring a new beam quality, allowing calibration at installation and acceptance testing. Adjustments and calibrations for the new beam quality are now available from three vendors for new measuring instruments or as an upgrade.

Evaluation of the effectiveness of a new x-ray beam quality in digital mammography

M. Rouxel, R. Klausz, Y. Le Meur, H. Souchay, R. Shi, F. Jeunehomme Patoureaux; *Buc/FR (marionrouxel@ge.com)*

Purpose: Evaluate the performances of a new anode/filter combination in digital mammography in terms of image quality, patient dose and patient comfort.
Methods and Materials: A rhodium anode/30µm silver filter combination was evaluated in comparison with rhodium anode/25µm rhodium. Using a spectral model, the signal-difference-to-noise-ratio (SDNR) of 0.2mm thickness aluminium, average glandular dose (AGD) and exposure times, were compared for 28-36kVp and 35-75mm PMMA thickness in 10mm steps. A factor of merit (FOM) equal to $SDNR^2/AGD$ was computed. The kVp ranges providing optimal FOM values per thickness were determined. The FOM values and exposure times were also compared at constant SDNR.
Results: For both anode/filter combinations the FOMs were found optimal within 5% between 29 and 34 kVp over the whole PMMA thickness range. For 35mm the FOM for Rh/Ag is lower than for Rh/Rh by less than 2%. At 45mm PMMA, FOM and exposure time are similar. At 55, 65 and 75 mm PMMA the FOMs are, respectively, 3%, 5-8% and 8-11% higher for Rh/Ag depending on kVp. At 34 kVp, exposure times are reduced by 5%, 8% and 10% at 55, 65 and 75 mm PMMA with RhAg compared to Rh/Rh.
Conclusion: With a rhodium anode, replacing the rhodium filter with a silver filter allows improving the FOM with shorter exposure times. This reduces the risk of patient movement, improves her comfort, and may benefit to the patient throughput.

The relationship between molecular subtypes of breast cancer and ADC values calculated with diffusion MRI
A. Tanyeri, F. Taşkin, M.B. Cildağ, V.S. Özturk, A. Ünsal, C.Z. Karaman; *Aydin/TR (dr.a.tanyeri@gmail.com)*

Purpose: To investigate the relationship between molecular subtypes of breast cancer and ADC values calculated with diffusion MRI.
Methods and Materials: 193 patients who had been preoperatively evaluated and diagnosed as breast cancer between January 2013 and January 2016 in our institution were retrospectively evaluated. ADC values of these lesions were calculated with diffusion MRI. These patients were classified according to the molecular subtypes of breast cancer. Difference between the average ADC values of each molecular subtype was compared. Independent sample T test was used for statistical analysis.
Results: Subtypes of breast cancer and average ADC values for each subtype in this study group were as following: luminal A (75 cases, 39%; ADC value: 0.96 ± 0.16), luminal B (68 cases, 35%; ADC value: 0.99 ± 0.15), triple negative (33 cases, 17%; ADC value: 1.02 ± 0.15) and Her-2 positive (17 cases, 9%; ADC value: 1.00 ± 0,12). Average ADC value for entire study population was 0.99+/-0.15 (range: 0.60-1.34). No statistically significant difference was found between the average ADC values of molecular subtypes of breast cancer.
Conclusion: Diffusion MR imaging contributes well to the diagnostic performance of breast MRI. Despite the slightly higher ADC values of triple-negative and HER2-positive groups, there was no significant relationship between molecular subtypes and ADC values in this study. On the contrary to morphologic MRI findings, ADC values may not contribute to distinguish the molecular subtypes of breast cancer. Further prospective and multicentre studies are needed to verify our findings.

B-1123 10:47

Correlating pericyte gene expression signatures with pharmacokinetic parameters of dynamic contrast enhanced MR and intravoxel incoherent motion imaging in invasive breast cancer
W. Tsai, K. Chang, K. Kao; *Taipei/TW (wctsai@kfsyscc.org)*

Purpose: To investigate whether quantitative dynamic contrast material-enhanced (DCE) parameters and intravoxel incoherent motion imaging (IVIM) are correlated with pericyte gene expression signature in invasive breast cancer.
Methods and Materials: With the IRB approval and signed informed consents from 119 breast cancer patients, we performed additional DCE breast MRI studies followed by diffusion-weighted images (DWI) at 11 b values values (from 0 to 1200 s/mm^2) on a 1.5T MR system before breast surgery. Gene expression profiling was conducted on fresh biopsy or frozen surgical breast cancer tissue. Expression of six genes (ACTA2, ANGPT1, CSPG4, LAMB1, PDGFRB and RGS5) associated with pericytes was measured and a combined expression score was determined by principal component analysis. Associations between quantitative parameters from DCE MRI (K^{trans}, K_{ep}, V_e, V_p), IVIM (D, f and D*), and the kinetic curve analysis, and pericyte gene signature scores were evaluated using Spearman's correlation analysis with a significance level of 0.05.
Results: Pericyte gene signature score showed significant negative correlation with DCE MRI parameters kep (r=-0.2544, p=0.0052), vp (r=-0.2429, p=0.0078) and max slope of signal increase(r=-0.2282, p=0.0133); and positive correlation with ve (r=0.3275, p=0.0003) and D(r=0.2675, p=0.0037).
Conclusion: Invasive breast cancer with higher pericyte gene score showed lower perfusion pharmacokinetic parameters (kep, vp), higher extra-vascular extracellular space (ve) and less restricted diffusion, which means fewer blood vessels and less leaky in tumour. These associations revealed that DCE-MR parameters could be considered in guiding anti-angiogenesis treatment of breast cancer.

B-1124 10:55

Correlation of diffusion-weighted apparent diffusion coefficient values with prognostic factors of invasive breast cancer
B. Ubeda, S. Vizcaya, J.L. Browne, F. Terrel; *Barcelona/ES (belube@dexeus.com)*

Purpose: To correlate the apparent diffusion coefficient (ADC) values of invasive breast cancer with pathological and molecular prognostic factors.
Methods and Materials: Magnetic Resonance (MR) and diffusion-weighted images (DWI) were retrospectively reviewed in 310 patients with pathologically proven invasive breast cancer (267 invasive ductal carcinoma (IDC), 34 lobular invasive carcinoma (ILC), 9 other types). DWI were acquired at b values of 0 and 600 s/mm^2. Mean ADC values were correlated with MR morphological type of lesion (mass vs non-mass), histological features and molecular subtypes. Histological evaluation included tumoUral type, tumour size and grade, expression of oestrogen and progesterone receptors (ER, PR), HER2 status and Ki67 index.
Results: Mean ADC values were 0.97 x 10^{-3} mm^2/s for IDC and 0.95 x 10^{-3} mm^2/s for ILC. No significant difference of ADC was found with tumour size or morphological type of lesion. Mean ADC value of grade I lesions was significantly higher than grade II and III lesions (0.998 ± 0.21 x 10^{-3} mm^2/s vs 0.96 ± 0.18 x 10^{-3} mm^2/s and 0.87 ± 0.86 x 10^{-3} mm^2/s). There was no significant correlation between ADC value and ER, PR and HER2 expression status. Mean ADC of Ki67 index positive cancers (0.934 ± 0.19 x 10^{-3} mm^2/s) was significantly lower than that of Ki67 index negative cancers (1.006 ± 0.21 10^{-3} mm^2/s).
Conclusion: Our study showed statistically significant association between ADC values and histological and molecular features of breast cancer related to increased cellular proliferation such as tumour grade and Ki67 index.

B-1125 11:03

Is DWI a stand-alone or complimentary parameter to DCE-MRI of the breast for cancer detection?
K. Pinker-Domenig[1], L. Moy[1], E. Sutton[1], M. Weber[2], M. Jochelson[1], S. Thakur[1], T.H. Helbich[2], E. Morris[1]; [1]*New York, NY/US*, [2]*Vienna/AT (pinkerdk@mskcc.org)*

Purpose: To assess whether DWI can serve as a stand-alone parameter for breast cancer detection and to compare it to DCE-MRI and multiparametric MRI (mpMRI).
Methods and Materials: In this IRB-approved retrospective study two experienced reader independently evaluated mpMRI of 110 breast tumours. DWI and DCE-MRIs were randomly assessed by independent review, i.e. readers assessed DWI without DCE-MRI and vice-versa. Additionally, mpMRI using the combined information of DWI and DCE-MRI were evaluated. Lesions were classified as normal/benign or suspicious and a BI-RADS classification was assigned. Histopathology was used as the standard of reference. Appropriate statistical tests were used to assess sensitivity, specificity and diagnostic accuracy for DWI, DCE-MRI and mpMRI.
Results: There were 42 benign and 68 malignant tumours. DCE-MRI was the most sensitive test for breast cancer detection (r1 100%, r2 97%). DWI as a stand-alone parameter was significantly less sensitive (r1 and r2=85%, p=0.001 and 0.003) but more specific (r1 and r2=86%, p=0.004 and 0.048) compared to DCE-MRI (r1=69%, r2=74%). MpMRI had a sensitivity of 96% for both readers,which was not significantly different from DCE-MRI (p=0.076 and 0.53) and a specificity almost as good as DWI (r1 81%, r2 86%, p=0.147 and 1) with the best diagnostic accuracy (r1 90%, r2 92%).
Conclusion: DWI cannot be used as a stand-alone parameter for breast cancer detection. DCE-MRI is the most sensitive test. MpMRI using DWI and DCE-MRI maintains a high sensitivity, increases specificity and maximises diagnostic accuracy for breast cancer.

B-1126 11:11

Synthetic biomarkers using IVIM and non-Gaussian diffusion MRI: diagnostic performance and comparison with BI-RADS categories in differentiation of malignant/benign breast tumours
M. Iima, M. Kataoka, S. Kanao, N. Onishi, M. Kawai, A. Ohashi, R. Sakaguchi, A.K. Ohno, K. Togashi; *Kyoto/JP (mamiiima@kuhp.kyoto-u.ac.jp)*

Purpose: To evaluate the diagnostic performance in differentiation of breast lesions using IVIM, non-Gaussian diffusion parameters and synthetic ADC, and compare the performance of DWI derived categories with BI-RADS categories.
Methods and Materials: 405 patients were prospectively enrolled and 210 lesions (malignant 158/ benign 52) were included. IVIM (fIVIM, D*) and non-Gaussian diffusion (ADCo, K) parameters using IVIM and Kurtosis model were estimated from DWI series with 16 b values up to 2,500 sec/mm^2. Synthetic ADC (sADC) obtained from different combinations of 2 key b values (200/1500, 400/1500, 400/2000, 600/2000 sec/mm^2) and standard ADC (0/800 sec/mm^2) were calculated. The IVIM/diffusion parameters in malignant and benign lesions were compared using Mann-Whitney test. Then, equivalent BI-RADS

categories were computed by mixing these IVIM/diffusion parameters, through two diagnostic approaches; combined parameter thresholds and Bayesian analysis. These categories derived from DWI datasets was compared with standard BI-RADs categories, by assigning category 2/3 as benign, while category 4/5 as malignant.
Results: All IVIM/diffusion parameters and sADCs were different between malignant and benign breast lesions (p< .01). AUC for sADC200_1500 was the highest (0.923). The sensitivity and specificity for diagnosis was 89.9% and 78.8% for sADC200-1500, 93.0% and 80.8% for the combined thresholds approach, 88.6% and 73.1% for Bayesian analysis, and 100% and 78.8% for BI-RADS.
Conclusion: Synthetic approaches combining various IVIM and non-Gaussian diffusion MRI parameters may provide BI-RADs equivalent category comparable to BI-RADS without the use of contrast agents. sADC showed a fairly high diagnostic performance for breast cancer.

B-1127 11:19

Is the necrosis/wall ADC ratio useful for the differentiation of benign and malignant breast lesions?

I. Durursubasi[1], A. Durur-Karakaya[2], A. Karaman[3], M. Seker[2], E. Demirci[3], F. Alper[3]; [1]*Ankara/TR*, [2]*Istanbul/TR*, [3]*Erzurum/TR (irmakdurur@yahoo.com)*

Purpose: To determine whether the necrosis/wall apparent diffusion coefficient (ADC) ratio was useful for the benign-malign differentiation of necrotic breast lesions.
Methods and Materials: Breast MRIs were performed using a 3T system. In this retrospective study, calculation of the necrosis/wall ADC ratio was based on ADC values measured from necrosis and from the wall of malignant and benign breast lesions by diffusion-weighted imaging (DWI). All the diagnoses were pathologically confirmed. Statistical analyses were performed with the independent samples t test and receiver operating characteristic (ROC) analysis.
Results: A total of 53 female patients were enrolled, 27 of whom had necrotic breast carcinoma and 26 of whom had breast abscess. ADC values were obtained from wall and necrosis. The mean necrosis/wall ADC ratio (±SD) of carcinoma was 1.49±0.26 and abscess was 0.61±0.11. The area under the curve (AUC) values for necrosis ADC, wall ADC and the necrosis/wall ADC ratio were 0.967, 0.027 and 0.991, respectively. A wall/necrosis ADC ratio cut-off value of 0.83 demonstrated a sensitivity of 100%, specificity of 93%, positive predictive value of 96%, negative predictive value of 92% and accuracy of 94% to determine the malign nature of a necrotic breast lesion.
Conclusion: Necrosis/wall ADC ratio seems to be a reliable and promising tool for discriminating breast carcinoma from abscess using DWI.

B-1128 11:27

Discrimination of malignant and benign breast masses using automatic segmentation and region of interest-based features extracted from MRI

X. Jiang, F. Xie, L.-Z. Liu, Y.-X. Peng, H.-M. Cai, L. Li; *Guangzhou/CN (jiangxh@sysucc.org.cn)*

Purpose: To investigate whether combining morphology, texture features and kinetic features with diffusion-weighted imaging (DWI) using quantitative analysis improves the accuracy of discriminating malignant from benign breast masses.
Methods and Materials: One hundred and four benign and 171 malignant lesions in 205 women were included. Thirteen texture and eleven morphology features were computed from each lesion using a semi-automated segmentation method. To increase prediction accuracy, a newly designed classification model, difference-weighted local hyperplane (DWLH), was used for statistical analysis of the combined effects of the features for predicting lesion type. The mean apparent diffusion coefficient (ADC) value for each lesion was calculated. Diagnostic performances of morphology and texture features, kinetic features and ADC alone and the combination of them were evaluated using receiver operating characteristics analysis.
Results: Malignant lesions had lower mean ADCs than benign lesions. By using ten-fold cross validation scheme, combined morphological and kinetic features achieved a diagnostic average accuracy of 0.87. Adding an ADC threshold of 1.37 × 10−3 mm2/s increased the overall averaged accuracy to 0.90. A multivariate model combining ADC values with six morphological and kinetic parameters best discriminated malignant from benign lesions.
Conclusion: Incorporating morphology and texture features, kinetic features and ADC into a multivariable diagnostic model improves the discriminatory power of breast lesions.

B-1129 11:35

Comparison between mono-exponential Gaussian diffusion and non-Gaussian kurtosis model for breast lesions evaluation

A. Christou[1], A. Ghiatas[2], D. Priovolos[2], K. Veliou[3], H. Bougias[3]; [1]*Doncaster/UK*, [2]*Athens/GR*, [3]*Ioannina/GR (alexandrachristou@gmail.com)*

Purpose: To compare Gaussian and non-Gaussian diffusion models in the characterisation and differentiation of breast lesions.
Methods and Materials: 49 patients with 53 breast lesions underwent magnetic resonance imaging (MRI). Diffusion-weighted imaging (DWI) was acquired on a 1.5T MRI utilising 5 b-values (0,400,800,1100,1300). The median ADC, Dapp (non-Gaussian apparent diffusion coefficient) and K (kurtosis) were calculated from the whole-lesion histogram analysis and compared by the Mann-Whitney U test (level of significance set at 0.05). Receiver operating characteristics (ROC) analysis was used to determine the most effective cut-off values for the differentiation between benign and malignant pathologies. Goodness-of-fit for each model was assessed using the Root Mean Square Error (RMSE).
Results: K values of benign lesions were significantly lower than those of malignant lesions. A cut-off value of 0.71 provided sensitivity 97.1% and specificity 93.7% with area under curve (AUC) 0.976. Dapp values of malignant lesions were lower than those of benign lesions at 1.57mm^2/sec sensitivity 91.2%, specificity 93.7%, AUC 0.949. Malignant ADC was significantly lower than benign ADC. A cutoff value of 1.09×10^{-3} mm^2/sec provided sensitivity 95.1% and specificity 91.7%, AUC 0.962. The kurtosis model provided the highest fitting performance. RMSE for the mono-exponential and kurtosis models was 3.8 and 0.8 for the malignant lesions (P<0.05) and 3.2 and 0.4 (P<0.05) for the benign lesions respectively.
Conclusion: Both diffusion models proved to have excellent accuracy rates with no significant difference. However, the kurtosis model measures also the deviation from the Gaussian diffusion model and thus characterise better heterogeneous masses.

B-1130 11:43

Your choice: not all sequences for diffusion-weighted imaging (DWI) of the breast yield the same results

F. Leone[1], R. Woitek[2], P. Clauser[2], P. Kapetas[2], K. Preidler[2], T.H. Helbich[2], P.A.T. Baltzer[2]; [1]*Monza/IT*, [2]*Vienna/AT (federica-leone@live.it)*

Purpose: While readout-segmented EPI sequences for DWI have been promoted as yielding superior results due to higher spatial resolution and less architectural distortion, the literature lacks a systematic comparison with standard EPI-DWI regarding image quality, reproducibility and diagnostic performance. This study aimed to address this field.
Methods and Materials: Consecutive patients undergoing multiparametric 3T (Siemens Skyra fit) breast MRI including readout-segmented (RESOLVE) and standard breast DWI (REVEAL) were prospectively collected for this IRB-approved observational study. Further inclusion criterion was histological verification of breast lesions visible on MRI. Two breast radiologists evaluated both sequences independently. Data collection included lesion conspicuity on an ordinal scale and mean as well as minimum ADC values from manually placed regions-of-interest. Statistical analysis included visual-grading characteristics, receiver-operating characteristics and inter-reader intraclass-correlation coefficient (ICC) calculation. P values <0.05 were considered statistically significant.
Results: 43 Patients with 43 index lesions (29 malignant, 14 benign) were included. ROC analysis revealed a significantly higher area under the ROC curve for REVEAL as compared to RESOLVE (P≤0.039, respectively). Measurement of minimum ADCs was not diagnostically superior to mean ADCs (P>0.05). Inter-reader ICCs did not differ between RESOLVE and REVEAL (0.985). Lesion conspicuity was equal for both sequences (P>0.05).
Conclusion: We found a superior diagnostic performance using standard EPI (REVEAL) compared to readout-segmented DWI (RESOLVE) for diagnosis of breast lesions. Reproducibility and lesion conspicuity did not differ between both sequences.

B-1131 11:51

Comparison of conventional imaging plus DWI and conventional imaging plus DCE-MRI in planning the surgical treatment of patients with breast cancer

L. Vassallo[1], E. Rachetta[1], G. Cappello[2], V. Doronzio[3], D. Regge[3], L. Martincich[3]; [1]*Savigliano/IT*, [2]*Avola/IT*, [3]*Candiolo/IT (lorenzo.vassallo1987@libero.it)*

Purpose: To compare conventional imaging plus DWI (Protocol 1) and conventional imaging plus DCE-MRI (Protocol 2) in planning surgical treatment of patients with breast cancer.
Methods and Materials: 66 consecutive patients with operable biopsy-proven breast cancer underwent pre-surgical MRI (1.5T magnet and 8-channel coil) consisting of DWI (axial EPI sequence; b-value 0 and 1500 s/mm2; thickness

4mm) and DCE-MRI (3DT1w sequence; thickness 2mm). Both protocols were independently reviewed. For DWI, areas of hyperintensity at large b-value were considered suspicious/suggestive for malignancy while DCE-MRI were reported according to ACR BI-RADS. Results were then prospectively used by multidisciplinary team in planning surgical treatment (mastectomy vs BCS, breast conservative surgery) and compared with pathology. McNemar and κ tests were used to assess diagnostic performance and inter-protocols agreement.
Results: 29 Patients underwent BCS while 37 mastectomy (2 for positive margins after BCS). Pathology identified 34 unifocal and 32 multiple cancers. Protocol 1 planned 34 BCS and 32 mastectomies while protocol 2 planned 31 BCS and 35 mastectomies. Inter-protocol agreement was excellent (k=0.9). Accuracy of protocol 1 and 2 were 92% (61/66) and 97% (64/66), respectively. Two multiple DCIS requiring mastectomy for positive margins after BCS were underestimated by both protocols. 2/3 cases in which protocol 1 incorrectly planned BCS were represented by multiple disease at pathology.
Conclusion: In planning surgical treatment, conventional imaging plus DWI shows more than acceptable accuracy (slightly lower than conventional imaging plus DCE-MRI) and could represent a reliable tool in pre-surgical setting. The study is still ongoing to confirm the results in a larger series.

Diffusion tensor imaging and fiber tracking biomarkers of intramedullary tumours of spinal cord for predictive resectabality scoring-observational comparitive study of 48 cases
R.S.V. Vadapalli, L. Chittem, V. Mudumba, A. Vadapalli, S. Bhattacharya; *Hyderabad/IN (rammohanvsv@yahoo.com)*

Purpose: The aim of this prospective study is to evaluate the role of Diffusion Tensor Imaging (DTI) in management of intramedullary spinal cord lesions (IMSCL) for predicting “safe resectibility” to assess subsequent outcomes.
Methods and Materials: DTI was performed in 65 patients with IMSCL along with conventional MRI. Tumour matrix fractional anisotropy (FA), tumour cord interface FA were assessed. Lesions were grouped into 3 groups as completely resectable, partially resectable, unresectable based on the presence of cleavage between the lesion and spinal cord. These results were compared and correlated with intraoperative findings, neurological outcome at the end of 1 year follow-up was assessed.
Results: There were 65 patients (38 male, 27 female; mean age of 37.5 years) in this study, 50 were neoplastic (19 ependymomas, 14 astrocytomas, 3 metastases, 4 hemangioblastoma, 5 cavernomas, 5 lipomas); 20 were non neoplastic (Tuberculoma (6), Neurocystecercosis (4) Tumefactive demyelination plaques (5) . DTI was used to classify the lesions as completely resectable (18), partially resectable (26) unresectable (6). The capability of DTI in predicting the presence of cleavage plane, resectability and prognostication were statistically significant. (P=<.001) Spearman’s Correlation coefficient between DTI prediction of cleavage plane and intra operative finding of plane was 0.84 (p value 0.0001) -significant. Correlation coefficient between DTI prediction of infiltration of tracts and neurological outcome (deteriorated or not) was 0.46 (p value 0.02) suggesting that DTI can be useful tool for prognosticating the IMSCL.
Conclusion: This study suggests that DTI is useful in predicting the safe resectability of IMSCL.

B-1133 10:38

Role of phase sensitive inversion recovery sequence compared to STIR and T2W_TSE in detection of cervical cord multiple sclerosis lesions
Z. Abidi; *Qaem Shahr/IR (abidi.z4805@yahoo.com)*

Purpose: Multiple sclerosis (MS) is a chronic inflammatory disease in brain and spinal cord. Spinal cord MS lesions usually are accompanied by brain lesions. But, about 20% of patients with spinal cord lesions have no plaques in their brain. T_2W_TSE, STIR (Short TI Inversion Recovery) sequences routinely are used in imaging study of MS patients to depict spinal cord MS lesions. We aimed to investigate the importance of PSIR(Phase Sensitive Inversion Recovery) sequence in detection of MS lesions in spinal cord.
Methods and Materials: Fifteen patients with MS underwent on a 1.5 Tesla Philips (Ingenia) MRI scanner using protocols included T2W_ TSE, STIR and PSIR sequences in sagittal plane with 3 mm thick slices.
Results: The contrast between MS lesions and surrounding tissues in spinal cord was significantly higher in PSIR compared to STIR and T2W images. Radiologist observed better delineation of lesions in PSIR compared to T2W_TSE and STIR sequences. The lesions in PSIR were shown more clearly. In addition to higher contrast, flow artifacts are less eminent in PSIR due to a short TE.
Conclusion: Spinal cord MRI would be beneficial for early diagnosis and recognising clinical subtypes of MS due to high spread of lesions in patients with definite MS. STIR is still considered as a gold standard sequence in detection of cervical cord lesions. but, the advantages of PSIR over STIR and T2-weighted images persuaded us to recommend PSIR as a complementary sequence to detect cervical cord MS lesions.

Causes of spinal haemorrhage in a level one trauma centre
R. Riascos[1], E. Bonfante[1], J.A. Mora[2], C. Sitton[1], J. Choi[1]; [1]*Houston, TX/US*, [2]*Bogota/CO (juanchomora83@hotmail.com)*

Purpose: The goal of this study was to determine the etiology and characteristics of spinal haematomas; also the effectiveness of the initial images in the diagnosis.
Methods and Materials: Retrospective observational study with a time period of seven months (December 2014- July 2015) was determined, then all patients diagnosed with spine haemorrage.
Results: 61 patients diagnosed with spinal haemorrhage, 40 men and 21 women with a median age of 49-53 years were included. It was established as the main mechanism. Trauma 83%, postsurgical 6.5%, insufficiency fracture 3.2%, pathological fracture 3.2% and spontaneous bleeding 3.2%. Were found 53 epidural haematomas and eight subdural haematomas Twenty-two cases were located in the lumbar spine,18 in cervical spine, eight thoracic spine, six thoraco lumbar, three cervical- thoracic and one sacrum. The location within the spinal canal 54% anterior, 45% posterior and 3.2% lateral. The average longitudinal diameter bruising models was 66 mm, with an extension of three vertebral segment on average. Sixty-three percent spinal haematomas has compressive effect and 37% showed no signs of compression. Seventy-seven percent of patients presented vertebral fracture associated with an average of three fractured vertebrae.
Conclusion: It was established as the main etiological factor of spinal bleeding is trauma associated with vertebral fractures, the effective diagnosis is important because most of the haemorrhage has compressive effects on the spinal cord; also MRI proved to be the modality of choice for diagnosis and follow-up while CT show has a low sensitivity diagnosed.

B-1135 10:54

Effects of appropriateness of cauda equina imaging on clinical risks, workload and costs
S. Gargalas, S. Karia; *Oxford/UK (sergios@gargalas.org)*

Purpose: Cauda equina (CE) is a neurosurgical emergency that requires imaging within 24 hours from symptom onset for optimum intervention results. Despite its naturally infrequent occurrence, requests to exclude CE constitute a significant portion of our department's workload. We investigate the appropriateness of the requests for such imaging and its effect on the clinical outcomes, costs and workload within the National Health Service (NHS).
Methods and Materials: We identified patients who had lumbar spine MRI with strong clinical suspicion for CE between 2014 and 2015. The clinical history, progression and outcomes were compared. Costs for inappropriate imaging and effects on workload have been calculated.
Results: A total of 705 cases were identified, accounting for average of 1.2 emergent lumbar spine MRI per day. A total of 131 studies (18.6%) did not meet published criteria for neurosurgical intervention and furthermore did not have radiological evidence of cauda equina. Overall positive rate was 6.8%.
Conclusion: We found that inappropriate referrals to exclude CE constitute 3% of total MRI inpatient workload. Each inappropriate study burdens the NHS £146 in tariff costs; however, the economic implications of added workload burden and/or misdiagnosis, as well as delay in "less urgent examinations" is expected to be far greater. Strict imaging criteria is a clear target in attempt to reduce these inefficiencies.

B-1136 11:02

Quantitative MRI-based three-dimensional volumetry of dural sac and vertebral bodies improves diagnosis of dural ectasia in Marfan syndrome

F. Rengier[1], O. Naas[1], T. Norajitra[1], M. Messerli[2], K. Kallenbach[1], M. Karck[1], K. Maier-Hein[1], H.-U. Kauczor[1]; [1]*Heidelberg/DE*, [2]*Zurich/CH*
(fabian.rengier@web.de)

Purpose: Assess MRI-based three-dimensional volumetry of dural sac and vertebral bodies for diagnosis of dural ectasia in Marfan syndrome compared to dural sac diameter ratios as current clinical standard.
Methods and Materials: In 188 patients being evaluated for Marfan syndrome 2012-2015 a single slab 3D T2-weighted TSE sequence of the lumbosacral spine was acquired with a spatial resolution of 1x1x1mm³. A random sample of 20 patients (mean 32.0 years, 7 female) was included. In nine of these patients diagnosis of Marfan syndrome was confirmed according to the 2010 Revised Ghent Nosology, 11 patients served as controls. Dural sac and vertebral bodies L5 and S1 were segmented using the Medical Imaging Interaction Toolkit (MITK). For comparison with current clinical standard, anteroposterior diameters of vertebral bodies and dural sac were measured halfway between the superior and inferior endplates. Ratios between dural sac volume/diameter at the respective level and vertebral body volume/diameter were computed for L5 and S1.
Results: L5-/S1-dural sac volumes were 11.0/13.8ml in Marfan patients compared to 6.9/5.0ml in controls (both $p<0.05$). Sensitivity, specificity, positive predictive value and negative predictive value for diagnosis of Marfan syndrome were: for 3D volumetry using 7.7/6.4ml as cut-off 78%/91%/88%/83%, for criteria of Habermann et al. 78%/45%/54%/71%, and for criteria of Oosterhof et al. 67%/73%/67%/73%.
Conclusion: MRI-based 3D volumetry of dural sac and vertebral bodies for quantifying dural ectasia is feasible and particularly improved specificity for diagnosis of Marfan syndrome compared to published quantitative criteria based on dural sac diameter ratios as current clinical standard.

B-1137 11:10

Diagnostic value of 3D FIESTA sequence in imaging of lumbar radiculopathy

F. Abubacker Sulaiman; *Chennai/IN (fasulaiman@hotmail.com)*

Purpose: This study is being conducted for establishing a new protocol for lumbar radiculopathy and to document the superiority of 3D FIESTA over conventional MRI protocol.
Methods and Materials: The study was divided into two groups. The control group consisted of 15 healthy volunteers and the experimental group consisted of 58 patients.
Results: In all patients who were evaluated in our study with both FSE T2W and 3D FIESTA sequences statistically the visibility of the evaluated structures and lumbar radiculopathy was excellent for axial 2D T2w TSE and axial 3D FIESTA (MPR) (74.2, 100 percent), respectively. As the visualisation of the normal structures were comparatively excellent for 3D FIESTA with good spatial resolution and adequate T2/T1 ratio.
Conclusion: The detection of lumbar radiculopathy in terms of each affected dermatomes has always proved to be a diagnostic challenge both for the physician and the radiologist, the use of 3D FIESTA sequences has greatly enhanced detection rates.

B-1138 11:18

Diffusion tensor imaging of the arm nerves: tractography and quantitative analysis

V. Durante, R. Gasparotti; *Brescia/IT (vale.durante@hotmail.it)*

Purpose: Diffusion Tensor Imaging (DTI) is an emerging MRI method that reveals micro structural characteristics of biological tissue and offers quantitative parameters as FA (fractional anisotropy). This parameter, which resulting different in base of disease, represent an added value in the patient's diagnostic workup becouse increase the specificity of magnetic resonance exam. We calculated this value,in healthy subjects, at the level of the arm for median, ulnar and radial nerves, because there aren't reference literature parameters.
Methods and Materials: We study 10 healthy volunteers (5men,5 women; mean age 23 years) using single-shot-spin-echo planar imaging sequence (TR/TE, 10700/77ms; b-value, 0, 1000 s/mm^2). Two indipentent readers performed post-processing and fiber tractography. Fiber tracts of median, ulnar and radial nerves in the arm were calculated and the FA value was calculated.
Results: Fiber tractography generated significantly longer fibers for three arm nerves in all subjects. No statistically significant differences ($p=0,67$) were found between FA values calculated by two readers, Mean FA values were as follow: 0,53 for median nerve, 0,54 for ulnar nerve and 0,51 for radial nerve.
Conclusion: The study showed that it is possible to examine the nerves of the arm through optimised DTI sequences and perform on them a quantitative analisys. The FA values obtained in healthy subjects rapresent an important stage for a better characterisation of pathology in the patients with neuropathy, using magnetic resonance imaging.

Ultrasound findings and anatomical correlations in periferal nerves damage neurosurgery

V. Dekan, A. Gaivoronsky, E. Zhurbin, A. Grishchenkov; *St. Petersburg/RU (dekanvs@mail.ru)*

Purpose: Research objective was to compare anatomic features of peripheral nerves of extremities and ultrasonographic findings in diagnostics of injuries of peripheral nerves and scheduling of neurosurgical treatment.
Methods and Materials: 25 patients with injuries of peripheral nerves, including gunshot wounds were examined by means of a sonography. All patients undergone surgical treatment. Sonography was performed with use of high resolution linear transducer. Main indicators which estimated at a sonography were:- identification of the site of injury of a nerve, definition of the true divergence of the ends at the complete break, definition of a depth of a nervous trunk and its ends, epicutaneous marking of localisation of a nervous trunk, place of its damage, ends of a nerve.
Results: In all cases the sonography allowed to locate damages of a trunk of a peripheral nerve, estimate a damage rate and its character, and also to define criteria, necessary for making decision on operative measure realization. Main types of pathology were: the complete transmural injury of a nerve with a divergence of the ends and formation of end neuromas (n=19), partial damage of a nervous trunk with preservation of an anatomic continuity (n=3), traction damage without violation of an anatomic integrity (n=3).
Conclusion: Ultrasound examination of injured peripheral nerves is high informative and accurate method of preoperative vizualisation and planning in various damages of peripheral nerves. This method is sufficient for final diagnostics and definition of indications to surgical treatment.

B-1140 11:34

Value of high resolution ultrasound in carpal tunnel syndrome diagnosis

S.P. Ivanoski[1], M. Bozinoska Smiceska[1], V. Vasilevska Nikodinovska[2]; [1]*Ohrid/MK*, [2]*Skopje/MK (v_vasilevska@yahoo.com)*

Purpose: To evaluate the diagnostic efficiency of high-resolution ultrasound in carpal tunnel syndrome (CTS) diagnosis in comparison to electromyography (EMG).
Methods and Materials: Prospectively, median nerves in 39 wrists of 22 patients with CTS diagnosed on EMG were evaluated sonographically. Majority of patients (77%) had bilateral CTS. 16 patients were women and 6 were men. 40 wrists of 20 asymptomatic volunteers consisted the control group. Ultrasound exam was performed by a radiologist with 5 years' experience in MSK ultrasound, within few days following the EMG. The radiologist was blinded with clinical and EMG data. Ultrasound criterion for carpal tunnel syndrome was a median nerve cross-sectional area ≥10 mm^2 at proximal carpal tunnel level. Sensitivity, specificity, positive and negative predictive value and accuracy of the method were evaluated.
Results: Ultrasound showed high sensitivity in diagnosis of carpal tunnel syndrome (87.18%), true positive finding was present in 34 of 39 patients diagnosed by EMG. Specificity was high (82.5%). There was positive predictive value of 82.93% negative predictive value of 86.84% and accuracy of 84.81% for ultrasound. Mean cross-sectional area in patients diagnosed with CTS was 13.7 mm^2, and 7.92 mm^2 in asymptomatic volunteers. Wrist/forearm ratio of median nerve was 2.11 in patients with proven CTS, compared to 1.45 in asymptomatic volunteers.
Conclusion: Ultrasound has high sensitivity, specificity and accuracy in diagnosis of carpal tunnel syndrome compared to EMG exam. Its availability, easiness of use, acceptance by patients and low cost make it quick and valuable method for evaluation of carpal tunnel syndrome.

B-1141 11:42

Diffusion tensor imaging in cervical and dorsolumbar spinal cord injury

M.K. Poonia, M.M. D'souza, A. Choudhary; *Delhi/IN (mahesh.poonia@gmail.com)*

Purpose: The study was performed to assess the role of diffusion tensor imaging (DTI) in assessment of spinal cord integrity after injury, beyond that delineated on conventional magnetic resonance imaging (MRI).
Methods and Materials: Conventional MRI and DTI of the cervical and dorsolumbar spine was performed using 3Tesla MR system (Magnetom Skyra, Siemens) on cases of spinal trauma (cervical n=20 and dorsolumbar n=10) and age- and sex-matched healthy controls (n=30). Fractional anisotropy (FA) and mean diffusivity (MD) of injured cord were compared with corresponding region of controls.

Results: Mean FA value at the level of trauma was lower in cases as compared to controls in cervical (0.43+/-0.08 vs 0.62+/-0.06 respectively, p <0.001) and dorsolumbar injury (0.29+/-0.07 vs 0.57+/-0.05 respectively, p <0.001). Additionally, mean MD value was higher in cases as compared to controls at the level of trauma (1.30+/-0.24 vs 1.07+/-0.12 respectively, p <0.001 for cervical and 1.39+/-0.16 vs 1.27+/-0.24 respectively, p <0.02 for dorsolumbar injury). 14 cases revealed significantly abnormal DTI indices, despite a normal conventional MR study. All patients with DTI abnormalities had sensorimotor deficit on clinical examination.
Conclusion: DTI appears to be a better diagnostic measure as compared to conventional MR imaging in depicting subtle changes in cord integrity after injury.

B-1142 11:50

Evaluation of neurovascular compression in trigeminal neuralgia using 3D-DRIVE MRI and correlation with surgical microvascular decompression

M.M.A.H. ElShafey, H.A.M.M. Abdel Daiem, A.H. Farhoud; *Alexandria/EG (mohamedeshafei@yahoo.com)*

Purpose: To present the role of 3D-CISS as a non-contrast enhancing high-resolution MR imaging sequence in the preoperative evaluation of neurovascular compression (NVC) in patients with trigeminal neuralgia (TN), and correlation with surgical microvascular decompression (MVD).
Methods and Materials: 30 patients with TN refractory to medical treatment performed 3D-CISS at 1.5 T MRI. Multiplanar reformation (MPR) was used for reconstruction of the source images in three dimensional planes. Assessment of trigeminal nerves was done on both sides for detection of the point of NVC (crushing point), it's site, length of affected segment and the offending vessel.
Results: Neurovascular compression was detected in all patients. The root entry zone (REZ) was the crushing point in all except one patient who showed NVC only at the cisternal segment of the trigeminal nerve. Five patients presented NVC at two points including REZ and the cisternal segment. Imaging findings were matching with the intraoperative findings in all patients. No significant postoperative complications encountered.
Conclusion: 3D-CISS MRI could be considered an essential diagnostic tool in the preoperative evaluation of TN patients.

A randomised controlled trial to evaluate tomosynthesis vs digital mammography screening: preliminary results on baseline detection rate

V. Iotti[1], A. Nitrosi[1], C. Coriani[1], S. Caffarri[2], C. Campari[1], V. Ginocchi[2], R. Vacondio[1], P. Giorgi Rossi[1], P. Pattacini[1]; [1]*Reggio Emilia/IT*, [2]*Guastalla/IT (valentina.iotti@asmn.re.it)*

Purpose: We are conducting a randomised trial on the efficacy of breast cancer screening with digital breast tomosynthesis (DBT) compared with digital mammography (DM) in reducing advanced and interval cancer incidence (NCT02698202). We present interim baseline data on detection rate by cancer diameter and breast density.
Methods and Materials: Consenting women presenting for a new screening round at the population-based (45-70 age range) mammography screening, were randomised to DM (usual care) or DBT+DM two-view bi-lateral examinations, both with double independent reading. Breast density was classified according to the Peak Breast Density computed by the mammography system and stored in image header. We report relative detection rate (RDR) with 95% confidence intervals (95%CI).
Results: From March 2014 to March 2016, 9782 were randomised to DM arm and 9623 to DBT+DM arm; 45 (6 in-situ) and 79 (14 in-situ) cancers were detected in DM and DBT+DM arm, respectively; overall RDR was 1.8 (95%CI:1.2-2.6), in-situ RDR was 2.4 (95%CI:0.9-7.5, p for heterogeneity 0.52); there was no difference by breast density (RDR 1.6, 95%CI:1.0-2.8 and 1.9, 95%CI:1.0-3.9, in dense and fat breast, respectively, p for heterogeneity 0.74), despite the absolute detection rate was 2.8 folds higher in dense than fat breast. The RDR was 1.7 (95%CI 0.9-3.5), 2.6 (95%CI 1.2-5.8), and 0.7 (95%CI 0.2-2.7) for T1<1cm, T1c and T2, respectively (p for heterogeneity 0.18).
Conclusion: DBT identified 80% more cancers than DM in this randomised trial. The detection was increased similarly for in-situ and invasive, <1 cm and T1c cancers, in dense and fat breast.

B-1144 10:38

Digital breast tomosynthesis vs digital mammography - early performance measures in a population-based screening program

S. Hofvind[1], T. Hovda[2], Å.S. Holen[1], J.L. Albertsen[3], H. Bjørndal[2], S.H.B. Brandal[1], L. Romundstad[1], E. Vigeland[3], P. Skaane[1]; [1]*Oslo/NO*, [2]*Drammen/NO*, [3]*Tønsberg/NO (solveig.hofvind@kreftregisteret.no)*

Purpose: To compare recall rate and rate of screen-detected breast cancer after one year screening with synthetic images and digital breast tomosynthesis (DBT) versus digital mammography (DM) in the Norwegian Breast Cancer Screening Program (NBCSP).
Methods and Materials: A total of 18 172 women residing in Oslo were screened with DBT in 2014, while a control group of 30 883 women was screened with DM, in the NBCSP. We performed descriptive analyses, and z-test to test for statistical significance (p<0.05) between the two groups.
Results: The recall rate due to abnormal mammographic findings was 3.2% (576/18 172) and 3.3% (1007/30 883, p=0.58) for DBT and DM, respectively. The rate of screen-detected breast cancer was 9.3 per 1000 screened with DBT and 6.4 per 1000 (p<0.01) screened with DM. Both the rate of screen-detected Ductal Carcinoma in Situ and invasive breast cancer was statistically significantly higher for DBT compared with DM (p<0.01 and p=0.02, respectively).
Conclusion: The rate of screen-detected breast cancer was about 50% higher for women screened with DBT compared with women screened with DM.

B-1145 10:46

The risk of progression of atypia into invasive breast cancer among women attending the Norwegian Breast Cancer Screening Programme

M. Lilleborge, S. Sebuødegård, S. Hofvind; *Oslo/NO (marie.lilleborge@kreftregisteret.no)*

Purpose: To estimate the risk of progression from atypia into invasive cancer in the ipsilateral breast, among women attending the Norwegian Breast Cancer Screening Programme (NBCSP).
Methods and Materials: A total of 2,764,782 screening examinations were performed among 677,932 women aged 50-69 years in NBCSP, 1995-2015. Out of 83,891 recall examinations, 50,130 were concluded negative after additional imaging and ultrasound only, while 1,177 included biopsy with corresponding classification for both breasts. Ductal carcinoma in situ (DCIS) or invasive breast cancer was identified in 15,659 cases, and 19,279 cases were classified as benign. A total of 1,167 women, free from ipsilateral DCIS and breast cancer, were diagnosed with atypia (last digit in the SNOMED code: 1 or 5). We followed the women for invasive breast cancer until end of follow-up (31.12.2015, date of death, emigration or diagnosis of invasive breast cancer, whichever came first). Cox regression was used to study the risk of ipsilateral invasive breast cancer among the women classified with atypia, stratified by age.
Results: The risk of an invasive breast cancer in the ipsilateral breast after a screening detected atypia was 93% higher compared with a negative recall after additional imaging and ultrasound only [HR= 1.93; 95% CI: 1.38-2.69]. The risk increased by age at atypia (1-year-intervals) [HR= 1.04; 95% CI: 1.03-1.05].
Conclusion: The risk of developing invasive breast cancer in the ipsilateral breast was about twofold for women recalled and diagnosed with atypia compared with those recalled and ruled out negative with additional imaging and ultrasound only.

B-1146 10:54

Grade, size, invasive status and breast density of screen detected and interval cancers in breast screening in the UK

L.M. Warren[1], L. Wilkinson[2], M.G. Wallis[3], R. McAvinchey[1], R.M. Given-Wilson[2], M.D. Halling-Brown[1], M. Patel[1], D.R. Dance[1], K.C. Young[1]; [1]*Guildford/UK*, [2]*London/UK*, [3]*Cambridge/UK (lucy.warren@nhs.net)*

Purpose: To compare the characteristics of screen-detected and interval breast cancers.
Methods and Materials: Breast cancer cases were collected from three UK screening centres between April 2011 and Feb 2016. Size, grade and invasive status were reviewed for 3294 screen-detected cancers and 477 interval cancers. Here, an interval cancer was defined as an invasive or in situ cancer diagnosed between normal screens (round length = 3 years). Volumetric breast density (VBD) from Volpara v1.5.1 was available for 2436 of the screen-detected cancers and 220 prior screening images of the interval cancers. Significance was tested using chi-squared.
Results: Compared to screen-detected cancers, a greater proportion of interval cancers were invasive (p<0.0001). The interval invasive cancers were

of higher grade (p<0.0001) and had a larger median diameter (20.5mm v. 16.0mm, p=0.004). Intervals also had a larger proportion of lobular, and smaller proportion of ductal cancers than screen-detected cancers (p=0.009). Mean age did not differ significantly between women with screen-detected cancers and women at the screening episode prior to their interval cancer (60 v. 59 years, p=0.14). Breasts were denser in women with interval cancers compared with screen-detected cancers (mean VBD of 10.2% v. 8.1%, p=0.0007). The proportion of women with VBD<4.5%, VBD=4.5-7.5%, VBD=7.5-15.5% and VBD>15.5%, were 14%, 28%, 39% and 19% for interval cancers and 24%, 38%, 29% and 9% for screen-detected cancers respectively.
Conclusion: The characteristics of invasive interval cancers differ significantly from screen-detected cancers, in terms of invasive status, grade, size and volumetric breast density.

B-1147 11:02

Frequency and characteristics of additionally detected ipsilateral breast lesions following recall at screening mammography

J.L.R. Lameijer[1], M.M. Mourits[2], J. Nederend[1], A.C. Voogd[3], L.E.M. Duijm[2]; [1]*Eindhoven/NL*, [2]*Nijmegen/NL*, [3]*Maastricht/NL (joostlameijer@gmail.com)*

Purpose: To determine the frequency and outcome of additionally detected ipsilateral breast abnormalities following recall at screening mammography.
Methods and Materials: We included a consecutive series of 97799 screening mammograms performed between January 1, 2014 and July 1, 2015. All mammograms were double read by a team of 13 certified screening radiologists, each assessing more than 9000 screening mammograms yearly. Clinical data, breast imaging reports, biopsy results and breast surgery reports were collected of all recalled women.
Results: A total of 3061 women were recalled (recall rate, 3.1%). In 452 (14.8%) of these women, an additional lesion was detected in the breast for which she had been recalled. Biopsy was more frequently performed of recalled lesions than of additionally detected lesions (44.3% (1156/2609) vs 20.1% (91/452), p<0.005). Recalled lesions were more frequently malignant than additionally detected lesions (23.6% (615/2609) vs 12.8% (58/452), p<0.005). Of all 91 biopsy procedures performed of additionally detected lesions, 48 had been done to confirm or rule out breast cancer multifocality or multicentricity (62.3% (30/48) of these biopsies were malignant), 3 biopsies revealed breast cancer at a different location in the ipsilateral breast for which the woman had been referred, and the remaining 40 biopsies showed benign findings.
Conclusion: A substantial proportion of women are analysed for additional ipsilateral breast lesions following recall. These lesions are significantly less frequently biopsied than recalled lesions and have a significantly lower probability of malignancy, unless biopsy is performed to confirm or rule out breast cancer multifocality or multicentricity.

B-1148 11:10

Breast compression and radiation dose in mammographic screening

G.G. Waade, A. Sanderud, N. Moshina, S. Sæbuødegård, S. Hofvind; *Oslo/NO (Gunvor-Gipling.Wade@hioa.no)*

Purpose: Radiation protection and keeping the radiation dose as low as reasonably achievable is particularly important in mammographic screening as mainly healthy women are examined. Breast compression is used in mammography amongst other to reduce radiation dose. However, there is limited knowledge about the dose reduction by breast compression. We investigated radiation dose by compression force and compressed breast thickness for digital mammography in the Norwegian Breast Cancer Screening Programme.
Methods and Materials: Information regarding compression force, compressed breast thickness and radiation dose was available from 17,951 randomly selected screening examinations, performed at 14 breast centres, January-March 2014. We calculated mean compression force (Newton, N), compressed breast thickness (millimetre, mm) and radiation dose (milliGray, mGy) with 95% confidence interval (95% CI) for the left craniocaudal (CC) and mediolateral-oblique (MLO) mammograms. Further, radiation dose by quartiles of compression force and of compressed breast thickness were investigated. ANOVA and Tukey's HSD test were used to identify statistically significantly differences.
Results: Mean values were 116.3N (95% CI: 116.0-116.6) for compression force, 57.4mm (95% CI: 57.3-57.6) for compressed breast thickness, and 1.09mGy (95% CI: 1.09-1.10) for radiation dose. Mean radiation dose increased statistically significantly by quartiles of compression force (p<0.05), while it decreased statistically significantly by quartiles of compressed breast thickness (p<0.05).
Conclusion: Radiation dose increased by increasing compression force. Our findings raise concern about the current practice of using compression force to reduce breast thickness and subsequently the radiation dose.

B-1149 11:18

Breast compression variability in the Norwegian Breast Cancer Screening Programme

G.G. Waade[1], P. Hogg[2], N. Moshina[1], S. Sæbuødegård[1], S. Hofvind[1]; [1]*Oslo/NO*, [2]*Salford/UK (Gunvor-Gipling.Wade@hioa.no)*

Purpose: In mammography, breast compression is assumed to increase image quality and to reduce radiation dose. However, there are no evidence-based guidelines regarding the optimal compression force to use. We compared the compression force applied between screening centres in the Norwegian Breast Cancer Screening Programme.
Methods and Materials: Information regarding compression force was available from 17,951 randomly selected screening examinations performed at 14 of the 16 breast centres during January-March 2014. We calculated mean compression force (Newton, N) and 95% confidence interval (95% CI) for the left craniocaudal (CC) and mediolateral-oblique (MLO) mammograms, by breast centre. ANOVA and Tukey's HSD tests were used to identify any statistically significantly differences.
Results: Mean compression force for all the mammograms was 116.3N (95% CI: 116.0-116.6), 108.0N (95% CI: 107.6-108.4) for CC and 124.6N (95% CI: 124.2-125.0) for MLO. Comparing the breast centres, the lowest mean compression force was 90.5N (95% CI: 89.7-91.3) while the highest was 146.8N (95% CI: 145.0-148.5). Mean compression force differed statistically significantly for five breast centres when compared to all the others (p<0.05 for all).
Conclusion: We observed a substantial variations in mean compression force between the breast centres. This difference might influence image quality, radiation dose and patient experience. There is a need for establishing evidence-based recommendations for compression force in mammography.

B-1150 11:26

Breast arterial calcification on screening mammography can predict clinically significant coronary artery disease (CAD) in the BreastCheck screening cohort

E. Scanlon, B. Kelly; *Dublin/IE (emerscanlon1308@hotmail.com)*

Purpose: Breast arterial calcifications (BAC) are vascular calcifications observed at mammography. BAC has been associated with an increased risk of coronary artery disease (CAD). We investigated the association of BAC with findings on Computerised Tomography Coronary Angiography (CTCA) and thus CAD within the BreastCheck screening cohort.
Methods and Materials: Women aged between 50-64 who underwent CTCA between 2014-2015 were included. The BreastCheck mammography database was cross referenced to determine how many of these had both CTCA and digital mammography. BAC was scored as absent, mild, moderate or severe by specialist breast radiologists. CTCAs were scored according to the CAD-RADs system by specialist chest radiologists. Any findings significant in the CONFIRM trial were also recorded. History of chronic kidney disease, diabetes, hypertension, hypercholesterolaemia and smoking were recorded.
Results: 484 women had CTCA during that time period. 219 were within the 50-64 age category. Of these, 95 patients with no previous history of MI or CAD had both CTCA and mammography performed. Using standard multiple regression BAC was independently associated with a finding of CONFIRM significant CAD on CTCA (p=0.008) and with a CADRADs score of ≥3 (p=0.008). Furthermore using the Pearson method there was a significant positive correlation between the patients BAC score and their CADRAD score (p<0.001).
Conclusion: BAC diagnosed on 2 yearly screening mammography predicts CONFIRM significant CAD and CADRADs ≥3 disease. This information could be used to communicate cardiac risk to patients' primary care physician through the medium of the radiologic report to identify potentially undiagnosed CAD.

B-1152 11:34

Comparison of recall and breast cancer rates for spontaneous and organised screening mammograms performed in the same department

N. Voyvoda[1], L.A. Carbonaro[2], C.G. Monaco[3], F. Sardanelli[2]; [1]*Kocaeli/TR*, [2]*San Donato Milanese/IT*, [3]*Milan/IT (nuraykad@gmail.com)*

Purpose: Spontaneous screening mammography usually shows a recall rate of 8-12%, compared to 3-5% of organised screening programs. This study aims to evaluate and compare recall rates and breast cancer detection in a healthcare setting where spontaneous and organised screening is performed.
Methods and Materials: In 2013, 2818 organised screening mammograms (asymptomatic women 50-69 years old without breast cancer(BC) history) and 3430 spontaneous screening mammograms were performed in our department. Organised screening mammograms were read independently by two radiologists and patients were recalled when a suspect finding was detected by one of the two readers. Spontaneous mammograms were read by one radiologist. Throughout the year, both spontaneous and organised

screening mammograms were read by the same three radiologists(10-, 6-, and 2-year experience in screening and 11-, 8-, and 4-year experience in breast imaging) in rotation. Of 3430 spontaneous mammograms, all asymptomatic patients between 50 and 69 years old without symptoms and BC history were included to compare results with organised screening mammograms. Chi-square test was used; p value<0.05 was considered statistically significant.
Results: 907 spontaneous mammograms were included. Of these, 36(4.0%) were recalled. 135 organised screening mammograms(4.6%) were recalled (P=0.304). Six (6.6/1000) and 12 (4.3/1000) BCs were detected at spontaneous and organised screening mammograms, respectively (P=0.373). The positive predictive value of recalls was 16.7% for spontaneous and 8.9% for organised screening mammograms (P=0.177).
Conclusion: Recall rates of spontaneous mammograms performed in a single department where a screening organised program is performed can be maintained as low as the latter with comparable cancer detection rates.

B-1153 11:42

The value of routine screening mammography in women aged 35 to 39 years in a symptomatic breast unit
A. Buckley, N. Healy, S. O'Keeffe; *Dublin/IE (bucklear@tcd.ie)*

Purpose: To determine the breast cancer detection rate in women aged 35-39 attending a symptomatic breast clinic, on routine bilateral screening mammography, in women of population risk profile with a normal clinical examination.
Methods and Materials: A retrospective analysis of all mammograms performed on patients aged 35-39 at our institution from 2011 to 2015 was carried out. Patients with moderate or high familial risk of breast cancer, personal breast cancer history or chest radiation, males, GP and internal hospital referrals, and those with abnormal clinical examinations were excluded. Included women had “normal”, “benign” or undocumented examination findings. Results of imaging including ultrasound and histopathological results were extracted from the hospital’s electronic record systems.
Results: 4,087 patients aged 35-39 had bilateral mammograms from 2011 to 2015. 2,148 patients were excluded from analysis. Of 1,939 included women, 4 (0.21%) were diagnosed with breast cancer confirmed at histology based on mammographic findings: 2 invasive ductal carcinoma (8 and 2mm) and 2 DCIS (4.5mm high grade DCIS and 2 mm low grade DCIS). Other histological findings included 2 B3, 46 B2 and 3 B1 lesions. Overall, 115 biopsies were performed in this cohort; 55 (47.8%) were attributable to mammographic screening, producing a biopsy rate of 2.8% due to mammography alone.
Conclusion: 2.1 cases of cancer were detected per 1000 women screened. This figure would be below accepted international thresholds to undertake screening mammography and raises radiation protection issues. Additionally, a large number of benign biopsies were undertaken. Further studies could inform national guidance.

Balloon sacroplasty (BSP), radiofrequency sacroplasty (RFS), vertebrosacroplasty (VSP) and cement sacroplasty (CSP) for the treatment of insufficiency fractures
R. Andresen[1], S. Radmer[2], J.R. Andresen[3], H.C. Schober[4]; [1]*Heide/DE*, [2]*Berlin/DE*, [3]*Vienna/AT*, [4]*Rostock/DE (randresen@wkk-hei.de)*

Purpose: To examine the feasibility and clinical outcome of the different treatment methods.
Methods and Materials: In 62 patients with a total of 93 sacral fractures, CT-guided cement augmentation was performed by means of BSP, RFS, VSP and CSP. Cement leakages were detected with a CT on the first postoperative day. Pain intensity was determined on a VAS before the intervention, on the second day, and 6, 12 and 18 months after the intervention.
Results: BSP, RFS, VSP and CSP were technically feasible in all patients. Leakage could be ruled out for the BSP - and the RFS group, in the VSP group there were 4 leakages in 17 fractures (24%) and in the CSP group 3 leakages in 19 fractures (16%). The mean pain score before the intervention was 8.6 in the BSP group, 8.8 in the RFS group, 8.6 in the VSP group and 8.7 in the CSP group. On the second postoperative day, a significant pain reduction was seen (p<0.001), with an average value of 2.5 for all groups. After 6 (12; 18) months, these values were stable at 2.2 (2.3; 2.0) for the BSP group, 2.3 (2.2; 2.0) for the RFS group, 2.4 (2.2; 2.0) for the VSP group and 2.4 (2.3; 2.2) for the CSP group.
Conclusion: BSP, RFS, VSP and CSP are interventional, minimally invasive procedures that achieve equally good pain reduction in the medium term. However, in the case of VSP and CSP, a higher rate of cement leakages is to be expected.

B-1155 10:38

Modic 1 signal evolution after intradiscal glucocorticoid injection (vs sham-procedure) for patients with chronic low back pain
A. Buisson, N.-E. Regnard, C. Nguyen, S. Poiraudeau, J.-L. Drape, A. Feydy; *Paris/FR*

Purpose: Assessment of the Modic signal evolution after intradiscal steroid injection versus sham-procedure for patients with chronic low back pain associated with active discopathy (Modic 1 MRI pattern).
Methods and Materials: Ninety chronic low back pain patients with active discopathy on MRI (Modic 1) and failure of first line treatments were included in a double-blinded, multicentric trial. Patients were randomized for an intradiscal injection of glucocorticoid or a sham-procedure. MRI before and twelve months after discography were assessed for evolution of the Modic type, extension and signal intensity, and the disc space narrowing, blinded to the procedure.
Results: At the 12 months evaluation, no significant difference were observed about the Modic signal changes between the 45 patients treated with an intradiscal glucocorticoid injection and the 45 patients with a single discography. The rate of persisting Modic 1 was similar in both groups (80% vs 73%, p = 0,62). The extent of endplate oedema did not change differently between the two groups, neither in volume (increase of 830 mm3 versus decrease of 99 mm3, p=0,60), nor in maximal height (-5% vs -1,7%, p=0,43), nor in maximal antero-posterior diameter (-6,1% vs -6,4%, p=0,95). The signal intensity changes after discography did not differ. The disc space narrowing at 12 months was similar in both groups (5% vs 3,9%, p=0,61).
Conclusion: Evolution of the vertebral body endplate oedema was similar after intradiscal injection of corticosteroids or after a sham-procedure. MRI should not be used as a predictive tool in the follow-up of patients with active discopathy.

Predictive value of MR-arthrography of the shoulder for pain relief after glenohumeral corticosteroid injection
B. Fritz[1], F. Del Grande[2], R. Sutter[1], C.K. Peterson[1], C.W.A. Pfirrmann[1]; [1]*Zurich/CH*, [2]*Lugano/CH (benjamin.fritz@gmx.net)*

Purpose: To determine the predictive value of MR-arthrography of the shoulder for pain relief after glenohumeral corticosteroid injection.
Methods and Materials: This study enrolled prospectively 212 patients (mean age 51.4 years; range 15 - 90) who underwent fluoroscopy guided glenohumeral corticosteroid injection for pain relief. All patients had an MR-arthrography of the shoulder up to 3 months prior to the infiltration and returned questionnaires which assessed patients’ shoulder pain using the 11-point numeric rating scale (NRS), covering a 1 month follow-up period. MR-arthrograms were retrospectively assessed for abnormalities of the rotator cuff, long biceps tendon, glenohumeral bone and cartilage and labrum as well as for synovitis, bursitis and signs of adhesive capsulitis. MR-arthrography findings were compared to patients’ NRS-change using univariate and multivariate linear regression analysis.
Results: Pain level reduction of ≥2 points was considered to represent clinically relevant improvement, which was seen by 74.0% after 1 month post-injection. Univariate analysis of MRI-findings showed that a non-torn labrum and signs of adhesive capsulitis were associated with significantly higher NRS-reductions after 1 month in comparison to patients without these findings (3.7 vs. 2.6, p=0.003 and 4.0 vs. 3.0, p=0.007). Multivariate analysis proved both factors to be independent predictors of improved outcome after 1 month (beta=0.212, p=0.001 and beta=0.176, p=0.039).
Conclusion: Glenohumeral corticosteroid injections for pain relief have a high success rate with 74.0% of patients reporting clinically relevant improvement after 1 month, with a non-torn labrum and signs of adhesive capsulitis on MR-arthrography being independent predictors of an even better outcome.

B-1157 10:54

Clinical and radiological outcome of platelet-rich plasma (PRP) vs stromal vascular fraction (SVF) to treat Achilles tendinopathy: randomised controlled trial
C. Messina, C. Maccario, L. De Girolamo, A. Corazza, F.G. Usuelli, L.M. Sconfienza; *Milan/IT (carmelomessina.md@gmail.com)*

Purpose: Injections of PRP and adipose-derived mesenchymal stem cells contained in the SVF are considered effective treatments for non-insertional Achilles-tendinopathy (NIAT). We prospectively compared the clinical and

radiological outcome of the PRP and the SVF for the treatment of chronic NIAT.
Methods and Materials: Forty-four patients were randomly assigned to PRP group (n=23) and SVF group (n=21), treated unilaterally or bilaterally (total=28 tendons per group). Patients (age range 18-55y) were followed up at baseline and at 15/30/60/120/180 days from the injection via VAS, VISA-A, AOFAS and SF-36. Patients were also evaluated by US and MRI before and at 4 (US) and 6 months (MRI) after treatment. On MRI, mean preoperative (MPREA) and postoperative (MPOSTA) lesion area were assessed.
Results: Statistically significant differences in favor of the SVF group were just found at the earliest follow up: VAS scored significantly better at both 15 and 30 days in the SVF group in comparison to PRP ($p<0.05$), as well as AOFAS (15 days) and VISA-A (30 days) ($p<0.05$). At the following time points the scores were not significantly different between the two groups, even if SVF always showed better results than PRP. US/MRI evaluation did not reveal significant differences of thickness, echotexture, or signal intensity between the two groups before and after treatment. PRP: MPREA=8.93±2.10mm^2, MPOSTA=8.67±2.10mm^2 ($p>0.05$). SVF: MPREA=10.70±3.38mm^2, MPOSTA= 10.46±3.37mm^2 ($p>0.05$).
Conclusion: Both PRP and SVF showed to be effective for NIAT. Patients treated with SVF obtained faster results. US/MRI are not sensitive enough to detect NIAT changes after treatment.

B-1158 11:02

Validity of T2 mapping sequences at 3T for the assessment of knee cartilage repair after treatment with platelet rich plasma (PRP)
F. Bruno, S. Quarchioni, S. Mariani, F. Arrigoni, L. Patriarca, L. Zugaro, A. Barile, C. Masciocchi; *L'Aquila/IT (federico.bruno.1988@gmail.com)*

Purpose: To define the ability of T2 mapping sequences to evaluate the efficacy of PRP injections characterizing qualitatively and quantitatively the grade of knee cartilage repair in patients with patellofemoral and tibiofemoral chondropathy.
Methods and Materials: 40 patients (17 men, 23 women, mean age 35.8 years), with clinical suspicion of chondropathy were examined on a 3T MRI scanner. T1WI, T2WI, and PDWI sequences were used for morphological evaluation of cartilage lesions, using a modified WORMS score. T2 mapping sequences were correlated to the morphological findings and used for qualitative and quantitative analysis of cartilage by means of colour-scale representation and ROI measurements of T2 relaxation time values. Patients were randomly assigned to 2 groups: 20 patients (group A) were treated with intra-articular PRP injections (3 times, 3 weeks apart), 20 patients (group B, control) were submitted to conservative therapy. MRI follow-up was performed at 6 months.
Results: Patients of group A showed pre-treatment mean T2 values of 51.39msec, and post-treatment mean values of 44.19msec ($p<0,001$). In patients of group B pre-treatment and post-treatment mean T2 values were 51.86msec and 50.70msec respectively ($p=0,274$). Mean post-treatment T2 values between group A and group B were statistically significant ($p<0,001$). In the study group, the overall Worms score had a 25% improvement, in the control group the improvement was of 3%.
Conclusion: T2 mapping is a valuable approach for the evaluation of cartilage, allowing better monitoring of the disease and the treatment-related changes over time in addition to standard morphological MRI sequences.

B-1159 11:10

Ultrasound-guided percutaneous treatment of plantar fasciitis: 5-year follow-up of three different approaches
V. Buscarino[1], D. Orlandi[2], E. Silvestri[2], M. Moscatelli[1], M. Catapano[1], L.M. Sconfienza[1]; [1]*Milan/IT*, [2]*Genoa/IT (valentinabuscarino@gmail.com)*

Purpose: To compare the short- and long-term outcome of US-guided percutaneous treatment of plantar fasciitis based on dry needling and local injection of steroid compared to patients treated with simple steroid injection or dry needling.
Methods and Materials: Among 75 patients referred for US-guided treatment of plantar fasciitis, 25 (12 males; age 43.8±7.6y) were treated with dry needling and local injection of steroid together; 25 (12 males; age 46.2±12.3y) were treated with dry needling only; 25 (11 males; age 52.7±10.0y) were treated only with local injection of steroid. Pain was assessed using the visual analogue scale (VAS) at baseline and at 7, 14, 30, 90, 180, 360 days and at five years after the procedure; fascial thickness was measured with US scanning at baseline and at 180 and 360 days later.
Results: Patients treated with complete procedure had a faster and more permanent decrease of symptoms (VAS at 7 days=1.2±0.4; at 360 days=0.0± 0.1). Patients treated only with injection of steroid had a quick decrease of pain that was not permanent on a long-term basis (VAS at 7 days=1.2±0.6; at 360 days=5.2± 0.4). Patients treated only with needling had a permanent but very slow decrease of symptoms (VAS at 7 days=5.7±0.5; at 360 days VAS=0.1±0.2). Difference was statistically significant ($p>001$). At five-year follow-up, VAS was 0.9±1.9 for the complete procedure, 1.5±2.4 for steroids only, 1.1±1.9 for needling only.
Conclusion: Patients treated with the combined procedure had faster and better outcome than others. At five years, outcomes were not significantly different.

B-1160 11:18

Soft tissue sarcoma diagnosis by imaging-guided core-needle biopsy: yield and limitations
P. Naval, J. Narvaez, M. Huete, J. Hernandez-Gañan, J. Sardiñas, X. Sanjuan; *Barcelona/ES (jose_a_narvaez@hotmail.com)*

Purpose: To evaluate the diagnostic yield of core-needle biopsy (CNB) guided by ultrasound or CT for the diagnosis of soft tissue sarcomas (STS).
Methods and Materials: We retrospectively revised all the cases of STS visited in the multidisciplinary musculoskeletal tumour unit of tertiary hospital during 5 years (2011-2015). We found 120 cases of STS in which imaging-guide CNB was performed. There were 63 males and 57 females, with an average age of 58 years (range 22-90).
Results: Image-guided CNB correctly established the diagnosis of sarcoma in 105 patients, with a sensitivity of 87.5% and a specificity of 100%. False negatives of CNC (n=15) mainly corresponded to well-differentiated liposarcomas diagnosed as lipomas (n=4), small local recurrences misdiagnosed as fibrotic changes (n=3), low-grade fibromyxoid sarcoma (n=2) and synovial sarcoma (n=2). Excluding well-differentiated liposarcomas diagnosed as lipomas, sensitivity increased to 94.8%, with a specificity of 100%. Only 9 cases of high-grade STS were classified as low grade by image-guided CNB. Only one procedure was stopped due to pain (nerve damage). No other serious complications occurred.
Conclusion: Our results suggest that CNB can replace open biopsy in the diagnosis of STS. Nevertheless, in our experience, the differentiation between lipoma and well-differentiated liposarcoma and difficulty in discerning histopathologic degree of STS present lower yield, and were the two main limitations of CNB.

B-1161 11:26

Benign bone tumours other than osteoid osteoma percutaneous ablation
J. Martel[1], F. Ruiz-Santiago[2], Á. Bueno[1], L. Guzmán[2]; [1]*Alcorcon/ES*, [2]*Granada/ES (jmartel@fhalcorcon.es)*

Purpose: Bone tumours ablative thermal methods are being widely used, especially to the osteoid osteoma curative treatment. However, other benign tumours can also be treated by means of these techniques. We review the radiofrequency, microwave and cryoablation CT-guided methods usefulness to the treatment of benign tumour bone conditions different from osteoid osteoma
Methods and Materials: For the last fifteen years we have performed 35 percutaneous ablations for the treatment of different benign bone tumours other than osteoid osteoma. 13 (37%) patients were female and 22 (63%) male. Mean age: 23.5 years (range 13 to 58 years). Location: femur (9 cases), pelvic ring (7), tibia (6), foot (5), spine (4), humerus (2) and hand (2). Follow-up period: 24-36 months. Percutaneous radiofrequency thermal ablation was used in most (30) of the patients, microwave ablation in 3 and cryoablation in 2 patients. In 5 cases these techniques were combined with cementoplasty. Biopsy was performed in all cases in order to confirm the diagnosis, in 14 cases just before the ablation procedure. 9 tumours proved to be chondroblastoma, 8 osteoblastoma, 5 giant cell tumour, 3 enchondroma, 3 aneurysmal bone cyst, 2 mesenchymal tumours, 5 other.
Results: All procedures were technically successful. All of patients were pain-free by the seventh-tenth day except in three patients (one chondroblastoma and two osteoblastoma). Only two single complications were recorded.
Conclusion: CT-guided thermal ablation can be curative to other benign bone tumours other than osteoid osteoma, mainly osteoblastoma, chondroblastoma, giant cell tumour and aneurysmal bone cyst.

B-1162 11:34

Diagnostic findings (MRI and CT) in long term follow-up of osteoid osteomas treated with RFA and MRgFUS: a pictorial review with clinical correlation
F. Arrigoni, S. Mariani, L. Zugaro, A. Barile, C. Masciocchi; *L'Aquila/IT (arrigoni.francesco@gmail.com)*

Purpose: To review and describe the main diagnostic findings that feature the follow-up, up to 5 years, after treatment of OO with RFA or MRgFUS, and to investigate their evolution over the time and relationship with clinical data.
Methods and Materials: Retrospectively we evaluated MRI and CT performed after ablation procedure (6, 12, 24 and 60 months) of patients successfully treated with RFA or MRgFUS (23 and 20 respectively) looking for signs proving the good outcome or, eventually possibility of complications. The evaluation also took into account the site of lesions: intrarticular or extraarticular. For each patient, the study of the imaging was coupled with clinical data.

Results: The main outcome that proves the success of the procedure is clinical: the pain disappears mainly in one week and it is the most precocious sign of the success of the procedure. Imaging features of the disease do not modify before 6 months after treatment: only synovial reaction (in case of intrarticular lesions) disappears at the follow-up at 6 months, instead at this follow-up, the bone edema can be less evident but disappears completely 1 years after treatment. The "ring sign", if present, can last up two years. About the CT, only for the MRgFUS treatments, we observed in all cases within 2 years a complete "restitutio ad integrum" of the bone segment.
Conclusion: The imaging in the follow up of this type of treatment confirms the good outcome of the procedure, but the most precocious sign is the clinical improvement.

B-1163 11:42

The safety and short-term efficacy of MR-guided focused ultrasound surgery for bone metastases-induced pain palliation

H. Xiong, J. Zhang; *Shanghai/CN (xionghairui@gmail.com)*

Purpose: To evaluate the safety and short-term efficacy of MR-guided focused ultrasound surgery (MRgFUS) for pain palliation of bone metastasis patients.
Methods and Materials: 14 patients with painful bone metastases were recruited in a prospective, non-randomised, controlled study. The treating efficacy is characterised by the brief pain inventory quality of life (BPI-QOL) survey, numerical rating scale (NRS), and Karnosky performance status scale (KPS). On the basis of survey results, the adverse events that occurred pre- and post-treatment were analysed, and the short-term MRgFUS treatment efficacy for painful bone metastases was discussed.
Results: 14 metastatic bone lesions of these patients were treated with MRgFUS. The average treatment time and sonication number was (111.07±34.03) minutes and (17.43±6.86) times. One patient died from pneumonia during the follow-ups, one patient dropped out of the study due to chemotherapy. After the treatment, three patients reported lower extremities numbness which relieved spontaneously within 7 days; only one patient developed deep venous thrombosis in one week; two patients had soft tissue oedema around the lesions. According to the survey, the NRS decreases from 6.83±2.12 to 3.42±3.58 from pre-treatment to post-three months. The tendency of BPI-QOL and KPS rating are from 40.54±9.42 to 29.14±19.46, 76.67±12.31 to 60.0±26.97, respectively. Pain palliation efficiency reached 75%, compared with the NRS of pre-treatment was significantly different (P<0.05), with statistical significance.
Conclusion: MRgFUS is proved to be a novel, safe, and noninvasive approach for bone metastases-induced pain palliation, which is effective in short term.

B-1164 11:50

Effect of MRI-guided high intensity focused ultrasound on local control of bone metastases

A. Bazzocchi[1], A. Napoli[2], R. Scipione[2], C. Marrocchio[2], G. Guglielmi[3], C. Catalano[2], U. Albisinni[1]; [1]*Bologna/IT*, [2]*Rome/IT*, [3]*Foggia/IT (abazzo@inwind.it)*

Purpose: MRI-guided high-intensity focused-ultrasound (MRgHIFU or FUS) treatment was proved to be effective and safe for palliating pain of bone metastases. The aim of this work was to provide evidence about the effect of MRgFUS on local tumour control of bone metastases.
Methods and Materials: Patients with painful bone metastases were prospectively enrolled and underwent MRgFUS, with imaging (CT/MRI) before and 3, 6 and 12 months after treatment. The primary endpoint of the study was the number of lesions with partial or complete response at 3 months according to MD-Anderson criteria.
Results: Out of 105 patients, 18 were lost and missed the 3-month imaging check. Eighty-seven patients with 89 lesions were evaluated. The procedure was successful in terms of local tumour control at 3 months in 53/89 lesions (60%) - complete-31, partial-22. A stable disease was observed in 26 lesions and a progression in 10. The single element influencing the outcome was the size of the lesion (up to 16cm), with 7cm as reasonable cut-off for supporting successful ablation (p<0.01). Results were statistically independent of previous radiation therapy (59%), histology, and lesion type, though osteolytic (or mixed) pattern, with complete accessibility of the margins to the ultrasound beam were generally better candidates. BMI, age and sex did not play a role in the final outcome.
Conclusion: MRgFUS for painful bone metastases may achieve a local control. In the future, this opportunity should be further explored and addressed even to patients with a potential primary intent of tumour ablation.

More than half of the patients with hip pain due to FAI present an abnormal femoral torsion

T.D. Lerch, I.A. Todorski, F. Schmaranzer, S.D. Steppacher, K.A. Siebenrock, S.F. Werlen, M. Tannast; *Berne/CH (inga.todorski@insel.ch)*

Purpose: Torsional deformities have been increasingly recognised as additional important factor in young patients with hip pain resulting from FAI or hip dysplasia. It is unknown how often torsional deformities are present in young patients with hip pain due to FAI. We questioned what is the prevalence of a pathological femoral torsion in hips with FAI or hip dysplasia?
Methods and Materials: An IRB-approved retrospective radiological study of 463 consecutive symptomatic FAI patients (539 hips) and MRI or CT scan to measure femoral torsion were performed. Out of 915 MRI we excluded 376 hips. The study groups were further classified into 10 groups (e.g. dysplastic (LCE<20°), valgus (CCD>139°), perthes hips(LCPD)). Femoral torsion was defined according to Tönnis et al. as angle between the axis of femoral neck and the posterior axis of the femoral condyles. Normal femoral torsion was defined 10-25°. Torsional deformities include decreased (<0°) and increased (>35°) femoral torsion.
Results: 51% of all 539 hips presented pathological values for femoral torsion. Torsion deformities (<0° or >35°) were measured in 17% of all hips with hip pain due to FAI.Analysis of Varianz (ANOVA) revealed significant differences (p<0,001) of torsion between normal (Mean: 17°) and dysplastic (Mean: 26°), valgus (Mean: 27°) and perthes hips (Mean: 32°).
Conclusion: More than half of the patients with FAI present an abnormal femoral torsion. In particular valgus, dysplastic and perthes hips have an abnormal high torsion. Femoral torsion should be measured in all patients with hip pain due to FAI or hip dysplasia.

B-1166 10:38

Pelvic inclination is not different in Pincer FAI due to acetabular retroversion compared to hip dysplasia

I.A. Todorski, T.D. Lerch, F. Schmaranzer, K.A. Siebenrock, S.D. Steppacher, M. Tannast; *Berne/CH (inga.todorski@insel.ch)*

Purpose: Pincer femoroacetabular impingement (FAI) can be due to overcoverage or acetabular retroversion. Pelvic inclination is a parameter for pelvic tilt and should be increased in hips with acetabular retroversion according to current literature. Pelvic incidence is a static parameter for sagittal balance and determines lumbar lordosis.Therefore we asked (1) Does pelvic inclination and (2) pelvic incidence differ in hips with pincer FAI compared to hip dysplasia?
Methods and Materials: A retrospective radiological controlled study including 151 consecutive patients (236 hips) with symptomatic FAI was performed. CT scan including the entire pelvis available for all hips allowed the calculation of pelvic inclination and pelvic incidence. These hips were allocated to 5 groups: overcoverage, acetabular retroversion, hip dysplasia, increased acetabular anteversion and valgus hips. Statistical analysis was performed using Analysis of Variance (ANOVA) with Bonferroni correction.
Results: (1) Pelvic inclination did not differ between 5 groups (p=0,311)(2) Pelvic incidence was significantly lower in hips with acetabular retroversion (42°) compared to dysplastic hips (55°), hips with increased acetabular anteversion (55°), valgus (54°) and overcoverage (54°) (p<0,001).
Conclusion: Pelvic inclination is not different in acetabular retroversion, but pelvic incidence was lower in patients with acetabular retroversion. This suggest that these patients should be present with decreased lumbar lordosis. Sagittal balance has to be considered during the clinical and radiological evaluation in patients with Pincer FAI.

B-1167 10:46

Is acetabular labrum size and tear pattern associated with femoral retrotorsion or increased femoral torsion in patients with FAI?

I.A. Todorski, T.D. Lerch, F. Schmaranzer, K.A. Siebenrock, S.D. Steppacher, M. Tannast; *Berne/CH (inga.todorski@insel.ch)*

Purpose: Acetabular labrum size and labral tears antero-superior are typical for femoroacetabular impingement (FAI). Femoral torsion (FT) is a novel cause for anterior FAI and influences labral size and tear pattern. Therefore, we asked (1) what is the anterior labral size and (2) which labral tear patterns are associated with femoral retrotorsion compared to hips with elevated FT.
Methods and Materials: Out of 620 consecutive MR arthrographies we excluded 491 hips with normal FT. An IRB-approved retrospective radiological study involving 129 hips with symptomatic FAI and abnormal FT was performed. Femoral retrotorsion was defined as FT <5° (58 hips), elevated FT was defined as >30° (71 hips). All patients underwent routine radiological evaluation using MR arthrography (3T) including distal femoral condyles for calculation of FT. Labral size and labral tear patterns were measured circumferentially on every clock position (15° intervals) on radial slices trough the femoral neck.
Results: (1) Anterior labral size was significantly decreased in hips with femoral retrotorsion (14mm2 vs 22mm2, p<0,001) compared to posterior in hips with elevated FT. Labral size was significantly smaller anterior compared to posterior hips with femoral retrotorsion (p<0,001). (2) Labral tear patterns were more frequently anterior (2 and 3 o'clock, p<0,001) in hips with elevated FT.
Conclusion: Anterior labrum was smaller in hips with femoral retrotorsion on the corresponding localisation of acetabular rim impingement. This has be considered during radiological diagnosis of FAI for hip-preserving surgery. Anterior labral tear patterns could be associated with anterior subluxation or instability in hips with elevated FT.

B-1168 10:54

MR hip arthrography: diagnostic perfomance of 3D-SSFP vs 2D TSE protocol

M. Kraus, U. Grosse, M. Notohamiprodjo, K. Nikolaou; *Tübingen/DE (mareen.kraus@med.uni-tuebingen.de)*

Purpose: To compare the diagnostic performance and image quality of an isotropic 3D-SSFP sequence to the current diagnostic standard 2D PD-TSE-protocol in hip MR arthrography (hMRA) with arthroscopy as a standard of reference.
Methods and Materials: Eighty-one patients (age 39.5 ± 11.1) with hip pain and suspected labral tears were included, who underwent hMRA at a 3T scanner. We acquired 2D PD-weighted TSE in 3 planes and a parasagittal 2D-SSFP sequence. Labral tears, cartilage pathology and bone marrow were assessed independently by two blinded experienced musculoskeletal radiologists using a 5-point Likert scale. In 39 patients, diagnostic accuracy could be determined using invasive arthroscopy as gold standard.
Results: Diagnostic confidence of labral and cartilaginour pathologies based on image quality was rated higher for 3D-SSFP (4.5 ± 0.8; 4.35 ± 0.7; p<0.0001). In the subset of patients with invasive arthroscopy, similar sensitivity (85.9%) but higher specificity (74.4% vs 42.9%), higher positive and negative predictive values were found for 3D-SSFP for evaluation of labral tears and cartilage alterations.
Conclusion: 3D-SSFP in hMRA offers an increased accuracy in detecting labral tears and cartilage alterations compared to 2D TSE-PD, whilst reducing the acquisition time. A major drawback of 3D-SSFP was the inferior diagnostic confidence for bone marrow evaluation; thus, 3D-SSFP should still be combined with conventional 2D-TSE-sequences.

B-1169 11:02

MRI hindfoot characteristics of genetic haemochromatosis: a case control study

A. Elstob, V. Ejindu, C.W. Heron, P.D.W. Kiely; *London/UK (alison.elstob@nhs.net)*

Purpose: From an early stage, many genetic haemochromatosis (GH) patients report arthropathy. There is an unexpectedly high prevalence of ankle involvement in GH, resembling primary osteoarthritis (OA). We evaluated distinguishing MRI features that might improve recognition of GH in undiagnosed cases.
Methods and Materials: Retrospective case-control study. Local ethical approval obtained. 30 MRI studies of GH patients with hindfoot arthropathy were identified from a specialist rheumatology database. 30 gender and age matched controls with primary hindfoot OA identified from PACS search. Anonymised MR images were independently scored by two specialist MSK radiologists using a semiquantative tool adapted from the MRI osteoarthritis knee score. The primary outcome score was bone marrow lesion (BML) and cyst size. Seven secondary outcomes were scored with scores generated for ankle joint and middle and posterior facets of the subtalar joint. Paired Student's T test and Chi squared test were used to compare outcome measures between GH and controls.
Results: BML/cyst size score at the ankle joint was significantly higher in GH cases compared with controls (p=0.001) but not at the subtalar joint (p=0.119, p=0.63). At the ankle joint, GH scores were significantly higher than paired controls for 5 of 7 secondary outcomes (p<0.05). At the middle facet subtalar joint, GH scores were significantly higher for 3 secondary outcomes (p<0.05).
Conclusion: In comparison to matched primary OA controls, GH patients have significantly higher MRI osteoarthritis scores at the ankle and middle facet subtalar joint. These MRI features may have potential diagnostic value for recognising GH.

B-1170 11:10

Talonavicular ligament: anatomy and stability

M. De Dea, C. Loizou, G. Allen, D. Wilson, N. Athanasou, P. Cooke, T. Cosker; *Oxford/UK (miriamdedea@yahoo.com)*

Purpose: To assess the anatomy of the talonavicular ligament (TNL) and its role in talonavicular joint stability.
Methods and Materials: 6 TNL were dissected from thawed cadaveric feet and sent for histological analysis. In further 6 feet the talonavicular joint was imaged with ultrasound (US) and two landmarks identified on each side of the joint in order to measure its movement caused by a stressing manoeuvre (great toe extension causing a rising of the arch of the foot as per windlass mechanism applied through the plantar aponeurosis). Measurements were taken at rest and with stress, with intact TNL and after its US guided division.
Results: The TNL is composed by bundles of collagen with parallel arrangement of fibres along its length. The talonavicular joint displacement assessed with US measured 0.18±0.08cm when the TNL was intact and 0.29±0.07 cm when divided (p<0.005).
Conclusion: The TNL has a structure suggesting a role in tensile force transmission. We have demonstrated by US that division of the TNL simulating a complete tear results in increased talonavicular joint displacement when the joint is stressed. A complete tear of the TNL may be implicated in later joint arthritis and symptomatology. It may be useful to include the TNL in the check list of ankle and foot: if injured early treatment might include immobilisation.
This abstract has been submitted in whole or in part to the British Orthopaedic Foot & Ankle Society Annual Meeting (2016).

B-1171 11:18

Ligament evaluation of the hind and midfoot: better depiction by using dixon method in ankle MRI

E. Park, S. Kim, E. Koh, E. Jung; *Jeonju/KR (kohesther@naver.com)*

Purpose: To determine if ankle magnetic resonance (MR) imaging using Dixon technique helps to depict hind and midfoot ligaments compared with those achieved without using Dixon technique.
Methods and Materials: From July to December 2015 ankle MRI using Dixon technique of 48 ankles was obtained from 25 asymptomatic healthy volunteers. Twenty-three ligaments from hind and midfoot were chosen for evaluation. Two experienced reviewers separately rated the depiction of 23 ligaments. Set 1 was MRI using Dixon technique which composed of all 7 sequences. Set 2 represented conventional MRI composed of subsets with 4 different sequences including 2 nonfat-suppressed and 2 fat-suppressed plane. Ligaments were divided in to two groups. Major ligament included ATFL, CFL, PTFL, Lisfranc ligament, deltoid ligament, spring ligament. Other ligaments were categorized as minor ligament. The depiction rate was calculated using generalized estimating equations.
Results: The depiction rate was significantly higher on set 1 compared with set 2; 91.3% versus 73.2 %, respectively. This was consistently observed for major ligament; 96.4% versus 76.1% (p<0.005). In set 2, the depiction rate was higher for subset with nonfat-suppressed axial and sagittal plane compared with those with axial and sagittal plane and coronal and saggital plane (82.7%, 77.6%, 70.7%, respectively).
Conclusion: For better depiction of hind and midfoot ligaments, all three axial, coronal and sagittal plane with non-fat suppressed sequences are required. The Ankle MRI using Dixon technique yielded better depiction rate of hind and midfoot ligaments by supplying both nonfat-suppressed and fat-suppressed sequences in single scan.

B-1172 11:26

High incidence of periprosthetic cystic lesions around CCI evolution ankle implant

S. Somodi; *Hvidovre/DK (sanja.somodi.03@regionh.dk)*

Purpose: The CCI evolution ankle prosthesis was abandoned due to failures and findings of bone loss at revision. The aim of this study was to a) determine our true revision rate, b) investigate prevalence, size and location of periprosthetic bone cysts through x-ray and CT c) relate these findings to patient-reported outcome measurements (PROMs) and alignment of implants.

Methods and Materials: 51 primary surgeries were performed - of these 36 patients were enrolled and underwent evaluation with metal artefact reduction CT-scans and conventional x-ray. They filled out 3 PROMs; SEFAS-da, SF-36, EQ-5D. Cyst volume larger than 0.1 ml was measured using VITREA volume tools and IMPAX built-in measuring tools. PROMs association to osteolytic volume and implant alignment was analysed by linear and logistic regression.
Results: 19 of the original 51 implants had secondary surgery; primarily because of large osteolytic lesions +/- non-traumatic fractures and non-union (9 true revisions), lesser osteolytic cyst cavities (5 allo-/auto-transplantations), exostosis (4 cases) and traumatic fractures (1 case). The 3- and 5-year rates were 14% and 18% for true-revisions and 17% and 29% for overall secondary surgeries. Cystic lesions were found in 81% of participants. Total cystic volume was not significantly related to PROM scores (P 0.16-0.5), but showed some association with implant alignment.
Conclusion: The implant investigated performs below standard, compared to public registries that report overall 5-year revision rates at 5-6.5% in comparable implants. Cysts were common, large and unrelated to PROMs. Malalignment of implants might be the cause of high failure rates.

B-1173 11:34

Follow-up study with sonoelastography after open surgery repair on Achilles tendon in professional athlets and balet dancers in comparance to non-sport related persons

V. Gazhonova, P. Pereyarchenko, V. Abelcev; *Moscow/RU (vx969@yandex.ru)*

Purpose: To compare strain ratio (SR) values in Achilles tendon after open surgery.
Methods and Materials: 39 patients (24 non-permanent sport persons, 15 active sportsmen and ballet dancers) with acute Achilles rupture after open surgical repair were included in the follow-up sonoelastography study. Rehabilitation was received in recommended amount according to time after surgery. Functional outcomes were assessed with AOFAS rating system. Sonoelastography Mean Strain Ratio values (SR1, SR2 values) of the regenerated Achilles tendon were measured in the longitudinal plane during the follow-up period (1 week, 3, 6, 12, 36-40 weeks after surgery). Student's t-test were used to consider statistical significance with $p<0.05$.
Results: There were significant differences with respect to the mean SR values and functional scores of the repaired Achilles tendon at 6, 12, and 24 weeks postoperatively between 2 groups. Tendon function was positively correlated with increase in SR values of the repaired Achilles tendon. Sport related patients showed more prominent and quick appearance of increase in stiffness of the regenerated tendon: SR 3 weeks 2.5+/-06, 4.1+/-1.4, p<0,001; SR6weeks 1.7+/-0.5, 3.6+/-1.7, p<0.005; SR12weeks 1.9+/-1.1, 3.8+/-1.3, p<0,007, correspondingly). Non-sport related patients showed prolongation in time for increase in tendon stiffness that result in longer rehabilitation time.
Conclusion: Sonoelastography is an effective method for monitoring regenerative processes of the Achilles tendon after operation, reflecting the elasticity of the collagen fibres which can be used for individual rehabilitation programs for sport related and non-sport related patients.

B-1174 11:42

Detecting fracture of ankle in MRI: improved sensitivity by Dixon technique including opposed phase imaging

E. Koh, E. Jung; *Jeonju/KR (kohesther@naver.com)*

Purpose: To evaluate if the opposed phase from Dixon image can increase sensitivity in the diagnosis of fracture of ankle compared with conventional MR imaging technique.
Methods and Materials: This study included 45 patients with 95 CT confirmed ankle fractures who performed MRI applying Dixon technique. The images were divided in to set 1; represented conventional MRI and set 2; opposed phase imaging. Two readers assessed 4 point confidence score to detect fracture. At first review session, readers were blinded to information and site of fractures. At second review, the information of site of the fracture was given. Sensitivity and positive predictive value (PPV) were calculated.
Results: In both session, the sensitivity of set 2 was significantly higher than those for the set 1 (session 1; 76.3 versus 62.6, respectively, session 2; 80.5% versus 65.3%). The PPV of set 2 was significantly lower compared with set 1 (85.8% versus 97.5%, respectively). While 8.9% showed lower movement of confidence score at set 2 compared with set 1, 33.6% of cases showed upper movement of confidence score. The devised possible causes of false lesions were small fractures, subcutaneous fat lobule, bone marrow edema, intraosseous vessel.
Conclusion: Opposed phase image from Dixon technique provides better sensitivity and better description of fractures compared with conventional MRI. However, cautions are required in opposed phase in diagnosis of fracture since it can be confused by adjacent BM edema or subcutaneous fat lobule.

B-1175 11:50

MRI study of plantar plate and associated lesions

B.C.S. Rabelo[1], R. Nobre Rodrigues[2], J. Mendes Torres[2], A. Abuhid Lopes[2], E. Salgado Ribeiro[2], M. Santana Firme[2], L. Gavio[2]; [1]*Itaúna/BR*, [2]*Belo Horizonte/BR (brenorabelomed@gmail.com)*

Purpose: Identify and provide data for comprehension of lesions that could be associated to metatarsophalangeal joint (MTPJ) instability and metatarsalgia based on analysis of MRI.
Methods and Materials: 52 forefoot MRI`s in 49 patients (mean age 59 years, ranging from 45-78) with plantar plate (PP) tear were retrospectively reviewed by two MSK radiologists using a 1.5T MRI. MRI was evaluated for MTP PP tear and for the presence of associated lesions.
Results: From 52 feet evaluated, 31 (59,6%) presented with PP tear only at the second MTF and 2 (3,8%) at the third MTF. 13 (25%) presented with combined lesions with 2 or more PP tears. 42 feet (81,6%) were classified as index minus. All feet had associated lesions with PP tear: hallux valgus (71,4%), Morton`s neuroma (63,3%), bursitis (55,1%), flexor tendonitis (46,9%), sesamoiditis (42,9%), arthrosis (30,6%), synovitis (24,5%). Most of the lesions (88.8%) were insertional, located at the base of the proximal phalanx.
Conclusion: The detection of associated lesions in patients with PP tear in MRI is crucial for adequate surgical planning, avoiding failure to correct lesions that may keep causing pain in the future and require further invasive interventions. The data from this study aims to help the evaluation of MRIs of feet with PP tear by providing predictability of the associated lesions in the feet, ultimately the high frequency of associated lesions shown is useful data and may contribute to differential diagnostic imaging of other causes of metatarsalgia.

Using programmable LED lighting to create a personalised ambience in the radiology environment

M.U. Knopp[1], M.M. Knopp[2], K. Binzel[3], C. Wright[3], M.V. Knopp[3]; [1]*Malibu, CA/US*, [2]*Atlanta, GA/US*, [3]*Columbus, OH/US (knopp@wcibmi.org)*

Purpose: Dedicated commercial solutions for ambient lighting have been available for years, however, broader utilisation has been limited due to their high costs. With programmable LED lighting now consumer products, we explored and assessed the feasibility and potential impact of deploying such systems in imaging environments.
Methods and Materials: We installed IP addressable LED lights using the ZigBee standard in different radiology rooms such as equipment, control, waiting and injection in order to assess a, the feasibility and b, how the different colours/hue are being perceived. In this feasibility study, we used staff and volunteers (n=13) in order to get base data to develop a clinical trial protocol. A visual perception assessment procedure was developed that used a questionnaire, pre-programmed light colour/hue settings and the ability of the subject to select the preferred setting that was found to be relaxing. The answers and setting such as RAL tone were tabulated.
Results: Technical implementation using consumer based LED lights was realized without any hardware/electric modifications. The installed IP programmable lights were readily controllable using smartphone/tablet based apps. The subject testing revealed substantial variabilities in light colour/hue perception, however clear trends were noted. In regard to which hue was perceived to enable a relaxed feeling, 62% indicated a blue tone, 23% a yellow and only 8% a red tone. Hue tones perceived to exacerbate anxiety were red 38%, yellow 38% and green 15%.
Conclusion: Programmable LED lighting can effectively and efficiently be implemented. Colour perception appears highly individualised suggesting a personalised approach is needed to create comforting atmospheres.

B-1179 10:38

Optimisation of fluoroscopic imaging of the Codman Hakim adjustable cerebrospinal fluid shunt valve

A. Bremnes, L. Kubosch, B. Ween; *Oslo/NO (alexander.bremnes@ahus.no)*

Purpose: To investigate the different fluoroscopic imaging techniques used to control the Codman Hakim adjustable valve (Codman/Johnson & Johnson, Raynham, Massachusetts) and to best practice in this image procedure. Cerebrospinal Fluid (CSF) Shunt valves, as the Codman Hakim valve, has become an important tool in hydrocephalus treatment. It has an adjustable valve and to control the adjustable valve settings fluoroscopic imaging is used.
Methods and Materials: Based on a survey on Codman Hakim imaging procedures used in hospitals in Norway, eight experimental images were acquired based on the imaging techniques seen in the hospitals. The images were measured for SNR values. Then evaluated and graded by 10 radiologists and 50 radiographers, subjectively and anonymously, using relative visual grading analysis.
Results: The image using the imaging technique with head support, grid, and the valve on the near side of the head when positioned towards the detector got 31% of the total score. The image using the imaging technique recommended by the manufacturer of the Codman Hakim adjustable valve got second highest total score with 22%. Image readers gave 64% of the total score to the imaging techniques with the valve on the near side of the head when positioned towards the detector.
Conclusion: The subjective and objective results show that images acquired using a head support, grid, and with the valve on the near side of the head when positioned towards the detector are most optimal. These is a potential to improve image optimisation in shunt radiography.

B-1180 10:46

The radiopaque anatomical side markers: have we forgot how to use them?

E. Saukko, J. Svegin, E. Svedström; *Turku/FI (ekaterina.saukko@tyks.fi)*

Purpose: The use of anatomical side markers within the primary beam of radiographs is considered as a best practice. CR and DR systems allow applying markers electronically during post-image processing and this has led to a decrease in use of radiopaque anatomical side markers. The aim of this study was to evaluate a clinical practice for use of anatomical side markers in radiography at our radiological department.
Methods and Materials: The use of anatomical side markers was evaluated from a total of 150 radiographic examinations of ankle, shoulder, cervical spine, lumbar spine and wrist. Data was collected consecutively from PACS during the period of five months in 2014 and each assessed examination consists of 1-3 images (n=330). An educational intervention was performed in 2015 and all radiographers were supplied with their own set of markers. After 12 months in 2016, a re-evaluation of anatomical side markers use was conducted by collecting the similar data to assess the impact of interventions.
Results: Results from 2014 demonstrate that anatomical side makers were used within primary beam on 28% of images, 74% of images had a marker added post-processing and 1.2% of images had an incorrect or absent anatomical side marker. In 2016 all assessed images were appropriately marked (100%) and 54% of them included anatomical side marker placed pre-exposure.
Conclusion: The use of radiopaque anatomical side markers was increased. Radiology departments should provide for radiographers an easy access to radiopaque anatomical side markers and carry out regular audits of practice.

B-1181 10:54

Radiation dose to newborns in a neonatal intensive care unit

L. Sousa, A.F. Abrantes, L.P.V. Ribeiro, J.P. Pinheiro, R.P.P. Almeida, S. Rodrigues, P. Sousa; *Faro/PT (jppinheiro@ualg.pt)*

Purpose: To assess the entrance surface doses (ESD) in newborns from chest radiographs performed in a neonatal intensive care unit of a public hospital.
Methods and Materials: A survey of technical parameters used in the mobile x-ray examinations was performed using a sample of 24 chest radiographs to determine the average parameters (kVp and mAs) according to the weight of the newborns (0-1000g; 1000-2000g; and >2000g). Using these parameters, ESD values were determined based on the mean and 75th percentile. Quality control of the mobile equipment was made with a semiconductor detector (Unfors Xi).
Results: The ESD values resulting for the 75th percentile was 27.3 µGy at 1 meter of Source-Image Distance (SID) and 16,17 µGy at 1.28 meters. Considering the weight intervals, ESD values for the 75th percentile were 18.4 µGy (0-1000g), 27.3 µGy (1000-2000g) and 34.76 µGy (>2000 g) at 1 meter of SID. The ESD values increased with the increase in the weight of newborn. The results of this study were also compared with three previous studies. The values of the ESD resulted from the mean of this study (23.1 µGy at 1 meter) only exceeded the results of a study which ESD was 20.0 µGy.
Conclusion: The results obtained did not exceed the limits required internationally. However, several actions should be pursued, including: remarking the ALARA (as low as reasonable achievable) concept, defining national guidelines for good newborn radiography and, retraining radiographers to be specialised for neonatal imaging and neonatal ionisation radiation hazards.

B-1182 11:02

Are radiographers prepared to meet children with special needs when seen for a radiographic examination?

B. Bjorkman; *Jönköping/SE (berit.bjorkman@ju.se)*

Purpose: Two previous national surveys showed, that none radiology and paediatric departments and a minority of anaesthesiology departments throughout Sweden use specific guidelines when interacting with children diagnosed with Autism Spectrum Disorders (ASD). Following, the purpose was to develop guidelines to use when caring for and preparing children with ASD for anaesthesia and callenging radiographic procedures.
Methods and Materials: A modified Delphi method was used, including 19 experts identified from the two aforementioned surveys. The questions considered in the Delphi process, proceeded from previous research and the results from the two national studies. The experts' responses regarding the importance of each item, were analysed and scrutinised between each round.
Results: The Delphi process resulted in guidelines consisting of 15 items and a checklist of 16 aspects. The items cover the areas: planning and involving parents/guardians, features in the environment, use of time, communication and the health care professionals. The checklist covers the child's pattern of communication, anxiety, sensory stimuli, special interests and likes/dislikes.
Conclusion: In order to obtain an optimum caring encounter with a child with ASD in the preoperative and radiology setting, a meticulous planning ahead to fulfil the needs of each specific child is important. Also the environment should be adjusted for the needs of the child and the health care professionals need to inherit knowledge about ASD in general and the specific needs of the individual child in particular. In order to accomplish this, guidelines need to be in place and be followed.

B-1183 11:10

Optimisation full-spine curvature radiography in paediatrics - impact of acquisition parameters

C.S. Reis[1], V. Harsaker[2], A. Bregman[3], R. Chêne[4], B. Cordeiro[5], T. Daniels[6], M. Johannessen[2], S. Vestli[2], M. Widmer[4], A. England[7], P. Hogg[7]; [1]*Perth/AU*, [2]*Oslo/NO*, [3]*Groningen/NL*, [4]*Lausanne/CH*, [5]*Lisbon/PT*, [6]*Bloemfontein/ZA*, [7]*Salford/UK (a.bregman@outlook.com)*

Purpose: To determine a set of acquisition parameters for infantile scoliosis in anteroposterior (AP) digita radiography using low effective dose (*E*) whilst retaining adequate image quality (IQ) for visual evaluation using 1 year-old anthropomorphic phantom.
Methods and Materials: 48 images of the phantom full spine were acquired in AP position varying beam energy (55-85kVp), source-to-image distance (SID) (160-200cm), beam intensity (6,3-0,8mAs) whilst applying the 10 kVp rule, air gap (with 20cm or without), added beam filtration (1mm Al+0,2mm Cu or without) to analyse the impact of E on IQ. IQ was evaluated by an objective approach using contrast-to-noise ratio (CNR) and a perceptual approach using 6 observers. Monte-Carlo modelling (PCXMC software) was used to estimate E. The Intraclass correlation coefficient (ICC) was used to calculate intra and inter-observer consistency.
Results: The results show that CNR was high at 65kVp, with SID of 180cm; but the lowest E was achieved using 160cm SID, 85kVp, 0.8mAs, no air gap and with a filtration of 1mm Al and 0.2mm Cu. The intra- and inter-observer ICC for visualising the anatomical structures was moderate to good varying between 0.596-0.890 and 0.631-0.988, respectively. Observers identified all relevant anatomical structures to draw the lines used for angle measurements in clinical practice.
Conclusion: The observers were able to perform the task related to diagnostic performance in the group of images produced with the lowest E. This study shows that it is possible to optimise radiography practice concerning infantile studies.

B-1184 11:18

Benefit-risk communication in paediatric imaging: an assessment of current practice among local referrers and practitioners

J.L. Portelli[1], J.P. McNulty[2], P. Bezzina[1], L. Rainford[2]; [1]*Msida/MT*, [2]*Dublin/IE (jonathan.portelli@um.edu.mt)*

Purpose: To investigate referrers' and practitioners' practice of providing benefit-risk information when imaging paediatric patients at a large general hospital in Malta.

Methods and Materials: A cross-sectional survey was conducted prospectively among 272 referrers and practitioners, namely: emergency medicine physicians (55), paediatricians (49), radiographers (146), and radiology practitioners (22). Apart from assessing whether participants had received any education or training in radiation protection, referrers and practitioners were asked about the type of information they generally provided to paediatric patients and their families; whether they would discuss benefits and/or risks associated with paediatric imaging examinations; and how confident they felt in their ability to communicate such information.
Results: A total of 168 participants (56 referrers and 112 practitioners) completed and returned the questionnaire, providing an overall response rate of 61.8%. Findings revealed that the practice of providing benefit-risk information varied, with a lower proportion of practitioners indicating that they would discuss associated benefits and risks of paediatric imaging examinations. Those who received education and training in radiation protection provided a significantly better ranking to their level of confidence and ability to communicate benefit-risk information, although only 36.7% of all participants actually indicated a high level of confidence in this regard.
Conclusion: The practice of discussing benefits and risks associated with paediatric imaging examinations is varied. Education and/or training activities are necessary to help improve referrers' and practitioners' confidence so as to encourage them to further engage in benefit-risk discussions with paediatric patients and their families.

B-1185 11:26

Wireless workflow in radiology: a pilot testing in portable x-ray
B.E. Koay, S. Li, S.K. Sanamandra; *Singapore/SG*
(koay.beng.ee@sgh.com.sg)

Purpose: The pilot test aims to simplify the work processes for the radiographers, reduce the reliance on paperwork and improve the turn-around-time (TAT) for the portable teams. This paper presents the findings from the pilot test
Methods and Materials: The LEAN thinking system was employed to evaluate the original workflows. Stakeholders identified valued, non-valued tasks and waste process from the workflow. Timing from the original workflow was benchmarked against the wireless workflow. For the wireless workflow, a Toughbook was issued to the portable team and RIS module was customized to facilitate readability and documentation on the Toughbook. Portable x-ray machine was configured to detect hospital Wi-Fi network. Both workflows were applied on the same portable team.
Results: Waste tasks contributed 25% to 30% to the total tasks. They posed potential errors in patient misidentification for ad-hoc additional procedures. With the removal of waste task and simplification of the process, lesser errors could occur. The process indirectly improved patient safety. Instructions were captured in RIS, allowing takeover shift to view outstanding issues from RIS worklist instead of paperwork. Equipped with an electronic signature pad, paperless workflow is achievable. By sending images wirelessly to PACS, the TAT for images to be available to physician improved by 27% to 40%. Overall, average time worked on a patient improved in the range of 12% to 21%.
Conclusion: Our pilot test showed improved results from the wireless workflow. This workflow could potentially extend to be paperless, saving 90 pieces of paper daily.

B-1186 11:34

Mobile radiography services in nursing homes: a systematic review of residents and societal outcomes
E. Kjelle[1], K.B. Lysdahl[2]; [1]*Kongsberg/NO*, [2]*Oslo/NO (elin.kjelle@hbv.no)*

Purpose: The purpose of this systematic review was to identify the outcomes of mobile radiography services for nursing home residents and society.
Methods and Materials: A systematic review based on searches in the Medline, Cochrane, PubMed, Embase and Svemed+ databases was performed. Titles and abstracts were screened according to a predefined set of inclusion criteria: empirical studies in the geriatric population, and reports of mobile radiography services in a clinical setting. All included publications were quality appraised using MMAT or CASP appraisal tools. Data were extracted using a summary table and results were narratively synthesised.
Results: 10 publications were included. Three overarching outcomes were identified: 1) reduction in hospitalisations and outpatient examinations or treatment, 2) reduction in transfers between hospitals and nursing homes and 3) increased access to x-ray examinations. These outcomes are interlinked with the more specific outcomes for residents and society reported in the literature. For residents there is a reduction in burdensome transfers, waiting time, an increase in adequate treatment and care. For society, released resources can be used more wisely, and overall costs are reduced substantially.
Conclusion: This review clearly indicates the benefits of mobile radiography services for nursing home residents, by reducing the burden of transfer, and providing more adequate Treatment and care. Mobile radiography services provide a better socio-economic solution compared to hospital or emergency room examinations. Further research is needed to evaluate the outcomes for residents and next of kin, and to estimate the cost-effectiveness.

Quantification of fibrosis with cardiac MR-T1-mapping using histologic quantification as a gold-standard
P.-A. Barral, J.-J. Izaaryene, A. Jacquier; *Marseilles/FR*
(pierre-antoine.barral@ap-hm.fr)

Purpose: Fibrosis is characterised by fibroblast accumulation and excess deposition of extracellular matrix (ECM) proteins, which leads to distorted organ architecture and function. The contribution of fibrogenesis to impaired cardiac function is increasingly recognised. The goal of this study is to validate T1-mapping for myocardial fibrosis quantification against histological fibrosis quantification as a gold standard, and to assess the link between ECV quantification and blood biomarkers of fibrosis.
Methods and Materials: Thirty patients with aortic pathology needed aortic valve replacement were recruited from the department of cardiac surgery in our institution. Cardiac magnetic resonance (CMR) for ECV quantification and blood samples were performed. T1-mapping (MOLLI) using “look-locker” technique, were performed before and 15 minutes after injection of gadolinium to assess ECV. Standard blood samples and specific fibrosis bio-marker were sampled during the week before surgery. Muscular interventricular septum biopsy was fixed in the formol and stained with picrosirius red.
Results: We found a significant correlation between ECV quantification and histologic evaluation of fibrosis with red picrosirius (p=0.0026), with a 95% confidence interval of 0.2771 to 0.8524. Correlation between ECV and biomarkers was significant for timp 1 (p=0.0378) with 95% confidence interval of 0.026 to 0.69 and for mmp2 (p=0.0475) with 95% confidence interval of 0.0056 to 0.68, but no correlation with galectine, cic p, piinp and icp was found.
Conclusion: T1-mapping and ECV quantification can provide accurate evaluation of myocardial fibrosis. Two biomarkers have also a strong correlation with myocardial fibrosis.

B-1188 10:38

Left ventricular interstitial fibrosis drives left atrial enlargement and impairment in arterial hypertension: novel insights from T1 mapping
J.C.L. Rodrigues, T. Erdei, A. Ghosh Dastidar, A.E. Burchell, M.C.K. Hamilton, J.F.R. Paton, A.K. Nightingale, C. Bucciarelli-Ducci, N.E. Manghat; *Bristol/UK*
(jonrodrigues@doctors.org.uk)

Purpose: Hypertensive left atrial enlargement (LAE) predicts cardiovascular morbidity and mortality. Impaired left atrial (LA) function also confers poor prognosis. We hypothesised that the burden of left ventricular (LV) interstitial fibrosis would be associated with LAE and impaired LA function.
Methods and Materials: 86 hypertensives (49±15 years, 53% male, office SBP 168±30mmHg, office DBP 97±14mmHg) underwent 1.5T cardiovascular magnetic resonance. LV mass and volumes were measured. T1 mapping (with validated modified look-locker inversion-recovery sequence) enables non-invasively LV extracellular volume fraction (ECV) estimation. LA volumes were assessed using the biplane area-length method. The phasic volumetric method generated estimates of LA reservoir, conduit and pump function.
Results: Structurally, as indexed LV mass increased, so did LA size (R=0.345, P<0.001). Functionally, increasing indexed LV mass was associated with significant reductions in LA reservoir (R=-0.439, P<0.0001) and conduit (R=-0.345, P<0.0001) but not pump (R=-0.149, P=0.117) function. At the intra/extracellular myocardial level, increasing ECV was associated with increasing LA size (R=0.359, P<0.001). Furthermore, increasing indexed myocardial interstitial volume was associated with significant reductions in both LA reservoir (R=-0.437, P<0.0001) and conduit (R=-0.316, P=0.003) but not pump (R=-0.167, P=0.125) function. In multivariate regression (controlling for age, gender, BMI, SBP and DBP) ECV remained the only significant independent predictor of LAE (odds ratio[95% confidence interval]: 1.35 [1.09-1.68], P=0.006).

Conclusion: LV interstitial fibrosis is associated with LAE and impaired reservoir and conduit function. LA pump function is preserved which offers hope that future anti-fibrotic agents may be able to cause reverse remodelling of hypertensive LA structural and functional abnormalities.

Evaluation of myocardial fibrosis in patients affected by diabetes mellitus type II and its correlation to left ventricular functional impairment

N. Galea, F. Ciolina, R. Ammendola, E. Giannetta, M. Francone, I. Carbone, C. Catalano; *Rome/IT (nicola.galea@gmail.com)*

Purpose: In diabetic cardiomyopathy (DCM), the chronic metabolic injury determines progressive impairment of cardiomyocytes contractility and fibrotic tissue infiltration, leading to ventricular dysfunction and dilation. The purpose of our study is to non-invasively investigate the relationship between myocardial fibrosis, geometric/function features and clinical data.
Methods and Materials: Sixty-two diabetic patients with preserved ventricular function and no history of ischaemic disease and 20 matching controls underwent CMR. Imaging protocol included: modified look-locker sequence before and 20 minutes after 0.2 mmol/kg gadoterate meglumine injection; T2-mapping; ventricular function module; tagged-cine MR module; late gadolinium enhanced (LGE) imaging. Native myocardial T1 (nT1) and T2 values, extracellular volume fraction (ECV), ventricular torsion angle and myocardial strain values have been calculated and correlated to lab and clinical markers of disease. Pearson Correlation, Mann-Whitney test and unpaired T test were used for statistical analysis.
Results: Patient group had higher nT1 and ECV values compared to controls (1035±94 ms vs975±38 ms, 28.2±3.3%vs24.8±4.3%, respectively, p<0.05 for both), whereas no significant differences occurred in T2 measurements (46.1±2.3ms vs47.0±2.8ms, respectively, p=0.23). nT1 and ECV correlated with glycated haemoglobin (HbA1c, nT1:r2=0.98, ECV:r2=0.95, p<.001) and disease duration (nT1:r2=0.98; ECV:r2=0.55, p<.001) in diabetic patients. nT1 and ECV showed a positive correlation with torsion (nT1:r2=0.98; ECV:r2=0.89, p<.001) and a negative correlation with strain value in tagged-cine MR analysis (nT1:r2=-0.98; ECV:r2=0.92; p<.001). Ischaemic LGE areas were found in four patients as marker of silent infarction.
Conclusion: In diabetic patients with preserved ventricular function, HbA1c values and disease duration showed a correlation with myocardial nT1 and ECV increase, as reflection of diffuse fibrosis, and torsion modification.

B-1190 10:54

Myocardial tissue characterisation by CMR in subjects with prediabetes, diabetes and normal controls with preserved ejection fraction from the general population

C. Storz[1], H. Hetterich[2], R. Lorbeer[2], S. Auweter[2], W. Rathmann[3], C. Schlett[4], A. Peters[5], J. Schulz-Menger[6], F. Bamberg[1]; [1]*Tübingen/DE*, [2]*Munich/DE*, [3]*Düsseldorf/DE*, [4]*Heidelberg/DE*, [5]*Neuherberg/DE*, [6]*Berlin/DE*
(corinna.storz@med.uni-tuebingen.de)

Purpose: To characterise myocardial tissue in subjects with prediabetes, diabetes, and healthy controls using CMR in a sample from the general population.
Methods and Materials: Subjects without history of cardiovascular disease and preserved left ventricular ejection fraction (LVEF) but established diabetes, prediabetes, and normal controls from a population-based cohort underwent contrast-enhanced 3 Tesla CMR. Obtained parameters included left ventricular (LV) function and morphology, late-gadolinium enhancement (LGE) for assessment of focal fibrosis as well as T1-mapping and derivation of extra-cellular volume fraction (ECV) by modified Look-Locker inversion recovery for diffuse fibrosis. Myocardial fibrosis (MF) and cell volume (CV) were calculated.
Results: Among 343 subjects (mean age: 56.1±9.2 years, 57% males), 14% subjects were classified as diabetic, 23% as prediabetes, and 64% as controls. LVEF was preserved in all patients but LV remodeling index was significantly higher in participants with prediabetes and diabetes, independent of BMI, hypertension, age and sex (1.17, 95%-CI: 1.11 to 1.23 and 1.28, 95%-CI: 1.20 to 1.36, p<0,002 respectively). ECV was decreased in subjects with prediabetes and diabetes compared to healthy controls (23.1±2.4% and 22.8±3.0%, both p<0.007, respectively). In contrast, CV was significantly higher in subjects with prediabetes and in diabetics as compared to healthy controls (109.1±23.8 ml and 114.9±32.3 ml vs. 96.5±26.9 ml, both p<0.03, respectively).
Conclusion: Subjects with prediabetes and diabetes but preserved LVEF had higher LV remodeling indices and cell volume than controls, indicating a role for hypertrophy in the pathogenesis of diabetic cardiomyopathy, while diffuse fibrosis appears to be less relevant.

B-1191 11:02

T1 relaxation-times, epicardial fat volume and left ventricular contractility in obese individuals with normal systolic left ventricular function: a cardiac magnetic resonance study

R. Homsi, D. Kuetting, A. Sprinkart, S. Fischer, J. Luetkens, M. Meier-Schroers, D. Dabir, H. Schild, D. Thomas; *Bonn/DE*
(r.homsi@hotmail.com)

Purpose: To investigate left-ventricular (LV) strain, epicardial fat volumes (EFV) and T1-relaxation times (T1) in obese non-hypertensive and non-diabetic individuals with a preserved LV ejection fraction (LVEF).
Methods and Materials: 68 subjects (mean age 56±14years [y]; BMI 29kg/m2) were examined at 1.5 Tesla. 28 individuals were obese (>30kg/m²) and 40 were non-obese (<30kg/m²). T1-RTs, LV peak longitudinal and circumferential strain (LS; CS) as well as EFV and pericardial fat volumes (PFV) were evaluated.
Results: EFV was increased and LS and CS were both decreased in obese (EFV: 69±27ml/m²; LS: -20±3%; CS: -23±5%) compared to non-obese subjects (58±20ml/m²; LS: 23±3%; CS: -27±4%; p<0.05, each). Obese individuals showed increased T1-RTs (990±37ms vs. 972±30ms), however these differences did not reach statistical. There were no significant differences regarding age or gender.
Conclusion: Obesity is associated with an increased EFV, a reduced LV strain in spite of a preserved LVEF, as well as with a trend towards higher T1-RT - as a marker of myocardial fibrosis. Evaluation of these parameters may identify early cardiac changes associated with obesity.

B-1192 11:10

Role of late gadolinium enhancement, myocardium native T1 value and texture analysis in patients affected by dilated cardiomyopathy: clinical score and outcome correlation

A. Scavuzzo, E. Faietti, D. Farina, E. Gavazzi, C. Foletti, I. Zorza; *Brescia/IT*
(alessandro.scavuzzo@gmail.com)

Purpose: To correlate late gadolinium enhancement (LGE), myocardium T1 value, texture analysis and the outcome in patients affected by dilated cardiomyopathy (DMC).
Methods and Materials: Retrospective evaluation on 104 DMC affected patients who underwent cardiac MR (CMR) between January 2012 and May 2015. Exam protocol included morphologic sequences, cine MR, native T1 mapping and after gadolinium PSIR sequences. LGE was analysed drawing ROIs on short-axis PSIR, T1 delineating the cardiac septum on native short-axis ShMOLLI and texture analysis delineating the septum on short-axis cine MR using TexRad software. Outcome was set as major cardiac events (MACE) 6 months within the exam.
Results: 53/104 patients presented LGE and they showed a higher percentage of MACE compared to patients without LGE (37% vs 7%, respectively, p=0.001). The extension of LGE did not correlate with MACE, the ejection fraction or the end-diastolic volumes (t test, p=ns). T1 was measured on 34 patients, 21 with LGE (mean 1033msec) and 13 without LGE (mean 1008msec) (p=ns). Significant difference was shown between T1 of patients with MACE (11/34, mean 1045msec) and without MACE (23/34, mean 1011msec)(p=0.02). Texture analysis showed correlation between patients with and without MACE, with kurtosis at 1mm filter being the most significant value (t test, p=0.0019).
Conclusion: Both the presence of LGE and native T1 value of myocardium correlate with MACE. Correlation between T1 and LGE has not been proved. Texture analysis has demonstrated a potential on defining diffuse myocardium fibrosis (particularly with thin filters) and is easily applicable, but it is not still supported by enough literature data.

B-1193 11:18

Cardiovascular magnetic resonance in cardiomyopathies with viral genome incorporated in cardiac tissue

A. Michalek, M. Lanckoroński, A. Pawlak, M.I. Furmanek, R.J. Gil, A. Nasierowska, M. Przybylski, J. Walecki; *Warsaw/PL*

Purpose: The aim of this study was to identify characteristic pattern of cardiovascular magnetic resonance (CMR) findings in patients with acute myocarditis or chronic dilated cardiomyopathy who had viral genome detected in cardiac tissue.
Methods and Materials: Sixty three patients who presented for work - up of myocarditis or unclear cardiomyopathy underwent CMR and endomyocardial biopsy (EMB) with viruses identification by nested PCR.
Results: Viral genome was identified in 39 patients (62%). Parvovirus B19 was most prevalent virus (29 biopsies), we also detected HHV6 (6), Adenovirus (1), EBV (3), CMV (1). Left ventricular ejection fraction was impaired both in viral positive and viral negative hearts, 45,25 (+/- 18,8) % vs 41,2 (+/- 18,07) % respectively, p=0,2. There was no difference in presence of late gadolinium enhancement (LGE) in accordance of viral genome. Typical non-ischaemic

LGE was presented in 26 (66,7%) viral positive patients and in 12 (50%) viral negative patients, p=3,4. In both groups LGE was detected in all segment with the majority of mid - segments. LGE was detected in all walls, with prevalence of infero/lateral and antero/lateral walls (52,6%, 44,7% LGE positive cardiac scans) and least in anterior wall (21% LGE positive scans) but without any difference in accordance of viral genome. There were 6 cases in viral positive group and 3 cases in viral negative group with typical CMR oedema, p - 1,8.
Conclusion: There is no typical pattern of CMR LGE specific for cardiomyopathy with cardiac tissue positive for viral genome.

B-1194 11:26

Myocardial T1 mapping and extracellular volume fraction (ECV) comparing MOLLI and SMART1Map sequences in 3T-MRI

L. Panebianco, V. Vellucci, L. Patriarca, E. Cannizzaro, P. Palumbo, R. Masi, E. Di Cesare, C. Masciocchi; *L'Aquila/IT (panebianco.luca@gmail.com)*

Purpose: Assessing variability in T1 mapping and extracellular volume fraction values between MOLLI (Modified Look Locker Inversion Recovery) and SMART1Map (Saturation Method using Adaptive Recovery Time) sequences, using ARC (Autocalibrating Reconstruction for Cartesian imaging) and ASSET (Array Spatial Sensitivity Encoding Technique) parallel imaging algorithms.
Methods and Materials: 54 patients underwent contrast-enhanced cardiac magnetic resonance (CE-CMR) on a 3T MRI scanner, after collecting their haematocrit values. Data acquisition was achieved with a cardiac phased-array 32-channel coil, and T1 mapping sequences were performed: MOLLI ARC, MOLLI ASSET, SMART1Map ARC and SMART1Map ASSET, acquired in one slice in short axis plane at mid-ventricular height, with electrocardiographic gating and during expiratory apnoea, before and after intravenous administration of gadobenate dimeglumine 2mmol/kg. For each sequence ECV was obtained by measuring the signal intensity of the antero-septal wall myocardium and of blood pool placing circular ROIs in T1- maps and correlating it with the haematocrit.
Results: A statistically significant difference ($p < 0.05$) for both pre- and post-contrastographic T1 values was observed in SMART1Map sequences (SMART1Map Asset medium 1510.88; SD ± 92.32 and SMART1Map Arc average in 1560; SD ± 135.17) in comparison to the corresponding MOLLI sequences (MOLLI Asset media 1171.61; SD ±40.63 and MOLLI Arc average 1182.1; SD ±54.81); the results showed no significative difference relatively to ECV values. Continuous variables were represented as means and standard deviations, and comparisons between groups were obtained by Student's t test for independent samples.
Conclusion: MOLLI and SMART1Map resulted to provide significantly different values of T1.

B-1195 11:34

MRI atrial fibrosis after cryoablation in patients with atrial fibrillation: a prospective feasibility study and its relation to endovascular procedure

E. Caramia, R. Faletti, L.J. Pavan, D. Tore, M. Matta, M. Anselmino, P. Fonio, F. Gaita, G. Gandini; *Turin/IT (espiguinha@hotmail.it)*

Purpose: cryoablation (CA) is a well-established technique for atrial fibrillation (AF) treatment. Many studies used late gadolinium enhancement magnetic resonance imaging (LGE-MRI) to evaluate left atrial (LA) fibrosis, but there is a lack of data regarding post-procedural structural changes. Our aim was to define the role of LGE-MRI in the identification and quantification of LA ablation induced fibrosis.
Methods and Materials: eight consecutive patients (mean age 56,4) with AF underwent CA (procedure parameters: minimum temperature, freezing and heating time, procedure duration for each ostium). LGE-MRI was performed prior the procedure, at 24 hours and after 1 month. Atrial fibrosis was evaluated qualitatively and quantitatively. Statistical analysis was performed by univariate analysis using Kruskal-Wallis test for continuous variables and X^2 analysis for categoric variables.
Results: 30 out of 47 applications were effective, 9 repeated and 8 ineffective. A difference between procedure duration (p=0,014), minimum temperature (p=0,002) and heating time (p=0,001) was found between effective and ineffective procedures. Procedure duration was lower for right ostia. At 1-month, fibrosis was identified in 26/32 (81,3%) of pulmonary veins (PV) ostia. Circumferential fibrosis was observed in 12/32 (37,5%) PV ostia. Right inferior PV ostium has a lower amount of fibrosis both qualitatively (fibrosis foci p=0.0045; circumferential fibrosis p=0,046) and quantitatively (mean fibrosis 39% vs 14.9% p=0.0088).
Conclusion: fibrosis foci were detected in large amount of PV ostia, otherwise their circumferentially involvement is quite rare and related to treatment temperature and duration. Lowest amount of fibrosis was detected at right inferior PV according to complex anatomy.

B-1196 11:42

Acute myocardial tissue characterisation using magnetic resonance native T1 mapping at 3.0 T

A. Clemente[1], F. Avogliero[1], A. Di Giambattista[1], N. Martini[1], A. Barison[2], D. Della Latta[1], D. Chiappino[1]; [1]*Massa/IT*, [2]*Pisa/IT (andreadigia@gmail.com)*

Purpose: To investigate the ability of native T1 mapping at 3.0 T to identify inflammatory processes involved in acute myocardial diseases.
Methods and Materials: Native T1 maps in short-axis view were acquired from 91 subjects using a modified Look-Locker inversion recovery sequence at 3.0 T with heart rate independency. Patients were grouped based on CMR findings and consisted of subjects with acute myocardial infarction (IMA, n=12), acute myocarditis (AM, n=7) and controls (n=72). Six-segment analysis was performed with manually drawn regions-of-interest.
Results: Global myocardial T1 relaxation time was significantly increased in IMA (1248.8±38.8 ms, p<0.01) and AM (1237.9±70.7 ms, p<0.01) compared to controls (1163.1±34.9 ms, p<0.01). T1 values were higher in segments with LGE than in those with no LGE in IMA (with LGE 1309.9±70.0 ms versus no LGE 1187.9±18.0 ms, p<0.01). T1 values were higher in segments with LGE than in those with no LGE in AM (with LGE 1330.0±41.0 ms versus no LGE 1206.3±74.0 ms, p<0.05). T1 values were both higher in segments with no LGE compared to controls in IMA (1187.9±18.0 ms, p<0.05) and AM (1206.3±74.0 ms, p<0.01).
Conclusion: Native T1 mapping at 3.0 T was found to be significantly higher in acute myocardial processes involved in no LGE segments compared to healthy controls.

B-1197 11:50

Native T1 mapping comparison of mean and median assessment reveal reduced T1 in normal anterior and anterolateral segments compared to the rest of the myocardium

P. Triadyaksa, T.A. D'Antonoli, N.H.J. Prakken, M. Oudkerk, P.E. Sijens; *Groningen/NL (p.triadyaksa@umcg.nl)*

Purpose: In pixel-wise analysis of the myocardium, assessment of median segmental T2* values was previously found to produce more reproducible results than assessment of the means. To our knowledge, pixel-wise comparisons of reproducibility of median and mean signal intensities has not yet been reported for native T1 mapping. The purpose of this study was therefore to compare the reproducibility of normal native T1 mapping of the myocardium in using mean and median assessment.
Methods and Materials: Retrospective analysis of 1.5T MOLLI sequence MRI data acquired with motion correction was applied to map native T1 in the myocardium of 63 patients that turned out to have a normal heart ejection fraction and stroke volume. For the myocardium measured at three short-axis slices, pixel-wise T1 quantification (mapping) with mean and median assessment was done on 16 AHA segments. Fitting with assessment of R^2 was used to evaluate precision.
Results: Median myocardial native T1 values were significantly lower than the means (P<0.001). Median assessment produced significantly less segmental T1 variation between patients with higher fitting precision (P<0.001) in global and segmental analysis. Evaluated either way, the apical lateral segment, anterior segment at three slices, and anterolateral segment at mid-ventricular and basal slices had significantly lower native T1 values than the other ten segments (P<0.001).
Conclusion: Median assessment reduces measurement variability in global and segmental native T1 mapping of the myocardium. Variation of normal heart T1 values was apparent on segmental analysis, a novel finding with implications for pathological evaluation.

Integrating clinical decision support for pulmonary embolism in the emergency department: a pilot study of feasibility and provider perspective

A. Goehler, J. Weinreb, H. Forman, C. Moore, A. Hsiao, J. Arango, L. D'Amato; *New Haven, CT/US (alexander.goehler@yale.edu)*

Purpose: In the context of a commercial EMR, we implemented a clinical decision support (CDS) intervention for CTA for pulmonary embolism (CTA-PE) in the emergency department (ED) and quantified its impact on ordering practices.
Methods and Materials: In a survey of 231 radiologists and clinicians in the ED, 78% identified CTA-PE as "overutilised". We developed an algorithm that combined established risk scores and local practice patterns to risk stratify PE workup. We integrated a mandated questionnaire for every CTA-PE study requested within the EMR. If answers were concordant with the clinical pathway, the study order was placed; if answers were discordant, alternative scenarios were recommended.
Results: Among the 853 studies conducted, 8.2% were positive for PE. The algorithm was highly accurate, with 10.4% and 10.0% positivity among studies that were recommended to proceed with CT or pursue D-dimer, respectively. In cases where cancellation was recommended, 2.6% of studies were positive, and one of these showed a clinically significant PE. Among the 879 studies requested, 479 (55%) were recommended to change their order: 6 (1.3%) studies were subsequently cancelled; 13 (2.7%) changed to a D-dimer, 460 (51%) proceeded with CTA despite the recommendation. Among providers who ordered ≥10 studies, concordance with the CDS recommendation ranged from 12 - 68% (mean 45%) with little (0.10) correlation between compliance and positivity rates.
Conclusion: While the CDS algorithm for PE was accurate, it had only a modest impact on ordering practices, in part due to substantial heterogeneity in physician adherence to the CDS intervention.

B-1199 10:38

Dematerialisation of informed consent in radiology: results from an Italian online survey

F. Coppola[1], L. Faggioni[2], C. Privitera[3], D. Regge[4]; [1]*Bologna/IT*, [2]*Pisa/IT*, [3]*Catania/IT*, [4]*Turin/IT (francesca_coppola@hotmail.com)*

Purpose: The aim of this study is to present the results of the Italian survey on dematerialisation of informed consent in radiology (DIC).
Methods and Materials: Two radiologists created an online survey using Survey Monkey. The survey consisted of 15 multiple-choice questions. Members of Italian Society of Medical Radiology (SIRM) were given 1 week to perform the survey.
Results: A total of 1791 radiologists, 18% of all SIRM members, participated. In Italy the radiological informed consent is used for CT and MRI (93.33%), interventional procedures (70.95%), ultrasound examinations with i.v. contrast media (42.40%), and for the exclusion of pregnancy in young women before x-ray examinations (70.22%). Seventy-two percent of radiologists evaluate the appropriateness of the diagnostic procedures before deciding to accept or reject the request. Ninety-five percent (n=1684) of responders have a positive opinion on DIC, while only 5% (n=93) have a negative one. The advantages are: storage and conservation of DIC is safer according to majority of responders (94.54%), its recovery is easier and faster (96.53%) in case of medico-legal disputes respectively and the reduction of paper used leads to reduced costs (90.67%). The disadvantages are: implementation of DIC is complex, in particular to obtain the preliminary approval for the utilization of advanced digital sign from each patients (51.76%) and to provide required dedicated area inside radiological unit (63.97%).
Conclusion: The majority of Italian radiologists are favourable on DIC. However, they have concerns that the implementation of DIC could be complex.

How to prescribe imaging tests and to make clinical decisions? - effectiveness of a virtual classroom for undergraduate students in radiology

A. Viteri Jusué[1], A. Tamargo Alonso[1], A. Bilbao González[2], D. Grande Icaran[2], T. Palomares Casado[2]; [1]*Vitoria-Gasteiz/ES*, [2]*Bilbao/ES (ainhoa.viterijusue@osakidetza.net)*

Purpose: To develop a virtual learning environment for teaching to medical students the following skills: prescribing imaging tests and making decisions based on their results. To assess its feasibility, effectiveness and students´ satisfaction.
Methods and Materials: An ad-hoc virtual classroom was implemented in the Moodle platform consisting on videolectures, practical exercises and e-learning resources. Sixth-grade students were recruited and gave informed consent prior to randomization into the experimental or the control group. Research Ethics Committee approved this project. Performance (ability to prescribe imaging tests and to take diagnostic-therapeutic decisions based on their results) was evaluated with objective structured clinical exams. Weighted scores from 0 to 100 were compared between experimental and control groups with the non-parametric Wilcoxon test (SAS System for Windows, version 9.2). Satisfaction was assessed with an eleven-items, five-level Likert scale.
Results: Twenty-six students were included (8M/18F, median age 23y) and randomized (13 experimental/13 control group). 76.9% students in the experimental group completed the practical assignments. Mean self-reported time devoted to the virtual course 7.17 hours. Satisfaction: median satisfaction was high or very high in 10 out of 11 items. Efficacy: students in the experimental group performed better at prescribing imaging tests (mean score 55.9% vs 37.1%, p=0.0042) and at making clinical decisions (mean score 40.0% vs 29.5%, p=0.0403).
Conclusion: The abilities to prescribe imaging tests and to make clinical decisions with their results can be taught effectively and satisfactorily to undergraduate medical students through a virtual learning environment. Its use will be generalized to the remaining students.

Structured reporting: using the voice of the customer method to settle an ongoing debate about the future of radiology reporting

T. Heye, V. Gysin, D. Boll, E. Merkle; *Basle/CH (tobias.heye@usb.ch)*

Purpose: The presentation and clarity of a radiology report do not always meet the expectations of referring physicians. Meanwhile a debate about the future of radiological reporting is taking place. The purpose of this study is to assess the perception, preferences and expectations of recipients of radiology reports in terms of style and content.
Methods and Materials: A survey was conducted among general practitioner (GP) and hospital based physicians (HP) in north-western Switzerland. The questionnaire consisted of a demographic section, a part addressing current satisfaction and a section addressing expectations in content and structure. The participants were presented with four layouts of radiology reports (text, structured text, tables, images) and asked to rate each in comprehensibility and efficiency (range 1-10; 10 highest score).
Results: 434 participants (121GPs, 313HPs, 4 different hospitals) with 114 residents and 320 board-certified physicians completed the survey. Both GP and HP were equally satisfied with radiology reports with a mean of 7.2. Regarding layout preferences, structured text (mean 5.8-7.9;) and images (mean 6.6-8) rated highest in terms of readability, time savings and helpfulness in the communication with patients, when compared with tables (mean 4.5-5.4) and unstructured text (mean 3.3-4.6). Of all participants, 81% stated a report should allow for fast and efficient reading.
Conclusion: The voice of the customer approach offers valuable feedback and an indisputable argument in favor of structured reporting. Radiology has to facilitate easy communication while delivering comprehensive information. The form of this communication should be tailored to the referring physicians' preferences.

Guideline based query of conventional narrative "free text" radiological reports and structured reports: a solution for objective comparison

M.E. Maros[1], M. Frölich[2], C. Groden[1], W.H. Sommer[2], S.O. Schönberg[1], T. Henzler[1], H. Wenz[1]; [1]*Mannheim/DE*, [2]*Munich/DE (matt.maros@gmail.com)*

Purpose: Data on how well structured reports (SR) and conventional narrative reports (cFTR) comply with clinically relevant findings are scarce. A feasibility study of a text mining based scoring algorithm was performed to provide an objective intra-individual comparison of SR and cFTR by means of guideline-based key terms.
Methods and Materials: 25 suspected stroke patients with consecutive cMRI stroke protocol were re-assessed by two independent,blinded readers (experience:>2 [unxR]; >6yrs[exR]). SRs were generated using an online template-tool (www.smart-radiology.com) with additional free text (uxR:20/; exR:22/25). Corresponding pre-existing cFTR were retrieved from local database. A query-vector of key terms based on imaging recommendations for acute stroke and transient ischemic attack patients by the ASNR and the ACR was defined. Following automatic text retrieval, SR and cFTR were compared with guideline-query using term frequency-inverse document frequency based similarity index and Wilcoxon signed-rank test.
Results: All 18 (72%) cases with ischemia were identified by SR and cFTR (rho_{sp}=1, Cohen's Kappa=1). UnxR using SR had the highest median (0.82) and maximal (7.57) guideline similarity scores (GSS). SRs of exR had significantly (p_W=0.0020) higher GSS (median:0.72, range:0-5.4), than cFTR (median:0.57, range:0-5.7). Although SRs of unxU were not corrected by senior radiologist, they had similar GSS (p_W=0.50) like the reviewed cFTR,and were comparable to the SR of exR (Z=1.59,p=0.11).
Conclusion: An objective guideline-based comparison of SRs and cFTRs using term frequency is feasible and provides a scalable quality measure. In spite of additional free text, SR improved the adherence to guidelines of both senior- and junior radiologist when evaluating stroke suspected brain MRIs.

B-1203 11:10

Comparison of report characteristics of un- and experienced radiologists using an online-based structured reporting tool and conventional "free text" reports

M.E. Maros[1], M. Frölich[2], C. Groden[1], W.H. Sommer[2], S.O. Schönberg[1], T. Henzler[1], H. Wenz[1]; [1]*Mannheim/DE*, [2]*Munich/DE (matt.maros@gmail.com)*

Purpose: Online reporting tools (ORT) with predefined text blocks are gaining popularity to create structured reports (SR). However, their effects on report structure and reporting process are obscure. We compared SR of un-(uxR;>2yrs) and experienced radiologists (exR;>6yrs),and conventional narrative -"free text"- reports (cFTR) in the setting of MRI stroke diagnostics.
Methods and Materials: 25 patients with cMRI were randomly sampled from a population of suspected stroke cases (n=780). They were re-assessed blindly by uxR/exR using ORT (www.smart-radiology.com) and SR were created. Parameters of interest were: correctness, reporting time (RT), word count (Wc) of SR, and pre-existing cFTR. Factors like free text in SR (uxR|exR:20|22), extra MRI-sequence (13/25) and subjective case complexity (SCC; 5-point-Likert scale) were also considered. Inter-rater reliability, Spearman's rank correlation, Wilcoxon signed-rank test, and linear mixed models with outcomes RT, Wc including aforementioned factors were applied.
Results: There was perfect agreement (kappa=1) of ischemia (18/25) in all SR and cFTR. SCC was similar (r_{sp}=0.79,p<0.001) between users showing substantial association with RT (r_{uxR}=0.70;r_{exR}=0.67,p_{both}<0.01). ExR was significantly (p<0.01) faster (median=6.75min;range:2-12min) than uxR (8min;range:2-13.5min) using SR. SR of exR were significantly shorter (Wc) than SR of uxR (p<0.001) and cFTR (p<0.01) corrected by senior radiologists. SR of uxR had comparable Wc to supervised cFTR ($p_{findings}$=0.37;$p_{impresssion}$=0.70). SCC had the most decisive effect on Wc by both SR and cFTR when adjusted for aforementioned factors.
Conclusion: ORT enables a standardized, valid and time-effective SR creation, while improving RT and Wc of both senior- and junior radiologist when evaluating stroke suspected brain MRIs.

B-1204 11:18

Recall of unstructured radiology reports is significantly inferior to that of structured reports

B. Buckley, G.N. Allen, L. Daly, C.A. Ridge; *Dublin/IE (bryan.buckley@ucdconnect.ie)*

Purpose: To measure recall by clinicians immediately after reading a structured compared to an unstructured radiology report.
Methods and Materials: Institutional review board approval was obtained. A structured radiology report is a uniform report template that uses headings and subheadings followed by standardized statements to create uniformity and improve communication with referring physicians. A structured radiology report differs from the "freetext" radiology report, which lacks headings or a standardised format. Four hypothetical radiology reports were devised based on a review of common cross sectional imaging studies. Two structured and two unstructured reports followed immediately by a 7-response cloud-based multiple-choice questionnaire were used to survey physicians at multiple institutions whose demographics and training data were collected. The proportion of all correct answers, correct critical findings, sensitivity and specificity were recorded. A paired t-test was used to compare results.
Results: 148 physicians completed the survey. The frequency of incorrect diagnoses was 6.2% for structured reports compared to 18.2% for unstructured reports (p<0.001). Critical diagnoses were missed in 17.4 % of structured reports compared to 35% of unstructured reports (p <0.001). Average physician sensitivity and specificity was greater for structured reports (64.2% and 95.5%, respectively) compared to unstructured reports (59% and 83%, respectively) (p≤0.001).
Conclusion: Physician recall of unstructured radiology reports is significantly inferior to recall of structured reports immediately after reading a radiology report. Structured reports are a more accurate means of conveying the salient findings of a radiology study.

Eye-tracking analysis of interpretation characteristics in detection of alimentary tract lesions on body CT

F. Ichinohe, A. Yamada, T. Nonaka, T. Aonuma, K. Oyama, K. Todoroki, M. Nakamura, Y. Fujinaga, M. Kadoya; *Matsumoto/JP (tattuqoltuae.42@gmail.com)*

Purpose: To clarify interpretation characteristics of radiologists in detecting alimentary tract lesions on body CT using eye-tracking technique.
Methods and Materials: 3 radiologists (1, 2, 12 years of experience) and 3 non-radiologists (2 residents and 1 medical student) were asked to detect lesions suspected as malignant tumours within 3 minutes without any clinical information on thoracic and abdominal CT obtained from 10 patients with histologically proven malignant tumours in the alimentary tract. Gaze path was recorded by eye-tracking technique during interpretation to calculate gaze time at each voxel (GTV) on CT. The lesion detection rate (LDR) and interpretation characteristics in eye movement were statistically analysed.
Results: GTV fitted to the Burr distribution (P<0.001); however, the observed GTV was relatively longer than estimated GTV from the Burr distribution above the 95th percentile. Therefore, the intentional gaze was defined where GTV was longer than 95th percentile GTV (GTV95%) estimated from the Burr distribution in this study. The mean value of LDR, GTV95%, and the percentage of gazed area in patient's body were 46.7%, 0.18 s, 25.0% in radiologists, 0%, 0.36 s, 16.1% in non-radiologists (P<0.001, P=0.002, P<0.001), respectively. The intentionally gazed lesions were significantly fewer than unintentionally gazed lesions in undetected lesions by radiologists (P=0.049).
Conclusion: Radiologists can detect more lesions than non-radiologists due to effective gazes and the diagnostic ability for intentionally gazed lesions. Undetected lesions were located more in unintentionally gazed area; therefore, making radiologists pay attention to the area utilizing gaze path information may improve their diagnostic performance.

B-1206 11:34

Radiological counseling, a new approach to radiologist-patient relationship

F. Rigiroli, D. Fazzini, A. Malasevschi, P. Arnaldi, B. Colombo, S. Papa, G. Cornalba; *Milan/IT (francesca.rigiroli@unimi.it)*

Purpose: The aim of the study is to analise the results of the Radiological Counseling (RC) service introduced in C.D.I. Diagnostic Imaging Department. By using this service the patients can meet the radiologist to get information about radiological exams and medical report, and to discuss diagnostic imaging issues.
Methods and Materials: The RC service started in September 2015 and the patients were informed about RC by a notice in the radiological report and in the institutional website. The service outcome has been investigated by a survey on the first 50 patients that used the RC: afterwards the meeting with

the radiologist, they answered to a questionary about their age and sex, the discussion satisfaction, as well as the preferred comunication modality in normal or pathologic findings.
Results: The survey shown complete satisfaction of the meeting with the radiologist, with a score of 4,5 of 5. The 60% of the cases are under 60 years-old. The majority of the patients answer that they prefer to receive the radiological report by a meeting with the radiologist: 50% if there are normal findings and 80% if pathological.
Conclusion: The RC is a useful service for the patient and can improve the relationship between the patient and the radiologist, who gains a new clinical role. We are satisfied about this results that will help us to improve this service to raise our patient's trust in our institution.

B-1207 11:42

Frequency & analysis of non-clinical errors made in radiology reports using the national integrated medical imaging system (NIMIS) voice recognition dictation software

R.E. Motyer, S. Liddy, W.C. Torreggiani, O. Buckley; *Dublin/IE (ronanmotyer@gmail.com)*

Purpose: Voice recognition (VR) dictation of radiology reports has become the mainstay of reporting in many institutions worldwide. Despite benefit, such software is not without limitations, and transcription errors have been widely report. We evaluated the frequency and nature of transcription error using VR software.
Methods and Materials: Retrospective audit of 378 finalised radiology reports. Errors were counted and categorised by significance, error type and sub-type. Data regarding imaging modality, report length and dictation time was collected.
Results: 67 (17.72%) reports contained ≥1 errors, with 7 (1.85%) containing 'significant' and 9 (2.38%) containing 'very significant' errors. A total of 90 errors were identified from the 378 reports analysed, with 74 (82.22%) classified as 'insignificant', 7 (7.78%) as 'significant' and 9 (10%) as 'very significant'. 68 (75.56%) errors were 'spelling and grammar', 20 (22.22%) 'missense' and 2 (2.22%) 'nonsense'. 'Punctuation' error was most common sub-type, accounting for 27 errors (30%). On average, complex imaging modalities had higher error rates, with computed tomography containing 0.57 errors per report compared to plain film with 0.08. Longer reports had a higher error rate, with reports >25 sentences containing an average of 1.23 errors per report compared to 0-5 sentences containing 0.09.
Conclusion: These findings highlight the limitations of VR dictation software. While most error was deemed insignificant, there were occurrences of error with potential to alter report interpretation and patient management. Longer reports and reports on more complex imaging had higher error rates and this should be taken into account by the reporting radiologist.

B-1208 11:50

Evaluation of a patient safety tool: the preferred reading of the radiology report - has it been useful?

P. Fraga, C. Benito, L. Garcia del Salto, J. De Miguel, A. Marco, E. Fraile; *Madrid/ES (patricia.fraga@salud.madrid.org)*

Purpose: To submit a software tool that allows us to warn about the preferred reading of those reports showing unexpected radiological findings, emergency and incidental findings that imply a change in clinical management of patients. To analyse its use and effectiveness in a radiological hospital service since its implementation.
Methods and Materials: A computer tool of radiological alert reports was implemented in 2012. We review its use, analysing its distribution by modality and requesting service. We analyse the most frequent causes that have produced these warnings and the implications for the management of patients. We also evaluated the problems found in its use.
Results: We review the alert filed in the 574,006 reports performed from January 2012 to September 2016 in our department. We send alerts in 0.13% of the reports, (CT 35,5% , MR 19,8%,US 15,1% and mammography 0,25%) , 94.2% of them were in out patients. The discovery of unsuspected tumour pathology is the main cause of that alert (45.2%). We found some problems, like the communication with primary care.
Conclusion: The radiological alert of preferred reading of a report is part of the radiology daily activity, both for, transmits unexpected or incidental findings and to enable rapid action on the patient. It is an important element for patient safety. It should be a useful, simple, and effective tool known by all physicians involved. 0.13% of our reports were subsidiaries of prioritising reading mainly CT and MR.

Improvement of image quality in dual layer unenhanced head CT using virtual monoenergetic image reconstructions

V. Neuhaus, N. Abdullayev, N. Große Hokamp, C. Kabbasch, A. Mpotsaris, D. Maintz, J. Borggrefe; *Cologne/DE (victor-frederic.neuhaus@uk-koeln.de)*

Purpose: To determine optimal kiloelectron volt levels of virtual-monoenergetic-images (VMI) to yield optimal image-quality, in particular in regard to the assessment of grey-white matter differentiation (GWMD) and reduction of artefacts.
Methods and Materials: 40 patients that received unenhanced head-CT using a dual-layer-CT (DLCT, Philips, Amsterdam, Netherlands) were included. CTs were acquired at 120kV/320mAs and VMI were reconstructed in between 40-120keV. Attenuation and standard deviation of supra- and infratentorial grey and white matter were measured to calculate signal-to-noise-ratios (SNR) and contrast-to-noise-ratios (CNR). Artefacts were detected close to the calvarium (SAI) and in the posterior fossa (PFAI). Two radiologists rated image quality regarding GWMD and subcalvarial space.
Results: Continuously higher SNR and CNR of grey and white matter were observed at lower keV in VMI, which were superior to RCT (p<0,0001). Subcalvarial artefacts were significantly lower in VMI at higher keV (p<0,02). Artefacts measured in the posterior fossa were lower in VMI, however not statistical different. VMI were rated superior to conventional images in regard to all four quality criteria. Optimal assessment of GWMD was found at 65keV, optimal assessment of subcalvarial space was found at 120keV.
Conclusion: VMI reconstructed from unenhanced DLCT of the head improved image-quality compared to RCT. Even though CNR increases with decreasing keV and is greatest at 40 keV, subjective image analysis found 65 keV superior in the assessment of GWMD due to the artefacts caused by the calvarium at lower keV.

Improved image quality of low-dose brain CT using knowledge-based iterative reconstruction technique: effect on the noise reduction and low-contrast detectability

Y. Lee, H. Seo; *Ansan/KR (younghen@korea.ac.kr)*

Purpose: To evaluate the image quality of low-dose brain CT obtained by knowledge-based iterative model reconstruction (IMR), we compared noise and low-contrast detectability of CT images between hybrid iterative reconstruction and IMR.
Methods and Materials: Based on the medical record review, we retrospectively identified the 40 patients (M:F=20:20, mean age 51.3±14.8 years) with unremarkable finding on non-contrast brain CT examination using our routine CT protocol during the recent two months. We then reconstructed the CT images using IMR routine level 1 (Philips Healthcare), in addition to our routine hybrid iterative reconstruction (iDose4, level 2, Philips Healthcare). At the same axial levels of supra- and infratentorial brain, the mean CT attenuation value, noise, signal to noise (SNR) and contrast to noise ratio (CNR) were calculated for basal ganglia, internal capsule, pons and adjacent cistern for a pairwise comparison between IMR and iDose4.
Results: With radiation at 100 peak kVp and 120mAs (effective dose: mean 0.46mSv), improvement of SNR was achieved in the CT images reconstructed with IMR compared to iDose 4 by the significantly decreased noise (mean 60.9% reduction) at both supra-and infratentorial brain levels (p<0.01), while their mean CT attenuation values were not significantly affected. Regarding to noise reduction and low-contrast detectability, the CT images reconstructed with IMR was significantly better than iDose4 (p<0.01).
Conclusion: IMR might be considered as a feasible technique to improve the image quality of brain CT examination at the lower radiation dose.

B-1211 10:46

Detection of vessel occlusion in acute stroke is facilitated by color-coded 4D-CTA

M. Meijs, S. Pegge, M. Prokop, B. van Ginneken, F.J.A. Meijer, R. Manniesing; *Nijmegen/NL (midas.meijs@radboudumc.nl)*

Purpose: To perform a pilot study to explore the effect of a new post-processing technique for 4D-CTA on speed and accuracy of the detection of intracranial vessel occlusions in acute stroke. This technique color-codes the contrast arrival time in the cerebral vasculature in 4D-CTA so that abnormally delayed vascular territories are easily detected.
Methods and Materials: We selected 10 patients without and 10 patients with a single vessel occlusion, confirmed by consensus reading, on CTA from our database of acute ischaemic stroke patients, so that occlusions of the ICA, MCA, ACA and PCA of varying subtlety were included. Whole-brain CT perfusion was performed on a 320 detector-row scanner. Color-coded 4D-CTA images were obtained by centering the color scale of vessel time-to-peak (TTP) on the modus of the TTP histogram. Temporal MIP of 4D-CTA with and without color-coding were evaluated in random order for the presence of vessel occlusion by two neuroradiologists. Time-to-detection and accuracy of detection of vessel occlusions were evaluated.
Results: One false-positive vessel occlusion was rated on color-mapping by both observers. Overall, the average time-to-detection decreased from 37.0s to 19.4s ($p<0.03$) and the average accuracy of vessel occlusion detection increased from 0.825 to 0.85 with color-mapping.
Conclusion: Color-mapping of cerebral vasculature in 4D-CTA improves the speed and may improve the accuracy of the detection of vessel occlusions in acute stroke patients.

Robust segmentation of the cranial cavity in non-contrast CT and CT perfusion of the brain

A. Patel, F.J.A. Meijer, M. Prokop, B. van Ginneken, R. Manniesing; *Nijmegen/NL (Ajay.Patel@radboudumc.nl)*

Purpose: Cranial cavity segmentation in CT is the essential first step for subsequent image processing and automated detection of cerebral pathology. This becomes complicated in the presence of skull fractures, metallic foreign objects or due to connected soft tissues such as the orbit. A robust and accurate method is presented to segment the cranial cavity in CT images.
Methods and Materials: We propose a multi-atlas based method that uses atlas selection based on anterior skull variations, followed by a two-stage level set refinement. The method was developed using a set of 99 non-contrast CT and 18 CT perfusion (CTP) scans obtained for emergency indications on a 320-row detector CT scanner. It was evaluated on a different set of 200 non-contrast CT and 100 CTP scans obtained for the same indications. Quality of segmentations was visually assessed. The reference standard consisted of three randomly selected orthogonal slices per patient that were manually annotated by trained observers. The corresponding slices were extracted and compared to the reference standard. Dice similarity coefficient (DSC) and 95th percentile Hausdorff distance (95% HD) were reported.
Results: The segmentation results were evaluated as very good to excellent. The method achieved a mean DSC of 0.98±0.03 and mean 95% HD of 0.60±2.15 mm in comparison to the reference standard.
Conclusion: The proposed method is capable of accurate segmentation of the cranial cavity in non-contrast CT and CTP independent of gross pathology or foreign objects. The method provides a fundamental first step towards automated evaluation of cranial CT.

Parameters based on blood flow velocity obtained from 3D cine PC-MR on cerebral intracranial aneurysms: comparative study with computational fluid dynamics

K. Ishiguro[1], H. Isoda[1], Y. Takehara[1], M. Terada[2], T. Naito[3], C. Tanoi[2], T. Kosugi[4], Y. Ohnishi[5], A. Fukuyama[1]; [1]*Nagoya/JP*, [2]*Iwata/JP*, [3]*Kasugai/JP*, [4]*Hamamatsu/JP*, [5]*Tokyo/JP (ishiguro.kenta@d.mbox.nagoya-u.ac.jp)*

Purpose: Some studies regarding haemodynamic analysis of intracranial aneurysmal growth and rupture using computational fluid dynamics (CFD) have discussed parameters such as inflow concentration index (ICI), energy loss (EL) and pressure loss coefficient (Plc) based on blood flow velocity. The purpose of our study was to compare these parameters between magnetic resonance fluid dynamics (MRFD) and CFD quantitatively.
Methods and Materials: We performed 3D time-of-flight (TOF) MR angiography (MRA) and 3D cine phase contrast (PC) MR for 20 patients, each of who had an unruptured internal carotid artery aneurysm. We created patient-specific vascular geometries and obtained the patient-specific volume flow rate (VFR) of each vessel based on MR data sets using Flova. We performed CFD based on our acquired data. At peak systole we acquired spatially averaged inflow velocity into the aneurysm, ICI, EL and PLc with MRFD and CFD. We calculated the interclass correlation coefficient (ICC) of these parameters between MRFD and CFD. We also obtained scatter diagrams of these parameters and calculated their correlation coefficient between MRFD and CFD.
Results: ICC was >0.80 and correlation coefficient was >0.85 between MRFD and CFD for all parameters. Internal carotid arteries were large enough to be analysed with good accuracy. Therefore, MRFD showed accurate velocity and volume flow rate for each artery.
Conclusion: Average velocities, ICI, EL and PLc obtained by MRFD were similar to those obtained by CFD. MRFD may be a useful way to quantitatively analyse these parameters in the clinical setting.

Comparison of spoiled gradient recalled acquisition and spin echo magnetic resonance images in detection of pituitary ACTH secreting adenoma

R. Kidzinski[1], E. Frankowska[1], M. Żabicka[1], M. Kania-Pudlo[1], A. Sciuk[2], K. Tomczykiewicz[1], G. Zielinski[1]; [1]*Warsaw/PL*, [2]*Houston, TX/US (rafalkidzinski@gmail.com)*

Purpose: The objective of the study was to compare the efficacy of spoiled gradient recalled acquisition (SPGR) and spin echo (SE) magnetic resonance images in detection of pituitary ACTH secreting adenoma. SPGR images have the potential to improve tumour detection because of better soft tissue contrast, thinner sections, higher image resolution and faster acquisition than SE images.
Methods and Materials: We compared SPGR and SE images in 7 patients (mean age 44 years) that underwent surgery with histological confirmation of the ACTH secreting adenoma. All patients had negative MR studies on 1.5T scanner. We obtained coronal pre- and postgadolinium SPGR and SE images using 3T scanner. SE scans were performed over 4:39 min with 16 cm field of view and contiguous slices 2.7 mm. SPGR scan parameters were analogically: 4:32 min, 16cm and 2.5mm. Three radiologists interpreted the images, pointing exact localisation and assessing visibility of tumours. Localisation of tumours proposed by radiologist was compared to findings at surgical resection.
Results: In retrospective assessment, tumours were not visible in 1 of 7 patients. Sensitivity of tumour detection was 44% for SPGR images and 39% for SE images.
Conclusion: 3T MR studies proved to be superior to 1.5T in Cushing syndrome. There was no significant difference between SPGR and SE images.

B-1215 11:18

Different consistency of pituitary adenomas evaluated with dynamic constrast MRI acquisition

A. Di Napoli, L. Pasquini, A. Boellis, A. Romano, A. Bozzao; *Rome/IT*

Purpose: Our hypothesis was that pituitary macroadenomas show different areas of consistency detectable by enhanced magnetic resonance imaging (MRI) with Dynamic study during gadolinium administration.
Methods and Materials: We retrospectively analysed 21 patients with pituitary macroadenomas between June 2013 and June 2015. The ethics committee of our Institution approved the study protocol and informed consent was obtained from all patients. All patients underwent trans-sphenoidal surgery and neurosurgeon described whether macroadenomas consistency was hard or soft considering a lower and an upper compartment. Similarly, two neuroradiologists manually drew regions of interest (ROIs) inside the solid-appearing portions of macroadenoma (upper and lower) and in the normal

white matter both on dynamic and post-contrast acquisitions. The ratio between these ROIs, defined as Signal Intensity Ratio (SIR), allowed obtaining signal intensity curves over time on dynamic acquisition and a single value on post-contrast MRI. SIR values best differentiating solid from soft macroadenoma components were calculated and correlated with pathologic patterns. A two-sample T-test and empiric receiver operating characteristic (ROC) curve of SIR was performed.
Results: According to ROC analysis, the SIR value of 1,92, obtained by dynamic acquisition, best distinguished soft and hard components. SIR values from post-contrast MRI didn't allow this differentiation. All the specimens from soft components were characterised by high cellularity, high representation of vascularisation and micro-haemorrhage and low percentage of collagen content. The reverse was evident in hard components.
Conclusion: We demonstrated that dynamic MRI acquisition could distinguish with good accuracy macroadenomas consistency.

B-1216 11:26

MRI tractography comparing diffusion tensor and kurtosis tensor imaging

J. Leote, R.G. Nunes, R. Loução, L. Cerqueira, H.A. Ferreira; *Lisbon/PT (jlleotte@gmail.com)*

Purpose: The topographical delineation of the corticospinal tract (CST) is of paramount importance for surgical procedures in primary brain tumours. We evaluated if diffusion kurtosis imaging tractography (DKI-tract) brings up additional resolution to the delineation of the CST obtained using conventional diffusion tensor imaging tractography (DTI-tract).
Methods and Materials: We recruited 6 patients with brain tumours and 8 healthy subjects to perform a 1.5T MRI with a 12-channel head coil. Scans comprised volumetric T1-weighted data and diffusion-weighted images (repetition/echo time of 5800/107 ms; 82x82 resolution; 3x3x3 mm^3 voxel size; b-values of 0, 1000, 2000 s/mm2, 64-32 directions). CST was estimated using DTI and DKI methods between cerebral peduncles and frontoparietal regions-of-interest (ROIs). We also selected a passing through ROI with 10% of the lesion volume. We extracted diffusion metrics of the tracts' courses and volumes at the strongest deviation point of the CST from the midline and compared the two methods in both groups and between hemispheres using an asymmetry index.
Results: It was possible to estimate the CST using both methods. However, the DKI-tract depicted significantly more volume than the DTI-tract in 83% of patients. The fractional anisotropy mean values were significantly lower in patients, with higher asymmetry index between hemispheres. Lower kurtosis metrics were denoted in pathological hemisphere despite no statistical difference.
Conclusion: DKI-tract showed a broader image of the CST than DTI. Since DKI image acquisition and analysis is also compatible with a high patient throughput, DKI-tract assessment seems to be safer than DTI for pre-surgical planning.

B-1217 11:34

Accuracy of SWI sequences compared to T2*-weighted gradiente echo sequences in the detection of cerebral cavernous malformation

G. Sparacia, A. Anastasi, C. Speciale, F. Bencivinni, A. Banco, M. Midiri; *Palermo/IT (andreaanastasi@hotmail.it)*

Purpose: To assess the accuracy of SWI sequences compared with GRE T2* sequences in assessing cerebral cavernous malformations (CCV).
Methods and Materials: We retrospectively evaluated 11 patients with familial form of CCV (4 men, 7 women; age: 32-77 years; mean age, 53,7 years). MR protocol included nonenhanced and contrast enhanced FSE T1w sequences, FSE T2w, FLAIR, GRE T2*w and SWI sequences. Images were reviewed by two expert neuroradiologist to assess location, number, size and conspicuity of the lesions on GRE and SWI sequences. Statistical differences of lesions seen on SWI and GRE images were assessed with the nonparametric Wilcoxon signed rank test.
Results: The number of cerebral cavernous malformations (CCV) was significantly higher (P <.001) on SWI images (n=152) than on T2*weighted GRE images (n=55). Lesion size was significant higher (P <.001) on SWI images (mean 0.42cm, SD ∓ 0.55) than on T2*weighted GRE sequences (mean 0.25cm, ∓ 0.51) and differences were statistically significant (P<.001). Lesion conspicuity was significant higher (P <.001) on SWI than T2*weighted GRE images. In one patient, who underwent two months followup for the onset of sudden neurologic symptoms, it was identified a cerebral haematoma in the site of a CCV demonstrated previously only on the SWI images.
Conclusion: SWI sequence allowed to identify malformations that didn't appear in GRE T2 * images. Thus, routine clinical neuroimaging protocols should contain SWI sequences for the evaluation of patients with or suspected cerebral cavernous malformations to assess the true prevalence of lesions in order to improve the diagnosis.

B-1218 11:42

Evaluation of the communication between arachnoid cysts and neighbouring cerebrospinal fluid spaces by T2W 3D-SPACE with variant flip-angle technique at 3T

O. Algin; *Ankara/TR (droktayalgin@gmail.com)*

Purpose: PC-MRI is a broadly used technique for determination of possible communication of arachnoid cysts (ACs). 3D-SPACE technique is a relatively new-method for 3D-isotropic scanning of entire cranium within a short time. In this research, we aimed to evaluate the usage of the 3D-SPACE technique in differentiation of communicating or non-communicating type's ACs.
Methods and Materials: We retrospectively examined 35 ACs in 34 patients. 3D-SPACE, PC-MRI and contrast-material enhanced cisternography (if present) images of the patients were analysed. Each cyst was described according to cyst size/location, third ventricle diameter, Evans ratio, and presence of hydrocephalus. Communication was defined as absent (score 0), suspected (score 1) or present (score 2) on each sequence. Results of PC-MRI and cisternography (if available) examinations were used as a gold standard techniques to categorize all cysts as communicating or non-communicating type. The results of 3D-SPACE were compared with gold standard techniques. The comparisons between groups were performed using Mann-Whitney and fisher's exact tests.
Results: There is a perfect agreement between 3D-SPACE and gold standard test findings (p<0.001). Correlation between 3D-SPACE and gold standard tests results is 97% for communication assessment of the cysts. For other analysed variables, there is a significant difference or correlation between the groups.
Conclusion: 3D-SPACE technique is an easy, useful and non-invasive alternative for the evaluation of morphology, topographical relationships, and communication status of ACs.

B-1219 11:50

Determination of intra-axial brain tumours cellularity through the analysis of T2 relaxation time of brain tumours before surgery using MATLAB software

J. Abdolmohammadi; *Baharan/IR (Abdolmohammadi.jamil@gmail.com)*

Purpose: Timely diagnosis of brain tumours could considerably affect the process of patient treatment. To do so, para-clinical methods, particularly MRI, cannot be ignored. MRI has so far answered significant questions regarding tumour characteristics, as well as helping neurosurgeons. In order to detect the tumour cellularity, neurosurgeons currently have to sample specimens by biopsy and then send them to the pathology unit. The aim of this study is to determine the tumour cellularity in the brain.
Methods and Materials: In this cross-sectional study, 32 patients (18 males and 14 females from 18-77 y/o) were admitted to the neurosurgery department of Shohada-E Tajrish Hospital in Tehran, Iran from April 2012 to February 2014. In addition to routine pulse sequences, T2W Multi echo pulse sequences were taken and the images were analysed using the MATLAB software to determine the brain tumour cellularity, compared with the biopsy.
Results: These findings illustrate the need for more T2 relaxation time decreases, the higher classes of tumours will stand out in the designed table. In this study, the results show T2 relaxation time with a 85% diagnostic weight, compared with the biopsy, to determine the brain tumour cellularity (p<0.05).
Conclusion: Our results indicate that the T2 relaxation time feature is the best method to distinguish and present the degree of intra-axial brain tumours cellularity (85% accuracy compared to biopsy). The use of more data is recommended in order to increase the percent accuracy of this techniques.

Perfusion CT: a novel quantitative and qualitative imaging biomarker in gastric cancer
J. Kruk-Bachonko; *Lublin/PL (asiakruk1@wp.pl)*

Purpose: The aim of this research was to examine whether perfusion computed tomography (P-CT) exam can estimate gastric cancer neoangiogenesis in vivo. We attempted to explore whether and which P-CT parameters can be used in neoangiogenesis and neoadjuvant therapy effects evaluation. An additional aim was to recognise a positive prediction value of P-CT in responders and non-responders.
Methods and Materials: 51 patients with biopsy and/or clinically proved gastric cancer were involved in the P-CT exam. 26 of them were qualified for systemic treatment (16 patients received chemotherapy and 10 patients received radiochemotherapy). Perfusion-CT exam was conducted using 64-row GE tomograph, based on deconvolution model in first pass protocol perfusion. In P-CT exam, we estimated four parameters: blood flow (BF) - tumour vasculature and progression marker, blood volume (BV) - tumour vasculature and mitotic activity marker, mean transit time (MTT)- perfusion pressure parameter, permeability surface (PS) - vessels maturity and tightness marker.
Results: Patients with a positive treatment response showed decreased BF, BV, PS perfusion parameters with an increased MTT. Tumour dimension reduction after neoadjuvant therapy was significantly correlated with BF and PS. Neoadjuvant therapy was more effective for patients with higher output BF and PS values. We did not register a significant relationship between BV and MTT parameters and tumour dimension reduction.
Conclusion: P-CT exam allows non-invasive gastric cancer assessment in vivo. It enables neoadjuvant treatment monitoring and determines early treatment answer for chemotherapy and radiochemotherapy in gastric cancer. P-CT has positive predictive value in neoadjuvant therapy effects evaluation.

CT volumetry for primary gastric lesions in predicting pathologic response to neoadjuvant chemotherapy in locally advanced gastric cancer
I. Shrainer; *Moscow/RU (shrainer@gmail.com)*

Purpose: It is difficult to assess the response to neoadjuvant chemotherapy (NAC) in gastric cancer (GC) using standard CT-based RECIST criteria. CT volumetry might be a valuable alternative. We aimed to evaluate the accuracy of CT volumetry in terms of predicting response to NAC in locally advanced GC.
Methods and Materials: From February 2014 to April 2015 39 patients with stage II-III GC underwent 3 cycles of NAC followed by surgery. Contrast-enhanced CT was obtained after gastric distention with water before and after 3 cycles of chemotherapy. Pre- and post-chemotherapy volume of the tumour were measured using a dedicated 3D software and compared to histopathologic assessment of response.
Results: In 38 (97%) patients tumour size decreased. In 16 patients there was good tumour response (grade 1-2 according to Mandard score), other 23 patients had poor response (grade 3-4). In patients with good response, median tumour volume decrease was 54% (32-72%) vs 21% (0-48%) in patients with poor response, p<0.0001. Cutoff value was determined to be 37% by means of Youden's index, with sensitivity 92% and specificity 92%. Negative predictive value, positive predictive value, overall accuracy were 96%, 86%, 92%. respectively. Area under the ROC curve was 97%.
Conclusion: CT volumetry with a cutoff 37% of tumour volume reduction predicts good morphological response after 3 cycles of NAC in locally advanced GC with an overall accuracy of 92%. This finding needs further external validation and a larger cohort of patients to evaluate its predictive value after the first cycle of NAC.

Tumour volume at MDCT association with lymphatic invasion and N categories in resectable gastric adenocarcinoma: study in large surgical specimens
H. Li, X.-l. Chen; *Chengdu/CN (lihang111222@126.com)*

Purpose: To determine whether gross tumour volume (GTV) of resectable gastric adenocarcinoma at MDCT could predict presence of lymphatic invasion and N categories.
Methods and Materials: 350 consecutive patients with gastric adenocarcinoma who underwent gastrectomy in 1 week after contrast-enhanced MDCT were retrospectively identified. GTV was evaluated on MDCT images. Univariate and multivariate analyses were performed to determine whether GTV could predict presence of lymphatic invasion and regional lymph node metastasis (LNM). Mann-Whitney U test was performed to compare GTV among N categories. With pathologic confirmation, cutoffs of GTV were first investigated in 202 patients (group A) and then validated in an independent 148 patients (group B) for predicting presence of lymphatic invasion and N categories.
Results: Univariate analysis showed GTV could predict presence of lymphatic invasion and regional LNM (P<0.0001). Multivariate analyses indicated GTV as an independent risk factor of presence of lymphatic invasion (P=0.026,odds ratio=2.284) and regional LNM (P=0.000,odds ratio=7.991). The Mann-Whitney U test showed GTV could distinguish N0 from N1-N3 categories, N0-N1 from N2-N3, and N0-N2 from N3 (P<0.0001 for all). In group A, GTV could predict presence of lymphatic invasion (cutoff,16.6 cm^3; AUC, 0.780) and differentiate N0 from N1-N3 (cutoff, 12.3 cm^3; AUC, 0.870), N0-N1 from N2-N3 (cutoff, 16.6cm^3; AUC, 0.878) and N0-N2 from N3 (cutoff, 24.6cm^3; AUC,0.869). In group B, GTV could predict presence of lymphatic invasion (AUC,0.760), and differentiate N0 from N1-N3 categories (AUC, 0.853), N0-N1 from N2-N3 (AUC, 0.850), and N0-N2 from N3 (AUC,0.862).
Conclusion: GTV of resectable gastric adenocarcinoma at MDCT demonstrated capability in predicting presence of lymphatic invasion and N categories.

B-1223 14:33

Application of spectral CT in differential diagnosis of the gastric cancer and the high-risk gastric stromal tumours
X.-W. Wang; *Zhengzhou/CN (wxw0724@126.com)*

Purpose: To evaluate the application value of gemstone spectral imaging (GSI) in differential diagnosis of the gastric cancer and the high-risk gastric stromal tumours (GST).
Methods and Materials: Dual-phase enhanced CT scans by GSI mode were analysed retrospectively on 30 gastric cancer patients and 24 high-risk GST patients that confirmed by pathology.The spectral curve were obtained with GSI viewer software, and calculated the slopes for spectral curve in the 40~70,70~140 and 40~140keV energy ranges respectively. Iodine concentration (IC), water concentration (WC) and normalised iodine concentration (NIC) of tumours were also obtained. Data were analysed statistically by independent t test.
Results: During the vein phase,the IC (23.78±6.85) (100μg/m1) and NIC (0.54±0.15) of gastric cancer were higher than these of the high-risk GST (16.87±2.67) (100μg/m1) and (0.34±0.04) (P<0.05). The slope of the gastric cancer in the 40~70,70~140 and 40~140keV energy ranges (4.64±1.28, 0.68±0.21 and 1.87±0.53) were higher than these of the high-risk GST (3.35±0.52, 0.48±0.11 and 1.34±0.20) (P<0.05). And there was no significant difference in the WC between the two groups (P>0.05). During the artery phase, there were no significant differences in the IC, NIC, WC and the slope in every energy ranges between the two groups (P>0.05).
Conclusion: Spectral CT parameters are helpful in differential diagnosis of the gastric cancer and the high-risk GST.

B-1224 14:41

CT imaging features of internal hernia: post Roux-en-Y gastric Bypass - our experience in an Indian tertiary care setup
K. Sikund, G. Aggarwal, B. Aggarwal; *New Delhi/IN (ksikund@gmail.com)*

Purpose: To describe the CT findings in internal hernia seen after laparoscopic RYGB. To study the sensitivity of CT abdomen in diagnosing internal hernia.
Methods and Materials: Retrospectively data was collected of post bariatric laparoscopic RYGB patients (2009-2014) who presented with symptoms of abdominal pain, distention and vomiting in our institution. Records of 40 such patients were obtained in whom Internal hernia was diagnosed on diagnostic laparoscopy. Unfortunately CT records of only 21 patients were available. CT signs of internal hernia included: whirlpool sign- swirled appearance of

mesentery, mushroom shape of the hernia, clustered loops of small bowel, small bowel obstruction, small bowel other than duodenum posterior to superior mesenteric artery and right side location of distal jejunal anastomosis. Sensitivity of abdominal CT in diagnosing internal hernia was also calculated.
Results: CT findings of internal hernia were seen in 13/21 patients (sensitivity 61.9%) while remaining 8/21 patients had normal findings. CT findings - swirling of the mesentery was seen in 10/13 patients. Atypical bowel configuration with mushroom shape of the hernia was seen in 10/13 patients. Laparoscopy confirmed presence of internal hernia in 21 of these patients, with 5 showing peterson s defects, 10 mesenteric defects and 6 combined defects.
Conclusion: The sensitivity of abdominal CT in diagnosis of internal hernia in postoperative RYGB is 61.9% with mesenteric swirling snd mushrooming being the best CT indicator.

B-1225 14:49

MRI assessment of delayed gastric emptying and motility in Parkinson's disease: a feasibility study

J. Cho; *Seongnam/KR (jungheum.cho.md@gmail.com)*

Purpose: To examine the feasibility of evaluating delayed gastric emptying and motility in Parkinson's disease (PD) patients by magnetic resonance imaging (MRI), in comparison with healthy volunteers.
Methods and Materials: 38 PD patients without gastrointestinal illness (mean age, 67.3 years; 20 males; 18 females) and 5 healthy volunteers (mean age, 32.6 years; 3 males; 2 females) were recruited. Unified Parkinson's disease rating scale (UPDRS) and gastric symptom were assessed by self-reporting survey in each patient. After at least 6 hours of fasting, each participant underwent MRI of the stomach before and after a fluid meal (400 mL), which was followed up to 120 minutes. Gastric content volume and total gastric volume were measured by semi-automatic method using volume analysis software and gastric motility index (GMI) was calculated from measurements in cine MRI. Gastric emptying, accommodation, and GMI were compared between the two groups using repeated measures ANOVA and Mann-Whitney tests. Pearson's correlation analysis was also performed for UPDRS, gastric symptom score, gastric emptying, accommodation, and GMI.
Results: Gastric emptying tended to be delayed in PD patients at 10 minutes after meal (0.94 vs 0.90, P = .226) without statistical significance. Gastric accommodation (3.47 vs 5.89, P = .011) and GMI at 30 minutes (5.58 vs 12.09, P = .010) were decreased in patient group compared with control group. However, there was no significant correlation between UPDRS, gastric symptom scores, and MRI measurements.
Conclusion: MRI is feasible for assessment of delayed gastric emptying, decreased accommodation, and GMI in PD patients.

B-1226 14:57

Gastric remnant volume on radiology as a predictor of weight loss after laparoscopic sleeve gastrectomy for morbid obesity

A. Bertesso, I. Zotta, G. Barbiero, M. Zuliani, A.C. Frigo, L. Prevedello, M. Foletto, F. Pomerri; *Padua/IT (alberto.bertesso@gmail.com)*

Purpose: To correlate initial gastric remnant volume after laparoscopic sleeve gastrectomy (LSG) with volumetric changes and patient's weight loss (WL).
Methods and Materials: A retrospective review was conducted on 430 upper gastrointestinal contrast studies concerning 159 obese patients with body mass indexes (BMI) exceeding 40 kg/m^2 or 35 kg/m^2 and comorbidities who underwent LSG from 2007 to 2016 and were followed up for periods ranging from 3 months to 6 years. Radiological images of the gastric remnants were broken down into multiple components and volumes were calculated with appropriate software. Percent excess weight loss (%EWL) and reduction in BMI were also calculated in all patients at each follow-up. Relationships between variables were assessed with Spearman's rank correlation coefficient, Wilcoxon's signed-rank test and Student's t-test.
Results: The mean gastric remnant volume on the first postoperative day (t=0) was 130.7±53ml, and then increased at most of the follow-up intervals analysed (p<0.0001). The reduction in BMI was greatest at 1 year (57.3±40%), 2 years (79.2±70%), and 6 years (64.8±37%). The highest %EWL was identified at 6 months (44.8±20%), 2 years (52.7±26%), and 3 years (47.8±25%) and was positively correlated with a gastric remnant volume of 125ml or less at t=0 (p<0.05). No correlation emerged between gastric volumetric changes and %EWL.
Conclusion: A direct relationship was documented between an initial sleeve volume of ≤125ml and a satisfactory WL after LSG. The increase in gastric remnant volume on radiology after surgery did not affect the WL achieved over the long-term follow-up.

B-1227 15:05

Intestinal type ampullary adenocarcinoma vs duodenal adenocarcinoma: role of ampullary MDCT in preoperative differentiation

Z. Kovacevic, A. Ivanovic, D. Masulovic; *Belgrade/RS (zeljka.kovacevic.bg@gmail.com)*

Purpose: To evaluate the utility of ampullary MDCT in the non-invasive, preoperative differentiation of duodenal carcinoma and intestinal-type ampullary carcinoma.
Methods and Materials: In this retrospective study, 20 [8 females (age 38-77 years)] patients with resected ampullary adenocarcinoma and duodenal adenocarcinoma who underwent preoperative contrast-enhanced ampullary MDCT were included. Two radiologists, blinded to pathological diagnosis of adenocarcinoma subtype, evaluated the presence of five MDCT features in consensus. Correlation between MDCT findings with ampullary cancer subtypes was performed using $\chi 2$ and Fisher's exact test.
Results: When evaluated with ampullary MDCT, intestinal- type ampullary adenocarcinomas were significantly different in terms of lesion morphology (p:<0.0001), shape of the papilla (p:<0.0001), CBD infiltration (p:0.003) and dilation (p:0.0004) and duodenopancreatic groove infiltration (p:0.0009).Duodenal carcinomas were more often infiltrative in morphology (9/10 [90%]), showed retracted papilla (8/10 [80%]), CBD (3/10[30%]) and MPD infiltration (2/10 [20%]), dilated CBD (3/10 [100%] and MPD (2/10 [20%]), "fixed" duodenopancreatic groove appearance (5/10 [50%]). Intestinal-type ampullary carcinomas were significantly more frequently nodular in shape (10/10 [100%]), had a bulging papilla (9/10 [90%]), "free" duodenopancreatic groove appearance (10/10[100]).
Conclusion: A tailored ampullary MDCT protocol can be useful to differentiate intestinal adenocarcinoma from duodenal adenocarcinoma preoperatively.

B-1228 15:13

Radiological management after bariatric surgery

P. Venetucci[1], A.G. Tucci[1], A. Macca[1], F. Venetucci[2], M. Quarantelli[3], A. Brunetti[1]; [1]*Naples/IT*, [2]*Mercato San Severino/IT*, [3]*Portici/IT (pierovenetucci@gmail.com)*

Purpose: To illustrate an imaging protocol after bariatric surgery, based on upper gastrointestinal series and MDCT, in the presence or in the absence of complications.
Methods and Materials: 954 patients were evaluated with radiographic upper gastrointestinal series following the most common procedures for obesity: laparoscopic adjustable gastric banding (269), sleeve gastrectomy (525) and Roux en Y gastric bypass (160). In the presence or in suspect of early or late complications they performed also MDCT.
Results: 882 patients had normal post-operative findings after radiographic gastrointestinal series. 72 patients had signs suggestive of complications and they performed also MDCT scan. Major complications after gastric banding were 46 (26 band slippage and 20 small bowel obstructions); after sleeve gastrectomy were 16 (10 gastric leaks, 3 haemorrhages, 3 small bowel obstructions); 10 complications were found following Roux en Y bypass (3 internal hernias, 3 leaks, 3 anastomotic strictures, 1 volvulus). Upper gastrointestinal complications that required a new surgery occurred in 6% of patients (58/954).
Conclusion: Upper GI series and CT are essential tools for the evaluation of complications after bariatric surgery. All patients should perform upper gastrointestinal series as first step. In the presence of signs or in suspect of major complications, MDCT is necessary to identify and characterize the type of complication. This protocol can modify patient's outcome, directing to surgery patients who require reintervention.

A MRI-guided high-intensity focused ultrasound-triggered wax-coated capsule for temporally and spatially supertargeted drug release

S. Matoori[1], M. Roveri[1], A. Romagna[1], O. Voznyuk Wuerthinger[1], P. Tiefenboeck[1], O. Kolokythas[2], J.M. Froehlich[2]; [1]*Zurich/CH*, [2]*Winterthur/CH*

Purpose: To prepare an orally-applied temperature-sensitive wax-coated capsule containing a gadolinium-based contrast agent (GBCA) to visualize drug release; and to test the release of its content upon applying a MRI-guided high-intensity focused ultrasound (HIFU) trigger.
Methods and Materials: A mixture of lanolin and cetyl alcohol was optimized to a suitable melting point. Cellulose capsules were coated using the Michelangelo method based on carving out the GBCA-containing capsule embedded in the wax mixture (n=10). The melting of the wax-coating was tested by applying a MRI-guided 200W HIFU beam (n=3). The release of the capsule content was verified with a T1-weighted MR-sequence visualizing the release of the encapsulated contrast agent (n=3).
Results: The capsules were coated with a 1:1-mixture of lanolin and cetyl alcohol (melting point 43°C, n=10). The coating resisted for 24h upon exposure to simulated gastrointestinal fluids (n=3). A 200 W MR-guided HIFU pulse was

able to selectively melt the coating and release the content of the capsule (n=3).
Conclusion: We provide a reproducible method to coat a capsule with a highly temperature sensitive waxy composition and a proof-of-concept of using MRI-guided HIFU to trigger the release of the capsule contents. This wax-coated capsule addresses a currently unmet clinical need in personalised medicine as it provides the opportunity for HIFU-MR-guided temporally and spatially supertargeted drug release. Therefore, this drug delivery system promises to enable targeted local therapy of gastrointestinal lesions.

Focal autoimmune pancreatitis vs pancreatic adenocarcinoma in the pancreatic head: MRI-MRCP findings
R. Negrelli[1], E. Boninsegna[1], G.A. Zamboni[1], G. Avesani[2], S. Mehrabi[1], R. Manfredi[1], R. Pozzi-Mucelli[1]; [1]*Verona/IT*, [2]*Bolzano/IT*
(ricky.negrelli@gmail.com)

Purpose: Focal form of autoimmune pancreatitis (AIP) represents a challenging mimicker of pancreatic adenocarcinoma (PAD). The aim of our study is to retrospectively evaluate the MRI-MRCP findings of focal AIP and PAD, to find helpful patterns for the differential diagnosis.
Methods and Materials: 48 patients with a solid lesion of the pancreatic head underwent MRI-MRCP, 20 patients had focal AIP and 28 PAD. We excluded patients who underwent different imaging, lesions of the body-tail and diffuse AIP. Image analysis included: lesion volume, signal intensity abnormalities, enhancement pattern, common bile duct (CBD) caliber, main pancreatic duct (MPD) stenosis, presence of upstream MPD and side branches dilation.
Results: AIP lesions tend to be larger than PAD (p<0,001). Both AIP and PAD appeared hypointense on T1-WI and slightly hyperintense on T2-WI (p=NS). Although both lesions were hypovascular in the arterial-phase (p=NS), AIP presented progressive enhancement and contrast retention (p<0,001). The CBD resulted dilated in 9/20 (45%) cases of AIP and in 14/28 (50%) of PAD (p=NS). On MRCP, 60% of the AIP showed multiple stenoses of the MPD, opposed to none of the PAD (p<0,001). The caliber of the upstream MPD was larger in PAD (mean: 6,2mm) than in AIP (3,7mm; p<0,001); side branches dilation was found in 26/28 (93%) and in 12/20 (60%), respectively (p=0,02).
Conclusion: The most suggestive features of AIP are large mass-forming lesions, with contrast retention, delayed washout and multiple stenoses of the MPD, without a marked dilation of the upstream MPD at MRCP.

B-1231 14:17

Diagnostic performance of apparent diffusion coefficient in acute pancreatitis; correlation with revised Atlanta and Japanese severity score
R.M. El Kady, S.H. Bakr, H.I. Megally, W.A. Abbas, E. Abo Elhamd; *Assiut/EG (dr.eman_08@yahoo.com)*

Purpose: To investigate the role of apparent diffusion coefficient (ADC) in evaluating acute pancreatitis patients and rule out pancreatic necrosis.
Methods and Materials: Prospective study with 34 patients with acute pancreatitis and 20 control cases underwent magnetic resonance imaging using 1.5T machine include T1, T2 WI, SPIR, and DWI using b-values of (0,200,400,800). The ADC values of pancreatic head, body and tail were averaged and correlated with clinical scoring based on revised Atlanta classification and Japanese score.
Results: The mean ADC of normal pancreatic tissue, mild pancreatitis, moderate pancreatitis and necrotic tissue in severe pancreatitis was (1.54 ± 0.05), (1.18±1.16), (1.14± 0.06), (1.99±0.06) X 10-3 mm2/S respectively .The ADC significantly correlates with both revised Atlanta and Japanese classifications in differentiating normal cases from acute pancreatitis and in differentiating cases of moderate edematous pancreatitis from severe necrotising pancreatitis (p < 0.001 for each classification respectively). The ADC couldn't significantly differentiate between mild and moderate forms of acute pancreatitis. Using ROC curve analysis to differentiate normal cases from acute pancreatitis, the AUC was 0.85 and the best ADC cut-off value was 1.26 X 10-3 mm2/S with sensitivity 85.3% and specificity 95.8%. To differentiate mild to moderate acute pancreatitis from severe necrotising pancreatitis the AUC was 0.98 and the best ADC cut off value was 1.8 X 10-3 mm2/S with sensitivity 100 % and specificity 98%.
Conclusion: ADC measurement is helpful in evaluating acute pancreatitis patients. It provides a safe alternative to the use of contrast media in these patients.

B-1232 14:25

Characterisation of patients with abdominal pain and signs of acute pancreatitis on CT without threefold increase of normal serum lipase levels
M. Avanesov, A. Löser, J.M. Weinrich, G. Adam, J. Yamamura, M. Karul; *Hamburg/DE (m.avanesov@uke.de)*

Purpose: To evaluate the prevalence, severity and characteristics of patients with abdominal pain and signs of acute pancreatitis on contrast-enhanced CT(CECT) <3x increase of serum lipase (lip-) compared to patients with ≥3x increase of normal serum lipase levels (lip+).
Methods and Materials: 272 patients with abdominal pain, CT with signs of acute pancreatitis and serum lipase levels on admission were retrospectively evaluated. The severity of acute pancreatitis was assessed in 124 patients (61 lip-,63lip+) by 3 different CT severity scores for pancreatic (CTSI,mCTSI) and extrapancreatic changes (mCTSI,EPIC). A serum lipase of ≥180U/l was regarded as threefold increase.
Results: In 61 patients (22%, 53y, 48men) serum lipase levels were less than three-fold of the reference value (lip-) despite of signs of acute pancreatitis on CT, whereas 211 patients (56y,131men) belonged to the lip+ group. In lip- patients, CTSI and mCTSI scores revealed similar values (CTSI 4.3vs.4.8, p=0.2, mCTSI 5.3vs.6.1, p=0.1) compared with 63 lip+ patients, whereas EPIC score was significantly lower in lip- patients (2.6vs.3.4, p=0.01). In the lip- group, significantly more patients had an acute on chronic pancreatitis compared with the lip+ group (67% in lip- vs. 26% in lip+, p<0.001).
Conclusion: 22% of patients with abdominal pain and acute pancreatitis on CT belonged to the lip- group. In the lip-group acute on chronic pancreatitis was 3 times as common as in the lip+ group. Only the extrapancreatic changes assessed by EPIC score were significantly altered in both groups. In lip- patients a CECT is crucial for correct diagnosis of acute pancreatitis.

B-1233 14:33

Paraduodenal pancreatitis: MRI features and differential diagnosis with pancreatic adenocarcinoma
E. Boninsegna, R. Negrelli, G. Zamboni, G. Tedesco, R. Manfredi, R. Pozzi-Mucelli; *Verona/IT (boninsegnae@gmail.com)*

Purpose: Paraduodenal pancreatitis (PDP) is an uncommon type of chronic pancreatitis affecting the "groove", a region between the head of the pancreas and the duodenum. It has been recently defined and few studies have been conducted to define its imaging characteristics. It presents common features with pancreatic adenocarcinoma (PA) and differential diagnosis could be difficult. We evaluated its MRI aspects, to identify distinctive elements with PA.
Methods and Materials: 56 patients had been included; 28 were affected by PDP, 28 by PA; everyone had performed an MRI examination and a biopsy. For both groups we evaluated: size of the lesion, presence of cystic components, signal intensity on T1- and T2-weigthed images (WI), on DWI and after contrast medium administration, presence of dilatation of hepatic duct and main pancreatic duct.
Results: On T1-WI 18/28 (64,3%) PDP and 25/28 (89,3%) PA were hypointense to the healthy pancreas; on T2-WI 19/28 (67,9%) PDP were isointense and 18/28 (64,3%) PA were hyperintense (p>0,05). On DWI, 20/28 (71,4%) PDP were isointense and every PA was hyperintense (p<0,01). In the delayed phase 18/28 (64,3%) PDP were hyperintense and 14/28 (50%) PA were isointense (p<0,01). Cysts were present in 24/28 (85.7%) PDP; 15/28 (53,6%) PA presented the "double duct" sign; 11/15 (73.3%) PDP presented calcifications within the lesion. PDP mean volume was 59,9 cm^3, PA volume 10,7 cm^3 (p<0,01).
Conclusion: PDP features useful for the differential diagnosis with PA are: presence of cysts and calcifications, normal ADC values, high signal intensity on delayed phases and greater dimensions.

B-1234 14:41

Comparative evaluation of CT and MRI in non-invasive detection of infection in fluid collections of acute pancreatitis
N.A. Dikshit; *Chandigarh/IN (drnadz@gmail.com)*

Purpose: The study was undertaken to compare CT and newer MRI sequences namely DWI and MR Spectroscopy in non-invasive detection of infection in collections of acute pancreatitis.
Methods and Materials: Total of 30 patients diagnosed as acute pancreatitis with fluid collections and untreated suspected infection were included. They

underwent CECT and MRI followed by microbiological analysis (Gram stain and culture) of the guided diagnostic aspirate. Presence of gas bubbles in the collections on CT images were considered to be a criteria for diagnosing infection. Collections were analysed for diffusion restriction on b 400 and b 800 images and corresponding ADC maps. Objective assessment of the ADC values was also performed both from peripheral and central part of the collection. Multivoxel proton spectroscopy was applied to an area showing diffusion restriction and a control area within the collection.
Results: Culture detected infection in 13 collections, 11 showed qualitative and quantitative diffusion restriction with only 5 of them showing gas bubbles on CECT. Mean central and peripheral ADC values (b value=800) had a higher sensitivity (92.3%) and specificity (88.2%) for identifying infected collections. Mean I value of aminoacids showed 92.3% sensitivity and 58.8% specificity for identifying infected fluid collections.
Conclusion: DW-MRI can be used in non-invasive detection of infection in fluid collections of acute pancreatitis with higher sensitivity and accuracy than CT. MRS can substantiate the detection of pyogenic infection in collections by detection of amino acids at 0.9 ppm.This may obviate the need for unnecessary diagnostic and therapeutic aspirations.

B-1235 14:49

MRI for detailed assessment of pancreatic morphology and function in chronic pancreatitis

J. Frøkjær[1], A. Madzak[1], S. Olesen[1], I. Haldorsen[2], A. Drewes[1]; [1]*Aalborg/DK*, [2]*Bergen/NO (frokjaer@mail.tele.dk)*

Purpose: Chronic pancreatitis (CP) is characterised by abnormal pancreatic morphology and impaired endocrine and exocrine function. As little is known about the relationship between pancreatic morphology and function, and also the association to etiology and clinical manifestations of CP, the aim was to explore pancreatic morphology and function with advanced MRI.
Methods and Materials: Eighty-two CP patients and 22 healthy controls (HC) were included. Morphological imaging parameters included pancreatic main duct diameter, gland volume, Dixon fat signal fraction, and apparent diffusion coefficient (ADC) values. Functional imaging parameters included quantitative bowel fluid volume assessment of pancreatic secretion and changes in pancreatic ADC before and after secretin stimulation. Patients were classified according to the modified Cambridge and M-ANNHEIM classification system. Fecal elastase was collected as proxy for exocrine pancreatic function.
Results: All imaging parameters differentiated CP patients from HC. However, correlations between morphological and functional parameters in CP were weak. Patients with alcoholic and non-alcoholic etiology had comparable MRI findings. Fecal elastase was positively correlated to pancreatic gland volume (r= 0.68, P=0.0016) and negatively correlated to Cambridge classification (r =-0.35, P<0.001). Additionally, gland volume was negatively correlated to the CP duration (r=-0.39, P<0.001) and baseline ADC (r =-0.35, P=0.027). When stratified by clinical stage (M-ANNHEIM), pancreatic gland volume was significantly decreased in severe stages of CP (P=0.001).
Conclusion: Secretin-stimulated MRI provides detailed information about pancreatic morphology and function and represents a promising non-invasive imaging method for characterising pancreatic pathophysiology and may enable monitoring of disease progression in patients with CP.

B-1236 14:57

Comparison of radiological scoring systems, clinical scores, neutrophil-lymphocyte ratio and serum C-reactive protein level for severity and mortality in acute pancreatitis

N. Gezer, G. Bengi, A. Baran, P. Erkmen, Ö. Topalak, C. Altay, O. Dicle; *Izmir/TR (agahbaran1@gmail.com)*

Purpose: To compare radiological scoring systems, clinical scores, serum C-reactive protein (CRP) level and neutrophil-lymphocyte ratio (NLR) in predicting severity and mortality of acute pancreatitis (AP).
Methods and Materials: Demographic, clinical and radiographic data from 80 patients with AP were retrospectively evaluated. Harmless acute pancreatitis score (HAPS), systemic inflammatory response syndrome (SIRS), bedside index for severity in acute pancreatitis (BISAP), Ranson and Balthazar scores, modified computed tomography severity index (CTSI), extrapancreatic inflammation on computed tomography (EPIC) score and renal rim grade were recorded. Prognostic performance of scoring systems, NLR at admission and CRP level at 48 hours were compared for severity based on definition of revised Atlanta classification and mortality. Receiver operator characteristic curves and area under the ROC (AUROC) were calculated.
Results: Out of 80 patients, 19 (23.8%) had severe AP and 9 (11.3%) died. AUROC for BISAP score was 0.836 (95%CI: 0.735-0.937) having the highest value for severity. With a cut-off of BISAP ≥2, the sensitivity and specificity were 68.4% and 78.7%. AUROC for NLR was 0.915 (95%CI: 0.790-1) having the highest value for mortality. With a cut-off of NLR>11.91, the sensitivity and specificity were 76.5% and 94.1%. Among radiological scoring systems, EPIC score had the highest AUROC which was 0.773 (95%CI: 0.645-0.900) for severity and 0.851 (95%CI: 0.718-0.983) for mortality with a cut-off value ≥6.
Conclusion: BISAP score and NLR might be preferred as early determinants of severity and mortality in AP. EPIC score might be suggested among current radiological scoring systems.

B-1237 15:05

Detection of inflammation in primary sclerosing cholangitis using gadolinium-based contrast enhancement index (CEI)

S. Keller, J. Weinrich, C. Schramm, G. Adam, J. Yamamura; *Hamburg/DE (s.keller@uke.de)*

Purpose: To evaluate the feasibility of conventional magnetic resonance imaging (MRI) T2-weighted images (T2wI) and the T1wI relative contrast enhancement index (CEI) for detection of intrahepatic inflammation in patients with primary sclerosing cholangitis (PSC).
Methods and Materials: 3T MRI scans were retrospectively reviewed in 27 patients (42.9 ± 15.6 y) with known PSC and in healthy controls (n=19). Wedge-shaped areas with hyperintense signal in T2wI and PSC-typical MR imaging findings such as intrahepatic bile duct dilatation and irregularities were defined by two radiologists. The inter-observer agreement was calculated by using Cohen`s kappa coefficient. The patients' contrast enhancement index (CEI) was calculated both for wedge-shaped T2w hyperintense (CEI_{hyper}) and normal appearing (CEI_{normal}) areas and compared to one each other and also to the CEI of healthy controls ($CEI_{healthy}$). The CEI ratio (hyper/normal) in patients was correlated statistically to disease specific laboratory parameters.
Results: The inter-observer agreement for detection of hyperintense areas in T2wI was very good (κ = 0.92; 95% Confidence interval 0.78-1.0). In patients, the mean CEI_{normal} (53.53±6.5%) of normal appearing tissue in T2wI corresponded to the CEI of healthy controls (53.2±2.7%, p>0.97). The patients' CEI_{hyper} (81.7±10.68) was elevated compared to the CEI_{normal} (p=0.03) as well as to the controls (p=0.01). No correlation of the patients' functional laboratory parameters and the CEI ratio was observed.
Conclusion: The CEI is a useful additional tool for assessment of inflammatory alterations in PSC liver parenchyma.

Image monitoring of hepatic oxygenation and Kupffer activity during preneoplastic changes induced with obstructive cholangitis and N nitrosodimethylamine in a mouse model

J. Kim, S. Lee, J. Lee, H. Eun, J. Han; *Seoul/KR (jhkim2008@gmail.com)*

Purpose: To investigate serial changes of the impaired phagocytic activity of Kupffer cells (KC) and liver oxygen saturation (sO_2) using Sonazoid-enhanced ultrasound imaging (SEUS) and photoacoustic imaging (PI) during preneoplastic changes induced with obstructive cholangitis and N-nitrosodimethylamine (NDMA) in a mouse model.
Methods and Materials: A mouse cholangitis model was created by ligation of the common bile duct (n=33, G1) and had taken NDMA for 8 weeks. The cholangitis group was compared to the control group (n=19, G2). Serial changes of echogenicity and sO_2 by SEUS and PI were measured at baseline, four, six, and eight weeks after NDMA administration. Serial pathologic changes including H&E staining and KC fraction using CD68 staining were compared using ANOVA and Unpaired t-test.
Results: Serial pathologic changes showed biliary epithelial hyperplasia, some foci of dysplasia. CBD ligation group showed serial decreased of parenchymal intensity (-29.8 dB vs. -30.5 dB, -35.0 dB vs. -30.4 dB, and -38.2 dB vs. -31 dB) on SEUS and liver oxygen saturation (45.2% vs. 51.9%, 43.0% vs. 49.0%, and 31.3% vs. 49.7%) of PI as compared with the control group at the 4th, 6th, and 8th weeks after administration, respectively (P<0.05). However, the KC fraction showed an increase in the ligation group than in the non-ligation group at 6th, and 8th weeks (P<0.05).
Conclusion: During preneoplastic changes induced with obstructive cholangitis and NDMA, SEUS and PI are a useful tool for monitoring of the serial change of impaired phagocytic activity of Kupffer cells and liver hypoxic state.

Contrast-enhanced CT of abdomen in acute pancreatitis: can we predict the development of necrosis simply by CT number measurements?

N. Gezer, G. Bengi, A. Baran, Ö. Topalak, O. Dicle; *Izmir/TR (agahbaran1@gmail.com)*

Purpose: Pancreatic necrosis is an important prognostic factor in acute pancreatitis. It is associated with tissue ischaemia due to vasospasm of intrapancreatic arteries. However, ischaemic tissue may not always be observable early in the course by contrast-enhanced computed tomography (CT). Demonstration of enhancement on contrast-enhanced CT is a reliable sign of vascularisation and measurable as CT numbers expressed in Hounsfield Units (HU). Our aim was to evaluate if a routine contrast-enhanced CT of abdomen can detect tissue ischaemia and predict the development of necrosis by CT number measurements in acute pancreatitis.

Methods and Materials: 69 patients with acute pancreatitis (17 necrotic, 52 oedematous) whose contrast-enhanced CT images were obtained 48-72 hours after onset of symptoms were included in the study. The highest (relatively normal-HUp1) and lowest (presumably ishemic-HUp2) CT numbers of pancreatic tissue, CT numbers of spleen (HUs) and abdominal aorta (HUa) were measured. The follow-up CT examinations 3-4 weeks after were evaluataed to identify patients with necrotic or oedematous pancreatitis.
Results: In 6 (35%) of 17 necrotic pancreatitis, pancreatic necrosis was not diagnosed by initial CT but proved in the latter. Mean HUp1, HUp2, HUs and HUa of necrotic group were 70.5±11.3, 31.8±14.3, 94±24, 205.5±80.3. Mean HUp1, HUp2, HUs and HUa of oedematous group were 71±15.5, 47.7±17.6, 93.4±19.7 and 169.9±61.2. Statistical differences in HUp2, HUp1/HUp2, HUs/HUp2, HUa/HUp2 were shown between necrotic and oedematous pancreatitis.
Conclusion: CT number measurements on a standard contrast-enhanced CT of abdomen may help to distinguish between necrotising and oedematous pancreatitis.

Liver fat storage in patients with NAFLD: differences between metabolic syndrome and genetic aetiology
M. Di Martino, A. Capalbo, K. Koryukova, S. De Vizio, C. Catalano; *Rome/IT (micdimartino@hotmail.it)*

Purpose: To compare the hepatic fat fraction (HFF) at Magnetic Resonance Spectroscopy (MRS) and proton density hepatic fat fraction (PD-HFF) in patients with genetic and metabolic syndrome determined NAFLD.
Methods and Materials: This prospective study comprised three groups: control group (50 patients), genetic NAFLD group (57 patients) and metabolic syndrome NAFLD group (55 patients). Magnetic Resonance (MR) examination was performed on a 3.0T scanner. MRS was acquired with a single voxel breath-hold PRESS sequence (TR 4000, TE 30-40) with an acquisition time of 24 s. PD-HFF was determined with a breath-hold low-flip angle, T1-weighted, 2D multiple-echo, spoiled gradient-echo (GRE) sequence (TR5.1/TE from 0.8 to 3.8, flip angle 5°, FOV 33-40 cm; section thickness, 10 mm; intersection gap, 0, matrix 128 × 128, acquisition time 2 × 17s) and with a 3D GRE T2* sequence (IDEAL-IQ GE; TR12.9 msec; TE 6 echos from 1.6 to 9.8 FOV, 35-40 cm; matrix, 224x 160; flip angle, 5°; section thickness, 10 mm. Differences between study groups were evaluated by ANOVA and Kruskall-Wallis test. Pearson's correlation coefficient was used for comparison among MR techniques.
Results: Patients with NAFDL reported a significantly greater HFF than healthy subjects, with a trend to a higher value in metabolic syndrome group (8.7% vs 24.7% and 31.4%; p < 0.0001). Good correlation was found between PD-HFF sequences and MRS (0.51 and 0.55 respectively).
Conclusion: Subjects with metabolic NAFLD have a higher hepatic fat than patients with genetic NAFLD. IDEAL-IQ sequence should replace MRSfor non-invasive diagnosis of liver steatosis.

B-1241 14:08

Simultaneous dual-energy CT based monochromatic imaging and US with normalised local variance analysis for quantification of hepatic steatosis: correlation with pathology
P. Rogalla, G. Guenette, A. Rattansingh, M. Roest, K. Mao, B. Hoppel; *Toronto, Ontario, ON/CA (Patrik.Rogalla@uhn.ca)*

Purpose: To analyse dual-energy monochromatic CT imaging in patients with suspected fatty liver disease and compare to simultaneously acquired normalised local variance (NLV) ultrasound imaging and histopathology.
Methods and Materials: 41 patients with clinically indicated liver biopsy for fatty liver disease were prospectively enrolled in this study. Biopsies were performed under US guidance (Aplio 500) within the CT suite (Toshiba Aquilion Vision). Prior to the liver biopsy, three measurements were performed using investigational US software that provides NLV of the target liver area in the right lobe. A single dual-energy CT volume (16 cm, 320 slices) was acquired with the needle in situ. Two cores were taken from the liver for clinical pathology evaluation. Monochromatic images were reconstructed in 5 keV intervals from 35 to 130 keV. Attenuation in 2 ROIs measured at the needle tip were curve fitted to generate DE-CT-I_0. NLV was measured in a 3 cm ROI (each with 12,000 samples) placed at the site of biopsy. All values were correlated to pathology.
Results: There were no biopsy related complications. The mean/SD for the pathology steatosis score, NLV, DE-CT-I_0 and HU for 80kVP and 135kVp images were 0.57/0.72, 1.16/0.13, 54.94/12.04, 45.8/11.0 and 52.84/11.24 respectively. The correlation/two tailed p-value of DE-CT-I_0 vs biopsy, NLV vs biopsy, and NLV vs DE-CT-I_0 were r^2= 0.76/p<0.01, r^2= 0.59/p<0.01 and r^2=0.61, p<0.01, respectively.
Conclusion: Both US and CT correlate well with each other and allow predicting the degree of hepatic steatosis, with monochromatic DE-CT performing slightly better than NLV analysis on US.

The performance of multi-echo chemical shift magnetic resonance imaging for the evaluation of liver steatosis: a meta-analysis
Y. Qu, J. Chen, B. Song; *Chengdu/CN (yali_qu_xray@163.com)*

Purpose: To evaluate the diagnostic performance of multi-echo chemical shift magnetic resonance imaging (CS-MRI) for the evaluation of liver steatosis (LS).
Methods and Materials: A systematic literature search was performed to identify relevant original studies. Quality analyses were conducted by Quality Assessment of Diagnostic Accuracy Studies (QUADAS-2). Diagnostic data were extracted for each steatosis stage (G0-G3). A bivariate mixed-effect binary regression model was used to produce pooled sensitivity, specificity and summary receiver operating (SROC) curves. The areas under SROC curve (AUC) were calculated as the indicator of the diagnostic accuracy.
Results: We included 10 studies with 11 subsets of data discriminating LS from normal (LS≧G1) and 5 studies differentiating moderate or severe LS from mild or no LS (LS≧G2). The sensitivity, specificity, diagnostic odds ratio and AUC for LS≧G1 were 0.92 (95% confidence interval (CI) 0.88-0. 95), 0.93 (95% CI 0.86-0.97), 160 (95% CI 79-327) and 0.97, and for LS≧G2 were 0.83 (95% CI 0.67-0.92), 0.86 (95% CI 0.79-0.91), 30 (95% CI 13-67) and 0.90.
Conclusion: Multi-echo CS-MRI revealed excellent diagnostic accuracy for the staging of LS≧G1 and LS≧G2. This technique shows notable potential in the evaluation of LS.

B-1243 14:24

Magnetic resonance spectroscopy for differentiation between non-alcoholic steatohepatitis and simple hepatic steatosis
K.-H. Yoon, T.-H. Ahn, R.-H. Kim, H. Jun, Y. Lee, M. Lee, E. Cho; *Iksan/KR (whitezombi88@naver.com)*

Purpose: To study the hepatic metabolite difference between patients with non-alcoholic steatohepatitis (NASH) and simple hepatic steatosis, and study the diagnostic accuracy of proton magnetic resonance spectroscopy (^{1}H-MRS) with long echo-time (TE).
Methods and Materials: The local institutional review board approved this study and waived written informed consent. ^{1}H-MRS measurements were performed on a localised voxel of the liver using a point-resolved spectroscopy sequence and hepatic metabolites of the alanine (Ala), lactate/triglyceride (Lac/TG), and TG were analyzed in patients with NASH (n=11), simple steatosis (n=15), and healthy controls (n=6). The group difference was tested with the ANOVA and Tukey's post-hoc tests, and diagnostic accuracy was tested by calculating the area under the receiver operating characteristics (ROC) curve. The values of metabolites were correlated with the histopathology and non-alcoholic fatty liver disease (NAFLD) activity scores.
Results: Patient with NASH showed significant elevated the Ala (p<0.001), Lac/TG (p<0.001), TG (p<0.05) concentration when compared with patients who had simple steatosis and healthy controls. The patients with NASH were significantly higher levels in Ala (mean ± standard deviation, 52.5±8.3 vs 2.0±0.9; p<0.001), Lac/TG (824.0±168.2 vs 394.1±89.8; p<0.05) than simple steatosis. The area under the ROC curve to distinguish NASH from simple steatosis was 1.00 (95% confidence interval; 0.1.0, 1.00) with Ala and 0.782 (95% confidence interval; 0.61, 0.96) with Lac/TG. The Ala and Lac/TG levels were well correlated with steatosis grade, lobular inflammation, and NAFLD activity scores.
Conclusion: ^{1}H-MRS with long TE would be useful for differentiation of patients with NASH and simple hepatic steatosis.

Staging steatosis using quantitative ultrasound, validation with pathohistology

G. Weijers, I.D. Munsterman, A.S.S. MMeel-van den Abeelen, J.M. Thijssen, E.T.T.L. Tjwa, J.P.H. Drenth, C.L. de Korte; *Nijmegen/NL (Gert.Weijers@radboudumc.nl)*

Purpose: Quantitative ultrasound can be an attractive non-invasive alternative for liver biopsies to stage steatosis. We validated the Computer Aided Ultrasound (CAUS) method for staging human steatosis.
Methods and Materials: Analysis of a prospectively obtained dataset (biopsy and CAUS) of a cohort consisting of consecutive patients referred for liver biopsy with a variety of clinical indications. From this cohort retrospectively, patients (n=24) with positive histology scores for steatosis (Brunt score 1-3) were selected. As a reference, patients without steatosis and without fibrosis were selected (n=26). Five ultrasound image per patient were analysed using the CAUS protocol, which estimates average and depth dependent histogram and texture parameters. Mean and variance of 15 parameters as well as Pearson correlations to the Brunt score were obtained. Leave one out multiple linear regression analysis and receiver operating characteristics revealing the area under curve (AUC) were estimated.
Results: Highly significant correlations were found for 11 out of 15 US parameters. Best correlating parameters were: mean echo level (MU, R=0.801, p<0.01), residual attenuation coefficient (R=0.736, p<0.01) and depth dependent speckle signal to noise ratio (R=0.774, p<0.01). Regression analysis with these three parameters revealed an AUC of 0.944. Histology also revealed fibrosis in 75% of the patients, however only a weak correlation of the MU (R=0.414, p=0.019) with fibrosis score was observed.
Conclusion: The high AUC value indicates the potential of CAUS for screening a population for steatosis. Despite the presence of fibrosis, good predictive results for staging steatosis were obtained indicating the robustness of CAUS.

B-1245 14:40

Attenuation coefficient measurement (ACM) as a newest mode for ultrasound quantitative hepatic steatosis assessment

O. Dynnyk, N. Kobyliak, O. Fedusenko; *Kyiv/UA (Obdynnyk@Gmail.Com)*

Purpose: The presence of fat droplets in the hepatocytes (hepatic steatosis) under condition of chronic diffuse liver disease (CDLD) increases the attenuation of ultrasound (US). A group of Ukrainian scientists proposed an original algorithm for US attenuation coefficient measurement - ACM and accuracy navigation by B-mode.
Methods and Materials: From total of 3274 patients who underwent to comprehensive abdominal US (2015-2016) in our clinic, 949 have been diagnosed with fatty liver according to Hamaguchi criteria. All these patient we provide ACM (dB/cm) measurement by SoneusP7 device (Ultrasign, Ukraine), with a 1-6MHz convex transducer in the right lobes. For diagnostic accuracy assessment we used CT as standard and comparison with CAP by Fibroscan (Echosens, France) we included 142 patients for subanalysis.
Results: From total of 3274 patients who underwent to comprehensive abdominal US (2015-2016) in our clinic, 949 have been diagnosed with fatty liver according to Hamaguchi criteria. All these patient we provide ACM (dB/cm) measurement by SoneusP7 device (Ultrasign, Ukraine), with a 1-6MHz convex transducer in the right lobes. For diagnostic accuracy assessment we used CT as standard and comparison with CAP by Fibroscan (Echosens, France) we included 142 patients for subanalysis.
Conclusion: The ACM as novel real-time ultrasound approach can be used for non-invasive hepatic steatosis diagnosis, allows clinicians to follow-up disease progression and response to treatment.

B-1246 14:48

Accuracy of automated liver contouring, fat fraction and R2* measurement on T1-weighted q-Dixon magnetic resonance images

D. Stocker[1], K. Schawkat[1], M. Bashir[2], S. Kannengiesser[3], C.S. Reiner[1]; [1]*Zurich/CH*, [2]*Durham, NC/US*, [3]*Erlangen/DE (daniel.stocker@usz.ch)*

Purpose: To evaluate the accuracy of automated liver contouring and volumetry and its influence on automated fat signal fraction (FSF) and R2* measurements in the multi-echo T1-weighted q-Dixon magnetic resonance (MR) sequence compared with manual measurements in the liver.
Methods and Materials: Unenhanced multi-echo q-Dixon MR-images were retrospectively evaluated in 30 consecutive patients without prior liver surgery (21 females, 9 males; mean age 59±13.4 years; mean BMI 24.8±5.1) undergoing clinically indicated liver MRI on a 3T-scanner. Liver volume (LV), FSF_{vol} and $R2^*_{vol}$ measurements across the whole liver volume were automatically generated by the MR-scanner on q-Dixon images. Similar measurements were manually performed by one radiologist. Differences between automated and manual measurements were assessed with the related-samples Wilcoxon signed rank test and Bland-Altman plots.
Results: Automatic LV (1576.8 ± 434.8 ml) was significantly smaller than manual LV (1829.9 ± 758.5 ml) with a relative difference of -10±13.3% ($p < 0.01$). Mean automatic $R2^*_{vol}$ (80.7±65 s^{-1}) was slightly but significantly lower than manual $R2^*_{vol}$ (85.7±84.4 s^{-1}) with a relative difference of -2±7.5 % (range, -25.3% to 21.3%; $p < 0.01$). Mean automatically measured FSF_{vol} was 6.5±5.1% and was not significantly different to manual FSF_{vol} 6.8±4.6 % with a relative difference of -3.2±30.5% (range, -54.1% to 100.3%; p=0.185).
Conclusion: Automated liver contouring lead to slightly but significantly smaller liver volumes and lower R2* values compared to manual measurements. FSF_{vol} was not significantly influenced by differences in automated and manual liver contouring in this group of patients with normal to slightly elevated FSF.

Liver iron measurement by R2* in comparison to R2 and biosusceptometry

J. Yamamura, S. Keller, B. Schönnagel, E. Tahir, P. Nielsen, R. Grosse, G. Adam, R. Fischer; *Hamburg/DE (j.yamamura@uke.de)*

Purpose: To develop a breathhold liver MRI-R2* sequence as an alternative method for SQUID biomagnetic liver susceptometry (BLS) reference method and compare the results with R2 rates from the literature.
Methods and Materials: 34 patients with transfusional siderosis (ß-thalassemia major n=24) underwent a gradient recalled ECG-gated multi-echo sequence. LIC by BLS is calculated from the SQUID. R2* is determined from a mono-exponential fit to the echo-time-dependent signal amplitudes averaged over a whole liver slice with constant signal level offset. A correlation between BLS and R2* was determined statistically.
Results: The expected non-linear relationship, $R2^* = 30 + (0.007\pm0.003)\cdot LIC \cdot (1 + LIC0.39\pm0.05)$ ($r2 = 0.97$), was found in the range between 100 and 8000 µg/g liver. The Spearman rank correlation coefficient RS = 0.98 ($p < 10\text{-}4$) was similar to the reported R2 calibration versus liver biopsy (St. Pierre et al., 2005). Mono-exponential fit convergence for R2*(TE) at LIC > 6000 µg/g was poor due to the available first echo-time of 1.3ms. A comparison with formerly measured R2 rates resulted in a conversion factor of 4.9 ± 0.3 for the approved MRI-R2 calibration by St. Pierre et al. (2005) using freeze-dried liver biopsies.
Conclusion: In patients, where liver susceptometry is spoiled by local magnetic contaminations (dental braces, etc.) or by severe obesity, alternative breathhold MRI-R2* method within known limitations can be used to determine the liver iron concentration.

B-1248 15:04

Non-invasive staging of liver fibrosis in patients with chronic viral hepatitis: performance of a shear wave measurement method

G. Ferraioli, L. Maiocchi, R. Lissandrin, A. De Silvestri, C. Tinelli, C. Filice; *Pavia/IT*

Purpose: This single center cross-sectional study aimed at prospectively assess the performance of a point shear wave measurement (SWM) method by using transient elastography (TE) as the reference standard.
Methods and Materials: Consecutive patients with chronic viral hepatitis were enrolled. Liver stiffness was assessed with the SWM method implemented in the HI VISION Ascendus ultrasound system (Hitachi Ltd, Japan) and with the TE method of the FibroScan device (Echosens, France). The liver stiffness measurements with the SWM method were performed before the measurements with TE. For staging liver fibrosis we used the TE cutoffs of a previous meta-analysis, i.e. 7.0, 9.5 and 12.0 kiloPascal, respectively, for significant fibrosis (F>=2), advanced fibrosis (F>=3), and cirrhosis (F=4). The diagnostic performance of the SWM method was assessed by calculating the area under the receiver operating characteristic (AUC) curve.
Results: 411 individuals [218 males, 193 females; mean age, 61.2 (13.2) years] were studied. 382 (92.9%) of them were affected by chronic hepatitis C. 179 (43.6%) individuals were in F0-F1 stage, 75 (18.2%) in F2 stage, 41 (10.0%) in F3 stage, and 116 (28.2%) in F4 stage. The optimal cutoff values of the SWM method for staging F>=2, F>=3, F=4, respectively, were 6.44, 7.82 and 8.40 kiloPascal. AUC calculations showed values of 0.92 (0.89-0.94) for F>=2 [sensitivity, 83.3% (77.4-88.2); specificity, 87.4% (81.4-92.0]; 0.92 (0.88-0.94) for F>=3 [sensitivity, 86.0% (78.8-91.5); specificity, 82.6% (77.2-87.2)]; 0.94 (0.91-0.96) for F=4 [sensitivity, 92.3% (84.8-96.9); specificity, 82.1% (77.1-86.5)].
Conclusion: These preliminary results show that the SWM method is a useful tool for non-invasively staging liver fibrosis in patients with chronic viral hepatitis.

Diagnostic performance of 2D-shear wave elastography using comb-push techniques for liver fibrosis evaluation: a prospective study

S. Lee, J. Lee, J. Yoon, W. Chang, H.-J. Kang, H. Yang; *Seoul/KR (twin393@hanmail.net)*

Purpose: To evaluate the diagnostic performance of a new 2D-shear wave elastography (2D-SWE) using the comb-push technique in hepatic fibrosis detection using histopathology as the reference standard.
Methods and Materials: This prospective study was approved by the institutional review board, and informed consent was obtained from all patients. The liver stiffness (LS) measurements were obtained from 140 patients, using the 2D-SWE (GE LOGIQ E9), which uses comb-push excitation to produce shear waves and a time-aligned sequential tracking method to detect shear wave signals. Intraobserver reproducibility was evaluated in the 114 patients with histologic diagnosis, and interobserver reproducibility was evaluated in 20 patients without histologic diagnosis. LS values and histologic results were compared by using Spearman correlation and receiver operating characteristic (ROC) curve analysis.
Results: The technical success rate of 2D-SWE was 92.11% (105 of 114). Intraclass correlation of interobserver agreement was 0.873 and the value for intraobserver agreement was 0.951. LS values showed high correlation with estimation of fibrosis (r=0.712, p<0.001) and mild correlation with necroinflammation (r=0.340, P=0.0004), while steatosis did not show correlation with LS values (r=0.053, P=0.590). The area under the ROC curve (AUC) of LS values for stage F2 fibrosis or greater, stage F3 or greater, and stage F4 fibrosis was 0.874 (95% confidence interval [CI]: 0.794,0.930), 0.905 (95% CI : 0.832,0.954), and 0.894 (95% CI : 0.819,0.946), respectively.
Conclusion: 2D-SWE using the comb-push technique can be used as a reliable method for accessing hepatic fibrosis with excellent repeatability and reproducibility.

Early changes of liver stiffness assessed using shear wave elastography after novel direct antiviral therapy in chronic hepatitis C virus induced liver fibrosis

S.R. Marticorena Garcia, J. Guo, H. Tzschätzsch, M. Dürr, F. Halleck, K. Jöhrens, B. Hamm, I. Sack, T. Fischer; *Berlin/DE (stephan.marticorena-garcia@charite.de)*

Purpose: Chronic hepatitis C virus (HCV) infection predisposes to liver fibrosis. The purpose of this study is to non-invasively monitor the liver elasticity using shear wave elastography (SWE) after direct antiviral therapy.
Methods and Materials: In this prospective study 8 patients with chronic HCV infection and liver fibrosis (age 52±14 years) were treated with direct-acting antivirals (Daclatasvir/Sofosbuvir), their liver stiffness was monitored over 6 months and compared to a healthy control group (ctr, n=7). In all patients liver biopsy and histopathological analysis were performed prior to the treatment. SWE was performed before (d0) and after antiviral treatment (3 and 6 months) at a high-end ultrasound device (Aplio500, Toshiba) with a 5 MHz broadband convex transducer. HCV load is assessed by real-time PCR over 6 months.
Results: Liver fibrosis was detected in 7 patients (stage 1-3). HCV load was below detectable levels after 19 days (range 8-29 days) of treatment initiation. SWE shows a decrease in liver shear wave velocities (SWV) after 6 months (SWV: d0, 2.12±0.61m/s; 3mo, 1.73±0.26m/s; 6mo, 1.54±0.23m/s; d0 vs. 3mo, ns; d0 vs. 6mo, *P*<0.05; one-way ANOVA). Significant differences in liver SWV between HCV patients and ctr were only seen before antiviral treatment (SWV, ctr: 1.48±0.23m/s; d0 vs. ctr, *P*=0.008; 3mo vs. ctr, *P*=0.052; 6mo vs. ctr, *P*=0.450; Mann-Whitney-test).
Conclusion: Direct antiviral therapy is associated with decrease of liver stiffness after 6 months and SWV could be used as biomarker for non-invasive monitoring of liver stiffness during therapy.

Hypertension following aortic coarctation repair: is the 'selfish brain' to blame?

J.C.L. Rodrigues, M. Jaring, M.C.K. Hamilton, S.L. Curtis, J.F.R. Paton, E.C. Hart, N.E. Manghat; *Bristol/UK (jonrodrigues@doctors.org.uk)*

Purpose: 20-30% repaired aortic coarctation (CoA) patients develop hypertension, resulting in significant cardiovascular morbidity and mortality. We recently demonstrated that vertebral artery hypoplasia and incomplete posterior circle of Willis (VAH+ipCoW) is associated with increased cerebrovascular resistance and decreased cerebrovascular blood flow, which occur before increased sympathetic nerve activity in borderline hypertensives suggesting brainstem hypoperfusion may evoke hypertension to maintain cerebral blood flow: the 'selfish brain' hypothesis. We now assess whether similar mechanisms account for the pathogenesis of hypertension in repaired CoA.
Methods and Materials: CoW time-of-flight magnetic resonance angiography from 79 repaired CoA patients (33±12 years, 57% male, SBP135±23mmHg, DBP 76±11mmHg) was compared blindly with 33 normotensive controls (41±14 years, 48% male, SBP 124±10mmHg, DBP 76±8mmHg). VAH was defined as <2mm and ipCoW as hypoplasia of one or both posterior communicating arteries.
Results: VAH+ipCoW was significantly higher(P<0.05, Fisher's exact test) amongst CoA (26/79, 33%) than controls (3/33, 9%). Subgroup analysis by repair type (stent, balloon angioplasty, patch repair, subclavian flap or end-to-end anastomosis) revealed no significant difference in prevalence of VAH+ipCoW, suggesting it is not related to the cerebrovascular deformation. In multivariate logistic regression analysis controlling for age and gender, VAH+ipCoW was a significant independent predictor of hypertension (odds ratio 2.67 [95th confidence interval: 1.09-6.52], P=0.031).
Conclusion: VAH+ipCoW predicts hypertension in repaired CoA and is unrelated to repair type. CoA may be marker of a wider congenital vascular problem. Understanding the role of the 'selfish brain' in the pathogenesis of this condition will help guide future treatment strategies.

Aortic wall thickness is associated with high serum concentrations of the thyroid-stimulating hormone: a cross-sectional population-based study

C. Klausenitz[1], T. Ittermann[1], R. Lorbeer[2], M. Dörr[1], A. Quadrat[1], T. Schneider[1], H. Völzke[1], B. Mensel[1]; [1]*Greifswald/DE*, [2]*Munich/DE*

Purpose: To investigate the influence of thyroid function by measuring the serum levels of thyroid-stimulation hormone (TSH) on promotive factors in the pathogeneses of artherosclerosis such as aortic wall thickness (AWT) and aortic diameter.
Methods and Materials: Data of 3,904 individuals from two independent population based trials of the Study of Health in Pomerania was analysed. Imaging of the aorta was performed on a 1.5-T MRI scanner. Measurements of AWT and aortic diameter were perfomed at the layer with concentration of the right pulmonary artery displaying the ascending and the descending aorta.
Results: There was a significant association between TSH, treated as a continuous variable, and the AWT of the descending aorta (p=0.015, ß=0.11, 95% confidence interval (CI) 0.02-0.21) but not with the AWT of the ascending aorta (p=0.081, ß=0.20, 95% CI -0.01-0.21). High serum levels of TSH (>3.29 mIU/L) were significantly associated with the AWT of the ascending aorta (p=0.018, ß=0.12, 95% CI 0.02-0.23) but not with the AWT of the descending aorta (p=0.212, ß=0.06, 95% CI -0.04-0.16). There were no statistical significant associations between serum TSH levels and aortic diameters.
Conclusion: The values of AWT increase with increasing levels of serum TSH. Therefore a hypothyreotic state might be considered as a precursor for aortic arteroscleroses. These findings are in line with previous investigations stating an increased atherosclerotic risk in the hypothyroid state.

Dynamic 3D angiography in patients with aortic dissection as risk factor for chronic aortic expansion

M. Trojan[1], M. Müller-Eschner[1], D. Kotelis[1], S. Partovi[2], C. Karmonik[3], H. von Tengg-Koblingk[4], D. Böckler[1], H.-U. Kauczor[1], F. Rengier[1]; [1]*Heidelberg/DE*, [2]*Cleveland, OH/US*, [3]*Houston, TX/US*, [4]*Berne/CH (michael.trojan@med.uni-heidelberg.de)*

Purpose: Assess dynamic contrast-enhanced MR angiography in patients with chronic expanding or stable aortic dissection and evaluate its role as potential risk factor for chronic aortic expansion.
Methods and Materials: 20 patients with aortic dissection underwent dynamic contrast-enhanced 3D MR angiography of the aorta at 1.5T and follow-up CT (mean follow-up 6.1 years). 7 patients (mean 65.3 years) showed chronic aortic expansion, 13 patients (mean 64.3 years) had stable aortic diameters. MR angiographies were evaluated by placing regions of interest in the centre of the lumen of the non-dissected arch and of the false lumen of the descending aorta at the thoracoabdominal transition. From resulting time-intensity-curves the following parameters were calculated: full width at half maximum (FWHM), upward slope, downward slope, and time delay of peak intensity in the false lumen compared to the non-dissected aortic arch.
Results: The values were for the expansion/stable group: FWHM 0.19±0.02/0.41±0.17 (p=0.009), upward slope 10.97±3.11/7.64±2.68 (p=0.038), downward slope -6.55±0.87/-1.97±2.67 (p=0.013), time delay of peak intensity in the false lumen 1.32±0.25/1.42±0.24 (p=0.027).
Conclusion: Time-resolved 3D MR angiography showed significant differences of contrast dynamics between patients with chronic expanding and stable aortic dissection as an expression of accelerated inflow into and outflow from the false lumen. The technique may help to advance understanding of the complex pathophysiology of chronic expansion and has potential as a risk factor for aortic expansion.

Morphological and functional CFD-based analysis for predicting abdominal aortic evolution

O. Meyrignac, C. Zadro, R. Moreno, L. Bal, B. Saint Lebes, A. Sewonu, A. Jacquier, P. Piquet, H. Rousseau; *Toulouse/FR (meyrignac.o@chu-toulouse.fr)*

Purpose: Abdominal aortic aneurysm (AAA) is a common pathology where the need for surgical intervention is mostly determined on maximal diameter. The purpose of this study was to identify volumetric and computational fluid dynamics (CFD) parameters to predict AAA evolution.
Methods and Materials: In our multicentre and prospective study, we included 82 patients with AAA between September 2012 and June 2014. Patients underwent two CT examinations separated by a one-year interval to assess aneurysms evolution. Fifty patients were eligible for CFD analysis. Based on a 10ml threshold of total volume progression we classified patients into slow and rapid progression groups. Initial aneurysm morphological parameters and CFD functional parameters were analysed including: maximal diameter and surface, thrombus and lumen volumes, maximal parietal pressure and wall shear stress (WSS).
Results: There was a significant difference between the two groups regarding aneurysm lumen volume (P=0.0051) and mean WSS variation (P=0.0240). Conversely, mean maximal diameters were identical (P=0.71). We found a significant correlation between lumen volume (R=0.47, P=0.0015), reduction of the mean WSS variation value (R=-0.42, P=0.0062) and total aneurysm volume evolution. We further used these parameters to compute a model to predict the progression of AAAs, displaying better area under ROC than the only measurement of maximal diameter (0.75 vs 0.52, P=0.0037). Depending on the threshold, our model yields either excellent sensitivity (95.00% [IC95% 75.1, 99.9]) or specificity (90.00% [IC95% 73.5, 97.9]).
Conclusion: Combined analysis of lumen volume and WSS provides better information than maximal diameter to assess rapid volumetric evolution risk.

B-1254 14:32

Aortic arch plaque characterisation by computed tomography angiography in acute ischaemic stroke: fast technique for high quality vessel analysis

C. Parra-Fariñas, J. Juega, M. Ribó Jacobí, A. Tomasello Weitz, P. Coscojuela Santaliestra, C. Vert Soler, E. Almazán Mesa, J. Pagola, Á. Rovira; *Barcelona/ES (carmenparrafarinas@gmail.com)*

Purpose: Aortic arch atheroma was suggested as critical ischaemic stroke determinant. Properly detection is of the utmost clinical importance. Computed tomography angiography (CTA) provides rapid plaque characterisation and high diagnostic accuracy. This study aimed to investigate CTA features to characterise aortic arch plaque in acute ischaemic stroke patients.
Methods and Materials: From March 2010 to August 2016, a prospective study of 199 consecutive patients who underwent CTA within 8 hours from symptoms onset was performed. Maximal plaque thickness was measured in ascending aortic arch, perpendicular to aortic wall, proximal and distal sections. Complex aortic plaques (CP) were defined as plaque ≥4 mm in thickness or those with irregular ulcerations. Ulcerated plaques (UP) were defined as having craters ≥2 mm in depth and width. Plaque instability gradation was assessed by its composition.
Results: Mean age was 69.0±13.5, 54.8% male. Proximal aortic arch was affected in 81.6% patients (mean plaque thickness: 1.5±1.8 mm) and distal in 89.7% (2.7±2.1 mm) (p=0.730). CP were detected in 34.2%: 2.5% proximal arch, 20.6% distal, 11.1% both proximal and distal. UP were detected in 8.5%: 0.5% proximal, 5.5% distal, 2.5% both. Proximal arch plaque composition was 57.9% fibrolipid, 3.7% calcic, 59.3% mixed. Distal arch plaque composition was 17.9% fibrolipid, 22,2% calcic, 60.3% mixed. Brachiocephalic artery was involved in 14.6%, left common carotid artery in 16.7%, left subclavian artery in 28.6%.
Conclusion: CTA allowed quick and accurate evaluation of aortic arch atheroma, being useful for measuring plaque thickness, discovering ulceration, and examining its components in acute ischaemic stroke.

Automated tube voltage selection with adapted contrast media injection protocols in CT angiography of the thoraco-abdominal aorta

N. Eijsvoogel, B.M.F. Hendriks, M. Kok, C. Mihl, B. Horehledova, G.H. Schurink, B.M.E. Mees, J.E. Wildberger, M. Das; *Maastricht/NL (nienke.eijsvoogel@mumc.nl)*

Purpose: To optimise radiation dose and contrast media (CM) application for patients undergoing CTA of the aorta using automated tube voltage selection (ATVS).
Methods and Materials: 54 consecutive patients referred for thoraco-abdominal aortic CTA were included. kVp settings between 70-90 kVp were chosen automatically (CAREkV; Siemens Healthcare). Scans were acquired on a 3rd-generation DSCT (Somatom Definition Force, Siemens) with 2*192*0.6 mm collimation, pitch 0.6, gantry rotation time 0.5 s, quality reference tube current 150 mAs_{ref}, and image reconstruction at 1 mm slice thickness and increment 0.8mm (kernel Bv36/iterative reconstruction strength 3). CM (300 mgI/ml) injection was adapted to kVp setting (volume/flow rate): 40 ml/3.0 ml/s (70 kVp); 44 ml/3.3 ml/s (80 kVp); and 49 ml/3.7 ml/s (90 kVp), respectively. Patient characteristics (BMI) were collected. Objective and subjective image quality (SIQ) were determined by attenuation values (HU), contrast-to-noise ratio (CNR), signal-to-noise ratio (SNR) and 4-point Likert scale (1=non-diagnostic/2=sufficient IQ/3=good IQ/4=excellent IQ).
Results: Patient distribution was 39(70 kVp), 3(80 kVp) and 12(90 kVp). Overall attenuation was 362±71 HU, 312±46 HU and 311±48 HU for 70/80/90

kVp. Aortic attenuation was diagnostic (>200 HU), except for the lower aortic levels in eight cases (15%) in the 70 kVp/90 kVp group due to high BMI, contrast-pooling in large aneurysms and aortic stenosis. SIQ was diagnostic in all scans (59% excellent IQ). Mean CNR/SNR was 14±6/11±4 (70 kVp), 16±5/11±5 (80 kVp) and 18±8/14±4 (90 kVp). Overall effective radiation dose for different groups (70-90 kVp) was 1.8±0.3 mSv, 2.8±0.2 mSv and 3.7±0.5 mSv, respectively.
Conclusion: Optimising CTA protocols using ATVS shifts image acquisition to low kVp settings with significantly lower radiation and CM dose while maintaining diagnostic IQ.

Increased aortic wall shear stress and wall shear stress gradient in patients with an anatomically shaped sinus prosthesis using 4D flow-MRI
V. Schultz[1], T. Oechtering[1], M. Sieren[1], M. Scharfschwerdt[1], A. Hennemuth[2], M. Hüllebrand[2], H.-H. Sievers[1], J. Barkhausen[1], A. Frydrychowicz[1]; [1]*Lübeck/DE*, [2]*Bremen/DE (victoria.schultz@web.de)*

Purpose: Despite near physiological haemodynamics in the aortic bulb, patients with an anatomically shaped sinus prosthesis for valve-sparing aortic root replacement have altered flow characteristics distal to the prosthesis. Vessel wall parameters derived from blood flow such as the wall shear stress (WSS) may thus be altered. Hence, it was the aim of this study to analyse WSS using 4D flow-MRI.
Methods and Materials: 12 patients (1f, 55±15y) with sinus prosthesis and 12 age-matched volunteers (10f, 55±6 y) were examined on a 3T MR-scanner using a 4D flow-sequence. WSS was determined using GTFlow (GyroTools, CH) in 8 analysis planes with 8 segments, placed orthogonal to the aorta. The maximum WSS averaged over all segments per plane ($maxWSS_{avg}$), segmental temporal WSS minimum and maximum ($minWSS_{Seg}$,$maxWSS_{Seg}$) and the WSS gradient per plane ($gradWSS_{Seg}$=$maxWSS_{Seg}$-$minWSS_{Seg}$) were calculated.
Results: In patients, $maxWSS_{avg}$ showed a trend to be similar or lower close to the prosthesis and increased distal to the prosthesis with a maximum in the distal ascending aorta, differences not reaching statistical significance. Segmental $maxWSS_{Seg}$ was increased distal to the prosthesis with a maximum in the arch (1.22±0.45 vs 0.90±0.16N/m^2, p<0.05). Interestingly, the WSS gradient per segment ($gradWSS_{Seg}$) was increased throughout all planes, the maximum of 1.03.±0.43 vs 0.72±0.26N/m^2 (p<0.05) in the ascending aorta.
Conclusion: This study confirmed WSS alterations in patients after sinus prosthesis in comparison to age-matched healthy individuals. Of special interest was the WSS gradient with increased results throughout the entire aorta. Now larger patient cohorts are warranted to correlate findings with clinical outcome.

B-1258 14:56

70kV automated tube potential selection at third-generation high-pitch dual-source CTA of the whole aorta: comparison to a standard protocol
A.M. Bucher, A. Zierden, J.E. Scholtz, M.H. Albrecht, B. Kaltenbach, M. Kaup, B. Bodelle, T.J. Vogl, M. Beeres; *Frankfurt a. Main/DE*

Purpose: To compare the feasibility of low-voltage automated tube potential selection (ATPS) in an unselected patient population at high-pitch dual-source CT angiography (DS CTA) of the full aorta in third-generation dual-source CT against a standard DS CTA protocol.
Methods and Materials: Two groups of 65 consecutive patients each underwent clinically indicated DS CTA in high-pitch mode using ATPS on a second-generation (group 1) or third-generation (group 2) dual-source CT. Subjective image quality was scored by two independent readers, qualitative image quality parameters by an independent investigator. A reference of 70kV was set in group 2, a reference of 100kV in group 1, with the remaining image quality settings and contrast administration kept constant. Radiation exposure was compared according to CT-dose index and dose-length product.
Results: All images were of diagnostic quality. Patient characteristics were comparable (p>0.06 each). At constant overall image quality (p>0.08 overall) group 2 received substantially lower radiation doses compared to group 1 (p<0.001). Mean radiation dose in third-generation DS CTA was 3.1±1.8 mSv (group 2); in second-generation DS CTA 6.9±2.1 mSv (group 1). Overall dose reduction equalled 55%. Inter-reader agreement was very good (k=0.8, p=0.002). In group 1, ATPS indicated a level of 120kV for most cases; in group 2, 90kV was indicated in most cases.
Conclusion: Third generation high-pitch dual-source CTA using latest generation ATPS at low tube voltage selection is feasible in the clinical routine against a standard protocol and is associated with significantly lower radiation exposure.

B-1260 15:04

Diagnostic accuracy of free-breathing contrast-enhanced T1 sequences in comparison with breath-hold sequences, in the assessment of the aorta, having CT angiography as reference
C.R.G.L. Talei Franzesi, D. Ippolito, S. Drago, S. Lombardi, E.B. Orsini, S. Sironi; *Monza/IT (ctfdoc@hotmail.com)*

Purpose: To evaluate the diagnostic efficacy of contrast-enhanced T1 free-breathing gradient echo sequences in the evaluation of aortic disease, in comparison with standard MR-angiographic sequences and CT-angiography.
Methods and Materials: Forty-one patients, with known aortic disease established at CT-angiography evaluation, were prospectively enrolled. All patients were evaluated on a 1.5T magnet(Achieva,Philips),with a phased array multi-coil, after the intravenous injection of 0.1mL*Kg of gadobutrol, using standard MR angiography protocol with 3D-angiographic sequences and T1 breath-hold sequences (THRIVE). Multiplanar T1 free-breathing gradient-echo fat-suppressed (THRIVE-FB) sequences were additionally performed in all the examinations. Two radiologists independently compared the diagnostic quality of different MR-angiographic sequences with CT-angiography studies, in terms of visualization of aortic wall and lumen and main arterial branches. Vascular calipers measured at different aortic levels were compared between the MR-sequences and CT evaluations and statistically analyzed. Interobserver agreement was assessed using the Intraclass Correlation Coefficient(ICC).
Results: Free breathing sequences showed good diagnostic accuracy in the assessment of vascular calipers and walls, with no significant differences in comparison with standard breath-hold sequences and CT-studies.THRIVE-FB also demonstrated high sensitivity and specificity in the evaluation of vascular plaques, thrombus and adjacent structures.Not significant differences were obtained in terms of overall diagnostic quality between THRIVE-FB sequences, standard angiographic sequences and CT-angiography, with a good interobserver agreement (ICC of 0.84).
Conclusion: Free-breathing contrast-enhanced T1 gradient-echo fat-suppressed sequences, combined with high relaxivity contrast agent, demonstrated high diagnostic efficacy, permitting to correctly evaluate the aorta and its major branches, with no significant differences in comparison with standard breath-hold MR-sequences and CT-evaluations.

B-1261 15:12

The benefits of the evaluation of endoleaks with CT angiography using multiphase technique and high temporal resolution with iterative reconstruction
P. Armelin; *Campinas/BR (plinioarmelin@hotmail.com)*

Purpose: Assess the initial experiment, the viability and diagnostic performance of CT angiography with high temporal resolution protocol with 8 phases of low dose and iterative reconstruction (idose 4) after aortic aneurysm by endovascular technique compared to traditional phase angiotomographic study.
Methods and Materials: A retrospective study of 10 patients with aortic aneurysms treated with stent. The tests were performed in a CT scanner Phillips Brilliance 64-channel using injection pump Medtron AG, endovenous nonionic iodised contrast (60 ml), injected the speed of 5.0ml/s, followed by saline bolus of 100 ml; protocol 80 kV and 120 mA, 1,078 pitch composed of 8 layers of 3 seconds each with 27 cm scan range, after reconstruction processing using interactive idose 4.
Results: It conducted a comparative study evaluating the presence or absence of endoleaks and their classification, as well as compared to the total dose mSv of this protocol with the conventional three-phase study before used in our service. Following the principles ALARA total radiation dose is reduced by about 50% compared to conventional examination, despite the increase in noise level no loss in diagnostic quality of images. Furthermore, the contrast volume used is lower.
Conclusion: Angiotomography with high temporal resolution multiphase technique with iterative reconstruction proved to be more conspicuous in the detection and classification of endoleaks than conventional three-phase study.

Percutaneous discectomy in lumbar radiculalgia: an international multi-centric study about 77 patients (6 months follow-up)

G. Gallo[1], O. Andreani[2], F. Torre[2], N. Amoretti[2]; [1]*Menton/FR*, [2]*Nice/FR (giacomo.gallo83@gmail.com)*

Purpose: To show a new technique for the percutaneous treatment under CT guidance and local anaesthesia of lumbar radiculalgia due to an herniated disc in patients resistant to conservative treatment.
Methods and Materials: An international multi-centric study (four European centers) has been performed. Inclusion criteria were: lumbar radiculalgia with CT/MRI evidence of the hernia; pain lasting from more than one month; VAS (0-10) over 6. Both postero-lateral and trans-laminar accesses have been performed. VAS have been collected at 1 and 6 months of follow-up. Interventions have been performed under CT and fluoroscopic guidance with a percutaneous mechanised device that, once in the hernia, can turn around to soften and then aspirate the herniated material.
Results: The average VAS pre-intervention was 8 (6-10), one month after it decreased to 3 (0-8) (p <0.001). No significant differences were found between the different centres. Only three patients left the follow-up for surgery within the first month after the intervention. At 6-month follow-up, 91% of patients present a modification of the VAS not greater than 1 point.
Conclusion: The results show the high rate of effectiveness of this percutaneous therapy, which is performed under local anaesthesia, and that presents minimal risk compared to the surgical discectomy (such as failed back surgery syndrome or intracanalar fibrosis). It permits a faster return to normal life (usually within one week) with evident advantage in terms of quality of life. Furthermore, the failure of this intervention does not threaten the possibility of a surgical solution.

B-1263 14:08

CT-guided pulsed radio frequency treatment of the lumbar dorsal root ganglion (DRG) in patients with acute and sub-acute radicular low back pain

A. Napoli, R. Scipione, M. Anzidei, C. Marrocchio, H.-P. Erasmus, C. Catalano; *Rome/IT (alessandro.napoli@uniroma1.it)*

Purpose: To determine the clinical impact of pulsed radiofrequency for the treatment of patients with neuro-radicular low back pain.
Methods and Materials: Patients were eligible for this study if they presented acute or sub-acute neuro-radicular low back pain (EMG confirmed) refractory to usual treatments and if they could safely undergo pulsed radiofrequency procedure. Clinical evaluation was conducted with visual analogue scale (VAS) and Oswestry disability index (ODI) for quality of life assessment, both obtained at baseline and at 1-week, 1-month and 1-year follow-up.
Results: Over a 3-year period, 80 patients were treated with pulsed radiofrequency (Cosman). Median VAS scores decreased from 7.8 at baseline to 3.5 at 1 week after treatment, to 2.6 at 1 month and 1.3 at 1 year; median ODI scores decreased from 78.0 at baseline to 12.5 at 1 week, to 6.0 at 1 month and 5.5 at 1 year (p<0.001). Overall, 90.0% of patients reached a 0 VAS score within the first month after treatment, and 97.5% had a decrease of at least 20 points in ODI score in the same interval. There were 6 patients considered partial responders that required a second PRF session.
Conclusion: Pulsed radiofrequency has shown to be a promising and effective percutaneous treatment option for patients with acute or sub-acute neuro-radicular low back pain; the results of this study are superior to those reported from the literature for usual care strategies or injections and may avoid surgery for a substantial number of patients with sciatic disc compression.

B-1264 14:16

Vertebral augmentation with the Spine Jack device in non-acute (> 1 month) vertebral compression fracture

J. Chiras, E. Cormier, F. Clarençon; *Paris/FR (jacques.chiras@psl.aphp.fr)*

Purpose: The efficacy of Spinejack® device (Vexim SA) to reduce fresh vertebral fractures (≤1 month) is well established. Older painful fractures are usually treated by vertebroplasty. However, this technique may fail to reduce the kyphosis or may be potentially dangerous in Magerl's A3 fractures as it can be responsible of increased protrusion of bone fragment into the spinal canal. Vertebral augmentation with SpineJack®could be an alternative. The objective of the study is to evaluate the feasibility and efficacy of a vertebral augmentation with the SpineJack in vertebral compression Magerl's A3 fractures older than one month with major kyphosis.
Methods and Materials: Retrospective , monocentre, investigator initiated study. 19 patients (16 F, 3 M) with A3 vertebral fracture with important kyphosis (11 cases) (kyphosis angle: 20-37^0) and/or intra spinal bone fragments (17 cases) were treated with the Spinejack® expansion device between one month and one year after the fracture. The vertebral augmentation was performed under general anesthesia during a 2 days' hospital stay.
Results: Immediate kyphosis reduction >25% after procedure : 21/31.Bone fragment bulging : None.Clinical complications: None.Pain reduction: VAS pre op: 6.85 (3-9); VAS post op: 2.1 (0-7) MID TERM RESULTS: New fractures: 3/31 patients. 2 patients presented an adjacent fracture at 1 month post op; 1 patient presented a distant fracture at 6 months.
Conclusion: Vertebral augmentation with SpineJack® device is feasible in vertebral compression fractures older than 1 month. Significant kyphosis reduction is obtained in about 67% of the cases.

B-1265 14:24

Percutaneous screw fixation for complex pelvic fractures: a key role for the interventional radiologist

O. Andreani[1], A. Rudel[1], G. Gallo[2], F. Torre[1], N. Amoretti[1]; [1]*Nice/FR*, [2]*Menton/FR (andreani.olivier@gmail.com)*

Purpose: Therapeutic management of complex pelvic fractures is challenging. Although orthopaedic surgeons play a major role, interventional radiologists' role is crucial to treat some pelvic fractures. The goal of our study is to show the technical feasibility of acetabular roof and sacro-iliac lesion percutaneous screw fixation under CT-guidance.
Methods and Materials: We present a consecutive series of 20 patients treated for acetabular roof and/or sacro-iliac post-traumatic lesions. Therapeutic procedure were all made under general anaesthesia. Procedures were minimally invasive thanks to a percutaneous approach, under CT-guidance and fluoroscopy. Post-interventional CT-scan assessed the technical success or failure of the procedure.
Results: Procedures have been conducted in our 20 patients. Screw positioning was good in 19 cases. Approach was bilateral in 8 patients. The mean procedure time was less than 60 minutes. No major complications occurred during and after procedures.
Conclusion: Percutaneous screw fixation is a safe and effective procedure to manage acetabular roof and sacro-iliac fractures. CT-guidance allows a short learning curve.

B-1266 14:32

Hamstring tendinopathy: pre-procedural MRI correlation with clinical outcome in therapeutic image-guided injection

D.J. Bowden, C.A. Byrne, A. Alkhayat, E. Kavanagh, S.J. Eustace; *Dublin/IE (dermotbowden@gmail.com)*

Purpose: To assess the correlation between severity of hamstring tendinopathy on MRI with clinical outcome post-percutaneous hamstring injection of corticosteroid.
Methods and Materials: Patients undergoing image-guided hamstring injection were identified by chart review. Patients with pre-procedural MRI were selected for inclusion and imaging reviewed by two musculoskeletal radiologists. Severity of tendinopathy was graded: mild, moderate or severe. Discrepancies were resolved by consensus. At follow-up, outcome was assessed and the following data were recorded: resolution of pain: none, partial or complete; duration of resolution; timing of recurrences.
Results: 26 patients underwent injection with pre-procedural MRI during the study period. 23 were available for follow-up, 13 males, 10 females mean age 44.6 yrs (range 16-88). 12 mild, 9 moderate, 2 severe. 78% experienced improvement following injection, 26% partial, 52% complete. 7 experienced recurrence (39%) at mean of 6.1 months post-treatment. Mild group: equal proportions (33.33% - 4 patients each) reported no improvement, partial improvement and complete resolution. Recurrence rate 37.5% (3 of 8). Moderate group: 89% experienced benefit from treatment - complete resolution in 67%, partial in 22%. Recurrence rate was 25% (2 of 8) at mean of 2 months. Severe group: 2 patients had 100% resolution, but both patients experienced recurrence at mean of 10 months.
Conclusion: Image-guided hamstring injection is effective in the majority of patients; however, patients with moderately severe disease on pre-procedural MRI may be most likely to benefit from this treatment.

B-1267 14:40

Non-invasive MR-guided focused ultrasound (MRgFUS) therapy is associated with bone integrity restoration in patients with osteoid osteoma

R. Scipione, A. Napoli, M. Anzidei, C. Marrocchio, H.-P. Erasmus, C. Catalano; *Rome/IT (roberto.scipione@uniroma1.it)*

Purpose: To analyse MRgFUS outcomes for osteoid osteoma (OO) treatment, and the relationship of residual nidus vascularity with bone remodelling.
Methods and Materials: Patients with clinical and radiological diagnostic findings of OO, suitable for MRgFUS and anaesthesia, were recruited. The study was designed with an intention-to-treat protocol and bone behaviour was analysed before and after MRgFUS; patients underwent CT and dynamic contrast-enhanced (Gd-BOPTA, Bracco) MRI scans yearly, over a 3-year period. Nidus perfusion was measured using a semi-quantitative method; bone remodelling was determined with CT scans for complete or partial restoration. Multivariate analysis was conducted to understand the relationship between imaging and clinical outcomes (visual analogue scale, VAS) BMI, sex and age.
Results: Among 35 subjects recruited, 30 underwent MRgFUS; 28 had a complete clinical benefit with VAS=0 during follow-up; 2 patients required re-treatment with RFA at 1 month because of residual pain. At 36 months, absence of residual nidus perfusion was found in 76.7% of cases, with restitutio ad integrum in 30% of cases. Multivariate analysis demonstrated that restoration is associated with absence of perfusion and patient age: subjects younger than 18 years presented complete restoration, a 0% residual perfusion and a complete clinical response, while older patients more frequently showed variable results on restoration, irrespective of clinical outcome. These results are independent of BMI and sex.
Conclusion: MRgFUS is an effective treatment option for OO; results are dependent on subject age, and patient selection may be influenced by this factor in the future when seeking complete bone restoration.

B-1268 14:48

Middle- and long-time follow-up of percutaneous computed tomography and fluoroscopy-guided injection of bone cement in treatment of subchondral cysts

F. Torre[1], O. Andreani[1], A. Caudal[1], G. Gallo[2], A. Rudel[1], D. Palominos[1], B. Padovani[1], N. Amoretti[1], E. Benattar[2]; [1]*Nice/FR*, [2]*Menton/FR (fede.torre@libero.it)*

Purpose: To evaluate long-time follow-up of subchondral cysts treatment through percutaneous computed tomography and fluoroscopy-guided injection of bone cement.
Methods and Materials: A single-centre prospective study involving 23 patients (14 women, 9 men) with symptomatic subchondral cysts was developed. Average age was 61 years. Patients underwent percutaneous CT-guided injection of bone cement into the subchondral cysts. Surgical treatment was not indicated or refused by patients. All the lesions were localised in weight-bearing bones. A quantification of pain was evaluated using the visual analogue scale (VAS) before treatment, at one, six months and up to 8 years after treatment.
Results: Within 23 patients, 22 were satisfied after the procedure had been performed. The feasibility was 91%. We reported one case with para-articular asymptomatic cement leak at the knee and an unsatisfactory filling of the lesion. There were no other immediate or delayed complications observed. One patient had no relief of his pain after the treatment and underwent hip surgery. Our results show a significant decrease of the pain felt by patients between before procedure and one month after the procedure ($p<0.001$), six months after the procedure ($p<0.001$) and years after the procedure ($p<0.001$).
Conclusion: Percutaneous injection of bone cement under CT and fluoroscopy guidance seems to be a rapid, safe and efficient therapeutic option for symptomatic subchondral cysts. We suggest that significant decrease of patient's pain deal to consider this procedure as an alternative to classic surgery, when invasive interventions are contraindicated or refused by patients.

B-1269 14:56

Percutaneous image-guided screw fixation of bone lesions in cancer patients: double-centre analysis of outcomes including local evolution of the treated focus

R. Cazzato[1], X. Buy[2], J. Garnon[1], G. Koch[1], J. Caudrelier[1], G. Tsoumakidou[1], J. Palussiere[2], A. Gangi[1]; [1]*Strasbourg/FR*, [2]*Bordeaux/FR (gigicazzato@hotmail.it)*

Purpose: To review outcomes and local evolution of treated lesions following percutaneous image-guided screw fixation (PIGSF) of pathological/insufficiency fractures (PF/ InF) and impeding fractures (ImF) in cancer patients at two tertiary centres
Methods and Materials: 32 consecutive patients (mean age 67.5 years) with a range of tumours and prognoses underwent PIGSF for non/minimally displaced PF/InF and ImF. Screws were placed under CT/fluoroscopy or cone-beam CT guidance, with or without cementoplasty. Clinical outcomes were assessed using a simple 4-point scale (1 = worse; 2 = stable; 3 = improved; 4 = significantly improved). Local evolution was reviewed on most recent follow-up imaging. Technical success, complications, and overall survival were evaluated.
Results: 36 lesions were treated with 74 screws mainly in the pelvis/femoral neck (58.2 %); including 47.2 % PF, 13.9 % InF, and 38.9 % ImF. Cementoplasty was performed in 63.9 % cases. Technical success was 91.6 %. 87.1 % of lesions were improved at 1-month follow-up. Three major complications (early screw-impingement radiculopathy; accelerated coxarthrosis; late coxofemoral septic arthritis) and one minor complication were observed. Unfavourable local evolution at imaging occurred in 3/24 lesions (12.5 %) at mean 8.7-month follow-up, including poor consolidation (one case) and screw loosening (two cases, at least 1 symptomatic). There were no cases of secondary fractures.
Conclusion: PIGSF is feasible for a wide range of oncologic patients, offering good short-term efficacy, acceptable complication rates, and rapid recovery. Unfavorable local evolution at imaging may be relatively frequent, and requires close clinico-radiological surveillance.

B-1270 15:04

Trans-isthmic screw fixation with CT and fluoroscopy guidance: precision of the procedure

E. Cervantes, O. Andréani, N. Amoretti; *Nice/FR (elodie.cervantes@live.fr)*

Purpose: To evaluate the precision of the trans-isthmic screw fixation with CT and fluoroscopy guidance in the care of low-grade isthmic spondylolisthesis.
Methods and Materials: Fifty patients (28 women and 22 men mean age 50 years old [min 17-Max 80, SD 18.9]) presenting a low-grade isthmic spondylolisthesis, resistant to medical regimen, treated by percutaneous screw fixation. The procedure was performed under local anaesthetic with both CT and fluoroscopy guidance. The positioning of the screws was considered optimal on the control scanner, once all the surgical criteria were applied accordingly.
Results: Ninety-nine procedures were carried out in 50 patients. CT control by the end of the intervention confirms that 96 screws out of 99, or in 96.9% of the cases were correctly positioned. 99 screws had an optimal entry point, the trajectory and completion of 96 screws were optimal. The tree displacement failures (3%) were caused a suboptimal trajectory, not penetrating the isthmic defect through its centre thus breaking the medial cortex of the blade and having an intraosseous completion, but located in the lower third of the pedicle. No complication during or following the operation has been reported in case of good positioning.
Conclusion: These results confirm that the trans-isthmic screw fixation with CT and fluoroscopy guidance procedure performed under local anaesthesia is both precise and safe.

B-1271 15:12

MRI-guided high-intensity focused ultrasound: a new first-line technique in the treatment of osteoid osteoma?

A. Napoli[1], A. Bazzocchi[2], R. Scipione[1], M. Anzidei[1], S. Dababou[1], C. Catalano[1]; [1]*Rome/IT*, [2]*Bologna/IT (alessandro.napoli@uniroma1.it)*

Purpose: To demonstrate that non-invasive ablation of osteoid osteoma (OO) with MRI-guided focused ultrasound (MRgFUS) is a safe, effective and durable treatment option.
Methods and Materials: Patients with typical clinical and radiological diagnostic findings of OO, suitable for MRgFUS and anaesthesia, were enrolled in a dual-centre study. Safety (rate of complications) and clinical effectiveness (visual analogue scale [VAS] score reduction) were considered as primary outcomes, tumour control (nidus ablation) at imaging as secondary outcome. All patients underwent a 3-year follow-up.
Results: Among 50 subject screened, 45 were enrolled and underwent MRgFUS. No treatment-related complications were observed. A complete and durable response was achieved in 80% of cases. Median VAS score dropped from 8 (IQR: 7-9) to 0 at 1 week and all subsequent follow-ups (1 month, 6 month, 12 month, 24 month and 36 month). Scores evaluating interference of pain with sleep, physical and daily activities showed a similar trend. Among subjects with partial response (20%), 4 received a second treatment (3 with CT-guided radiofrequency ablation, 1 with MRgFUS), and 5 did not need any other treatment. All re-treated patients achieved a 0 VAS score. Overall, 87% of patients after MRgFUS treatment reached and maintained a stable 0 VAS score during follow-up. At 3-year MRI OO showed no vascularisation in 76% of patients.
Conclusion: MRgFUS is safe and effective in the treatment of OO. This technique provides relevant advantages in the treatment of such a small, benign, impairing disease affecting mostly young population: no ionising radiation, incisions, needles nor complications. MRgFUS is candidate as first-line treatment.

B-1272 15:20

US-guided injection of triamcinolone in Morton neuroma (MN) is safe and can avoid the need of surgical treatment: retrospective review of 307 procedures

A. Viteri Jusué[1], C. Morandeira Arrizabalaga[2], A. Bilbao González[2], R. Zabala Landa[2], I. Korta Gomez[2], J. Del Cura Rodríguez[2]; [1]*Vitoria-Gasteiz/ES*, [2]*Bilbao/ES (ainhoa.viterijusue@osakidetza.net)*

Purpose: To evaluate the feasibility, safety and effectiveness of ultrasound-guided intralesional triamcinolone injections for MN.
Methods and Materials: Retrospective review of all patients with MN treated at our department between Jan 2010 and Dec 2014. Institutional Review Board approval was obtained. Procedure: US-guided intralesional injection of 40 mg of triamcinolone acetate. Patients´ characteristics, treatment administration, complications, and therapeutic failure (measured as need of surgical rescue) were assessed. Statistical analysis: Chi-square and Fisher's exact test. Time to surgery: Kaplan-Meier. SAS System for Windows, version 9.2.
Results: We treated 143 patients (18.2% M /81.8% F, mean age 58.9y, SD 10.1) totaling 307 procedures in 174 neuromas. 86 pts (60.1%) underwent >1 procedures, and 17 pts (11.9%) underwent >3 administrations. Mild and reversible complications were seen after 10 procedures (3.2%): pain/haematoma/skin problems/other: 3/2/2/3. Complications only presented in patients with musculoskeletal comorbidity (p= 0.022). No statistically significant differences according to total dose of steroids or number of administrations were seen. Surgery-free survival at 5 years was 85.3%, with a trend towards higher surgical needs for female patients (17.1% vs 3.9%, p=0.084) and patients ≤ 60 years (17.5% vs 11.1%, p=0.28). No statistically significant differences were found for comorbidity, number of procedures or total steroid dose.
Conclusion: Ultrasound-guided intralesional injection of steroids in unselected patients with MN is safe and effective, and can be repeated to delay and/or avoid the need of surgical treatment. Thus, this remains the initial treatment in patients with MN in our institution.

Diffusion-weighted imaging planning percutaneous lung biopsies

C.E. Zurstrassen, M. Guimaraes, A. Bitencourt, P. Barbosa, M.F. Arruda, C. Tyng, J. Italo, M. Amoedo, R. Chojniak; *Sao Paulo/BR (charles.zurstrassen@accamargo.org.br)*

Purpose: We prospectively evaluated the role of diffusion-weighted imaging (DW-MRI) in planning biopsies of suspicious lesions of lung cancer through the calculation of the mean values of apparent diffusion coefficient (ADC).
Methods and Materials: After the calculation of the mean values of ADC, were collected samples from both the area with the highest mean value of ADC, that we called hot area, as well as from the smallest mean value of ADC, that we called cold area. The results of biopsies from both areas were recorded and then compared with regard to histopathology and differentiation degree.
Results: Twelve patients were included, 6 men and 6 women, mean age 59.4 years (37-75 years). The mean lesion size was 75.4mm, varying from 33 to 110mm. The mean ADC value in the hot area was 1,129 x10-3mm^2/s (0.381 to 2.821 x10-3mm^2/s) and in the cold area was 1,706 x10-3mm^2/s (0.733 - 3,437x10-3mm^2/s), which was statistically significant (p and lt 0.001). There were correlation between histological diagnosis obtained in the two areas in most of the cases (n=9; 75.0%). However, in two cases (16.7%) the results were different, being insufficient for diagnosis in the cold area, and in 1 case (8.3%) the histological diagnosis from both areas were different.
Conclusion: The study by DW-MRI may be useful in the evaluation of suspected lung cancer lesions prior to the percutaneous biopsy. Misdiagnosis may occur in 25% of cases.

B-1274 14:17

Metabolic guidance in CT-guided lung biopsies: Does ^{18}F-FDG PET/CT increase the rate of successful biopsies and diagnostic yield?

A. Goldman[1], T. Jacob[1], M. Miligkos[2], T. Senbanjo[1], A. Witwit[1], S. Paramothayan[1], J. Vlahos[1], K. Stefanidis[1]; [1]*London/UK*, [2]*Larissa/GR (anouchka.goldman@gmail.com)*

Purpose: To evaluate the role of Fluorine-18 fluorodeoxyglucose (^{18}F-FDG) PET/CT as a metabolic guide in increasing the accuracy and diagnostic yield of CT-guided lung biopsy.
Methods and Materials: Retrospective analysis of consecutive patients with suspicious lung nodules, masses or extensive disease that underwent lung biopsy over a 2-year period. Patients were divided into two groups; those that had ^{18}F-FDG PET/CT metabolic information guiding needle position for biopsy and those who did not. Correlation was made with the histopathological result. Biopsy results were considered diagnostic if malignant cells were detected or malignancy could be excluded.
Results: A total of 219 patients were evaluated in our study. Of those, 15 patients were excluded. ^{18}F-FDG PET/CT findings were available for 82 cases prior to biopsy. 122 cases had CT-guided lung biopsies without metabolic information available. The overall rate of a diagnostic biopsy was 89% (n=204). The proportion of patients with a diagnostic biopsy result following an ^{18}F-FDG PET/CT was significantly higher than those who did not undergo an ^{18}F-FDG PET/CT scan (97.6% vs. 83.6%, p = 0.003). In patients with extensive disease (n=28), although 9/10 cases with ^{18}F-FDG PET/CT prior to biopsy yielded a diagnostic sample compared to 11/18 that did not have ^{18}F-FDG PET/CT, this did not reach statistical significance (90% vs 61%, p=0.24), likely due to the small number of patients.
Conclusion: Metabolic information provided by ^{18}F-FDG PET/CT can assist in guiding CT-guided lung biopsies, improve diagnostic accuracy and increase the probability of achieving a definite diagnosis.

B-1275 14:25

Lung lesion motion in the z-axis during CT-guided lung biopsy is greater in the lower lung and after intravenous sedation

G.N. Allen, C.D. Gillespie, L. Daly, C.G. Cronin, J.G. Murray, C.A. Ridge; *Dublin/IE (grainne.allen@ucdconnect.ie)*

Purpose: Operators hypothesize that lung lesion motion is least in the prone position, the lung apices and when sedation is not used. This study aims to test these hypotheses.
Methods and Materials: Institutional review board approval was obtained. Consecutive patients underwent CT-guided lung biopsy by experienced operators over a 3-year period. Lung lesions <4cm were included. Lung lesion motion in mm was determined by the table position of the lesion on axial images during CT-guided biopsy. z-axis motion was the difference between maximum and minimum table positions during the procedure. Lesion size, location, patient position, radiation and sedation use were recorded. A paired t-test and multivariate analysis were used to compare variables.
Results: 124 patients were included. Median z-axis lesion motion was 7 mm (0-43.5). Lower lung location and intravenous sedation increased z-axis motion ($p < 0.0001$ and $p = 0.0007$, respectively). Prone positioning did not decrease z-axis nodule motion. Median estimated radiation dose was 671 mGym/cm. z-axis motion was proportionate to total radiation dose ($r = 0.298$; $P = 0.001$)
Conclusion: Lung lesion motion in the z-axis is greatest in the lower lung and when intravenous sedation is administered. Prone positioning has no effect on nodule motion. Increased nodule motion is associated with increased radiation dose during CT-guided biopsy.

B-1276 14:33

CT-guided lung biopsy in the lateral decubitus position: effect on the incidence of pneumothorax and haemoptysis

O. Drumm, E. Joyce, T. Gleeson, E. McCarthy, J.F. Meaney, R. McDermott, P. Beddy; *Dublin/IE (odrumm@yahoo.co.uk)*

Purpose: To assess the effect of positioning the patient in the lateral decubitus position during CT-guided lung biopsy on the incidence of pneumothorax and haemoptysis.
Methods and Materials: This was a retrospective IRB approved study. Between March 2014 and January 2016, percutaneous CT-guided lung biopsy was performed in 277 patients. 145 biopsies were performed in the supine or prone position (group 1) and 132 were performed with the patient positioned in the lateral decubitus position with the tumour side down against the CT table (group 2). Standard biopsy was performed with an 18 or 20G co-axial technique. Patient demographics, lesion characteristics, biopsy technique and complications were assessed.
Results: There was no significant difference in the age, sex or incidence of emphysema between group 1 and 2. There was a significant difference ($p<0.01$) in the incidence of pneumothorax between groups 1 and 2, with 40 (27%) pneumothoraces in group 1 and 14 (10%) in group 2. Eight patients in

group 1 required a chest drain and five in group 2 (p=0.2). Eleven patients in group 1 had haemoptysis compared with seven in group 2 (p=0.2). Diagnostic samples were obtained in 95% of patients in group 1 and 98% in group 2.
Conclusion: CT-guided lung biopsy in the lateral decubitus position with tumour side down significantly reduces the rate of pneumothorax. The reduction in drain insertion and haemoptysis was not statistically significant.

B-1277 14:41

CT-guided percutaneous transthoracic core biopsy (PTCB) of deep thoracic lesions using pure virtual navigation guidance (PVNG) with magnetic-tracking system: preliminary experiences

G. Bizzarri, A. Bianchini, D. Valle, L. Di Vito, L. Velari, S. De Nuntis, A. Dell'Era; *Albano Laziale/IT (bizzarrigiancarlo@libero.it)*

Purpose: CT-guided PTCB is essential in the diagnosis of pulmonary and mediastinal tumour and cellular characterization. Usually it is performed under cognitive-CT-guidance. Reports continue to show major complications and death. Possible impact of PVNG for deep thoracic lesion not visible on US was explored.
Methods and Materials: MyLabTwice ultrasound scanner with Virtual Navigation (VN) software and hardware was used (ESAOTE,Italy). The procedure was performed with convex transducer CA541 (1-5 MHz) probe with single use guiding system and reusable tracking brackets for magnetic sensor (CIVCO, USA). Biopsy was performed using coaxial technique and 18G trucut needles. 15 patients with mediastinal or pulmonary lesions were enrolled. Preliminary CT scan was performed with reference tool fasten on patient skin. Images were coregistered with probe position and VN modality activated. After local anaesthesia coaxial needle was advanced using the probe-guiding system. CT scan was performed to rule out complications and, if the coaxial needle was in correct position, biopsy procedure was performed.
Results: 35 samples were obtained on 15 lesions (range 40-15mm.; mean 25) in 15 patients (age 45-85, mean 72). In all cases a single step procedure was possible without the necessity of needle repositioning. All biopsies were diagnostic (mets 3, lung carcinomas 12). No major complication were encountered. 4 pneumothorax and 3 parenchymal haemorrhages resolved spontaneously. Biopsies required 25-45min., mean 35.
Conclusion: PVNG is a promising technique for increasing the accuracy of needle positioning during thoracic biopsies potentially reducing major complications, time and radiations versus cognitive-CT-guidance. Technological improvements are mandatory.

B-1278 14:49

Risk factors for complications of CT-guided percutaneous transthoracic needle biopsy: utility of SIR classification of complications

A. Elshafee[1], A. Karch[1], K. Ringe[1], H.-o. Shin[1], H.-J. Raatschen[1], N. Soliman[2], F. Wacker[1], J. Vogel-Claussen[1]; [1]*Hannover/DE*, [2]*Mansoura/EG (elshafee.amany@mh-hannover.de)*

Purpose: To detect risk factors for complications of CT-guided transthoracic needle biopsy and to classify these complications using the Society of Interventional Radiology (SIR) classification.
Methods and Materials: 387 biopsies were evaluated. Studied risk factors were patient related (age, sex, position, chronic lung diseases), lesion related (size, location, lesion pleural distance and thoracic wall thickness at needle path), and procedure related risk factors (times of pleural puncture, number of tissue samples, fissures penetration, duration and images of the procedure, needle blood vessel angle, technical success, histopathology). Complications were classified into no or minor (SIR0-2) and major (SIR3-6). Data were analysed using logistic and ordinal regression.
Results: Complications were pneumothorax in 143 patients (37%) and pulmonary haemorrhage in 22 patients (6%). 341 patients (88%) were classified as SIR0-2, 46 patients (12%) were SIR3-4, no permanent injury (SIR5) or death (SIR6) occurred. Patient age, lesion size, lesion pleural distance, times of pleura punctures, fissure puncture, procedure duration and images were significant risk factors in univariable analysis. Lesion pleural distance remained the only significant factor in multiple logistic regression model (OR=1.7 per cm, p &lt 0.001). No statistical difference of complication rate between the radiologists performing the biopsies was observed.
Conclusion: Transthoracic CT-guided needle biopsy is a safe technique. Careful planning is necessary to traverse least amount of aerated lung.

B-1279 14:57

Patient selection prior to lung volume reduction: impact of FEV1 and emphysema score

F. Doellinger, R.-H. Huebner, D. Theilig; *Berlin/DE (felix.doellinger@charite.de)*

Purpose: Aim of this retrospective study was to evaluate the relevance of baseline forced expiratory volume in one second (FEV1) and baseline emphysema score to predict a clinical benefit after endoscopic lung volume reduction (ELVR) with endobronchial valves.
Methods and Materials: Sixty-two patients with severe chronic obstructive pulmonary disease (GOLD-stages III and IV) and pulmonary emphysema were treated with endobronchial valves in our institution. All patients underwent pulmonary function tests and computed tomography (CT) before and at least three months after the valve implantations. At both time points emphysema score was determined using quantitative CT analysis. Emphysema score was defined as the proportion of all lung voxels with a density below a threshold of -950 HU. Linear regression analysis including established influencing factors as well as baseline FEV1 and baseline emphysema score was performed to determine the impact of both parameters on a beneficial outcome, which was defined as an improvement of FEV1.
Results: In regression analysis, baseline FEV1 showed to have a statistically significant impact on clinical outcome after ELVR (coefficient of determination R^2 = .40). Baseline emphysema score did not show such statistical correlations.
Conclusion: In patients with severe COPD and pulmonary emphysema, a lower baseline FEV1 prior treatment seems to predict for a higher relative improvement of FEV1 after ELVR. Emphysema score prior to treatment did not show strong correlations with a beneficial clinical outcome.

B-1280 15:05

How to calculate an interlobar emphysema heterogeneity index in the context of lobar lung volume reduction therapy

D. Theilig[1], F. Doellinger[1], A. Poellinger[2], R.-H. Hubner[1]; [1]*Berlin/DE*, [2]*Berne/CH (dorothea.theilig@charite.de)*

Purpose: A standardised definition for interlobar emphysema heterogeneity in the context of endoscopic lung volume reduction (ELVR) is lacking. The aim of this study was to elucidate the most appropriate way to define a heterogeneity index (HI).
Methods and Materials: We retrospectively analysed 62 patients who had undergone ELVR with placement of one-way valves at our institution and were prospectively monitored using lung function tests and CT scans acquired in inspiration and expiration before and after ELVR. Quantitative analysis of the CT scans was performed and the HI of the targeted lobe was determined with six different methods, each from inspiratory and expiratory CT scans. The differently defined HIs were correlated with the increase in absolute forced expiratory volume in one second (FEV1) after ELVR and their predictive accuracy was assessed with receiver-operating characteristic (ROC) curve analysis assuming a minimum difference in FEV1 of 100ml to indicate a clinically important change. DeLong's test was used to test for significant differences between ROC curves.
Results: Most HIs showed a statistically significant, albeit weak, positive correlation with ELVR outcome assessed as FEV1 improvement. The HI defined as targeted lobe emphysema score minus emphysema score of the lung without the targeted lobe on inpiratory CT scans showed the best predictive accuracy in ROC analysis (AUC=0.68, p=0.019). However, the DeLong's test showed no statistically significant differences between the ROC curves.
Conclusion: This study reveals the most appropriate ways to calculate an emphysema heterogeneity index in the context of ELVR.
Author Disclosures:

Evaluation of three iterative metal artefact reduction algorithms in postsurgical chest computed tomography

J. Aissa, J. Boos, L. Sawicki, N. Heinzler, P. Kröpil, G. Antoch, C. Thomas, B.M. Schaarschmidt; *Düsseldorf/DE (Benedikt.Schaarschmidt@med.uni-duesseldorf.de)*

Purpose: To evaluate the impact of three iterative metal artefact reduction (MAR) algorithms on image quality in CT of patients with metallic devices.
Methods and Materials: Twenty-seven consecutive patients (68.1±11.1 years, 22 male/5 female) with thoracic implants who underwent postsurgical chest-CT were retrospectively included. Images were reconstructed using three different iterative MAR algorithms (iterative MAR-Algo1: cardiac algorithm, iterative MAR-Algo2 = pacemaker algorithm, iterative MAR-Algo3 = thoracic coils algorithm). Weighted filtered back projection (WFBP) reconstructions served as reference standard. Artefacts were subjectively classified into mild and severe. Subjective image quality was evaluated on a 5-point scale by two independent readers (1: severe artefacts, non-diagnostic; 5: no artefacts, excellent image quality). Objective image quality was assessed using region of interest measurements and measuring artefact strength (in Hounsfield Units, HU).
Results: Artifacts were significantly lower for the iterative MAR-Algo1 (58.9±36.HU), iterative MAR-Algo2 (52.7±43.9HU) and the iterative MAR-Algo3 (51.9±44.1HU) compared to WFBP (91.6±78.3HU, p<0.01 for all). Subjectively,

all MAR reconstructed images showed significantly lower mild artefacts (MAR-Algo1 and 2: 4.5±0.5, MAR-Algo3: 3.8±0.5) and severe artefacts (MAR-Algo1 and 2: 3.8±0.4, MAR-Algo3: 3.3±0.5) compared with WFBP (mild: 3.6±0.5; severe: 1.7±0.4)($p<0.01$, respectively). MAR-Algo2 and MAR-Algo3 decreased mild artefacts more effectively compared to MAR-Algo1 ($p<0.01$) while there was no difference for severe artefacts.
Conclusion: All three iterative MAR algorithms improved image quality and reduced artefacts compared to WFBP in postsurgical chest-CT after metallic device implementation. The iterative MAR-Algo2 and MAR-Algo3 were best for mild artefacts while iterative MAR-Algo1 was superior for severe artefacts.

B-1282 15:21

USG-guided thoracocentesis using pigtail catheter with or without pleurodesis in the palliation of recurrent/refractory malignant pleural effusions

A.K. Madayambath, S. Thulkar, A.S. Bhalla, S. Bhatnagar, S. Mishra, M. Jana; *New Delhi/IN (anoopmkcmc@gmail.com)*

Purpose: To evaluate the efficacy of ultrasound-guided pigtail thoracocentesis followed by pleurodesis in patients with symptomatic and refractory malignant pleural effusions.
Methods and Materials: We recruited 57 patients with malignant pleural effusions due to intrathoracic (n=17) and extrathoracic malignancies (n=40). Ultrasound-guided thoracocentesis was performed using 10F pigtail catheter. Those in whom the pigtail drain output dropped to <150ml/day and adequate re-expansion of the underlying lung occurred, pleurodesis was performed (n=33) by intrapleural instillation of Bleomycin (60 IU). Various factors precluded pleurodesis in the remaining patients (n=24). The post-pleuordesis follow-up ranged from 1 to 12 weeks. Pre- and postprocedural clinical scoring was done using NYHA dyspnoea and ECOG performance status scoring systems. Chest radiographs were performed at regular intervals to detect fluid re-accumulation.
Results: 17 patients followed till 12 weeks post-pleurodesis, showed improvement in their clinical and radiological status. Technical success rate of thoracocentesis was 100%, procedural success of pleurodesis was 91% and clinical success rate after Bleomycin in our study was 68%.
Conclusion: We concluded that pigtail thoracocentesis followed by pleurodesis is an effective and safe procedure for palliation of dyspnoea in malignant pleural effusions and hence, strongly recommend early consideration of pleurodesis with Bleomycin.

Dynamic MR of the pelvic floor: impact of the PCL on the grading of pelvic floor descent

S. Picchia, M. Rengo, D. Caruso, D. Bellini, D. De Santis, A. Laghi; *Latina/IT (lisiva@alice.it)*

Purpose: To evaluate the impact of three methods for drawing the pubococcygeal line (PCL) on the grading of pelvic floor descent.
Methods and Materials: Patients with suspected pelvic floor dysfunction were prospectively included. Exams were acquired on a 1.5 Tesla MR scanner. Rectum and vagina were filled with 200ml and 50ml of ultrasound gel. The acquisition protocol included TSE T2-weighted sequences on axial, sagittal and coronal planes for morphological evaluation. A steady-state sequence, in the midsagittal plane, was acquired during straining and defecation. The anterior aspect of all PCL was the pubic symphysis while posterior aspects were the tip of the coccyx (PCLtip), the sacrococcygeal joint (PCLsc) and the last coccygeal joint (PCLcc). The grade of pelvic floor descent was measured with the M line. Measurements of M line were compared as differences of absolute measures and differences of grading.
Results: A total of 29 consecutive female patients were included in the study (mean age 56.07 yy ± 10,52). M line measured using the PCLtip was significantly smaller than the one measured using both the PCLsc or PCLcc in all measurements. The grading of pelvic floor relaxation, using PCLtip, was underestimated in 13 patients (44%) at rest, in 19 patients (65%) during straining and in 16 patients (55%).
Conclusion: A significant difference was observed for the measurement of the M line according to the three PCL used. A significant underestimation of the pelvic floor descent was observed when the M line was measured using the PCLtip as reference.

B-1284 14:17

Intrauterine devices in MRI: not every IUD is safe and MR compatible

S. Bussmann; *Zurich/CH (bussimon88@gmail.com)*

Purpose: The lack of safety information on intrauterine devices (IUD) in MRI is a practical problem for radiologists. Thus, the aim of the study is the evaluation on safety and imaging compatibility in both 1.5T and 3.0T MRI of selected metallic IUD.
Methods and Materials: A variety of MR compatibility tests were performed in a 1.5T/3.0T MRI: assessment of displacement force, measurement of torque effects of the implant, evaluation of image artefacts (3.0T) and evaluation of heating effects (1.5/3.0T) were performed with the following IUD: Mona Lisa, Gold Luna, Nova T (gold/copper) and Chinese ring (steel).
Results: Most IUD (Mona Lisa, Gold Luna, Nova T) presented deflection angles of 0.33°, corresponding to a calculated magnetic force of 0.3mN. In contrast, in Chinese rings a distinct magnetic force (41.66° with an additional 58.1 g increase of mass) was induced corresponding to a calculated magnetic force of 5'706mN. Manual rotation of all IUD showed no signs of any torque effects at all. Heating measurements at 1.5T/3.0T showed a temperature increase of 1.4°C/3.4°C (Chinese ring), 3.2°C/3.8°C (Gold Luna), 3.3°C/4.8°C (Mona Lisa), 3.8°C/4.8°C (Nova T) and 2.2°C/3.6°C (negative control). The artefacts of the copper/gold IUD in the 3T MRI reach a diameter of 3.8mm ± 0.5mm while the Chinese ring achieves 20cm (gradient echo) and 14.9cm ± 0.2mm (spinecho), respectively.
Conclusion: Standard IUD consisting of copper/gold can be considered as safe, while the Chinese ring IUD disturbs images with big artefacts and is potentially harmful to patients during MRI due to significant magnetic forces.

B-1286 14:25

CT and MR imaging of clear-cell carcinoma of the ovary

Y. Shin, H. Joo; *Incheon/KR (joohaele_rd@hanmail.net)*

Purpose: We explored the clinical and imaging features in patients with pathologically proven clear-cell carcinoma (CCC) of the ovary.
Methods and Materials: Twenty patients with hitologically confirmed CCC of the ovary from 2005 to 2016 were enrolled. The staging of these patients is decided by surgical staging (FIGO staging). Retrospectively, two reviewers independently analysed by dividing into two groups. The one group is early stage and another group is advanced stage. And we found the common findings in each groups and also in all groups, regardless of stage. Imaging studies were evaluated for the following: (a) location, (b) maximal transverse diameter, (c) shape (d) margin (e) solid, solid and cystic regions, or cystic, (f) attenuation of the cystic portion, (g) enhancement pattern of the solid portions of the tumour, and (h) secondary manifestations.
Results: Contrary to previous study, our study revealed that the diagnosed stage of CCC of ovary is relatively advanced stage (III/IV). Common imaging findings of CCC was smooth margined cystic mass, unilocular cystic mass, relatively high attenuation in cystic portion (20-30HU). Predictable factor of early stage was mainly cystic tumour, a few and small, round or papillary luminal protruding mass. Predictable factor of advanced stage was mixed type tumour (higher proportion of solid portion than cystic portion), many and large, irregular luminal protruding mass.
Conclusion: The ovarian CCCs are rare tumours, and familiarity with clinical setting and imaging features will facilitate prompt and accurate diagnosis and treatment.

B-1287 14:33

Role of MRI in the staging of primary carcinoma cervix and its correlation with clinical FIGO/histopathological staging

N. Mohan, A. Prahladan, V. Jiji, K. Ramachandran; *Trivandrum/IN (drnehamohan@gmail.com)*

Purpose: To assess the role and accuracy of multiparametric MRI in staging primary carcinoma cervix and its agreement and correlation with clinical FIGO and histopathology. To assess the impact of MRI in revised FIGO staging and change in treatment plan. To study the role of ADC values in histological characterisation of carcinoma cervix.
Methods and Materials: MRI of 193 carcinoma cervix patients were studied. Non-parametric Spearman's rho (rank correlation) test and percentage agreement were calculated to assess the correlation between the MRI, clinical

stage and histopathology. For the surgically treated patients, histopathology was taken as gold standard and sensitivity, specificity, negative predictive value, positive predictive value, accuracy, over staging and under staging were calculated for MRI. Mean ADC values of different histopathological types were tested for significance using ANOVA and independent sample t test.
Results: MRI had a high tumour detection rate of 94.3%, over all staging accuracy of 78.26%, very strong correlation with histopathology (r = 0.886). Clinical FIGO and MRI based staging (r = 0.615) had agreement only in 51.81%. MRI changed the clinical stage in 48.19% patients and subsequent primary treatment plan in 26.6%. Mean ADC value was lower for squamous cell carcinoma (p 0.004).
Conclusion: MRI is highly accurate in evaluating carcinoma cervix and has high correlation with histopathology. Agreement between clinical and MRI based FIGO stage is low. ADC values are lower for squamous cell carcinoma. MRI has a considerable impact in altering treatment decisions and should be available to all patients with carcinoma cervix.

B-1288 14:41

Quantitative MRI analysis of cervical cancer treated with external beam chemoradiotherapy followed by MRI-assisted HDR intracavitary Brachytherapy

A. Jacques, K. Stavrou, V. Tse, S. Natas, O.A. Westerland, A. Winship, V. Mullassery, V.J. Goh; *London/UK (dianastavrou@gmail.com)*

Purpose: To evaluate quantitative morphological MRI parameters at baseline, pre & post brachytherapy in locally advanced cervical cancer and correlate with clinical outcome.
Methods and Materials: Quantitative assessment of T2 signal intensity(T2SI) was made in a subset of 33/100 patients(mean age 54.8 yrs) who were treated with External Beam Chemotherapy(EBRT) followed by brachytherapy(BT), at baseline, pre & 3 month post BT. Clinical data included age, histology, stage & follow up(median 30 months). Mean tumour T2SI & T2SI ratio(T2SIr) was calculated. Change & percentage change in T2SIr and estimated tumour size before & after BT were compared with outcome.
Results: 28/33(84.5%) had biopsy proven squamous cell carcinoma & 5/33(15.2%) adenocarcinoma. 30/33(90.9%) presented with FIGO stage 2b disease. 6/33(18%) relapsed. Median tumour size significantly reduced between treatments**;** 77.8% reduction post EBRT(p=0.00); 33.7% post BT(p=0.00) but did not differ signfiicanctly between relapse & non-relapse groups at all 3 time points. Persistent T2 hyperintensity was seen in 17/33 patients post BT & in 3/6 who subsequently relapsed. Median T2SIr measured 3.37 at baseline & decreased significantly to 2.7 pre BT(p=0.026) & 1.58 post BT(p=0.00), corresponding to visual lowering of signal intensity. Median T2SIr was significantly higher(1.9 vs 1.6; p=0.015) & corresponding T2SIr percentage change was lower in the relapse group(p=0.021) at 3 months.
Conclusion: Initial results suggest that simple quantitative morphological MR metrics are capable of showing significant differences post therapy for locally advanced cervical cancer, & suggest a potential biomarker for disease relapse in patients who may be suitable for early salvage surgery.

B-1289 14:49

The utility of apparent diffusion coefficient in differential diagnosis of neuroendocrine carcinoma of the uterine cervix

C. Zhang, J.-L. Cheng; *Zhengzhou/CN (13733891344@163.com)*

Purpose: To assess the value of diffusion weighted imaging(DWI) and apparent diffusion coefficient(ADC) in differential diagnosis of neuroendocrine carcinoma of the uterine cervix(NECUC).
Methods and Materials: A total of 12 NECUC,39 squamous carcinoma of the cervix(SCC)and 21 adenocarcinoma of the uterine cervix(AUC) confirmed by pathology were analyzed retrospectively. All the patients performed conventional and diffusion weighted MR scan. The ADC values were measured and compared between NECUC, SCC and AUC. Diagnostic performance of ADC was compared using receiver operating characteristic curves (ROC).
Results: The mean ADC value of NECUC, SCC and AUC was$(0.66\pm0.11)\times10^{-3}mm^2/s$, $(0.86\pm0.11)\times10^{-3}mm^2/s$ and$(1.04\pm0.17)\times10^{-3}mm^2/s$, with statistical differences among each group. The optimal cutoff values of ADC for differentiating NECUC and SCC was $0.681\times10^{-3}mm^2/s$ with sensitivity of 94.9%,specificity of 75.0% and accuracy of 90.2%. The optimal cutoff values of ADC for differentiating NECUC and AUC was $0.824\times10^{-3}mm^2/s$ with sensitivity of 95.2%,specificity of 91.7% and accuracy of 93.9%.
Conclusion: The differences of the mean ADC value are helpful in the differential diagnosis of NECUC, SCC and AUC.

B-1290 14:57

Assessing of depth of myometrial invasion and preoperative staging of endometrial cancer: the added value of diffusion-weighted imaging and dynamic contrast-enhanced MRI sequences

I. Alves[1], M. Ramalho[2], T.M. Cunha[2]; [1]*Funchal/PT*, [2]*Lisbon/PT (inesmpalves@gmail.com)*

Purpose: To compare T2-weighted image (T2WI) vs dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) vs diffusion-weighted imaging (DWI) for the evaluation of depth of myometrial invasion and preoperative overall staging of endometrial cancer.
Methods and Materials: This retrospective study included forty-four women with endometrial cancer who underwent 1.5 Tesla pelvic MRI as part of their initial preoperative staging. T2WI, DCE-MRI, and DWI sequences were obtained. Retrospectively, two radiologists performed a consensus interpretation of all images interpreted the depth of myometrial invasion, overall stage, and presence of pitfalls. Surgical histology was available for each case and was the gold standard for comparison. The accuracy, sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for each method were assessed.
Results: Respective diagnostic accuracy, sensitivity, specificity, PPV and NPV in assessing the depth of myometrial invasion were: T2WI 61%, 58%, 64%, 55% and 67%; DCE-MRI 86%, 84%, 88%, 84% and 88%; DWI 95%, 95%, 96%, 95% and 96%. DWI correctly staged more patients (41/44) than DCE-MRI (34/44) and T2WI (22/44) ($P<0.05$). For overall cancer staging, κ values were 0.29 with T2WI, 0.59 with DCE-MRI, and 0.89 with DWI.
Conclusion: DWI considerably improved the diagnostic sensitivity and accuracy of MRI compared to DCE-MRI and T2WI in assessing both depth of myometrial invasion and overall staging in endometrial cancer.

B-1291 15:05

Collision tumour of ovary: pathological features and imaging diagnosis

H. Wang, J. Guan, M. Liu; *Guangzhou/CN (usefulkey0077@hotmail.com)*

Purpose: To explore imaging findings and pathological features of ovarian collision tumours, to further improve the imaging diagnosis.
Methods and Materials: 12 female patients with ovarian collision tumours were confirmed by surgical pathology. All imaging findings (9 CT, 2 CT and MRI, 1 non-enhanced MR) and pathological features were retrospectively analysed.
Results: All ovarian collision tumours in 12 cases consisted of two different types of tumours, originated from surface epithelial cells, germ cell, or sex cord-stromal cell. 7 masses localised in left ovary, and 5 were in right. Collision tumours in 9 consisted of surface epithelial tumour and germ cell tumour (6 with mucinous cystadenoma and teratoma, 1 with mixed cystadenoma and teratoma, 1 with serous cystadenoma and struma-ovarii, 1 with undifferentiated carcinoma and teratoma). Collision tumours in 3 consisted of surface epithelial tumour and sex cord-stromal tumour, mucinous cystadenoma and fibroma were detected in 2 and serous cystadenoma and fibroma were detected in 1. Imaging findings included: 1. All collision tumours presented large multiple cystic mass with complicated densities/signals in diameter from 9 to 28 cm. 2. Germ cell tumour or sex cord-stromal tumour were usually smaller (11/12), and lied inside (n=4) or on the wall (n=8) of surface epithelial tumour. The two types of tumours in collision tumour can be well differentiated. 3. Typical imaging features of different tumours in ovarian collision tumours can be detected on CT or MRI.
Conclusion: Pathological and imaging features of ovarian collision tumours are characteristic. Accurate preoperative diagnosis is possible.

B-1292 15:13

Factors influencing MRgFUS efficiency for uterine fibroids treatment

A. Hocquelet, T. Lerebour, N. Frulio, C. Salut, H. Trillaud; *Bordeaux/FR (nonobdx@gmail.com)*

Purpose: The aim of this study was to assess uterine fibroids stiffness and perfusion as independent factor associated with MRgFUS efficiency.
Methods and Materials: We present the preliminary results of the PERAGUS study (NCT02386137). Fibroids stiffness was assessed by ARFI and perfusion by contrast-enhanced US using Sonovue injection and VueBox software. MRgFUS efficiency was defined as the non-perfused volume/the total volume of treatment cells size.
Results: The first 20 patients were included corresponding to 20 fibroids with a median size of 145cc, with 14 grade 1, 4 grade 2 and 2 grade 3 of Funaki classification. The mean NPV was 40%. Funaki grade (P=0.01) and fibroid stiffness (P=0.046) were associated with MRgFUS efficiency. No CEUS perfusion parameter was associated with MRgFUS efficiency.
Conclusion: Fibroids stiffness assessed by ARFI is associated with MRgFUS efficiency like the well-documented Funaki grade.

Whole-body MRI with DWI in lesion detection, staging and response evaluation in FDG-avid lymphomas: comparison with 18F-FDG-PET/CT

M. Ciliberto, L. Calandriello, L. Leccisotti, A. Giordano, A. Larici, L. Bonomo; *Rome/IT (dott.mariociliberto@gmail.com)*

Purpose: To assess diagnostic capability of WBMRI with DWI in lesion detection, staging and response evaluation in FDG-avid lymphomas, namely Hodgkin lymphoma (HL) and diffuse large B-cell lymphoma (DLBCL), in comparison with PET/CT.
Methods and Materials: 16 patients with histologically proven HL and DLBCL underwent both 18F-FDG-PET/CT and WBMRI with morphological sequences and DWI (b values=0-50-1000) for initial staging and for treatment response evaluation. For each patient, 30 nodal and extra-nodal stations were evaluated. We assessed diagnostic accuracy of WBMRI in comparison with PET/CT for Ann Arbor staging. We also assessed sensitivity, specificity, PPV, NPV and accuracy of WBMRI in nodal and extra-nodal lesion detection, and concordance between the two imaging modalities in evaluating response to therapy. Gold standard was represented by PET/CT and concordance between the two modalities was assessed with Cohen's kappa.
Results: Sensitivity, specificity, PPV, PPN and accuracy for nodal and extra-nodal lesions were respectively 83.7, 96.3, 85.4, 95.8 and 93.8% for WBMRI with a very good agreement with PET/CT (k=0.81). Although these differences, there was a perfect agreement (16/16) between WBMRI and PET/CT in Ann Arbor staging. At the end of treatment WBMRI and PET-CT demonstrated excellent agreement in evaluating response to therapy (k=0.92) with only two discordant cases.
Conclusion: WBMRI with DWI, compared to PET/CT, showed a very good agreement and diagnostic accuracy in staging and therapy response assessment of FDG-avid lymphomas, and has the potential to be a "radiation-free" alternative modality in these patients.

B-1294 14:08

Whole-body MRI, FDG-PET/CT and bone marrow biopsy, for the assessment of marrow involvement in patients with newly diagnosed lymphoma

D. Albano, C. Patti, L. La Grutta, E. Grassedonio, A. Mulè, A. Costa, M. Midiri, R. Lagalla, M. Galia; *Palermo/IT (albanodomenico@me.com)*

Purpose: To compare whole-body MRI (WB-MRI) with diffusion-weighted imaging (DWI), FDG-PET/CT, and bone marrow biopsy (BMB), for the evaluation of bone marrow involvement (BMI) in patients with newly diagnosed lymphoma.
Methods and Materials: Two independent radiologists and one nuclear medicine specialist reviewed all WB-MRI and FDG-PET/CT scans prospectively performed on 104 patients with newly diagnosed lymphoma (53 males; 47 Hodgkin; mean age: 44, range 15-86) between 2013 and 2015. The delay between imaging scans and BMBs was up to 10 days. The diagnostic accuracy of WB-MRI (1.5 Tesla MR scanner, with T1w, T2w-STIR and DWI sequences) was evaluated using BMB and FDG-PET/CT as the reference standard. We applied Cohen's kappa coefficient to assess the inter-observer agreement in WB-MRI interpretation and to compare WB-MRI, FDG-PET/CT and BMB. The Student's t test was done to compare pelvic marrow ADC values of patients with positive and negative BMB. A p-value of <0.01 was considered significant.
Results: Inter-observer agreement was excellent (k=0.937). Agreement between WB-MRI and FDG-PET/CT was excellent, with a k=0.935. Agreement between WB-MRI and BMB was moderate (k=0.489), and fair between FDG-PET/CT and BMB (k=0.370). WB-MRI and FDG-PET/CT were falsely negative in four indolent non-Hodgkin lymphomas with BMI<30% of marrow cellularity. Conversely, WB-MRI and FDG-PET/CT detected all cases with a BMI>30% of marrow cellularity. Mean ADC values in patients with positive and negative BMB were not significantly different (p=0.049).
Conclusion: WB-MRI and FDG-PET/CT are valuable tools for the assessment of BMI.

B-1295 14:16

Whole-body diffusion-weighted MR and FDG-PET/CT in Hodgkin lymphoma: predictive role before treatment and early assessment after two courses of chemotherapy

D. Albano, C. Patti, D. Matranga, L. La Grutta, E. Grassedonio, C. Ortolano, M. Midiri, R. Lagalla, M. Galia; *Palermo/IT (albanodomenico@me.com)*

Purpose: To evaluate whether whole-body MR has a predictive role before treatment and may assess the response after two courses of chemotherapy in comparison to FDG-PET/CT.
Methods and Materials: We reviewed the whole-body MR and FDG-PET/CT scans performed on 41 patients (20 males, mean age: 32.6, 15-66; 21 females, mean age: 30.8, 16-56) with newly diagnosed Hodgkin Lymphoma, before and after two courses of chemotherapy (ABVD) between 2013 and 2016. We used the Multivariate GEE model to assess the statistical association between being-responder and baseline-SUV_{max}, pre- and post-treatment-ADC and size, percentage change of ADC and size during chemotherapy, site of disease, bulky and stage.
Results: After two ABVD, 10/41 patients (24%) were positive on interim-PET. Mean baseline-SUV_{max} was 11.18±5.58 (3.1-28.0) and baseline-ADC was 0.70±0.14 mm^2/s (0.39-0.98). Mean post-treatment-SUV_{max} of non-responder lesions was 5.68±3.13. Post-treatment-ADC was 1.83±0.34 mm^2/s (1.31-2.90) in responder lesions and 1.01±0.27 mm^2/s (0.49-1.48) in non-responder ones (p<0.001). There was a significant difference also based on post-treatment-size (p=0.009) and bulky (p=0.002). There was no significant difference based on baseline-SUV_{max} (p=0.713), baseline-ADC (p=0.253), percentage change of ADC (p=0.058), size changes (p=0.085), site of disease (p=0.209), stage (p=0.290), baseline-size (p=0.064).
Conclusion: Baseline-SUV_{max} and ADC do not have a predictive role. The occurrence of bulky is the most helpful imaging parameter to predict suboptimal response after two courses of chemotherapy. Post-treatment-ADC is useful for identifying non-responder lesions, whereas size changes are not helpful.

B-1296 14:24

Whole body MRI with DWI as surveillance imaging for lymphoma patients

A. Balbo Mussetto, C. Saviolo, S. Cavanna, M. Petracchini, C. Lario, A. Macera, C. Arese, T. Gallo, S. Cirillo; *Turin/IT (annalisa.balbomussetto@gmail.com)*

Purpose: The aim of our study was evaluating diagnostic performance of Wb-MRI-DWI in periodical surveillance after therapy and for recurrence identification in lymphoma patients compared with PET-CT.
Methods and Materials: 71 patients with previous lymphoma diagnosis (31 HL and 40 NHL) underwent to Wb-MRI-DWI for surveillance (mean 2,4 examination/patient for 42 mounts). When disease relapse was suspected, definitive diagnosis was obtained with FDG PET-CT or biopsy.
Results: During surveillance, Wb-MRI-DWI correctly identified all 13 patients with recurrence (4 HL, 7 DLCL, 3 FL, 1MCL, 1 ATCL). Only in 1 case both Wb-MRI-DWI and PET-CT suspected disease but biopsy was negative. Sensitivity and specificity, respectively, were 1.00 (I.C. 95% 0.77-1) and 0.98 (0.91-1) with NPV 1.00 (0.94-1) and PPV 0.93 (0.69-0.99).
Conclusion: Wb-MR-DWI thanks to its high sensitivity and NPV is a feasible examination for periodical surveillance in lymphoma patients.

B-1297 14:32

Comparing whole-body CT with x-ray skeletal survey for staging monoclonal plasma cell disease: results from an international, blinded reader study

S. Delorme[1], V. Koutoulidis[2], J. Mosebach[1], T. Hielscher[1], J. Hillengass[1], H.-P. Schlemmer[1], L.-A. Moulopoulos[2]; [1]*Heidelberg/DE*, [2]*Athens/GR (s.delorme@dkfz-heidelberg.de)*

Purpose: To compare the sensitivities of Whole-Body Low-Dose CT (WBLDCT) and conventional skeletal survey (CSS) for bone lesions due to monoclonal plasma cell disease.
Methods and Materials: CSS and WBLDCT from 8 international centres were read in consensus by 3 radiologists blinded for the presence of focal osteolyses or osteoporosis. Differences in sensitivity were tested with the exact McNemar test.
Results: 160/308 patients were previously untreated, and of these, 56 had smoldering multiple myeloma (SMM) according to CSS. 80/160 untreated patients were free of lesions with either modality, and 33 had lesions visible on both. In 38 patients, lesions were only visible with WBLDCT, and in 9 they were detected on plain films only (OR, 4.22 (p<0.0001)). WBLDCT was superior to CSS for the iliac bones, the thoracic and lumbar spine, and the ribs, but not for the proximal extremities. Osteoporosis was diagnosed with WBLDCT only in 29, with CSS only in 10, and with both techniques in 63 /157 patients (OR, 2.9 (p=0.003)). Out of the 56 patients with SMM, 12 (21.4 %) showed lytic bone lesions on WBLDCT (p=0.0005).

Conclusion: WBLDCT was significantly more sensitive for bone lesion detection than plain radiographs in the axial skeleton, ribs, and pelvis, but somewhat less sensitive for lytic lesions in the extremities, partly for technical reasons. On the whole, 20% of patients with SMM were upstaged to symptomatic myeloma based on WBLDCT findings. We suggest that imaging standards for multiple myeloma staging be reconsidered.

Prognostic relevance of focal lesions in whole-body MRI in multiple myeloma patients before and after allogeneic stem cell transplantation

J. Mosebach, S. Shah, N. Fard, H. Goldschmidt, S. Schönland, U. Hegenbart, H.-P. Schlemmer, S. Delorme, J. Hillengass; *Heidelberg/DE (j.mosebach@dkfz-heidelberg.de)*

Purpose: To investigate predictors of survival in patients with multiple myeloma before and after allogeneic stem cell transplantation (alloSCT) by assessing the tumour burden with whole-body-MRI.
Methods and Materials: Diagnostic WB-MRI was performed in 1.5 T scanners. Of initially 79 patients with stage II multiple myeloma or higher, according to the Salmon and Durie classification, 63 completed imaging before and after alloSCT. Lesions were characterised by corresponding focal signal changes in T1w-(hypointens) as well as in T2w- fat-saturated sequences (hyperintens) and size >5mm. Statistical analysis included univariable and multivariable Cox regression models. Distribution of survival times was estimated with the Kaplan-Meier method and Log rank test was used to determine prognostic impact of the presence of focal lesions on survival.
Results: Presence of focal infiltration was associated with a shorter progression free survival (PFS; 2nd MRI: HR 2.52, p=0.035 and 1st MRI: borderline statistical significance, HR 1.95 P=0.079) and overall survival (OS; 2nd MRI HR 3.8, p=0.032). Increasing number of focal lesions at baseline proved to be an additional adverse prognostic factor (PFS: HR 1.02, p=0.047; OS: HR 1.02, p=0.013). Kaplan-Meier estimates at 60 months of follow-up showed OS rates of 31% for patients with focal infiltration after therapy and 74% for patients without.
Conclusion: Multiple myeloma patients in this setting with any focal lesion have a higher risk of progression as well as shorter OS, and may benefit from continuous consolidating therapy. WB-MRI before and after alloSCT can be recommended to detect prognostic relevant lesions.

Whole-body MR imaging vs conventional x-ray examination in patients with plasmacell neoplasia

A. Cassarà, A. Trisoglio, L. Sukhovei, G. Leale, S. Berardo, F. Buemi, L. De Paoli, A. Stecco, A. Carriero; *Novara/IT (alessandratrisoglio@outlook.it)*

Purpose: Multiple myeloma (MM) is the most common primary malignant neoplasm of the skeletal system. Radiological findings on conventional x-ray examinations of MM considered by International Myeloma Working Group criteria are multiple focal lytic lesions of the bone ≥5mm in size and >1 focal lesions on Magnetic Resonance Imaging (MRI) studies. In the next 10 years whole-body MRI (WB-MRI) has become an important additional tool. The aim of this study was to compare findings on conventional x-ray examinations with findings from wb-MRI to subsequently determine the influence of wb-MRI on therapy changes.
Methods and Materials: In 40 patients of Haematology Department with Plasmacell Neoplasia (including Smouldering Myeloma, Plasmocytoma and MM) with a mean age of 62.5+/-11.9 years, WB-MRI examinations were correlated with a recent conventional x-ray. The results were independently assessed by two radiologists. The disease was staged according to Salmon and Durie and Salmon and Durie PLUS.
Results: In all, 320 skeletal regions were compared; 38 regions were positive on conventional x-ray examination vs 95 regions on WB-MRI. An increased degree of infiltration was identified on wb-MRI with significant differences ($p < 0.05$) between the modalities in both lower extremities. Based on wb-MRI, tumour stage was upgraded in 13 of the 40 patients. In 11 out of these 13 patients, the WB-MRI results influenced for making the decision to initiate further therapy due to the degree of bone infiltration.
Conclusion: WB-MRI provides a more detailed assessment of the pattern of bone marrow infiltration and influences therapeutic strategies.

Whole-body MRI in multiple myeloma: a retrospective study comparing ADC maps and dynamic contrast-enhanced imaging (DCE-MRI) in evaluation of post treatment response

P. Arcuri, S. Roccia, S. Molica, A. Anoia, D. Lagana', G. Fodero; *Catanzaro/IT (arppaolo@alice.it)*

Purpose: The aim of our study was to compare,in WB-MRI,the diagnostic capabilities of apparent diffusion coefficient (ADC) maps and dynamic contrast enhanced (DCE-MRI) in evaluation of post treatment response of Multiple Myeloma (MM).
Methods and Materials: The retrospective study includes forty-five patients affected by MM,all underwent radio/chemotherapy or autologous stem cell transplant.The protocol included coronal WB and sagittal (axial skeleton) TSE T1 ,STIR T2 and axial DWIBS (b: 0-1000 mm2/sec) sequences.Imaging post-contrast was performed immediately after injection during the first 2 min.Mean ADC values of focal suspected lesions and diffuse localisations were calculated. DCE-MRI images of the spine,were analysed with regions-of-interest (ROI) and Time-Intensity-Curves (TIC). Quantitative analysis was performed by means of K statistic.The qualitative interpretation of TICs based on the shape of the curve.Paraprotein evolution was considered the reference standard.
Results: DWI sensibility in detection disease remission was 88%, specificity 71%; in the relapse cases,(were considered positive the mean ADC values: 1.09±0.21x10-3 mm²/sec in focal lesions, 0.71±0.22x10-3 mm²/sec in diffuse involvement) sensitivity was 94%, specificity was 88%.DCE-MRI showed, in remission of disease,74% of sensitivity and 93% of specificity.In relapse of disease DCE-MRI showed 74% of sensitivity and 93% of specificity.In some patients (9%),progressive disease was detected earlier by WB-DW-MRI than by the routine biochemical follow-up.
Conclusion: DCE-MRI approach showed greater specificity in the evaluation of both remission and relapse of disease.WB-DWI-MR increase detection of relapse of disease in myeloma patients in comparison to DCE-MRI.A combined evaluation of DWI and DCE-MRI provides a comprehensive assessment of post treatment response in MM.

B-1301 15:04

Apparent diffusion coefficient (ADC) values in multiple myeloma patients: a potential noninvasive marker for bone marrow involvement characterisation at staging

P.A. Bonaffini[1], D. Ippolito[2], A. Nasatti[2], C. Talei Franzesi[2], S. Sironi[3]; [1]*Desio/IT*, [2]*Monza/IT*, [3]*Bergamo/IT (pa.bonaffini@gmail.com)*

Purpose: To assess the role of quantitative analysis of ADC maps in bone marrow involvement characterisation at staging for patients with multiple myeloma (MM).
Methods and Materials: Fifteen MM patients (focal 6, diffuse 6, combined 3), undergone a 1.5T Whole-Body MRI examination (Achieva, Philips) for staging purposes, were retrospectively analysed. Coronal (skull vertex-ankle) and sagittal (whole axial skeleton) short-tau inversion recovery (STIR) T2 and T1 TSE and axial DWIBS (*b:* 0-500-1000 mm^2/sec) sequences were acquired. According to visual-qualitative analysis, up to 3 target bone localisations per patient were chosen. Regions of interest (ROIs) were manually drawn on corresponding ADC maps, obtaining the mean ADC values for focal (ADC1) and diffuse (ADC3) localisations. ADC1 and ADC3 were compared each other and with ADC calculated in normal bone marrow (ADC2).
Results: A total of 22 neoplastic bone lesions (10 focal, 12 diffuse), with high signal intensity on DWIBS (compared to normal bone marrow), were retrospectively evaluated. The mean ADC values were $1.06\pm0.27\times10^{-3}$ mm²/sec, $0.75\pm0.19\times10^{-3}$ mm²/sec and $0.34\pm0.07\times10^{-3}$ mm²/sec in focal lesions (ADC1), diffuse involvement (ADC3) and normal bone marrow (ADC2) respectively. The ADC values were significantly lower (p=0.003) in cases of diffuse involvement than those of focal pattern. The values of MM bone localisations (ADC1-ADC3) were significantly higher (p=0.001) of those of normal bone marrow (ADC2).

Conclusion: Quantitative analysis of ADC maps in staging of MM patients provides data potentially useful for the non-invasive characterisation of normal bone marrow and its pathologic involvement, even in terms of the different patterns of disease.

B-1302 15:12

Comparison of normal and metastatic lymph nodes with multi-energy computed tomography

M. Femia[1], S. Rizzo[1], L. Preda[2], D. Radice[1], R. Vigorito[1], P. De Marco[1], D. Origgi[1], M. Bellomi[1]; [1]*Milan/IT*, [2]*Pavia/IT (marco.femia@unimi.it)*

Purpose: To evaluate whether multi-energy computed tomography (CT) could help in differentiating between normal and metastatic lymph nodes.
Methods and Materials: Mediastinal and abdominal lymph nodes (LN) with pathological evaluation, among patients who underwent multi-energy CT, were retrospectively evaluated. Regions of interest (ROI) were traced on the selected LN. Iodine/fat, Iodine/water, fat/iodine and water/iodine material decompositions were calculated and compared between normal and metastatic LN. Inter-observer variability between two readers was evaluated for the first 12 LN. P<0.05 was considered significant.
Results: 101 LN were selected: 53 were mediastinal LN (31 normal and 22 metastatic LN from lung cancer), and 48 were abdominal (28 normal and 20 metastatic LN from gynaecological malignancies). Iodine/fat material decomposition was significantly higher for normal LN (4.19±1.05 mg/cm^3; 95% P-tiles 2.80,5.47) than for pathologic LN (3.70±0.89 mg/cm^3; 95%P-tiles 2.31,4.93), p=0.003. At iodine/water material decomposition iodine content was higher in normal LN (29.7±10.3 µg/cm^3; 95% P-tiles 16.7,41.6) than in metastatic ones (25.0±8.6 µg/cm^3; 95% P-tiles 12.4,37.1), p=0.002. There was no significant difference between normal and metastatic LN at fat/iodine and water/iodine material decomposition. ROC curves were traced for the statistically significant parameters identifying an AUC of 0.6723 for iodine/fat decomposition density and an AUC of 0.6834 for iodine/water material decompositions. There was no significant inter-observer variability.
Conclusion: Multi-energy CT derived iodine/fat and iodine/water material decomposition differ significantly among normal and metastatic LN. Evaluation of iodine content by using multi-energy CT may help in differentiating normal from metastatic lymph nodes.

Preoperative sentinel lymphnode (SLN) identification and mapping using SPION-MR in patients with prostatic cancer

T.S. Paulo, A. Winter, S.S. Amin, T. Kowald, P. Goos, S. Engels, H. Gerullis, F. Wawroschek, A. Chavan; *Oldenburg/DE*
(amin.sandeepsunder@klinikum-oldenburg.de)

Purpose: We assessed the role of intraprostatic super para magnetic iron oxid nanoparticle (SPION) injection for preoperative detection and mapping of sentinel lymphnodes (SLN) with MRI in patients with prostatic cancer (Pca) scheduled to undergo radical prosatectomie. To our knowledge, this has not been reported previously.
Methods and Materials: In a prospective study approved by the ethical committee, 50 patients with intermediate and high-risk PCa (PSA >10 ng/ml and/or Gleason score ≥7) received a transrectal intraprostatic SPION injection 1 day prior to radical prostatectomy. MRI (T1, T2 and T2*) was performed preoperatively one day before and after SPION injection. The number and localization of the visualized SLN was noted. Intraoperatively, the SLN were identified with the help of a magnetometer, their anatomical location noted before resection. Diagnostic rate was defined as number of patients with at least one detected lymph node / total number of patients.
Results: No adverse events attributable to SPION injection were observed. The diagnostic rate was 100% (50/50). SPION injection identified 890 SLNs (median 17.5; IQR 12-22.5). The anatomic distribution of the SLNs was: external iliac 19.21%, common iliac 16.63%, obturator fossa 15.84%, internal iliac 13.82%, presacral 12.13%, pararectal 12.02%, paraprostatic 3.71%, paravesical 2.25%, and other regions 4.38%.
Conclusion: SLN identification with MRI after intraprostatic SPION injection is feasible. SPION-MR reliably identifies SLNs draining the prostate in a high number of patients, especially outside the established extended node template. It has the potential to generate a reliable preoperative SLN- template to assist lymphadenectomy.

Parathyroids: frequently overlooked or over-reported glands?

E. Scapin, A. Mereu, L. Saba; *Monserrato/IT*

Purpose: To analyse if a clinical request can drive sonographers to find parathyroids more frequently.
Methods and Materials: 14,968 neck or thyroid ultrasounds (11,835 females, 3,133 males, age range 0-97 years), performed by a team of several sonographers, were retrospectively assessed. Included cases were categorised into four groups: ultrasounds performed because of clinical requests concerning parathyroids, in which these were found or not and ultrasounds performed because of clinical requests not concerning parathyroids, in which these were found or not. We compared expected versus observed cases with a two-tailed Fisher's exact test.
Results: Parathyroids were observed in 484 cases (3.2%): ultrasounds were oriented by specific suspected pathologies in 219 cases (45.2%) and were not in 265 cases (54.8%). In 1 case only (0.4%) suspected pathological parathyroids were not visualised, thus giving a success rate of 99.6%. Parathyroids were observed in a mere 1.8% of ultrasounds performed when it has not been provided a clinical request concerning them. Out of 220 suspected parathyroid pathologies, only 44 ones were confirmed; whereas 50 cases were found incidentally, instead of 22 cases expected according to epidemiology. By comparing expected versus observed cases, with a two-tailed Fisher's exact test, we found a statistically significant difference (p value<0.001).
Conclusion: Effective exploration of parathyroids is difficult, and this somewhat challenging examination could stimulate the sonographer to find them only when requested and rarely if not. Our findings demonstrate that there could be a vast mismatch between expected and observed cases if parathyroid pathology is suspected or not.

B-1305 14:08

Diagnostic value of shear wave elastography for parathyroid lesions and comparison with cervical lymph nodes

A.V. Polat, M. Ozturk, B. Akyuz, C. Celenk, C. Polat; *Samsun/TR*
(dr.mesutozturk@gmail.com)

Purpose: The aim of this study was to prospectively assess the feasibility of the Virtual Touch tissue imaging quantification (VTIQ) method of Shear Wave Elastography (SWE) for the discrimination of parathyroid lesions and to compare the lesions' stiffness with that of cervical lymph nodes.
Methods and Materials: Institutional review board approval and written consent from all participating patients were obtained for this study. SWE using VTIQ was performed on 87 histologically proven parathyroid lesions and 31 cervical lymph nodes in 95 patients. Tissue stiffness was calculated as shear wave velocity (SWV) in meters per second (m/s) and two consecutive measurements were performed. Mean SWV of the lesions was compared and receiver operating characteristic curve analysis was used to evaluate diagnostic performance. Agreement between the measurements was assessed with intra-class correlation coefficient.
Results: Pathology results revealed 54 parathyroid adenomas and 33 parathyroid hyperplasia. Mean SWV of parathyroid adenomas (2.16 ± 0.33 m/s) significantly differed from parathyroid hyperplasia and lymph nodes (1.75 m/s ± 0.28 m/s and 1.86 ± 0.37 m/s respectively, p < 0.001). Selecting a cut-off value of 1.92 m/s for diagnosing adenoma led to 80% sensitivity and 70%specificity (AUC: 0.780 (95% CI: 0.697-0.864), p < 0.001). Agreement of the two SWV measurements was excellent as the intra-class correlation coefficient was 0.960 (95% CI: 0.943-0.973, p < 0.001).
Conclusion: The VTIQ method of SWE contributes to the discrimination of parathyroid adenoma from parathyroid hyperplasia and cervical lymph node.

B-1306 14:16

The 5-tiered categorisation system based on the 2015 ATA guidelines for classifying a small thyroid nodule on ultrasound: comparison with the modified 4-tiered categorisation system

J. Lee, K. Han, E.-K. Kim, H. Moon, J. Yoon, V.Y. Park, J. Kwak; *Seoul/KR (easywg@yuhs.ac)*

Purpose: To compare stratification of malignancy risk in small thyroid nodules with the 5-tiered categorisation system and the modified 4-tiered categorisation system based on the 2015 American Thyroid Association (ATA) management guidelines.
Methods and Materials: From January 2015 to December 2015, 737 thyroid nodules measured ≥1 cm and <2 cm in 723 patients were included in this study. Ultrasound (US) features of these lesions were evaluated retrospectively. Each nodule was assigned a category with the US patterns described by the 2015 ATA guidelines and the modified 4-tiered categorisation system. Univariate analysis was performed to assess malignancy risk in thyroid nodule and diagnostic performances were calculated for each category and compared.
Results: In total, 737 thyroid nodules were assessed. On univariate analysis, there was no significant difference of malignancy risk between low suspicion and very low suspicion of malignancy nodules (P=0.584). Therefore, we suggested a modified 4-tiered categorization system which combines very low suspicion nodules and low suspicion nodules into one category, the very low suspicion nodules. When comparing the diagnostic performances of the 2015 ATA guidelines and the modified 4-tiered categorisation system, specificity, PPV, and accuracy were higher with the modified 4-tiered categorisation system (P<0.001 for all), whereas sensitivity, and NPV were not significantly different (P=0.087, and P=0.370).
Conclusion: The modified 4-tiered categorisation system allows more efficient management with better diagnostic performance and avoiding unnecessary FNA than the 5-tiered categorisation systemof the 2015 ATA guidelines in small thyroid nodules.

B-1307 14:24

Efficacy of ultrasound elastography in diagnosing thyroid lesions and correlation with FNAC or biopsy

P. Dhayalan, D.S. Phansalkar, K. Chokka, H. Rao; *Pondicherry/IN (dsphansa@yahoo.com)*

Purpose: To determine shear wave velocity values of thyroid lesions using Virtual Touch Tissue Quantification (VTTQ) method by Acoustic Radiation Force Impulse (ARFI) technique of ultrasound elastography for differentiating malignant from benign lesions. To correlate shear wave velocity values with FNAC or biopsy results of thyroid lesions. To assess the sensitivity and specificity of ultrasound elastography shear wave velocity values in differentiating malignant and benign thyroid lesions.
Methods and Materials: Prospective diagnostic study of ultrasound elastography was done to determine shear wave velocity values of 88 thyroid lesions proved by 2D ultrasound imaging in 86 patients on Siemens Acuson S-2000. The findings were correlated in all patients with FNAC or biopsy results. Statistical methods were ROC curve and likelihood ratio analysis.
Results: Out of 88 lesions, 15 (17%) were malignant and 73 (83%) were benign on FNAC or biopsy. The optimal cut-off point for shear wave velocity values in differentiation was 2.87m/s. The mean shear wave velocity was 2.17±0.84m/s for benign and 6.17±2.72m/s for malignant lesions. The sensitivity was 86.7%, specificity 94.5%, positive predictive value 76.5%, negative predictive value 97.2%, accuracy 93.2%, positive likelihood ratio 15.76 and negative likelihood ratio 0.14 for shear wave velocity values in differentiating malignant from benign thyroid lesions.
Conclusion: Shear wave velocity estimation by ultrasound elastography has high potential to differentiate malignant from benign lesions and can reduce unnecessary invasive FNACs/biopsies.

B-1308 14:32

Acoustic radiation force impulse imaging in the differentiation of benign and malignant thyroid nodules

N.N. Pandey, G. Pradhan, A. Manchanda, A. Garg; *New Delhi/IN (nirajpandey2403@gmail.com)*

Purpose: To evaluate the role of ultrasound elastography using Acoustic Radiation Force Impulse (ARFI) imaging in characterising and differentiating malignant vs benign thyroid nodules.
Methods and Materials: A total of 40 thyroid nodules were evaluated with conventional sonography and ultrasound elastography using Acoustic Radiation Force Impulse (ARFI) imaging. The final diagnosis was obtained from histologic findings.
Results: A total of 14 malignant and 26 benign nodules were diagnosed on the basis of histologic examination. Majority of the malignant thyroid nodules demonstrated presence of intranodular vascular flow, hypoechoic echotexture, absent halo, irregular margins and microcalcifications. However, a considerable overlap was noted in the sonographic features of malignant and benign thyroid nodules. On ARFI imaging, the mean shear wave velocity (SWV) values (mean ± SD) of malignant and benign thyroid nodules were 3.131±0.921m/s and 1.691±0.513m/s, respectively. A significant difference was observed between the mean SWV values of malignant thyroid nodules and benign thyroid nodules (p<0.0001). Applying a cut-off value of 2.53m/s, the sensitivity, specificity, and the area under ROC curve for the differentiation were 85.71%, 96.15%, and 0.922 respectively.
Conclusion: ARFI imaging is a promising elastography technique that provides quantitative information about tissue stiffness. It provides additional information and complements sonography as an effective diagnostic tool in characterising and differentiating benign from malignant thyroid nodules.

B-1309 14:40

Distinguishing benign from malignant thyroid nodules: utility of superb microvascular imaging and ultrasound elastography

H. Ahn, J. Lee, M. Seo, S. Park, B.I. Choi, J. Yoo; *Seoul/KR (ach0224@gmail.com)*

Purpose: To prospectively investigate the utility of the combined use of superb microvascular imaging (SMI) and ultrasound strain elastography in distinguishing benign from malignant thyroid nodules.
Methods and Materials: We analysed 52 thyroid nodules (malignant=26, benign=26) and a reviewer scored the likelihood of malignancy for three data sets (i.e., B-mode ultrasonography alone, B-mode ultrasonography + SMI, and B-mode ultrasonography + strain elastography). The area under the receiver operating characteristic curve (Az) values, sensitivities, and specificities of each data set were compared.
Results: The mean lesion size was 1.27cm (range, 0.4-4.6 cm). Among the three data sets, the B-mode ultrasonography + SMI set showed the greatest Az value (average, 0.917; range, 0.807-0.975); however, it was similar to that of B-mode ultrasonography alone (average, 0.888; range, 0.770-0.959) and B-mode ultrasonography + strain elastography (average, 0.902; range, 0.788-0.967). The sensitivity and specificity based on the management decision of whether to perform fine-needle aspiration (FNA) of B-mode ultrasonography alone was 96.2% and 11.5%, respectively. B-mode ultrasonography + SMI and B-mode ultrasonography + strain elastography showed similar sensitivity (92.3%) to but significantly higher specificity (34.6%) than B-mode ultrasonography alone (P=0.032).
Conclusion: The combined use of SMI and ultrasound strain elastography showed similar diagnostic performance to conventional ultrasonography alone in distinguishing benign from malignant thyroid nodules. Moreover, the combined use could increase the specificity in decision making for FNA without any change in sensitivity.

B-1310 14:48

Diagnostic performance of computer-assisted diagnosis in evaluating thyroid masses on ultrasonography

M. Seong, E. Ko, B.-K. Han, J. Shin, S. Hahn, J. Bae, J. Lee, S. Yang, J. Kim; *Seoul/KR (seong.minjung@gmail.com)*

Purpose: To evaluate and compare the diagnostic performance of breast ultrasonography (US)-dedicated computer-assisted diagnosis (B-CAD) and thyroid US-dedicated CAD (T-CAD) in assessing thyroid masses on US.
Methods and Materials: We prospectively collected US images of 372 thyroid masses in 329 consecutive patients. All lesions were histologically confirmed or had long term follow up images. US findings were recorded according to Korean Thyroid Imaging Reporting and Data System (K-TIRADS) by radiologists who were expert in thyroid US. B-CAD and T-CAD were applied by another radiologist who was blind to the pathologic result. We evaluated the sensitivity, specificity, accuracy of B-CAD and T-CAD, and compared the performance of both CADs and radiologists. We also analysed the agreement of US descriptions among the B-CAD, T-CAD and radiologists.
Results: Overall sensitivity, specificity, accuracy of radiologists were 72.5%, 99.2%, and 89.3%. B-CAD showed 46.3%, 78.2%, and 67.4%, while T-CAD showed 53.3%, 92.9% and 79.4%. T-CAD showed good agreement with radiologists on the final diagnosis (kappa = 0.632), while B-CAD showed fair agreement with others. Among the US descriptors, radiologist and T-CAD showed moderate agreement in describing margin, echogenicity, and composition (kappa = 0.468, 0.505, and 0.446). B-CAD showed poor or fair agreement with others, except moderate agreement in describing composition with T-CAD (kappa = 0.407).
Conclusion: T-CAD showed good agreement with expert radiologists in final diagnosis, and showed better performance than B-CAD. Although T-CAD did not show comparable performance with expert radiologists, is suggested to provide a good assistance in diagnosing thyroid mass on US.

Sonographic assessment for predictors of malignancy in Thy3a nodules

N.M. Hughes, A. Nae, J. Barry, L. Feeley, P. Sheahan; *Cork/IE (Nicolahughes@rcsi.ie)*

Purpose: Thy3a cytology poses difficult management decisions often leading to repeated ultrasound and FNA before undergoing diagnostic thyroid lobectomy. The purpose of this study was to assess sonographic features of these nodules for predictors of malignancy.
Methods and Materials: Preoperative ultrasounds of 67 patients with Thy3a cytology were retrospectively reviewed. The reviewing radiologist was blinded to histological diagnosis. Sonographic features evaluated included size, shape, echotexture, presence of a halo, margins, and micro- and macro-calcifications. All nodules were graded using the BTA classification system.
Results: There were 56 benign nodules and 11 malignant nodules. 4/11 malignant nodules were hypoechoic versus 12/56 benign thyroid nodules (p=0.44). 3/11 of the malignant nodules had a taller>wide shape versus 9/56 benign thyroid nodules (p=0.40). 8/56 benign thyroid nodules had irregular margins versus 3/11 malignant nodules (p=0.37). 4/11 malignant nodules had calcifications, 3 of which were microcalcifications compared with 17/56 of the benign nodules with any calcification, 13 of which were microcalcifications (p=0.73,p=0.72). 16/56 benign thyroid nodules and 3/11 malignant thyroid nodules had a halo (p>0.99). From the benign nodule group, 7/56 were correctly classified as benign(U2) and 26/56 were considered indeterminate(U3) but 23/56 were categorised as suspicious/malignant(U4/5). From the malignant nodule group, only 1/11 was classified as benign(U2), 4/11 were considered indeterminate(U3) and 6/11 were correctly categorised as suspicious/malignant(U4/U5).
Conclusion: 16.4% of Thy3a nodules were malignant. The histological and sonographic classification using the BTA guidelines did not correlate consistently in this subgroup. No statistically significant sonographic predictor of malignancy was identified when assessing Thy3a nodules.

B-1312 15:04

Role of ultrasound in predicting tumour invasiveness for follicular variant of papillary thyroid carcinomas

M.-r. Kwon, S. Hahn, J. Shin, J. Lee, S. Yang, J. Kim, M. Seong; *Seoul/KR (miri.kwon@samsung.com)*

Purpose: The purpose of this study was to assess the role of ultrasound (US) for predicting tumour invasiveness of follicular variant of papillary thyroid carcinomas (FVPTCs).
Methods and Materials: From Jan 2014 to May 2016, 151 patients surgically confirmed as FVPTCs were included. According to the pathologic analysis, we categorized FVPTCs into three groups (non-invasive follicular thyroid neoplasm with papillary-like nuclear features [NIFTP], invasive encapsulated FVPTC [iE-FVPTC], or infiltrative FVPTC [I-FVPTC]). The US pattern by the Korean Thyroid Imaging Reporting and Data System (K-TIRADS) and the American Thyroid Association (ATA) guidelines was assigned to each nodule. The correlation between the tumour invasiveness and the K-TIRADS category or ATA pattern was investigated using the Spearman's coefficient of rank correlation.
Results: Of total 152 FVPTCs, there were 48 NIFTPs (31.6%), 60 iE-FVPTCs (39.5%), and 44 I-FVPTCs (28.9%). Seventeen of the 152 FVPTCs (11.2%) were classified as “not specified” pattern by the ATA guidelines. All US characteristics of FVPTCs were significantly different according to tumour invasiveness (all P values ≤ 0.030). Tumour invasiveness significantly correlated positively with K-TIRADS (r = 0.591; P < 0.001) and ATA guidelines (r = 0.532; P < 0.001). According to both K-TIRADS and ATA guidelines, the most common subtype was NIFTP in low suspicion nodules (52.6% and 51.6%), iE-FVPTC in intermediate suspicion nodules (52.7% and 54.2%), and I-FVPTC in high suspicion nodules (82.5% and 69.4%), respectively.
Conclusion: US assessment with K-TIRADS and ATA guidelines is useful method for predicting tumour invasiveness for FVPTCs.

B-1313 15:12

Importance of thyroid microcalcifications in the absence of identifiable nodules

C. Whittle, E. Horvath, M. Garcia, C. Carrasco, J. Slater; *Santiago/CL (cwhittle@alemana.cl)*

Purpose: To analyse association of clinical and ultrasound (US) findings of thyroid microcalcifications in the absence of nodule with histological results. To determine the US and clinical findings associated with a higher risk of malignancy.
Methods and Materials: This was a IRB approved, retrospective study. All patients subject to US fine-needle aspiration biopsy (FNAB) for thyroid microcalcifications in the absence of sonographic nodules between 2008 and 2012 were identified. Demographic, clinical, US findings and pathological results were registered. Uni- and multivariable analysis was performed.
Results: 21 patients, mean age: 33.2 years (range 15 - 53 years). Mean age in patients with papillary carcinoma was 29.5 and 39 years in benign findings (p=0.0336). 18 patients were female (86%), no significant association among sex and cancer development was identified (p= 0.257). 11/21 patients had grouped microcalcifications and in 9 cases cancer was demonstrated. 10/21 patients had disperse microcalcifications and 4/10 had cancer. A non-statistically significant trend for association among cancer and grouped microcalcifications was found (p=0.063). 20/21 had findings suspicious for chronic thyroiditis. In all, Hashimoto’s thyroiditis was histologically confirmed. All patients with suspicious adenopathy in US (5/21) had FNAB positive for cancer. In multivariate analysis model for cancer, only age was significant OR=0.9 (p=0.05) with a discrimination capability of 79.3%. 13/21 patients had FNAB positive suspicious or diagnostic for cancer (62%). 11/13 had surgical thyroidectomy performed.
Conclusion: Our study suggests that the presence of thyroid microcalcifications without nodule is suspicious for papillary carcinoma. High suspicion should be considered in grouped microcalcifications in a background of Hashimoto’s thyroiditis.

B-1314 15:20

Utility of uptake rate in the thyroid bed measured by ^{123}I tracer study before ^{131}I radioactive iodine therapy for papillary thyroid carcinoma to predict treatment outcome

Y. Omiya, U. Motosugi, S. Ichikawa, T. Umeda, H. Onishi; *Yamanashi/JP*

Purpose: To predict the success of ^{131}I radioactive iodine therapy (RIT) for outpatients by measuring ^{123}I uptake rate in the thyroid bed in a pre-RIT tracer study.
Methods and Materials: Thirty-four patients (15 men and 19 women) with papillary thyroid carcinoma, who underwent total thyroidectomy and ^{131}I RIT, were included in the study. The mean age was 60.0 years (range, 37-80 years). Patients were enrolled from May 2011 to July 2016. No patients experienced distant metastases. An ^{123}I tracer study was performed before ^{131}I RIT, and the iodine uptake rate in the thyroid bed was measured. Initial RIT dose was 1,110 MBq ^{131}I. When RIT was completed with a single treatment, it was defined as “best indication.” We investigated whether “best indications” could be predicted using a pre-RIT ^{123}I tracer study. We analysed the following variables as potential “best indication” predictors: age, sex, tumour factor (lymph node metastasis, extrathyroidal extension, and differentiation), and the uptake rate in the thyroid bed after 4 and 24 hours.
Results: The uptake rate of ^{123}I tracer in the thyroid bed at 4 hours was significantly lower in the “best indication” group patients (n = 5; P = 0.0421), when compared to others (n = 29). No other significant differences were detected between the two groups. When 0.0033 was set as the cut-off value, negative predictive value was 100 % (5/5).
Conclusion: The uptake rate in the thyroid bed after 4 hours after in ^{123}I tracer study can predict “best indication” on ^{131}I RIT.

Hypointensity of the primary motor cortex in SWAN images at 3T in patients with amyotrophic lateral sclerosis

G. Donatelli, A. Retico, E. Caldarazzo Ienco, P. Cecchi, M. Costagli, L. Biagi, G. Siciliano, M. Tosetti, M. Cosottini; *Pisa/IT (graziella_donatelli@hotmail.com)*

Purpose: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease entailing both upper and lower motor neurons. Recent 7T-MR studies documented T2* hypointensity of deep layers of the primary motor cortex (M1) in ALS patients with severe upper motor neuron (UMN) impairment. Aim of this study was to investigate the ability of SWAN images in the assessment of M1 signal changes in ALS patients at 3T compared to 7T.
Methods and Materials: Nineteen ALS patients and 10 healthy subjects underwent a 3T-MR exam including a 3D multi-echo T2*-weighted sequence targeting M1. Signal intensity of M1 was assessed both visually by two observers and using a semiautomatic procedure. After drawing M1 profile, the algorithm produced a curve representing the average signal intensity along the

profile normalized with respect to that of the splenium of corpus callosum. M1 hypointensity was measured by the height of such curve. UMN impairment of patients was clinically assessed using the UMN-scale. Non-parametric statistics and ROC curve were used for analysis.
Results: At visual assessment, sensitivity was lower at 3T (0.42 and 0.58, respectively, for the two observers; inter-observer agreement=0.69) than that at 7T. At semi-quantitative analysis, M1 signal intensity was lower in patients than in controls ($p<0.0001$); sensitivity and specificity were 0.79 and 0.83 (AUC=0.88). In patients, M1 hypointensity correlated with the UMN impairment ($r=0.60$; $p<0.0001$).
Conclusion: Despite the unsatisfactory accuracy of qualitative assessment at 3T, semi-automated algorithms could increase the sensitivity in evaluating M1 signal changes in ALS patients with moderate-severe UMN impairment, reaching 7T performance.

Retinal neurodegeneration is associated with structural MRI markers of cerebral neurodegeneration

U. Mutlu, M.A. Ikram, P. Bonnemaijer, L.G.M. Cremers, W.J. Niessen, C.C.W. Klaver, M.I. Ikram, M.W. Vernooij; *Rotterdam/NL (u.mutlu@erasmusmc.nl)*

Purpose: Retinal neurodegeneration, quantified using optical coherence tomography (OCT), is considered a potential biomarker for cerebral neurodegeneration, evaluated on magnetic resonance imaging (MRI). We investigated the association of retinal nerve fiber layer (RNFL) and ganglion cell layer (GCL) on OCT with structural markers of cerebral neurodegeneration on MRI.
Methods and Materials: We included 2585 participants (age&gt45 years) from the population-based Rotterdam Study (2007-2012) who had gradable quality OCT images and cerebral MRI scans. Thickness of RNFL and GCL were measured on OCT images. Structural markers of cerebral neurodegeneration were assessed on MRI. Associations between retinal layer thickness and structural MRI markers were examined using linear regression models, adjusting for age, sex, intracranial volume, and cardiovascular risk factors.
Results: We found that thinner GCL was associated with smaller grey matter volumes, adjusted mean difference per standard deviation decrease in GCL: -0.032; 95% confidence interval: -0.055; -0.010). Also thinner RNFL was associated with smaller white matter volume: -0.033 (-0.056; -0.010). Furthermore, both thinner RNFL and GCL were associated with poor white matter microstructure, adjusted mean difference in fractional anisotropy per SD decrease in RNFL and GCL: -0.061 (-0.097; -0.026) and -0.067 (-0.104; -0.029), respectively. Finally, we found that thinner RNFL was associated with less hippocampal volume, adjusted mean difference per SD decrease in RNFL: -0.081 (-0.113; -0.049).
Conclusion: Retinal neurodegeneration is associated with micro-and macrostructural MRI markers of cerebral neurodegeneration. These findings suggest that specific changes in retinal layers may be considered as novel markers for cerebral neurodegeneration.

Dorsolateral putaminal hypointensity on diffusion-weighted imaging in differentiating parkinsonism-predominant multiple system atrophy from Parkinson's disease

K. Zheng, L. Ma; *Beijing/CN (zhengkuihong1971@sina.com)*

Purpose: To evaluate the diagnostic value of dorsolateral putaminal hypointensity on diffusion-weighted imaging (DWI) for differentiating parkinsonism-predominant multiple system atrophy (MSA-p) from Parkinson's disease (PD).
Methods and Materials: Eleven patients with MSA-p, 18 patients with PD and 30 age-matched controls were included. All subjects were examined with 3.0 T MRI using conventional and DWI protocol. Putaminal atrophy, slit-like T2-hyperintense rim of the dorsolateral putamen, and hypointensity on DWI were evaluated. The pattern of dorsolateral putaminal hypointensity on DWI was measured using a visual grading scale.
Results: Putaminal atrophy, slit-like T2-hyperintense rim, and dorsolateral putaminal hypointensity on DWI (with a score ≥2) were recognised in MSA-p patients in 54.5% (6/11), 63.6% (7/11) , and 81.8% (9/11), respectively, but in none of PD or control group. The score of putaminal hypointensity on DWI was significantly higher in MSA-p than in those of other groups ($p < 0.001$), and a score of ≥ 2 well-differentiated MSA-p from PD. The specificity and sensitivity of the dorsolateral putaminal hypointensity on DWI for distinguishing MSA-p from PD were 100% and 81.8%, respectively.
Conclusion: Dorsolateral putaminal hypointensity on DWI, along with both putaminal atrophy and slit-like putaminal T2-hyperintense rim, is a reliable MR imaging biomarker in differentiating MSA-p from PD.

The optimisation of magnetic resonance imaging pulse sequences in order to better detection of multiple sclerosis plaques

J. Abdolmohammadi; *Baharan/IR (Abdolmohammadi.jamil@gmail.com)*

Purpose: Magnetic resonance imaging (MRI) is the most sensitive technique to detect multiple sclerosis (MS) plaques. In some cases, the patients who were suspected to MS whereas MRI images are normal, but whether patients don't have MS plaques or MRI images are not enough optimised enough in order to show MS plaques? The aim of this study is evaluating the efficiency of different MRI sequences for better detection of MS plaques.
Methods and Materials: In this cross-sectional study which was performed at Shohada-E Tajrish in Tehran - Iran hospital between October, 2011 to April, 2012, included 20 patients who suspected to MS disease were selected and underwent routine brain Pulse sequences (Axial T2w, Axial T1w, Coronal T2w, Sagittal T1w, Axial FLAIR). Additional sequences such as: Sagittal FLAIR Fat Sat, Sagittal PDw-fat Sat, Sagittal PDw-water sat was also performed.
Results: The results in more than 19 lesions showed that, for the subcortical and infratentorial areas, PDWw sequence with fat suppression is the best choice, and in 33 plaques located in periventricular area, FLAIR Fat Sat was the most effective sequence than both PDw fat and water suppression pulse sequences.
Conclusion: Although large plaques may visible in all images, but important problem in patients with suspected MS is screening the tiny MS plaques. This study showed that for revealing the MS plaques located in the subcortical and infratentorial areas, PDw-fat sat is the most effective sequence, and for MS plaques in the periventricular area, FLAIR fat sat is the best choice.

Longitudinal diffusion tensor imaging in early stage Parkinson's disease

T. Minett[1], L. Su[1], E. Mak[1], R.A. Lawson[2], A. Yarnall[2], G.W. Duncan[3], R.A. Barker[1], D. Burn[2], J.T. O'Brien[1]; [1]*Cambridge/UK*, [2]*Newcastle upon Tyne/UK*, [3]*Edinburgh/UK (tsm34@medschl.cam.ac.uk)*

Purpose: To verify whether white matter microstructural changes are predictors of cognitive decline in Parkinson's disease (PD), and if longitudinal white matter microstructural changes differ between patients with PD with normal cognition and those with mild cognitive impairment (MCI).
Methods and Materials: A total of 123 patients with early PD were enrolled (48 PD-MCI and 75 PD-normal cognition) along with 49 controls. Participants were part of the ICICLE-PD (Incidence of Cognitive Impairment in Cohorts with Longitudinal Evaluation) study and underwent clinical, cognitive and DTI investigations at baseline and 18 months later. Baseline and longitudinal fractional anisotropy (FA) and mean diffusivity (MD) changes were analysed voxelwise using Tract Based Spatial Statistics in generalised linear models. To verify if baseline FA and MD were independent predictors of cognitive decline, partial correlation (pr) analyses were performed. All analyses were controlled for age, sex, education, levodopa dose and visit intervals.
Results: At baseline, patients with PD had significantly higher widespread MD then controls regardless of their cognitive status. At follow-up, all groups showed a further significant FA decrease and MD increase. However, in patients with PD-MCI, MD deteriorated significantly faster in frontal brain areas when compared to those without MCI. Furthermore, baseline MD was a significant predictor of cognitive decline in patients with PD (pr 0.23; p 0.014).
Conclusion: MD represents an important correlate and predictor of cognitive decline in PD: DTI is potentially a useful tool in stratification of patients into clinical trials and to monitor the impact of treatment on cognition.

Evolution of brain lesions in patients with antiphospholipid syndrome: a longitudinal MRI study

P. Svrckova, R. Jäger; *London/UK (psvrckova@doctors.net.uk)*

Purpose: Patients with antiphospholipid syndrome (APS) are prone to neurological complications, mainly ischaemic, frequently despite full anticoagulation. We conducted a longitudinal study with serial follow up to determine what types of brain lesions occur and in what proportion they progress.
Methods and Materials: All available MRI brain studies of 34 patients with APS under follow up at our regional haematology center were retrospectively reviewed. The brain lesions were categorised by type, chronicity and location. Comparison was made with previous imaging where available and note was made of any new lesions.
Results: The mean imaging follow up time was 3.5 (range 1.5-9.7) years. Of the 34 patients, 3 were excluded because of other significant pathology; 5 had had no interval scan. Of the 26 patients with follow up imaging, 14 had no new lesions and 12 had new lesions. 5 had a normal initial scan. The most frequently encountered lesions on initial scan were rounded/confluent white

matter lesions (WML; N=18), cortical infarct (N=9), basal ganglia/thalamic infarct (N=7), linear/wedge shaped WML (N=4) and venous thrombosis (N=3). The most frequently occurring new lesions on follow up imaging were rounded/confluent WML (N=12), cortical infarct (N=6), basal ganglia infarct (N=3), venous thrombosis (N=3) and linear/wedge shaped WML (N=1).
Conclusion: Despite maximum anticoagulation, a significant proportion of patients with APS develop new lesions, mainly WML, cortical and basal ganglia infarcts. Linear WML could potentially be venous infarcts. There is a need for optimisation of anticoagulation therapy to minimise the frequency of new lesions and associated disability.

B-1321 14:57

Associations among cognitive functions, plasma DNA, and white matter integrity in patients with early-onset Parkinson's disease

Y.-S. Chen, M.-H. Chen, C.-H. Lu, P.-C. Chen, H.-L. Chen, I.-H. Yang, N.-W. Tsai, W.-C. Lin; *Kaohsiung/TW (qqqqqq4545@cgmh.org.tw)*

Purpose: Early-onset Parkinson's disease (EOPD) patients are symptomatic at a relatively young age. Few studies have reported cognitive impairments in EOPD with diverse results. Furthermore, it is unclear what microstructural white matter (WM) changes are present in EOPD patients. We therefore conducted this study to investigate the microstructural WM changes experienced by EOPD patients and their association with cognitive function and plasma DNA levels.
Methods and Materials: We enrolled 24 EOPD patients and 32 sex- and age-matched healthy volunteers that underwent complete neuro-psychological testing (NPT) to evaluate their cognitive function and diffusion tensor imaging (DTI) scanning to determine their fiber integrity. The plasma DNA measurements included measurements of nuclear and mitochondrial DNA levels. Fractional anisotropy (FA) maps were compared using voxel-based statistics to determine differences between the two groups. The differences in DTI indices and NPT scores were correlated after adjusting for age, sex, and education.
Results: Our results demonstrate that EOPD patients have elevated nuclear DNA levels and wide spectrums of impairments in NPT, especially in the executive function and visuospatial function domains. Exploratory group-wise comparisons of the DTI indices revealed that EOPD patients exhibited lower DTI parameters in several brain locations. These poorer DTI parameters were associated with worse cognitive performances and elevated plasma nuclear DNA levels, especially in the anterior thalamic radiation region.
Conclusion: Our findings suggest that thalamus and its adjacent anterior thalamic radiation may be important in the pathogenesis of EOPD, as it appears to become involved in the disease process at an early stage.

B-1322 15:05

The morphometric parameters in MRI for differentiation progressive supranuclear Palsy from Parkinson's disease, multiple system atrophy and controls

E. Aydin[1], C. Eraslan[1], A. Acarer[1], E. Akyuz[2], Z. Colakoglu[1], C. Callı[1], O. Kitis[1]; [1]*İzmir/TR*, [2]*Aydın/TR (elcinaydin09@yahoo.com.tr)*

Purpose: The aim of this study was to evaluate the accuracy of magnetic resonance parkisonism index (MRPI) and cerebral peduncle angle compared with the other MRI measurements, in distinguishing progressive supranuclear palsy (PSP) from Parkinson's disease (PD), multiple system atrophy (MSA) and controls (C).
Methods and Materials: Nine PSP patients, 8 MSA patients, 6 PD patients, and 7 control subjects underwent MRI and, for each patient the pons area-midbrain area ratio (P/M) and MCP width-SCP width ratio (MCP/SCP) were used, and an index termed MR parkinsonism index was calculated [(P/M) _ (MCP/SCP)] and also the cerebral peduncle angle, that is, the angle between the two cerebral peduncles was measured. Differences in MR imaging measurements among groups were evaluated with Tukey HSD, Kruskal-Wallis test and Bonferroni correction.
Results: P/M and MCP/SCP were significantly larger in patients with PSP than in patients in MSA, PD and C groups. MRPI index value was significantly larger in patients with PSP (median, 17,75) than patients with PD (median, 7.42; P< .001), and control participants (median, 9.73; P <.001). The cerebral peduncle angle measurements were 64.28° (SD, 6.03°) in PSP patients, 54.79° (SD, 7.43°) in C group, 55.56° (SD, 1.15°) in patients with MSA, and 56.75° (SD, 2.07°) in patients with PD. MRPI and cerebral peduncle angle measurement showed higher accuracy to distinguish PSP from other groups (100% sensitivity and specificity).
Conclusion: MRPI and the cerebral peduncle angle are useful criterion for differentiating patients with PSP from PD, MSA patients and healthy persons.

B-1323 15:13

Combined R2* maps generated by IDEAL-IQ and cerebral blood flow by 3D-ASL as markers of cognitive deficit in Parkinson's disease

R.-H. Yan, X. Wei, J. Wang, Q. Wang; *Guangzhou/CN (yanrh@mail3.sysu.edu.cn)*

Purpose: To identify a PD-specific MRI pattern using combined iterative decomposition of water and fat with echo asymmetry and least-squares estimation quantitation (IDEAL-IQ) sequence and three-dimensional arterial spin labelling (ASL) to discriminate early cognitively impaired PD (PD-CI) from cognitively normal subjects and evaluate disease status.
Methods and Materials: Twenty-one PD-CI and 20 cognitively normal PD (PD-CN) patients,and 22 healthy controls underwent 3T MRI examination with R2* maps and cerebral blood flow (CBF) measurements. R2* and CBF in cerebral regions of interest (ROIs) were compared between three groups. Pearson's and Spearman's rank correlation analyses were performed to evaluate correlations between the above variables and clinical parameters. The stratified five-fold cross-validation was conducted to determine the efficacies of combined MRI parameters in evaluating cognitive status and diagnosing PD.
Results: Compared with controls, there was a susceptibility effect reflecting hyperintense on R2* maps in substantia nigra (SN) in both of PD-CI(p=0.001) and PC-CN (p=0.010),and declined perfusion in basal ganglia. The R2* in caudate nucleus (Cau) and putamen (Pu) were inversely correlated with cognitive deficit(Cau,r=-0.427,p=0.005;Pu,r=-0.321,p=0.041), whereas a positively correlation was observed between CBF and MMSE score in PD patients(Cau,r=0.449,p=0.003;Pu,r=0.344,p=0.028) . Stratified five-fold cross-validation identified Cau CBF and Pu R2* and the combination of them offered excellent accuracy (AUC 0.838) in distinguishing PD-CI from PD-CN.
Conclusion: This study characterises a multimodal approach using combined IDEAL-IQ and 3D-ASL for monitoring PD. These results demonstrate the changes in Cau CBF and Pu R2* values might serve as potential markers of early-stage cognitively impaired PD.

B-1324 15:21

White matter volume loss in amyotrophic lateral sclerosis: a metanalysis of voxel-based morphometry studies

G. Chen, B. Zhou, X. Huang, Q. Gong; *Chengdu/CN (cgx23ly2002@163.com)*

Purpose: To identify statistical consensus between published studies for white matter (WM) volume in amyotrophic lateral sclerosis (ALS).
Methods and Materials: A systematic search was conducted for the relevant studies with voxel-wise analysis of the WM volume in ALS. Effect-size signed differential mapping (ES-SDM) was applied to analyse the WM volume differences between ALS patients and healthy controls. Meta-regression was used to explore the effects of clinical characteristics on WM volume in patients with ALS.
Results: A total of 11 studies with 16 datasets including 283 patients and 255 healthy controls were identified. The pooled metanalysis revealed significant WM volume reductions in bilateral supplementary motor area (SMA), bilateral precentral gyri (PG), left middle cerebellar peduncle and right cerebellum in ALS patients relative to healthy controls. Fibre tracking indicated that the main WM tracts involved were the corticospinal tract, interhemispheric fibres running through the SMA, subcortical arcuate fibres and projection fibres to the striatum running through the PG, projection fibres from the cerebral cortex to pons and cerebellum running through the middle cerebellar peduncle. The ALSFRS-R was positively correlated with decreased WM volume in bilateral SMA. The duration of illness was negatively correlated with WM volume reduction in the right SMA and right PG.
Conclusion: This study provides a thorough profile of WM volume loss in ALS and further evidence that the involved brain regions include both motor and extramotor areas, supporting the view of ALS being a multisystem degenerative disorder.

B-1325 14:00

Volume-based histogram analysis of breast cancer (BC) before neoadjuvant chemotherapy (NAC): could MRI features predict tumour response?

C. Losio, A. Della Corte, M. Panzeri, P. Panizza, A. Del Maschio, F. De Cobelli; *Milan/IT (claudiolosio@yahoo.it)*

Purpose: Response of locally advanced BC to NAC is difficult to predict. Identification of predictive factors with multiparametric breast MRI has been attempted by tracing peritumoural ROIs on axial images, with non-univocal results. Volume-based histogram analysis of MRI parameters, including first-order texture kinetics, is an emerging method for a more accurate assessment of tumour heterogeneity, intrinsic to more aggressive subtypes. Our work has explored the relationship between this analysis and subsequent response to NAC.
Methods and Materials: Sixty-nine patients with locally advanced, biopsy-proven BC, eligible for a taxane and anthracycline-based regimen, were retrospectively selected. Image data from baseline MRI (T2-TurboSpinEcho, DWI with b-values of 0.900 s/mm^2, T1-GradientEcho dynamic study) were post-processed (OLEA Sphere 2.4, Olea Medical), generating maps for apparent diffusion coefficient (ADC), T2 signal intensity and all perfusion semiquantitative parameters. Peri-lesional Volume of interest (VOI) was semiautomatically drawn on these maps, and a histogram analysis including first-order texture kinetics was performed for each parameter. Correlations between these values and response to NAC (evaluated on the surgical specimen) were finally assessed with univariate and multivariate analysis.
Results: Univariate analysis revealed a significant association between non-responders and higher AUCmax (p value=0.0338), AUCrange (p value=0.0311), TME75^{percentile} (p value=0.0452), and lower washout (10,20,25,30^{percentile} p value<0.05). A multivariate model was found for prediction of non-response, based on lower TMEmin (LogOR=-3.2202) and T260^{percentile}. No mean values yielded significant results.
Conclusion: Histogram-derived texture analysis of MR images can identify potential predictors of non-response to NAC, in women affected by locally advanced BC. A more heterogeneous angiogenesis, the presence of fibrosis or necrotic areas seem to be markers of chemoresistance.

B-1326 14:08

MR imaging after neoadjuvant therapy in subtypes of locally advanced breast cancer - correlation with predictive pathologic models of response

R.M. Lorente Ramos, J. Azpeitia Armán, T. Rivera García, M. Lara Alvarez, A. Martín Escobedo; *Madrid/ES (rlorenter@yahoo.es)*

Purpose: To review correlation of magnetic resonance (MR) imaging findings in patients with Neoadjuvancy, with different pathological systems of response evaluation, including Miller Payne and Residual Cancer Burden.To analyse correlation of the differente types of radiological response to neoadjuvant therapy in different tumour subtypes.
Methods and Materials: We retrospectively reviewed 53 patients with locally advanced breast cancer undergoing neoadjuvant therapy (NAC) previous to surgery between January 2009 and February 2015. Pre and posttreatment dynamic MR and diffusion-weighted sequences were performed. Parameters that were evaluated: on pathology tumour response was clasified according to Miller-Payne System based on changes in cellularity and grade and response in lymph nodes, and Residual Cancer Burden system.On MR: T2 signal, changes in tumour size, type and percentage of response, contrast enhancement kinetics, apparent diffusion coefficient (ADC), and response in lymph nodes.
Results: Tumour phenotypes were Luminal A (16.6%), Luminal B (43%), Triple Negative (16.6%), HER2+ (23%). After NAC, pathological complete response (pCR) was found in 30% of cases. On MR response was complete in 23%, and partial in 63%: fragmentation in 20% and concentric shrinkage in 43 %. Failures in MR-pathology correlation were found mostly in patients with fragmentation type response.
Conclusion: MR correlation with pathology is high in the evaluation of response both with Miller-Payne and RCB systems. Response may be overestimated by MR in patients with non-mass lesions and fragmentation response when residual tumour consists of small or scattered foci. MR stimation shows better correlation in patients with triple negative and Her2 subgroups.

B-1327 14:16

The relationship between tumour response to neo-adjuvant chemotherapy and response patterns seen on breast MRI

B. Goorts, K. Dreuning, J. Houwers, L. Kooreman, M. Moosdorff, T. van Nijnatten, E. Boerma, M. Smidt, M.B.I. Lobbes; *Maastricht/NL (marclobbes@planet.nl)*

Purpose: To investigate the relationship between breast MRI and histopathological tumour response patterns in patients treated with neoadjuvant chemotherapy (NAC).
Methods and Materials: Breast cancer patients treated with NAC and having baseline and half-way breast MRI exams in 2012-2015 were considered. Exclusion criteria were previous ipsilateral breast surgery, previous systemic treatment because and presence of distant metastasis at time of diagnosis. Tumours were classified into six shrinkage patterns: type 0 (complete radiologic response); type 1 (>5mm concentric shrinkage without surrounding lesions); type 2 (concentric shrinkage with crumbling and surrounding lesions); type 3 (crumbling: shrinkage into residual multinodular lesions); type 4 (stable disease, i.e. no increase or decrease of >5mm); type 5 (progressive disease). Percentage of patients with good pathologic tumour response (>50% tumour reduction, Pinder 1-2ii) for each MRI response pattern was calculated.
Results: Eighty primary breast tumours (76 patients) were included. Tumours with type 0, 1 or 3 pattern had significantly higher good pathologic response rates compared to type 2 or 4 (p<0.001). All crumbling tumours (type 3) showed good pathologic response. Tumours with type 0 or 1 pattern showed good pathologic response in 80% and 93%. Tumours with type 2 or type 4 pattern showed 47% and 40% good pathologic response. No tumour showed type 5 response.
Conclusion: Tumour response patterns on breast MRI are correlated to pathologic tumour response. Crumbling tumours on MRI have highest good pathologic response rates and tumours that don't show response halfway chemotherapy (type 4) show lowest response rates.

B-1328 14:24

Results of diffusion-weighted and dynamic contrast-enhanced MRI as biomarkers for evaluation of breast cancer response to neoadjuvant chemotherapy

O.S. Shliapkina, E.A. Mershina, Y.N. Nenakhova, V.E. Sinitsyn, V.K. Lyadov; *Moscow/RU (shlyapkinaolga571@gmail.com)*

Purpose: To analyse the changes of apparent diffusion coefficient (ADC) and contrast enhancement during neoadjuvant chemotherapy (NAC) for prediction of breast cancer response.
Methods and Materials: 23 patients (55±10 y.o.) with pathologically proven breast cancer T2-T4 stages (TNM) who underwent NAC followed by surgery were retrospectively enrolled. MRI was performed with 3T MR system before NAC, after 2rd and 4-6th NAC cycles including dynamic contrast-enhancement sequences and DWI. ADC value (mean of three tumour ROI), types of enhancement curves, percentage of wash-in and the largest tumour size were analysed. The patients had 2-5 grades of pathologic response based on the Miller-Payne system.
Results: The largest tumour diameter before treatment was 42±19mm. After NAC it significantly decreased to 24±13mm (p<0.01, t=4.259). Percentage enhancement in arterial phase (wash-in) significantly decreased from 226±88% to 132±60% after NAC (p<0.01, t=3.607). Enhancement curves changed from washout and plateau types to slow progressive enhancement in 74%.The tumour ADC increased from 1.035±0.391x10^{-3}mm^2/s before treatment to 1.392±0.388x10^{-3}mm^2/s after treatment (p<0.01, t=3.417). The tumour ADC increased from 1.035±0.391x10^{-3}mm^2/s before treatment to 1.392±0.388x10^{-3}mm^2/s after treatment (p<0.01, t=3.417). ADC for grade 2 (4 pts) before NAC was 1.118±0.171x10^{-3}mm^2/s, after NAC - 1.250±0.215x10^{-3}mm^2/s; for grade 3 (10 pts) - 1.104±0.484x10^{-3}mm^2/s and 1.518±0.570x10^{-3}mm^2/s; for grade 4 (3 pts) - 1.057±0.514x10^{-3}mm^2/s and 1.453±0.385x10^{-3}mm^2/s; for grade 5 (6 pts) - 0.967±0.281x10^{-3}mm^2/s and 1.409±0.404x10^{-3}mm^2/s.
Conclusion: CE MRI and DWI showed significant changes after NAC. Their results could be used as imaging biomarkers to predict and assess pathologic response of breast cancer tumours to chemotherapy. Bigger population of patients should be investigated.

B-1329 14:32

Texture and geometrical analysis in breast MRI: prediction of response to neo-adjuvant chemotherapy (NAC)

M. Panzeri[1], C. Losio[1], P. Panizza[1], F. Gallivanone[2], A. Del Maschio[1], F. De Cobelli[1]; [1]*Milan/IT*, [2]*Segrate/IT (panzeri.marta@gmail.com)*

Purpose: The role of baseline breast MRI in predicting response to NAC is debated, mainly due to the lack of standardised and accurate methods for imaging biomarkers extraction. Both texture and geometrical analysis of MR images are new promising tools to evaluate tumour heterogeneity, but few studies evaluated their usefulness in breast cancer (BC). Our purpose was to assess the role of accurate quantification of MRI advanced parameters before the beginning of NAC.
Methods and Materials: We included 38 women with biopsy-proven locally advanced BC addressed to NAC and subsequent surgery at our institution. All patients underwent a baseline breast MRI (T2-TSE; DWI: b-value=0,900 s/mm2; T1-3D-FFE dynamic study) 2 weeks before NAC. Geometrical and textural features were extracted from ADC maps, T2 and subtraction images and a logistic regression model was applied to assess the correlation to pathological complete response (pCR).
Results: MR intensity-based features "Entropy" and "Skewness" were found to be correlated with pCR (p-value<0.05). Limiting the sample to Triple Negative tumours, the analysis showed that the geomatrical features "Compactness" and "Spherical disproportion" were found correlated with pCR. At multivariate analysis an independent statistically significant association was found (p< 0.05) between pCR, "Sphericity","Surface to Volume ratio", "Entropy", "Skewness", "Standard Deviation" "Uniformity" (p< 0.05), and "Variance".
Conclusion: Our results show that the features "Entropy" and "Skewness" are significantly associated with pCR. These two parameters are indexes of the tumoural heterogeneity. Multivariate analysis confirmed this result and also suggested that the geometrical properties of tumour volume could be related to pCR.

B-1330 14:40

Background parenchymal enhancement: correlation with pathological response after NACHT and tumour biological subtypes

L. Ballesio, S. Gigli, C. Boldrini, C. Catalano; *Rome/IT (adrenalina_1@hotmail.it)*

Purpose: To analyse the possible role of background parenchymal enhancement (BPE) in predicting response after neoadjuvant chemotherapy (NACHT) and to evaluate its correlation with the different biological tumour subtypes.
Methods and Materials: We reviewed the MR exams of 63 patients and classified the BPE intensity before and after NACHT according to the BIRADS lexicon (1: absent, 2: mild, 3: moderate, 4: severe). The tumours were classified based on their biological profiles as Luminal A, luminal B, HER2 + and triple negative. The final pathological response after chemotherapy was assessed on the surgical specimen classified according to Miller and Payne system as complete (CR grade 5), partial (PR grade 3-4) and non-response (NR grade 1-2). Fisher test was used correlate BPE with the final pathologic response and with the different tumour biological profiles.
Results: BPE intensity (1/2/3/4) was, respectively, 28/12/18/5 before NACHT and 52/8/3/0 after NACHT. We observed an overall decreasing trend of BPE intensity after NACHT (p<0.005). Premenopausal patients achieved a greater BPE decrease than postmenopausal women (mean reduction, respectively :1.0 and 0.4 , p<0.005). Triple-negative cancer was more frequently associated with marked BPE before treatment (p<0.02). 16 patients achieved pCR. We observed a statistic association between complete response and marked BPE reduction (p<0.001).
Conclusion: BPE intensity decrease should be proposed as a predictive response factor to NACHT. Triple-negative cancer often presents marked BPE before treatment.

B-1331 14:48

Predictive factor affecting residual metastatic axillary lymph node disease in patient with negative axillary imaging after neoadjuvant chemotherapy for breast cancer

N. Jung, W. Kim; *Daegu/KR (nari14133@gmail.com)*

Purpose: To evaluate predictive factors affecting residual metastatic axillary lymph node (ALN) in patients with negative axillary imaging after neoadjuvant chemotherapy (NAC) for breast cancer.
Methods and Materials: Among 206 eligible patients with breast cancers who underwent NAC and curative surgery, 154 patients (mean age, 46.7 years) showed no suspicious ALN in negative axillary imaging including ultrasound, MRI and PET/CT after NAC. Data collected included age, clinical T, N stage, initial tumour size, histologic grade, hormonal receptor (HR), human epidermal growth factor receptor 2 (HER2), Ki-67, and percent tumour size change (≥ 30% decrease, < 30% decrease). Multivariate logistic regression analysis was performed between patients with and without residual metastatic ALN.
Results: Of the 154 patients who showed negative axillary imaging, 55 patients (35.7%, 95% confidence interval [CI]: 26.9% - 46.5%) had residual metastatic ALN disease on surgical histology. Among them, 43 patients had 1 - 3 residual metastatic ALNs (27.9%, 95% CI: 20.2% - 37.6%) and 12 had more than 4 residual metastatic ALNs (7.8%, 95%CI: 4.0% - 13.6%). Clinical N stage (*P* = .075), low to moderate tumour grade (odd ratio [OR] = 5.2, *P* = .009), positive HR status (OR = 6.6, *P* = .003), negative HER2 status (OR = 2.6, *P* = .048) were independently associated with residual metastatic ALN.
Conclusion: Low to moderate histologic grade and positive HR status are predictors for residual metastatic ALN in patients with negative axillary imaging after NAC for breast cancer.

B-1332 14:56

Impact of image fusion technique for the localisation of the achieved clinically complete response (cCR) lesions in breast conserving surgery after neoadjuvant chemotherapy

S. Nakano, K. Fujii, T. Ando, T. Ishiguchi; *Nagakute/JP (snakano1@aichi-med-u.ac.jp)*

Purpose: An accurate evaluation of the extent of residual disease after neoadjuvant chemotherapy (NAC) for breast cancer appears essential for successful clinical outcomes. However, there are some limitations in the localisation of the achieved clinically complete response (cCR) lesions in breast conserving surgery (BCS). Recently, we have developed an image fusion technique (real-time virtual sonography; RVS). RVS can overlay a real-time ultrasound (US) image with the previously acquired MRI/CT/US images of the same site in real time. The objective of our study was to determine the relative accuracy of RVS in detecting US/MRI occult lesions after NAC.
Methods and Materials: Five breast cancer patients who achieved a cCR after NAC with stage IIA-IIB were enrolled in this study. All patients underwent mammography, US, MRI/CT, and RVS before and after NAC. MRI was performed with a 1.5-T scanner in the supine position using a flexible body surface coil to achieve the same position as that used in US. Based on MRI/CT/US results of pre-NAC, we determined the surgical resection area by using RVS.
Results: The average age of patients was 49. The mean lesion size on MRI was 23mm. Applying pre-NAC MRI/CT/US images in RVS, we accurately localised the resection area on the body surface and performed BCS on all patients. Three of five were diagnosed pathological CR, and all surgical margins were negative.
Conclusion: RVS is a useful imaging technique for the localisation of the achieved cCR lesions in breast conserving surgery after NAC.

B-1333 15:04

Early evaluation of pathological response to neoadjuvant chemotherapy in breast cancer using quantitative 1H-MRS

M. Signorini, L. Camera, I. Baglio, G. Meliadò, C. Cavedon, S. Montemezzi; *Verona/IT (manuel.signorini@alice.it)*

Purpose: The aim of this study was to retrospectively assess the accuracy of changes in choline signal-to-noise ratio (SNR) after the beginning of neoadjuvant chemotherapeutic treatment (NACT), with the aim of predicting the pathological response.
Methods and Materials: The study included 28 Patients with histological diagnosis of breast cancer who underwent breast Magnetic Resonance (MR) between June 2012 and February 2016. For each Patient, tumour volume at the diagnosis, after two NACT cycles and at the end of the treatment (six cycles) was calculated. MR-spectroscopy was also performed at the beginning and after two NACT cycles. All Patients underwent mastectomy and histological evaluation of the specimen to establish the pathological rate of response. Sensitivity, specificity, positive (PPV) and negative predictive value (NPV) of choline SNR and volume changes as predictors of complete pathological response (cpr) were calculated; correlation between these parameters using Pearson correlation index was evaluated.
Results: SNR<2 after two NACT cycles to predict cpr showed sensitivity=83,3% (±29,8%, CI:95%), specificity=72,7% (±18,6%, CI:95%), PPV=45,5% (±29,4%%, CI:95%) and NPV=94,1% (±11,2%, CI:95%). There was no statistically significant difference between choline SNR and volume variation in distinguishing Patients achieving cpr from ones who did not. These two parameters showed a moderate correlation (ρ=0.5318), stronger in the subset of Patients with cpr (ρ=0,69) and weaker in that with a 10-50% residual cancer (ρ=0,43).
Conclusion: MRS showed moderate sensitivity, good specificity and high NPV in predicting early cpr after NACT. No statistically significant difference was observed between accuracies of MRS and volume variation.

B-1334 15:12

Comparative evaluation of MR spectroscopy choline signal-to-noise ratio (SNR) with ki-67 as a prognostic indicator

S.B. Grover, P. Jain, S. Suman, S. Jain, A. Mandal; *New Delhi/IN (shabnamgrover@yahoo.com)*

Purpose: Breast cancer is governed by several established histopathological prognostic parameters. Ki-67 is a nuclear protein, being used as a marker for cellular proliferation. Therefore, higher Ki-67 levels are associated with higher tumour grades. Prognostic factors help in individualistic management, decision on treatment protocols and in post treatment follow up. Imaging studies using choline detection as a marker of tumour aggressiveness are relatively newer techniques under evaluation for non-invasive prognosis prediction.
Methods and Materials: Forty-two female patients with newly diagnosed, biopsy proven breast cancer, larger than 2 cm, were included in the study approved by the Institute Review Board. Choline presence was recorded by MR proton spectroscopy using signal-to-noise (SNR), and was considered positive, when the peak was obtained at 3.2ppm with SNR>2.5. Ki-67 labelling index was obtained from biopsy specimens. The association between these two parameters, choline SNR and Ki-67, was estimated using the Spearmans rank correlation coefficient.
Results: Positive correlation was found between choline SNR and Ki-67 index with a correlation coefficient of 0.42 and p=0.005. Choline SNR was significantly higher for tumours with higher Ki-67 labelling index.
Conclusion: Significant correlation between choline SNR and histological prognostic factors indicates its potential role as a future non-invasive imaging biomarker in predicting tumour aggressiveness. Another promising application is the role of choline in predicting response to breast cancer treatment. Changes in choline levels within 24 hours after the first dose can serve as an early indicator for predicting clinical response to chemotherapy.

B-1335 15:20

Assessment of response to neo-adjuvant chemotherapy in breast carcinoma using shear wave elastography

V. Ramalingam, S. Hari, S.B. Paul, S. Thulkar, S. Vyas, A. Gogia, S.V.S. Deo, V. Seenu, S. Mathur, V. Sreenivas; *New Delhi/IN (drrvidyasagar@gmail.com)*

Purpose: Shear wave elastography (SWE) is a novel imaging technique for neo-adjuvant chemotherapy (NACT) response evaluation in breast cancer. Aim of this study is to evaluate NACT response in breast cancer using SWE.
Methods and Materials: Breast cancer patients scheduled for NACT were enrolled. B-mode ultrasound (US) and SWE were done prior to start of NACT (baseline), post-NACT after first and second cycles (between 7 and 14 days) and prior to surgery. SWE qualitative features -shape (Eshape), homogeneity (Ehomo), colour (Ecolour), and quantitative parameters of tissue stiffness - maximum (Emax), minimum (Emin), mean (Emean), ratio (Erat) were evaluated and baseline parameters and elasticity changes post-NACT were correlated with Miller-Payne scoring on histopathology post-surgery (gold standard).
Results: Twenty-eight patients with 29 masses were evaluated post-NACT. The mean baseline elasticity of responders (n=13) and non-responders (n=16) were not significantly different and showed poor correlation with Miller-Payne score (r=-0.086). The difference in mean elasticity (Δstiffness), however, was significantly higher in responders than in non-responders (49.50 Kpa vs 15.97 Kpa, P<.001) after the first cycle and showed the same trend on subsequent assessments. ROC analysis showed area under curve of 0.802 (p=0.001) for difference in the mean elasticity after first cycle. A Δ stiffness threshold for distinguishing between responders and nonresponders at 29.5 Kpa gives 83.3% sensitivity and 75% specificity. Of the qualitative parameters, Ecolour showed the best discrimination between responders and non-responders (p<0.05).
Conclusion: SWE is a promising technique to assess NACT response in breast carcinoma. Early prediction of NACT response using SWE would help tailor the management.

High prevalence of vitamin D insufficiency among radiologists: are we a profession at risk?

C.A. Agten, B. Fritz, S. Bensler, A.B. Rosskopf, L. Margaroli, C.W.A. Pfirrmann; *Zurich/CH (christoph.agten@gmail.com)*

Purpose: To assess prevalence of vitamin D insufficiency in radiologists. Our hypothesis was that radiologists have a higher prevalence of vitamin D insufficiency because of the generally dark working environment, compared to non-radiologists.
Methods and Materials: This study was approved by the local ethics committee. Informed consent was obtained from all participants. The study was conducted at the Swiss Congress of Radiology in May 2016. Attendees (radiologists and non-radiologists) were asked to give a venous blood sample to measure vitamin D(25-hydroxyvitamin) blood serum level. Vitamin D insufficiency was defined <50nmol/l. We collected information on age, gender, profession, vitamin D supplements, sunny vacation in the last two months, eating fish. We compared vitamin D between radiologists and non-radiologists.
Results: In total 301 blood samples, 137 radiologists (mean-age 38-years; 38.7% female) and 164 non-radiologists (mean-age 40-years; 65.9% female) were analysed. Mean vitamin D in radiologists was 49.7nmol/l, in non-radiologists 47.5nmol/l (p=0.374). Vitamin D insufficiency was more frequent in radiologists (58.4% (80/137) vs 53.7% (88/164)), however this was not statistically significant (p=0.479). 26 radiologists and 17 non-radiologists were under vitamin D supplementation with higher vitamin D than those without supplementation (70.4nmol/l vs 44.7nmol/l; p<0.0005). There was no difference in vitamin D between radiologists and non-radiologists without vitamin D supplementation (44.9nmol/l vs 44.6nmol/l; p=0.884). Subjects with a recent sunny vacation had higher vitamin D (55.0 vs 45.9nmol/l; p<0.0005). Eating fish had no relevant impact on vitamin D.
Conclusion: Vitamin D insufficiency is very common among radiologists (58.4%), but not significantly higher than in non-radiologists.

B-1337 14:08

Comparison study of growth plate fusion using MRI vs plain radiographs for age determination

A.A. Jain, N. Bahri, H. Parekh, S. Chudasama; *Jamnagar/IN (a.jain56@yahoo.com)*

Purpose: To compare the grade of fusion of the wrist distal growth plate between MRI and plain radiographs.
Methods and Materials: We conducted a study of twenty five cases, presented in span of 6 months. Patients were subjected MR imaging after taking informed written consent and ethical clearance of hospital committee was taken. Each participant had coronal T1-weighted MRI and plain radiograph of wrist. X-rays of wrist: 300m.A. Philips M.R.S. MRI- 1.5 TESLA 8 CHANNEL SIEMENS MAGNETOM ESSENZA (Germany).
Results: MRI of the wrist offers an alternative and superior non-invasive method of age determination in 13-18 year-old adolescents. The inter-rater reliability for grading was high (r=0.91 and 0.92); all correlations were highly significant (p<0.001). The average age increased with a higher grading of fusion, and the correlation between age and grade of fusion was highly significant (r=0.69, p<0.001).
Conclusion: Skeletal age is defined as the age at which healthy children of the same sex generally achieve the skeletal maturation stage for a determined chronological age. Thus, skeletal age should correspond to the chronological age in healthy children of the same sex in attaining a similar degree of skeletal development. The wrist was chosen as the distal radius and ulna epiphysial plates are the sites of maximal endochondral ossification and physeal fusion in the age group of interest. However, for the purposes of comparing the x-ray and MRI, the larger distal radial epiphysis was chosen. MRI has become very sensitive modality for detection of fusion of epiphysis.

B-1338 14:16

Computer-aided bone age assessment of the wrist and carpal bones in comparison to Greulich and Pyle atlas method

C. Booz, J.L. Wichmann, S. Martin, D. Leithner, A. Al Kamali, L. Lenga, M. Albrecht, T.J. Vogl, B. Bodelle; *Frankfurt a. Main/DE (boozchristian@gmail.com)*

Purpose: To investigate bone age assessment of the wrist and carpal bones in children using a computer-aided diagnosis (CAD) system and Greulich and Pyle (GP) atlas method.
Methods and Materials: Data from clinically indicated hand and wrist radiographs of 238 patients (137 male, 101 female) were included. Bone age of left radius and the carpal bones were analysed by two radiologists using GP atlas method. In comparison, the left distal radius of each patient was analysed by CAD system (BoneXpert). Correlations between bone age derived from CAD system and GP atlas method were performed by Pearson product-moment correlation coefficient and Bland-Altman analysis.
Results: Mean bone age of all distal radius determined by CAD was 9.6 years and of all left distal radius determined by two radiologists was 10.0 years. Mean bone age of all carpal bones estimated by two radiologists was 10.0 years. The statistic analysis demonstrated a higher correlation between bone age values of left distal radius determined by two radiologists and the CAD system (r=0.9697) than bone age values of left distal radius determined by CAD and the carpal bones determined by two radiologists (r=9.962).
Conclusion: The correlation between bone age values of left radius determined by radiologists and the CAD system was higher than bone age values of the left radius determined by CAD and the carpal bones. A method which determines the bone age without analysing the carpal bones should be more accurate than methods analysing the left hand including the carpals like the GP-method.

B-1339 14:24

Can initial radiographs prevent useless dual-energy CT for urate crystal detection in work-up of gouty arthritis?

T. Finkenstaedt, S. Kupfer, S. Winklhofer, S. Tok, A. Becker, H. Alkadhi; *Zurich/CH (tim.finkenstaedt@usz.ch)*

Purpose: Due to inherent methodological reasons, urate deposits can be detected with dual-energy CT (DECT) only in the presence of hyperdense soft tissue deposits when a certain attenuation threshold is exceeded. Thus, we examined whether initial radiographs are capable to rule in or out soft tissue deposits in the work-up of gouty acroarthritis.
Methods and Materials: This retrospective study included 143 patients (52 female, 57±12ys) with suspected gouty arthritis who underwent clinically indicated DECT of the hand/wrist (n=60) and feet/ankle (n=83). Two blinded readers independently evaluated DECT images for the presence/location of soft tissue and subsequently urate deposits. Additionally, both readers evaluated corresponding radiographs (standard projections) for the presence/location of soft tissue deposits 4 weeks later. Finally, both datasets (DECT/radiographs) were evaluated to examine whether the particular location/density of the deposits may influence the deposit detection likelihood on radiographs.
Results: Inter-reader agreement for detection of soft tissue/urate deposits with DECT was excellent (κ=0.91/0.92, respectively) as was its detection on radiographs (κ=0.95). DECT showed periarticular deposits in eighty-seven of the 143 patients (61%). Thirteen of these 87 patients (15%) only had detectable deposits on radiographs (p<0.05). In sixty-eight patients (92%) of the remaining 74 patients the low deposit density and in 6 patients (8%) the particular deposit location was regarded as the main reason for missed detection on radiographs.
Conclusion: Radiographs are not sufficiently capable to rule in or out soft tissue deposits and thus cannot aid a priori if a dual-energy CT is reasonable in the work-up of gouty acroarthritis.

B-1341 14:32

ETD score: a pre-surgical prognostic evaluation in acetabular labrum's pathology on magnetic resonance arthrography

S. Magnani[1], S. Sdao[2], M. Brioschi[1], E. Nocerino[1], C. Messina[1], S. Rapisarda[1], A. Aliprandi[1], F. Sardanelli[1]; [1]*Milan/IT*, [2]*San Donato Milanese/IT (dr.smagnani@gmail.com)*

Purpose: Nowadays surgeons have more treatment options in labrum's pathology and repair of the labrum allow better outcomes for patients in comparison to labrectomy. Arthro-MRI is the investigation of choice in the pre-surgical evaluation. Our aim is to investigate the prognostic value of a score called ETD, in the pre-surgical MRI evaluation of labrum pathologies.
Methods and Materials: 47 patients were selected who have made an arthro-MRI of the hip and subsequently they underwent arthroscopy with repair of the labrum or labrectomy. The pre-surgical arthro-MRI images were evaluated with 3D DESS sequence (Dual Echo Steady State) by a radiologist blinded to the arthoscopic results. We have identified 3 parameters generating the ETD score, an acronym of: E = extension of the lesion; T = thickness of the labrum, D = damage, indicating the type of structural damage. The resulting scores ranges from 3 points up to 10 with the higher values expressing an higher probability of labrectomy. The score differences between groups of patients were evaluated with the Mann-Whitney test.
Results: 35 of the 47 patients (74%), during arthroscopy underwent repair of the labrum, the remaining 12 patients (26%) were subjected to a labrectomy. The ETD score differences between the two groups of patients proved to be significant with a p<0.01.
Conclusion: Today the hip arthroscopy allows multiple therapeutic options in the treatment of labral damage. The arthro-MRI evaluation with the ETD score would allow a more complete prognostic evaluation during the pre-surgical phase.

Errors within the musculoskeletal system: anatomical based checklist derived from discrepancy meeting database

S.C. Chin[1], J.R. Weir-McCall[1], P.M. Yeap[2], R.D. White[3], M.J. Budak[1], G. Duncan[1], B. Oliver[1], I.A. Zealley[1]; [1]*Dundee/UK*, [2]*Leeds/UK*, [3]*Cardiff/UK (sookcheng@doctors.org.uk)*

Purpose: Discrepancy meetings are an integral part of continued professional development. Error types have been classified and but specific patterns of anatomical sites of error have not been previously evaluated in a systematic fashion. We set out to interrogate a large discrepancy meeting database with the aim of deriving a short "checklist" of specific anatomical review areas where errors occur commonly.
Methods and Materials: A discrepancy meeting database from a single centre was retrospectively reviewed from a period covering 5 years. Errors were classified by type, modality, body system and specific anatomical location. Frequency of anatomical location within the musculoskeletal system were then analysed to derive common anatomical locations of errors.
Results: There were 561 errors in 477 examinations, of which 125 (19.9%) occurred in the MSK system. Sixty eight errors occurred in the axial skeleton, 42 errors in the appendicular skeleton and 15 in the soft tissues. The most common sites for errors to occur were: spine (37), thoracic cage (12), pelvis (10), sacrum (7) and calvarium (7). Commonly missed pathologies were: missed metastases (35); overcalling of metastatic lesions in those with known primary non-bony malignancy (12); and missed fractures (7).
Conclusion: Over 50% of all perceptual errors occurred in just five anatomical sites suggesting an avenue for focused review at the end of reporting.

B-1343 14:48

Ampleness of pertinent patient history on MRI spine referral forms

A.H. Rajaram; *Bangalore/IN (akashrajaram@gmail.com)*

Purpose: To determine if clinician referrals for MRI spine provide adequate patient history and to establish if patient questionnaires can add valuable supplemental history.
Methods and Materials: 170 referrals for MRI spine were retrospectively identified from Jan 2015 to June 2015. Two radiologists independently reviewed patient history on referrals and rated the quality of the information as follows: 5 outstanding; 4 above average; 3 average; 2 below average; and 1 poor. Referrals were considered high quality for mean score ≥ 4.0 and low quality for mean score ≤ 2.0. Subsequently, they compared referral history with self-reported history from patient questionnaires and assigned a score on a 5-point scale: 5 referral clearly superior; 4 referral slightly more useful; 3 equal usefulness; 2 patient information slightly more useful; and 1 patient information clearly superior. Two cohorts were compared using unpaired t test, Fisher exact test, and chi-square test.
Results: The mean quality score ± SD was 2.86 ± 0.83 for all radiology referrals, with 2.84 ± 0.83 for clinician referrals versus 2.88 ± 0.83 for patient history (p=0.774). A total of 8.7% of all clinician referrals were of low quality and 17.0% were of high quality. In comparison of clinician referrals and patient questionnaires, patient history was superior to clinician referral history for 22.0%, equal for 64.0%, and inferior for 14.0%.
Conclusion: Clinicians provide low-quality patient history on 1 of every 12 MRI spine referrals. Patient questionnaires provide better or equivalent information than clinician referrals 86% of the time.

B-1344 14:56

Consultation in radiology: reducing unnecessary radiological examinations

S. Staparski Dobravec, Z. Kumše; *Ljubljana/SI*
(staparskidobravec@gmail.com)

Purpose: Clinical guidelines for managing back pain do not recommend x-ray imaging in 4-6 weeks from onset of pain. Strain on radiology departments with inappropriately indicated imaging of spine and pelvis, especially in patients from 25-45 years, has prompted introduction of non-mandatory consultations with radiologists.
Methods and Materials: Before x-ray imaging, radiologist interviews patients and estimates how data gained through imaging would affect further course of treatment. He excludes »red flags« and informs patients about effective dose of radiation they can expect to receive from imaging. A feedback to referral physicians is written report from radiologist. Our goal was to assess effectiveness and safety of new practice. A survey was sent to 497 patients, who had undergone consultation within past three years, as well as to 151 referring physicians. Response rate was 30% for patients, and 38% for physicians. We also analysed all referrals received within this period.
Results: Within three years, number of referrals to x-ray imaging of spine and/or pelvis has decreased by 39%. 52% of patients who had undergone the consultation, consequently decided not to have x-ray imaging and later showed no need for it. 95% of referral physicians who completed survey responded that practice is safe. 90% of patients assessed their consultation with radiologist as much as needed.
Conclusion: We believe that introduction of consultations with a radiologist is a simple and cost-effective measure that can reduce unnecessary exposure of the population to ionising radiation and bring relief to overburdened radiology departments.

B-1345 15:04

Structured reporting of dual-energy x-ray absorptiometry exams for osteoporosis evaluation: a time-saving approach to creating high-quality reports

F. Schoeppe, L. Sobez, J. Spiro, A. Curta, R. Bodensohn, M. Goepfert, F. Ceelen, E. Kampmann, W.H. Sommer; *Munich/DE*
(Franziska.Schoeppe@gmail.com)

Purpose: To compare reporting times and report quality of structured reports (SR) to conventional free text reports (FTR) of dual-energy x-ray absorptiomety exams (DXA).
Methods and Materials: FTR and SR of DXA were retrospectively generated by 2 radiology residents (RR) and 2 final year medical students (MS). Time was measured from the first view of the exam until the report was finished. A random sample of DXA reports was selected and sent to referring physicians for further evaluation of report quality.
Results: A total of 108 DXA reports (both FTR and SR) were generated and 48 randomly selected reports were evaluated by referring physicians. Reporting times were shorter for SR in both, RR and MS with median reporting times of 2.7min. (RR: 2.7, MS: 2.7) for SR and 6.1min. (RR: 5.0, MS: 7.5) for FTR. Information extraction was perceived to be significantly easier from SR vs FTR (P<0.001). SR were rated to answer the clinical question significantly better than FTR (P<0.007). Overall report quality of SR was rated significantly higher for SR compared to FTR (P<0.001) with 95.8% of SR vs 79.2% of FTR receiving of high or very high quality ratings. All participants (RR, MS and referring physicians) preferred SR over FTR for DXA.
Conclusion: Template-based SR of DXA might lead to shorter reporting times among residents as well as medical students. At the same time our results point to an increased report quality of SR compared to FTR.

Structured reporting for x-ray examinations of the shoulder: is there an advantage over free text reports?

F. Schoeppe, W.H. Sommer, F. Schmidutz, D. Pförringer, M. Armbruster, K.J. Paprottka, J.L.V. Plum, F.G. Meinel, N.N. Sommer; *Munich/DE*
(Franziska.Schoeppe@med.uni-muenchen.de)

Purpose: To analyse structured reports (SR) and free text reports (FTR) of shoulder x-ray examinations evaluating the quality of reports and potential contributions to clinical decision-making.
Methods and Materials: We acquired 62 reports (FTR and SR) of patients with suspected degenerative changes who received an x-ray examination of the shoulder. For the SR a template was created based on the template ID 0000154 (Shoulder x-ray) from radreport.org and using an online software with clickable decision trees with concomitant generation of semantic SR. All reports were evaluated with regard to key features in terms of content, information extraction, clinical value and overall quality of the report.
Results: 62 reports were reviewed by two experienced orthopaedic and traumatology surgeons (5 and 7 years). SR achieved significantly higher mean ratings in all of the evaluated key features (p<0.05). The information on osteoarthritis were more complete in SR than in FTR (median rating: 10.0 vs 5.0; p<0.05). Information extraction was perceived to be easier in SR than in FTR (10.0 vs 2.5; p<0.05). SR were considered to answer the clinical question better than FTR (10.0 vs 5.0, p<0.05). The overall quality of SR vs FTR reports was significantly higher in structured reports (p<0.05); all of the SR received a high or very high overall quality rating (100%) compared to only 21% of FTR.
Conclusion: Structured reporting of x-ray examinations of the shoulder might provide reports of higher quality and better clinical decision support. It may thus lead to a higher satisfaction of referring surgeons.

Middle patellar tendon to posterior cruciate ligament (PCL): a new index for tibial tubercle position in patients with patellar instability (PI)

G. Pozzi[1], I. Merli[2], J. Almolla[1], R. Mesquita[3], L.M. Sconfienza[1]; [1]*Milan/IT*, [2]*San Donato Milanese/IT*, [3]*Lisbon/PT (ilaria.merli@gmail.com)*

Purpose: Tibial tubercle to trochlear groove (TT-GT) and tibial tubercle to PCL (TT-PCL) have been proposed as measures to establish PI risk. However, they need image post-processing for accurate calculation. We propose an alternate, easier method to calculate PI risk.
Methods and Materials: We reviewed knee MR images of 30 patients (13F,17M;45±17y) with history of PI. MR images of 60 patients with no history of PI (36F,24M;32±13y) served as controls. TT-PCL was calculated on two superimposed T2-weighted axial images separately by two operators. Then, the same operators separately selected the axial image where the PCL root was seen. There, the middle point of PT was calculated. A line parallel to the posterior tibial plateau was traced, two lines passing for the middle PT and medial edge of PCL were traced, and their distance calculated (PT-PCL). Differences of TT-PCL and PT-PCL between patients and controls, their correlation, and interobserver reproducibility were calculated.
Results: PT-PCL distance was 23.5±3.8mm in patients and 20.0±2.7mm in controls (P<0.001). TT-PCL distance was 22.9±3.9mm in patients and 20.5±2.7 mm in controls (P=0.002). Correlation between PT-PCL and TT-PCL was r=0.838, P<0.001. Interobserver reproducibility of PT-PCL and TT-PCL was very high (ICC=0.894, CI95%=0.839-0.930 and ICC=0.866, CI95%=0.796-0.912, respectively).
Conclusion: PT-PCL significantly correlates with TT-PCL with high interobserver reproducibility. Thus, PT-PCL may represent an alternate index to calculate PI risk, with the great advantage of being calculated on a single MR image, with no need of post-processing. A PT-PCL value >21.75mm may be used for increased PI risk.

B-1348 14:08

Suprapatellar fat-pad signal alteration on MRI is associated with degeneration of the patellofemoral joint over 48 months: data from the OAI

B.J. Schwaiger, J. Mbapte Wamba, A.S. Gersing, M.C. Nevitt, L. Facchetti, C.E. McCulloch, T.M. Link; *San Francisco, CA/US*

Purpose: To analyse associations of suprapatellar fat-pad (SPFP) hyperintense signal alterations and mass effect with progression of patellofemoral osteoarthritis (OA) and symptoms over 48 months.
Methods and Materials: Subjects from the Osteoarthritis Initiative (n=426; 51.8±3.8 years; 49.8% women) without radiographic OA underwent 3T-MRI of their right knees and clinical evaluation using the Knee Injury and Osteoarthritis Outcome Score at baseline and 48-months. Elevated SPFP signal compared to surrounding tissue was assessed on IW fat-saturated FSE images. Mass

effect was defined as convex posterior contour. Patellofemoral cartilage, bone marrow lesions (BML) and subchondral cysts were assessed with the Whole-Organ Magnetic Resonance Imaging Score (WORMS). Associations of SPFP imaging findings with morphologic and clinical progression were assessed using adjusted general linear models and logistic regressions.
Results: Baseline SPFP signal alterations were found in 51% of the subjects (n=217), of which 11% (n=23) additionally had a mass effect. Cartilage progression was significantly higher in subjects with signal alteration versus without (adjusted mean increases, 95% CI; patella: 0.29 [-0.07, 0.64] vs -0.04 [-0.40, 0.31]; p<0.001; trochlea: 0.47 [0.16, 0.77] vs 0.31 [0.01, 0.61]; p=0.007). BML progression was more likely in subjects with signal alteration (OR 1.75, 95% CI [1.09, 2.82]; p=0.021). Mass effect was not associated with joint degeneration and SPFP imaging findings were not associated with clinical worsening (p>0.18 for all).
Conclusion: Patellofemoral joint degeneration assessed with MRI over 48 months was significantly increased in subjects with SPFP signal alteration, suggesting the relevance of SPFP pathologies for the progression of patellofemoral OA.

B-1349 14:16

Contribution of SWI at 3T: detecting intraarticular haemosiderin accumulation in haemophilia patients

B. Akyüz, A.V. Polat, M. Ozturk, K. Aslan, L. Tomak, M.B. Selcuk; *Samsun/TR (behicakyuz@gmail.com)*

Purpose: To prospectively assess the feasibility of susceptibility-weighted imaging (SWI) at 3T to detect intraarticular haemosiderin accumulation in haemophilia patients.
Methods and Materials: We obtained Institutional Review Board approval and informed consent from all participating patients for this study. Forty-one joints in 24 haemophilia patients were imaged with conventional magnetic resonance imaging (MRI) and SWI sequences. Two experienced musculoskeletal radiologists (readers 1 and 2), and one radiologist with less experience in musculoskeletal imaging (reader 3), independently and separately rated images for haemosiderin accumulation: the final decision on accumulation was consensually determined by two experienced radiologists with both conventional MRI and SWI sequences. Diagnostic consistency of each MRI sequence with the reference, plus pairwise agreement between interpreters, was assessed with kappa statistics.
Results: Given conventional MRI sequences, diagnostic consistency of readers 1 and 2 was substantial with the reference (κ = 0.670 and κ = 0.658, respectively), diagnostic consistency of reader 3 with the reference was moderate (κ = 0.539). Interobserver agreement of readers 1 and 2 was almost perfect (κ = 0.869), whereas reader 3 (in conjunction with readers 1 and 2) was also substantial (κ = 0.655 and κ = 0.684, respectively). SWI interpretation by all readers demonstrated nearly perfect agreement with the reference (κ = 1, κ = 0.959, and κ = 0.959, respectively). Interobserver agreement was again almost perfect for all readers (κ = 1, κ = 0.959, and κ = 0.959, respectively).
Conclusion: SWI is an accurate and reliable method for determining intraarticular haemosiderin accumulation.

B-1350 14:24

MRI evaluation of knee osteochondritis dissecans treated with a cell-free biomimetic osteochondral scaffold vs microfracture technique: a multicenter randomised experience

L. Tonetti, M. Busacca, C. Tetta, A. Moio, S. Durante, G. Filardo, E. Kon, U. Albisinni, F. Perdisa; *Bologna/IT (lauratonetti.md@gmail.com)*

Purpose: To compare two arthroscopy approaches, biomimetic osteochondral scaffold implantation and microfractures, in treatment of knee osteochondritis dissecans (OCD) and to evaluate articular osteocartilaginous tissue's regeneration, using modified magnetic resonance observation of cartilage repair tissue (MOCART) score.
Methods and Materials: Thirty patients, affected by symptomatic knee OCD, were prospectively enrolled. Fifteen patients were treated with implantation of a three-dimensional multi-layered scaffold. The other fifteen patients underwent surgery treatment using Steadman microfracture technique. Two blinded radiologists, with more than 25 years of musculoskeletal imaging experience, prospectively evaluated MRI examinations, performed with a specific protocol at 1.5 or 3.0 Tesla, 6, 12 and 24 months after treatment, in 10 European centres. Modified MOCART score was assigned in MRI examinations.
Results: Modified MOCART score was compared among two groups of patients at 2-year follow-up. In group treated with biomimetic osteochondral scaffold implantation, 9 patients (60%) revealed improvement of modified MOCART score, in 2 patients (13.3%) MOCART score did not change and in the remaining 4 patients (26.7%) MOCART score decreased. In group which underwent surgery treatment with microfracture technique, 6 patients (40 %) showed MOCART score increased, in 3 patients (20 %) MOCART score did not change and in the remaining 6 patients (40 %) there was a decrease of MOCART score.
Conclusion: Biomimetic osteochondral scaffold was demonstrated to be a valid treatment option for knee OCD showing a good radiological outcome at 2-year follow-up. Modified MOCART score represented the best way to evaluate the osteocartilaginous tissue's regeneration after every arthroscopy approach.

B-1351 14:32

Patellar malalignment: a new method on knee MRI

H. Kurtul Yıldız, E.E. Ekin; *Istanbul/TR (eeeoner@gmail.com)*

Purpose: The medial patellofemoural ligament (MPFLL)/lateral patellar retinaculum (LPR) ratio were assessed in knees as a means to detect patellar malalignment. We also aimed to evaluate the prevalence of the various types of trochlear dysplasia in patients with patellar malalignment.
Methods and Materials: After approval of our institutional ethics committee, we conducted a retrospective study that included 450 consecutive patients to evaluate them for the presence of patellar malalignment. Parameters investigated were the trochlear type, sulcus angle, presence of a supratrochlear spur, MPFLL, LPR, patella alta, and patella baja by means of MRI. Overall, 133 patients were excluded because of the presence of major trauma, multiple ligament injuries, bipartite patella, and previous knee surgery. The Dejour classification was used to assess trochlear dysplasia. Two experienced radiologist evaluated the images. Their concordance was assessed using the kappa test.
Results: The frequencies of patellar malalignment and trochlear dysplasia were 34.7 and 63.7%, respectively. The frequency of trochlear dysplasia associated with patellar malalignment was 97.2%. An MPFLL/LPR ratio of 1.033-1.041 had high sensitivity and specificity for malalignment. The researchers' concordance was good (K=0.89, SE=0.034, Π<0.001).
Conclusion: Trochlear dysplasia is frequently associated with patellar malalignment. An increased MPFLL/LPR ratio is useful for detecting patellar malalignment on knee MRI, which is a novel quantitative method based on ligament length.

B-1352 14:40

T2-mapping correlates with histopathological degree of meniscal degeneration

S.M. Eijgenraam, F.A.T. Bovendeert, Y.M. Bastiaansen, D.E. Meuffels, J. Guenoun, S. Klein, M. Reijman, E.H.G. Oei; *Rotterdam/NL (s.eijgenraam@erasmusmc.nl)*

Purpose: To validate T2-mapping for meniscal tissue, by studying the correlation between T2 relaxation time and the degree of histopathological degeneration as the reference standard.
Methods and Materials: 10 patients undergoing surgery were included in this prospective observational study. From 5 patients, traumatically torn meniscal tissue was collected during arthroscopic partial meniscectomy. From the other 5 patients, degenerative menisci were obtained during total knee replacement surgery. All patients underwent a pre-operative MRI scan at 3 Tesla which included a 3D FSE T2-mapping pulse sequence with 5 echo times. Histopathological analysis was performed using the Pauli score, a validated semi quantitative grading system for human meniscal degeneration involving the following subdomains: surface integrity, cellularity, matrix and collagen organisation, and proteoglycan staining intensity. Mean T2 relaxation times were calculated in meniscal regions of interest corresponding with the areas scored histopathologically, using in-house developed post-processing software. The correlation between T2-mapping and histopathological degeneration was assessed using Spearman correlation tests.
Results: T2-mapping relaxation time was found to correlate well with the degree of histopathological degeneration in meniscal tissue (r_s = 0.64, P = 0.001). Meniscal tissue with mild to moderate degeneration was found to have statistically significantly higher T2 relaxation times compared to meniscal tissue without degeneration, 22.7 ± 3.0 ms and 18.2 ± 5.1 ms (P = 0.02) respectively.
Conclusion: T2-mapping relaxation time correlates well with histopathological degeneration in meniscal tissue and is a promising quantitative imaging biomarker to estimate meniscal degeneration.

B-1353 14:48

Microstructural evaluation of the anterior cruciate ligament (ACL) with MR-diffusion tensor imaging (DTI): correlations with knee stability

I. Voicu, L. Di Clemente, R. Navarra, P. Mattei, V. Panara, A. Cotroneo, M. Caulo; *Chieti/IT (p.voicu@rad.unich.it)*

Purpose: To assess if DTI metrics are correlated with microstructural anatomy of the anterior cruciate ligament (ACL) and with knee stability.
Methods and Materials: We examined both knees of 41 subjects: 23 healthy controls (11F, age 20-40) and 18 patients with previous ACL injury (9F, age 20-40). All subjects underwent clinical and KT1000 Knee Laxity Testing Compliance Index (CI) and an MR scan on a 1.5 T magnet. MR imaging protocol included conventional and axial DTI sequences. Quantitative analysis was performed by overlapping DTI sequences to T2 sequences. At least three ROI's on consecutive sections were manually drawn on the ACL. DTI metrics

were obtained using FMRIB Software Library (FSL). Differences of Fractional Anisotropy (FA) of ACLs between knees in healthy controls and patients were evaluated with a paired t-test. Correlations between FA and CI were evaluated with curve estimation analysis.
Results: FAs were significantly different in healthy and injured knees in the patient group (0.72±0.09, 0.60±0.09 respectively, p<0.001) but not in healthy control knees. Curve regression analysis indicated a statistically significant quadratic relationship between ACL FA and CI in controls (p=0.013) but no relationship in patients.
Conclusion: Injured knees presented a significant difference in ACL FA compared to healthy knees. This difference was not present when comparing contralateral knees in healthy subjects. The relationship between ACL FA and CI present in healthy subjects was not observed in injured knees. Further studies are required to determine if DTI FA could be used for early diagnostic, treatment evaluation and prognosis.

B-1354 14:56

MRI characteristics of torn and untorn menisci
R. Kijowski, A. Williams, H. Rosas, F. Liu; *Madison, WI/US (rkijowski@uwhealth.org)*

Purpose: To compare MRI characteristics of torn and untorn postoperative menisci.
Methods and Materials: The study group consisted of 140 patients with 148 partially resected menisci who were evaluated with repeat knee MRI examination and subsequent repeat knee arthroscopy. Two musculoskeletal radiologists retrospectively assessed the following MRI characteristics of the postoperative menisci: contour, T2 line through meniscus (no line, intermediate signal line, intermediate-to-high signal line, and high fluid signal line), number of images T2 line visualised, extent of T2 line though meniscus, and change in signal pattern through meniscus compared to baseline MRI. Positive predictive values (PPV) and negative predictive values (NPV) were calculated using arthroscopy as reference standard.
Results: All 36 menisci with no T2 line were untorn at surgery (100% NPV), while 46 of 79 menisci with intermediate T2 line, 16 of 18 menisci with intermediate-to-high T2 line, and 14 of 15 menisci with high T2 line were torn at surgery (58%, 89%, and 93% PPV respectively). Additional MRI characteristics associated with torn meniscus at surgery included irregular contour (86% PPV), T2 line on more than 5 images (82% PPV), T2 line extending through more than 75% of meniscus (66% PPV), and change in signal pattern (98% PPV).
Conclusion: Postoperative menisci with no T2 signal line are untorn at surgery. The most useful MRI characteristics to predict torn postoperative menisci at surgery are change in signal pattern compared to baseline MRI followed by high T2 line through meniscus, intermediate-to-high T2 line through meniscus, and irregular meniscus contour.

B-1356 15:04

T2 relaxation times in patients after ACL-repair with and without femoral notch sign
C. Behzadi, G.H. Welsch, A. Laqmani, F.O. Henes, G. Schoen, G. Adam, M. Regier; *Hamburg/DE (C.Behzadi@uke.de)*

Purpose: To quantitatively assess T2 relaxation times of articular cartilage of the anterolateral femoral condyle in patients after ACL-repair with and without a deep lateral femoral notch sign at initial MRI.
Methods and Materials: 58 patients underwent knee MRI at 3T 12 months after ACL-rupture and surgical treatment. In 27 of 58 re-evaluated patients a positive lateral femoral notch sign was present at posttraumatic MRI. For quantitative analysis, T2 relaxation time measurements (7 echo times ranging from 10-70 ms) were performed in sagittal orientation. By using the initial post-trauma MRI as an aid for orientation, a polygonal ROI encompassing the full cartilage layer was placed in the anterolateral femoral cartilage on the T2 map using a dedicated software tool (ImageJ). Statistical analysis included student t-test and 95%-confidence intervals.
Results: In patients with a positive lateral femoral notch sign, T2 relaxation times were significantly higher (14.1%) compared to those without a lateral femoral notch sign (p=0.003). In total, a mean relaxation time of 41.1ms (36.4-48.7ms) was determined for patients with a femoral notch sign, whereas a mean of 35.3ms (26.1-43.3ms) was calculated for patients with a negative femoral notch.
Conclusion: A trend towards elevated T2 relaxation times in the anterolateral femoral cartilage in patients with a positive femoral notch sign after ACL-rupture was noted compared to patients without a femoral notch sign. Therefore, a positive femoral notch sign in initial MRI seems to be associated with higher cartilage degradation and longitudinal studies are needed to further evaluate its clinical relevance.

B-1357 15:12

Diffusion tensor imaging of the anterior cruciate ligament graft at 3 Tesla: a feasibility and reliability study
P. Van Dyck[1], E. De Smet[1], M. Froeling[2], P. Pullens[1], M. Torfs[1], P. Verdonk[3], J. Sijbers[4], P.M. Parizel[1], B. Jeurissen[4]; [1]*Edegem/BE*, [2]*Utrecht/NL*, [3]*Antwerp/BE*, [4]*Wilrijk/BE (elinedesmet@hotmail.com)*

Purpose: A great need exists for objective biomarkers to characterize anterior cruciate ligament (ACL) graft healing. Our purpose was to demonstrate the feasibility and reliability of diffusion tensor imaging (DTI) to delineate the ACL graft and investigate its microstructural properties in vivo.
Methods and Materials: Axial DTI (b = 0, 400 and 800 s/mm^2 in 1, 10, and 10 directions repeated 16 times for a total of 336 diffusion weighted volumes; TR/TE: 1300/45 ms, voxel size: 1.5×1.5×6.0 mm^3, matrix: 128 × 128, slices: 10) of the knee was performed at 3T in twenty patients within 1 year after ACL reconstruction. Ttractography was performed by two independent observers to delineate the ACL graft. Fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD), and radial diffusivity (RD) were calculated within the graft. Interrater reliability was assessed using intraclass correlation coefficient (ICC) and scan-rescan reproducibility was evaluated based on the coefficient of variance (CV) across 20 repetition bootknife samples.
Results: In all subjects, the ACL graft was tracked successfully. Quantitative evaluation of diffusion properties of the graft yielded the following mean ± SD values: FA=0,224 ± 0,0424; MD=1,30± 0,125 x 10-3 mm^2/s; AD=1,60± 0,141 x 10-3 mm^2/s and RD=1,14± 0,125 x 10-3 mm^2/s. Interrater reliability was excellent (ICC= 0.907-0.981). Mean CVs for FA, MD, AD and RD were 5%, 4%, 4% and 4%, respectively.
Conclusion: This study demonstrates the feasibility and reliability of DTI for evaluating the ACL graft at 3T. These findings support the potential of DTI to serve as an objective biomarker to better characterize ACL graft healing.

Elasticity characterisation of vastus lateralis muscle by ultrasound quasi-static elastography
R.A. Santos[1], M. Valamatos[2], P. Mil-Homens[2], P. Armada-da-Silva[2]; [1]*Coimbra/PT*, [2]*Lisbon/PT (rutemartinssantos@gmail.com)*

Purpose: To validate the use of QSE for muscle elasticity mapping as a possible clinical and quantitative tool and to compare quantitatively the QSE mapping obtained in the vastus lateralis muscles of young adults when submitted to a program of training.
Methods and Materials: Twenty-eight healthy males volunteers (mean age 20 ± 3.3 years), participated in this study, divided into two groups: control group and training group. From the training group, 11 performed a concentric training and 9 submitted an eccentric training, during 15 weeks, on a total of 45 training sessions. All the participants were submitted to an ultrasound evaluation of the vastus lateralis on transverse plan before and after the 12 weeks of training program.
Results: It was found high intra-evaluation reliability for colour mapping values by QSE ultrasound. In few cases, ICC was below the acceptable 0.70 levels. Vastus lateralis muscle was defined as a soft tissue, with higher percentage of green colour, followed by the blue colour when in rest. In generally, there were significant differences on red colour percentage between the first and second evaluations and between the rest and contraction, showing on these two evaluations a less percentage of red colour that is an increase on the tissue hardness after dynamic exercise.
Conclusion: QSE is a useful technique for monitoring of musculoskeletal changings principally on long programs of training, by evaluating the elasticity of muscle structures.

B-1359 14:08

Sonographer's ability to detect and grade pathological findings in shoulder radiograph

M.J. Pakanen, J. Haverinen, M. Heiskanen, E. Liukkonen, J. Niinimäki; *Oulu/FI (pakanemi@gmail.com)*

Purpose: The aim of this study was to evaluate and improve the knowledge and ability of sonographers, who perform shoulder ultrasonography examinations, to detect pathological findings in shoulder x-ray images and furthermore, to examine which pathological findings can be reliably detected by sonographers. The focus of this study was to examine the interpretation process primarily in the evaluation of degenerative changes.
Methods and Materials: Study material consisted of 50 anonymised shoulder x-ray examinations of patients who had shoulder ultrasonography within two months of the x-ray study. Three sonographers evaluated research material independently, a semi-structured evaluation, of GH-joint, osteophytes, tendon calcification, acromial shape, subacromial space, AC-osteoarthritis and other observations. Musculoskeletal radiologist evaluated images blinded to the interpretation of sonographers. The results were compared between radiologist and sonographers.
Results: Sonographers' detection rates compared to radiologist were; GH-joint 96,7%, GH-joint space 94%, GH-joint articular surfaces 81,3%, osteophytes 72,7%, tendon calcification 81,4%, acromial shape 69,3%, subacromial space 93,8%, AC-osteoarthritis 39,4% and other observations 76%.
Conclusion: Radiographers' ability to interpret and report x-rays have been studied widely and good results have been reported in the interpretation of trauma x-ray images. In our study, sonographers (Radiographer University of Applied Sciences) performed well in detecting degenerative radiographic findings of shoulder x-ray images. GH-joint, GH-joint space and articular surfaces, tendon calcification and subacromial space were most accurately evaluated when compared to radiologist's interpretation. The research material will be further utilised in education to improve the sonographers' skills to evaluate AC-osteoarthritis, acromial shape and osteophytes.

B-1360 14:16

Thickness and echo-intensity characterisation of quadriceps muscle by ultrasound

R.A. Santos, F. Alves, D. Matos, A. Fidalgo, A. André; *Coimbra/PT (rutemartinssantos@gmail.com)*

Purpose: To characterise the thickness and echo-intensity of the quadriceps femoris muscle and analyse its relationship with gender, practice of sports, number of training and practice time.
Methods and Materials: 61 young individuals were submitted to an ultrasound examination to assess the thickness and echogenicity of the quadriceps femoris muscle, through the acquisition of images in longitudinal sections. The ultrasound images were processed using the Image J software and the data were analysed through SPSS 20.0.
Results: The quadriceps femoris muscle has an average thickness between 1.12 and 1.34 cm, and an echo-intensity between 74.83 and 81.65 values. There are significant differences in the thickness of the left and right medial vastus muscle between males and females and significant differences in the thickness and echo-intensity of the quadriceps femoris muscle in relation to the practice of sport and practice time.
Conclusion: The thickness of quadriceps femoris muscle is greater in males than in females; however, the opposite is observed regarding the echo-intensity of it. The practice of sports, number of workouts and practice time influence the echo-intensity and thickness of the quadriceps femoris muscle.

B-1367 14:24

Bioethics education for radiographers in Europe

A. Santos; *Coimbra/PT (adelinosantos@estescoimbra.pt)*

Purpose: The knowledge that radiographers have on bioethics (and the legal framework of care) can have a direct impact on the type and quality of care that patients receive. This work has the goal of knowing what kind of bioethics unit contents are taught to future radiographers.
Methods and Materials: Semi-structured interviews with accountable pedagogical coordinators and meta-analysis on available official information about curricular unit contents in the major official schools were performed on 22 colleges, 15 countries. Data was examined to exclude significant bias; for qualitative variables, frequencies and percentages were calculated; averages and standard deviations for quantitative ones.
Results: The characterisation of radiographers high-level education showed that only a minority (36%) have bioethics and/or deontology training, with the duration equal or more than 1 semester. Regarding the characterisation of type and quality of the education, bioethical contents revealed that the most pertinent alluded topics are Professional Skills (83%) and Awareness (90%). However, reference authors highlight that ethical behavior should focus on tolerance, prudence and discrimination capacity. These features are bioethics discipline characteristics. Therefore, they cannot be scattered by well-meaning programmes that do not develop critical and reflective ethical thinking.
Conclusion: The educational environment should combat the incongruence of these results. If future professionals do not learn and integrate the importance of bioethics for clinical practice, patients may suffer needlessly and their self-determination rights are ignored. To avoid this situation priority to bioethics should be given, ensuring mandatory character in training plans of all these professionals.

Sonographer's ergonomic pains, who cares

M. Abd El Bagi, F. Alkubaidan, A. Alkhalf, R. Albabtain, A. Wazira, N. Butt, A. Mohammed; *Riyadh/SA*

Purpose: Purpose work related injuries can affect staff well-being, decrease productivity and cause early career ending. The objective of this study is to determine whether our sonographers are suffering work related pains that require intervention and their awareness of ergonomics in comparison to a nationwide trend.
Methods and Materials: A questionnaire was conducted for the multinational practicing sonographers at an 800 bed tertiary care hospital. The general ultrasound sub-section was selected. The intervention, paediatric and women imaging sub-sections were excluded.
Results: 13 sonographers were involved.11 (85%) were females and 2 (15%) were males. Seven (54%) were Saudi's, five (38%) were Philipinos and one (8%) was Sudanese. Response rate was 100%. Only 3 (23%) were fully aware of ergonomics. 8 (62%) were suffering from various musculoskeletal pains compared to 89 (78%) nationwide of whom 58 (51%) suffered more severely and may consider leaving the profession. The vast majority of our staff 12 (92%) said they were over worked.
Conclusion: The issues of ergonomics are rarely addressed by management or staff. Our sonographers are mostly unaware of ergonomics. They are at risk of work related injuries and burn out syndrome but less than the nationwide pattern. An in-service education session was conducted by a physiotherapist. Subsequently regular staff exercise and stretching program was implemented at short breaks resulting in morale boosting. Impact on sick leave records was not studied.

Our experience with gamma knife treatment planning

A. Fedorov, A. Lavrentyeva; *St. Petersburg/RU, (fedorov@ldc.ru)*

Purpose: To evaluate define (geometry tag error) in planning station in patient with metal frame before gamma knife radiosurgery.
Methods and Materials: 34 patients with gamma knife metal frame were assessed (20 by head TxRx, 4 by flex small, 10 by head matrix lower plus body). Aera 1.5T scanner was used with CIVCO planning accessories. 3 coil configurations were tested: 2 flex small combinations, head TxRx, head matrix lower plus body matrix 18. All patients were scanned with Leksell localiser and gamma plan station. T2 TSE and T1 VIBE with spatial resolution 1.0x1.0x1.0mm were used.
Results: The results of define due to using flex small coil and TxRx coil were 0.9±0.3. Satisfactory define (0.4±0.1) in planning station were reached with combination Head matrix lower plus Body Matrix 18, by channels increasing and scanning protocols optimisation. In these cases, B1 filter and reduced EC sensitivity were activated, and gradient system regime was changed from fast to low Sar.
Conclusion: CIVCO accessories and coils combination of head matrix lower plus body matrix 18 are useful for gamma knife treatment planning (in difference with standard protocols and coils).

Radiation exposure assessment in educational setting: spine surgical programme with procedures simulated on cadavers

E.C. Antunes[1], M.S. Martins[2], M.M.C.P. Ribeiro[2], J.E.G. O'Neill[2], M.V. Casimiro[2]; [1]*Loures/PT*, [2]*Lisbon/PT (edgar.c.antunes@gmail.com)*

Purpose: Assess the amount of radiation dose in the spine surgical intervention in an educational setting, carried out in the dissection room using cadavers for training, and to evaluate if the exposure level is between the limits imposed by legislation to radiographers or medical students.
Methods and Materials: To evaluate the effective dose received by students, dosimetric evaluations were carried out in 6 students (five radiographers and one doctor) using thermoluminescent dosimeters (TLD-100) by (LiF:Mg,Li); bandwidth of 10μGy-10Gy, placed under the apron shield. In one student positioned in the place of the main surgeon, wrist and eye dosimeters were also used. The fluoroscopy time was obtained from the dose report print from the equipment (Ziehm Vision Vario 3D) used in pulsed emission mode. The data collection occurred during the all course time - 3 days.
Results: The effective dose measured under the apron for the whole body and in the eye gave the value of 0,00mSv for all students. The effective dose

results for the wrist were 0,69mSv Hp(0,07) and 0,74mSv Hp(10). The total time of exposition was between [11,51min-15,78Max]. The correlation between the cumulative dose and the exposition time was weak (R=0,29).
Conclusion: The radiation dose was lower than the limits imposed by legislation. We concluded that the training programs using fluoroscopy in cadavers revealed to be safe. It is safeguard the radiological protection for the students in lab area applying simulated techniques in cadaver, using the best practices that mimics the surgical theatre.

B-1364 14:56

Virtual autopsy: the role of CT and MRI
A. Silva, N. Pinto, A.F. Abrantes, L.P.V. Ribeiro, R.P.P. Almeida, K.B. Azevedo, J.P. Pinheiro; *Faro/PT (npinto@ualg.pt)*

Purpose: To demonstrate the role of CT and MRI examinations on the post-mortem analysis of a corpse.
Methods and Materials: In this case study, a person had to die in a violent manner by suicide or homicide (in these circumstances a conventional autopsy is mandatory according the nacional law) within the hospital area. For data collection purposes, the pathologist gave permission to be recorded during the course of conventional autopsy, and the radiology department agreed to perform the post-mortem imaging. The imaging was carried out with a 16 slices CT scanner and a 1.5 Tesla MRI.
Results: Both techniques viewed fluid in the thoracic cavity. Imaging did not detect the presence of sand in the larynx, pharynx, trachea and oesophagus, unlike conventional autopsy, but detected unspecific foreign bodies. In this parameter, the conventional autopsy was superior. However, this difficulty can be easily overcome since there are software programmes that enable the study of the tracheal lumen and the bronchial tree. In this case the imaging examinations were sufficient to determine the cause of death (drowning).
Conclusion: Literature reviews have shown good correlation between both techniques and this particular case study has shown that there was certainly a good congruence between the two modalities. The virtual method preserves the forensic evidence and, at the same time, represents an alternative to religious communities which do not accept the conventional autopsy. Virtual autopsy also creates another intervention field for radiographers, contributing to their professional development.

B-1365 15:04

Comparative study of plain radiography from three digital acquisition systems applied to works of Art
B. Barros, M.M.C.P. Ribeiro, D.A. Ramos, M.H.P. Martins, A. Candeias; *Lisbon/PT (beatrizcr-barros@hotmail.com)*

Purpose: In order to reinforce the cooperation between radiologic centres and the museums and enlarge the job-market of the Radiographers, this study aimed to give a contribution for a better understanding about the process used in the characterisation of radiography in painting and to optimise the exposition's parameters in 3 systems, comparing them.
Methods and Materials: With the help of an expert in Museology and Art History it was selected 5 paintings produced with different materials and techniques. The paintings underwent to three acquisition systems making a total of 21 images: 1-DR Siemens MultixSelect-DR; 2-CR Siemens Multix Pro combined with AGFA IP MD4.0 detector and scanner AGFA ADC Solo and 3-CR tube YXLON SMART 160E/0,4 belonging to José Figueiredo Lab from investigation and conservation of cultural heritage. All acquisition procedures were reproduced in all systems. Four observers classified the images: 2 experts in medical imaging and 2 in art. The dimensions of the check-list were: support conservation state; distinctness; contrast; contour; creative and technique process; components and materials.
Results: Globally the best images ranked by experts were obtained with the system 2 where was possible to see the fine contours, the brushstrokes or the matting of the canvas. However the system 3 gives some details inexistent in the others. The best acquisition parameters were the recommended by National Gallery's studies.
Conclusion: Radiography field and the knowledge of radiographers, through CR systems, may increase the image quality to expertise advice, validation and authentication of works of Art.

B-1366 15:12

An investigation into interface pressure (IP) and pressure ulcer (PU) risk of healthy volunteers whilst lying on medical imaging and radiotherapy tables
S.K. Angmorterh, A. England, J.-A. Webb, K. Szczepura, M. Stephens, P. Hogg; *Salford/UK (S.Angmorterh@edu.salford.ac.uk)*

Purpose: Determine whether IP risks exist on radiography/radiotherapy tables; determine the impact of a pressure relieving intervention on IP jeopardy areas.
Methods and Materials: Baseline study: An Xsensor pressure mapping system was used to measure IP of jeopardy areas in healthy volunteers (26 females, 23 males; aged 18-59 (mean=34.6±10.5)) on three radiography/radiotherapy tables. Volunteers also completed a pain/comfort questionnaire. Significant differences exist for mean IP for head, sacrum, and heels across the three tables ($p \leq 0.001$). Highest IP was recorded for the head (75.9±31.2mmHg) on the radiotherapy/planning table. This IP could induce tissue breakdown, predisposing to PU. Most pain occurred when lying on the radiotherapy table.
Results: Intervention study: A thin gel surface overlay, with low radiation attenuation, was assessed to reduce IP risk to the head. Pressure mapping was conducted on 20 healthy volunteers aged 25-53 years (mean=34.4±7.0). Significant difference in the mean IP with and without the intervention was identified (mean IP values of 62.4±6.1 and 83.9±8.1mmHg respectively, $p \leq 0.001$). There was a significant difference in the peak pressure index (PPI) of the head with and without the gel intervention (mean=159.8±26.8, and mean=205.1±28.2mmHg respectively, $p<0.05$).
Conclusion: IP and therefore PU risk exists for the head on radiotherapy/planning tables. A suitable intervention can reduce this risk. Further research is needed to assess interventions and also PU risk to high risk populations.

B-1368 15:20

Development of software for image quality assessment in cone-beam computed tomography
M.V.L. Oliveira[1], A.C. Santos[2], G. Paulo[2], P. Campos[1], J. Santos[2]; [1]*Salvador/BR*, [2]*Coimbra/PT (marcusradiology@gmail.com)*

Purpose: The purpose of this study was to develop free software, at low cost and with minimal time to evaluate the image quality in dental and maxillo-facial cone beam computed tomography (CBCT).
Methods and Materials: A polymethyl methacrylate (PMMA) phantom, CQP-IFBA, was scanned in three CBCT units with seven protocols. A macro-programme was developed, using ImageJ free software, to automatically evaluate the image quality parameters. The image quality evaluation was based on eight parameters: uniformity, signal to noise ratio (SNR), noise, contrast to noise ratio (CNR), spatial resolution (SR), artefact index, geometric accuracy and low contrast.
Results: The image uniformity was dependent on the applied protocols, as well as the noise. Regarding the CNR, the structures of high densities were more sensitive to the effect of scanning parameters. There were no significant differences between SNR and CNR in centered and peripheral objects. The geometric accuracy showed that all the distance measurements were lower than the real value. Low contrast resolution was influenced by scanning parameters and the 1mm rod was not depicted in three CBCT units. The smaller voxel sizes presented higher spatial resolution. There were no significant differences among protocols regarding artefact presence.
Conclusion: The package (phantom and macro) developed provided a fast, low cost and reproducible method for evaluation of image quality parameters in CBCT.

Fast, precise and accurate myocardium T1 mapping using a radial modified look locker NMR imaging sequence
B. Marty, B. Coppa, P.G. Carlier; *Paris/FR (b.marty@institut-myologie.org)*

Purpose: Quantitative NMR cardiac T1 mapping has become a popular modality to characterise myocardial tissue. The classical MOLLI sequence allows the acquisition of a single slice within a 17-heartbeat breath hold. Here, we developed a radial variant of the MOLLI (raMOLLI) allowing a decrease in acquisition time down to 5 heartbeats, while keeping high precision on T1.
Methods and Materials: After non-selective inversion, the raMOLLI sequence consisted in the acquisition of 5 shots of 80 radial spokes at end of diastole with a fast gradient echo readout. Fifty image were reconstructed using compressed sensing. The temporal signal evolution was fitted using Bloch equations to obtain a T1 map. The method was validated at 3T on phantoms, 4 healthy volunteers and a patient suffering from dilated cardiomyopathy. For comparison, conventional MOLLI was also acquired.
Results: In vitro, relative T1 differences were less than 3% between the raMOLLI and a gold standard sequence and the measures did not depend on the heart rate. On the four volunteers, the mean T1 estimated in the

myocardium were comparable between the two MOLLI variants. For the patient, the regions with decreased raMOLLI T1 values correlated with regions of late gadolinium enhancement.
Conclusion: The raMOLLI sequence offers several advantages compared to MOLLI. Acquisition time is substantially reduced and no effect of heart-rate on estimated T1 values were reported. Finally, the method allowed the reconstruction of a large number of images along the T1 recovery curve, providing a high robustness to the postprocessing.

B-1370 14:08

The value of feature/contour-based registration in quantification of myocardial extracellular volume fraction based on T1 mapping technique
L. Lin, X.-H. Zhou, M. Zheng, Q.-X. Xie; *Guangzhou/CN (xiangxiang_87@163.com)*

Purpose: Inconsistency of ventricular shape between pre- and post-contrast T1 maps or among T1 mapping images of different inversion time might cause artefacts, thus impact on the quantification of extracellular volume fraction (ECV). Feature/contour-based registration is a non-linear transformations using predefined myocardial contours to align multiple images before T1 map generation. We evaluated its influence on the accuracy of ECV quantification.
Methods and Materials: T1 mapping images of the mid-ventricular short axis slice (SAX) of 25 healthy volunteers were obtained using modified look-locker inversion recovery (MOLLI) on a 3.0T magnetic resonance imaging system (Magnetom Verio, Siemens). ECV was calculated using a software (cvi42 v5.3, circle cardiovascular imaging) by two methods: routine ECV by T1 maps automatically generated by the scanner, and registered ECV by T1 maps generated after feature/contour-based registration. Subjects were divided into deformation group (n=10) and control group (n=15) according to cardiac features. Paired comparison was done for ECVs within each group.
Results: There was statistical difference (P=0.025) between routine ECV (25.30±3.16%) and registered ECV (24.17±2.41%) of all the volunteers. In deformation group, routine ECV (26.76±3.47%) and registered ECV (24.03±2.10%) were statistically different (P=0.021). While in control group, there was no difference (P=0.707) between routine ECV (24.32±2.61%) and registered ECV (24.26±2.66%). 6 cases presented artefacts in routine ECV maps, which were eliminated or mitigated in registered ECV maps.
Conclusion: Feature/contour-based registration can improve the accuracy of ECV quantification in cases with ventricular shape deformation among source images.

Diffusion weighted imaging in cardiac magnetic resonance for diagnosis of acute myocarditis: could it be the missing criteria?
L. Pavan, R. Faletti, F. Gentile, E. Caramia, M. Gatti, G. Schivazappa, A. Romano, P. Fonio, G. Gandini; *Turin/IT (lucajpavan@gmail.com)*

Purpose: In addition to Lake Louise criteria, T1- and T2-mapping are becoming very useful tools for diagnosis of acute myocarditis, although few MRI scanners provide them at the moment. The aim of our study was to assess diffusion weighted imaging (DWI) as a diagnostic criteria for acute myocarditis, since it is available on the majority of MRI scanners.
Methods and Materials: Fourteen patients were prospectively enrolled for this study: 7 patients affected by acute myocarditis with infarct-like presentation and positive to all Lake Louise criteria (mean age 32±17y) and 7 negative controls with no previous cardiac diseases (mean age 34±16y). All patients performed examination with a 1,5T MRI scanner with 32-channel phased-array coil. Image analysis was performed by two radiologists in consensus, T2-ratio and DWI-ratio (based on ADC values) between myocardial muscle and skeletal muscle of the same slice were calculated for each patient and compared between the two groups.
Results: Comparison of DWI-ratio between pathologic and control group showed a statistically significant difference (mean 0,58±0,08 vs 1,00±0,18; p<0,0001), as well as T2-ratio comparison (mean 2,28±0,42 vs 1,22±0,26; p<0,0001).
Conclusion: Our study suggests DWI could be introduced in cardiac magnetic resonance as a sequence for assessment of acute myocarditis and maybe considered as a major diagnostic criteria in addition to Lake Louise criteria, although larger studies are needed to assess it properly.

B-1372 14:24

Detection of cardiovascular disease with MRI myocardial texture changes on routine non-contrast sequences
P. Talarczyk, J. Weir-McCall, S. Waugh, P. Guntur Ramkumar, G. Houston; *Dundee/UK*

Purpose: Texture analysis allows quantification of tissue heterogeneity and has been proven to provide powerful diagnostic and prognostic data in oncological imaging. However to date this technique has not been applied to the assessment of the myocardium. The hypothesis of the current study was that those with diabetes and cardiovascular disease (CVD) would have more heterogenous myocardium than those without.
Methods and Materials: 143 enrolled subjects were divided into 4 groups: diabetics with (group 1, n=31) or without CVD (group 2, n=55), and non-diabetics with (group 3, n=28) or without CVD (group 4, n=29). Cardiac MRI was performed in a 3T scanner. Image analysis was performed on a pre-contrast bSSFP short axis mid-ventricular slice at end-systole. Texture features were measured using MazDa software, using the co-occurrence matrix (with fine and coarse filter) and run-length matrix.
Results: There were significant differences in coarse entropy (F-test =2.94, p=0.035), fine entropy (F-test =2.96, p=0.034), coarse sum of squares measure (F-test =3.48, p=0.018) and fine sum of squares measure (F-test =2.76, p=0.044) between the four groups. Post hoc analysis showed these differences to exist between group 3 and 4, with group 3 exhibiting significantly higher entropy (2.21±0.2 vs 2.33±0.2, p=0.041 for coarse, and 2.50±0.1 vs 2.58±0.1, p=0.025 for fine feature entropy).
Conclusion: Myocardial heterogeneity on routine non-contrast sequences is increased in those with cardiovascular disease compared with controls, suggesting this is a new and novel way of quantifying myocardial structure without the need for additional sequences.

B-1373 14:32

On the selection of region of interest in measurement of cardiac magnetic resonance imaging T2* in patients with thalassaemia major
S. GholamiBardeji, M. Dodangeh, Z. Gholami Bardeji, S. Sefidbakht, R. Jalli; *Shiraz/IR (s_gholami@sums.ac.ir)*

Purpose: To investigate the correlation between T2* values of different Regions of Interest (ROIs) in the heart with the means of estimating the cardiac iron content in the thalassaemia major patients. Another purpose is to design a model which predicts T2* value of inter-ventricular septum (Septum) based on T2* value of other ROIs.
Methods and Materials: 130 patients underwent ECG-gated cardiac Magnetic Resonance Imaging(MRI), and T2* values were measured in different ROIs. The statistical analysis carried out using Matlabr R2015b. Full-thickness ROIs are drawn manually in Septum, whole LV wall, the region of the best visual conspicuity (Sharp), and Left Ventricular (LV) free wall.
Results: In patients with the cardiac T2* ≤ 20, the statistical analysis confirms a significant correlation ($\alpha = 0.001$) between T2* values of Septum and the ROIs named above. Moreover, the statistical results become more concordant with decreasing T2* values. In addition for patients with a T2* > 20, a weak correlation is noticed between T2* values of different ROIs. Three predictor models are provided to estimate T2* value of Septum using T2*values of whole LV wall, Sharp regions, and LV free wall.
Conclusion: The T2* values of the LV free wall and the whole LV wall are reliable alternatives to estimate the T2* value of Septum. The predictor model based on T2* value of whole LV wall provides the best estimation.

B-1374 14:40

Myocardial fibrosis (MF) and its associated ventricular impairment in adults with repaired tetralogy of Fallot (rTOF): role of delayed enhancement cardiac magnetic resonance (DE-CMR)
G. Schivazappa, R. Faletti, F. Angelino, A. Romano, M. Gatti, E. Caramia, F. Misischi, P. Fonio, G. Gandini; *Turin/IT (giulia.schivazappa@gmail.com)*

Purpose: To define utility of DE-CMR in evaluating MF and its correlation with ventricular volume and function, essential prognostic factors in adults with rTOF.
Methods and Materials: Twenty-four patients (15 male, 9 female; mean age 34±12,9 years) with rTOF were subjected to CMR examination and compared with a control group (22 healthy patients: 11 male, 11 female; mean age 34±16,3 years). Protocol included inversion recovery turbo field-echo (IR-TFE) sequences to identify late enhancement (LE) after contrast medium intravenous administration (Gadobutrol). Qualitative analysis of IR-TFE images was performed using Kim et al. scheme. Indexed ejection fraction (EF) and volume (EDV) of both ventricles (right RV, left LV) were calculated using cine short-axis images from base to apex. Variables were compared with student-T test.
Results: LE was present (septum/ventricular junction) in 15/24 patients (group-A) and absent in 9/24 (group-B). Ventricular analysis showed statistically significant (SS) difference (p<0,01) comparing rTOF to control group for values of RV-EDV, RV-EF and LV-EF. Group-A demonstrated even more increased RV-EDV and decreased RV-EF compared to group-B (EDV/BSA (ml/m^2) group-A=143,87±49,17; B=91,55±13,23; EF (%) A=36,53±6,81; B=50,54±7,66), with SS values, and also showed a reduced LV-EF (group-A=39,82±5,77; B 45,65±7,18) with p=0,05.
Conclusion: DE-CMR in patients with rTOF proved to be an essential tool in early MF detection. Presence of LE is related to EF reduction in both ventricles and RV-EDV increase compared to healthy patients. Patients with rTOF and positive LE showed increased RV-EDV, decreased RV-EF and an apparent further LV-EF reduction compared to those without LE.

B-1375 14:48

Cardiac MRI with T1 and T2 mapping in patients with phenylketonuria (PKU)

T.C. Walter, G. Knobloch, N. Tiling, U. Plöckinger, D. Blaschke, T. Denecke, B. Hamm, M.R. Makowski; *Berlin/DE (thula.walter@charite.de)*

Purpose: Phenylketonuria (PKU) is one of the most common congenital defects of the amino-acid-metabolism. A vast body of research exists on neurological damage in PKU. However, there is very little data on potential cardiac effects of PKU in adult patients. Novel MR mapping techniques allow a more detailed evaluation of the myocardium, beyond mere morphological and functional assessment. The aim of this study was to evaluate changes in myocardial tissue composition in adult PKU.
Methods and Materials: 23 PKU patients (13 male) and 23 matched healthy controls were included in this study. Informed consent was obtained from all patients. The local ethics committee approved this study. All included patients underwent standard cardiac MRI (1.5 T, 32 channel coil, Siemens Avanto), which was amended by non-enhanced T1- and T2-mapping. T1- and T2-maps were segmented according to the AHA-17- Segment model. Cardiac function, mass and morphology were evaluated and compared between the two groups.
Results: Sex, age and BMI were similar in PKU patients and controls (p>0.05). Segmental non-enhanced T1 values showed a significant shortening of native T1 the mid-cavity posterior segment 10 (p=0.035). Late enhancement imaging and CINE-MRI showed no corresponding morphological alterations in this segment. T2 values, LV-morphology and function were similar for PKU patients and controls in all segments.
Conclusion: This study demonstrated that a significant shortening in T1-time can be measured in the posterior mid-cavity segment of PKU patients. The aetiology and clinical consequences of these signal alterations are currently unclear.

B-1376 14:56

Myocardial T1- mapping in daily cardiac magnetic resonance study in hypertrophic cardiomyopathy

O.Y. Dariy, S. Aleksandrova, M. Shlyappo, V. Makarenko, L. Bockeria; *Moscow/RU (dariiolyka@mail.ru)*

Purpose: The purpose of our study is to define the role of T1 mapping in hypertrophic cardiomyopathy diagnosis algorithm. To evaluate the end-diastolic wall thickness (EDWT) correlation with native and postcontrast myocardial T1-time, extracellular volume quantification (ECV), focal fibrosis degree and myocardial shortening.
Methods and Materials: We performed 21 cardiac magnetic resonance studies. In vivo T1 mapping was performed at a ventricular short-axis slice at three levels before and after the infusion of a contrast agent. T1 mapping with a modified Look-Locker Inversion Recovery (MOLLI) pulse sequence was used to calculate ECV. Assessment of T1 relaxation-time and ECV values was based on areas where focal fibrosis was excluded.
Results: There were the maximum hypertrophy at the anterior and posteriorseptal segments of the basal myocardium, the minimum one at the apical segments. Native myocardial MOLLI T1 was 1300±44ms (p<0.01) significantly higher than the multicenter study published in the normal myocardium, the post-contrast T1 (497±62ms p>0,05). The significant correlation of EDWT and T1 values was not received. The basal EDWT with native T1 showed the correlation (r=0,6) and with the focal fibrosis (r=0,6). The weak correlation of EDWT with the ECV (r=0,2). The midwall fractional shortening and native T1 had the weak correlation (r=0,5).
Conclusion: The advent of absolute T1 measurement techniques allows by definition of the ECV to quantify the entire range of fibrosis neither diffuse or focal. The values of T1 relaxation time and ECV does not depend on the degree of hypertrophy and are independent predictors of myocardial damage.

B-1377 15:04

Diagnostic significance of MRI in patients with myocarditis

M. Djurdjic, R. Maksimovic, B. Banko, I. Živković, I. Milinkovic, P. Seferovic; *Belgrad/RS (djurdjic_milica@yahoo.com)*

Purpose: The purpose of this study was to analyse significance of MRI parameters in assessment of patients with myocarditis and their relations to clinical data, ECG and laboratorory findings.
Methods and Materials: The study included 73 patients, predominantely males 55 (75.3%), average age 55.3 years. All patients underwent clinical examination, ECG, laboratory testing and MRI examination within 14 days of establishing suspected myocarditis. MRI parameters were: LVEDD, LVESD, LVEF, LVESV, LVEDV, presence of oedema and late gadolinium enchancement (LGE).
Results: The edema was present in 22 patients (30.1%), LGE in 42 (57.5%), both LGE and edema was seen in 11 (15.1%) of patients. Patients with oedema has significantly lower EF 42,7±21.7% in comparisson to those without oedema (53,7±16.7%), p<0.05, increased EDV (181,5±85,4 ml vs 161,0±55,9 ml, p<0.05, respectively) and increased ESV (126,9±96,1 ml vs 78,6±55,4 ml, p<0.01, respectively). Patients with LGE had decreased EDV (163,6±51,4 ml vs 171,6±87,4 ml, p<0.05, respectively) and decreased ESV (82,9±53,9 ml vs 105,3±94,3 ml, p<0.01, respectively) but LVEF was not significantly different among two groups, 52,4±17.5% vs 48,1±20.5%, respectively. There was a significant correlation between increased BNP and troponin and systolic parameters of LV function, ESV, r=0,45, p<0.05, r=-0,35, p<0.05, respectively. Troponin was also associated with presence of LGE, r=0,38, p<0.05.
Conclusion: Presence of myocardial oedema and LGE has been associated with systolic function of the left ventricle and therefore has great importance in final evaluation and furhter therapeutical decision making in these patients.

B-1378 15:12

Meta-analysis on pre-ablation late gadolinium enhancement predicting post-ablation recurrence of atrial fibrillation

K. Diao, Z. Yang, Q. Zhao, B. Hu, X. Liu; *Chengdu/CN (kaiyuediao@qq.com)*

Purpose: To explore whether the pre-ablation myocardial fibrosis could constitute an independent risk factor for recurrence of arrhythmia after catheter ablation, corresponding to the call from the newest clinical guidelines.
Methods and Materials: PubMed, Cochrane, web of Science, EMBASE were searched for studies demonstrating LGE's prognostic value in AF patients. Studies recording pre-ablation LGE analysis and recognizing AF recurrence as the primary end point were included. Pooling of the odds ratio was performed using a fixed- or random-effect model. Meta-regression and sub-group analysis were also performed to find a possible resource of heterogeneity.
Results: Data was included from 7 studies with a total of 1385 patients and proximately one year's follow-up. Included patients had a mean age of 63.6. Patients with higher level (>10%) of LGE had a much larger chance of AF recurrence than the lower level LGE ones (OR, 0.34; 95% confidence interval, 0.21-0.55; P<0.0001; I^2=71.6%). Meta-regression showed age could have an effect and considering which could greatly decrease the heterogeneity (revised I^2=26.43% vs I^2=71.6%, p=0.0023). Sub-group analysis showed little pre-ablation LGE (<5%) had prominently smaller OR than patients without moderate and severe level LGE (OR, 0.0602; 95% confidence interval, 0.0081-0.4453; P=0.0059; I^2=0.00%).
Conclusion: The severity level of pre-ablation LGE can predict the AF recurrence, and patients with milder myocardial fibrosis can get a better chance to recover to sinus rhythm without symptomatic recurrence through the catheter ablation.

Pulmonary reperfusion injury following right ventricular outflow tract stenting

O.D. Garcia, J. Sandoval Jones, G. Aristizabal Villa; *Mexico City/MX (omarcillogarciag@yahoo.com.mx)*

Purpose: To determine if PRI (pulmonary reperfusion injury) was present (by chest x-ray) following right ventricular outflow tract (RVOT) stenting.
Methods and Materials: Prospective study including 12 consecutive children with ToF Tetralogy of Fallot (25% female) that underwent RVOT stenting between January and July, 2016. Clinical and procedural data were reviewed. A radiologist evaluated chest x-ray films before and after intervention to determine presence and severity of PRI, as well as its impact on days of ventilation and length of hospital stay.
Results: Mean age and weight were 32 months (range 1-139) and 10.8 kg (1.8-22) respectively. SaO2 increased from a mean of 71±9.8% to 97±6% post RVOT stenting (p<0.0001); PaO2 was 43±7.4 mmHg and 126±94 mmHg pre and post-stenting respectively (p<0.001). The radiological analysis results were as follows: of the 12 patients, diffuse lung opacifications were classified as severe in n=5(41%); moderate n=1(8%); mild n=3(25%); none n=3(25%) within 24 hs post-RVOT-stenting. Pulmonary infiltrates affected the right lung in 8(66.7) patients. Seventy-two hours post-RVOT-stent, 8(67%) patients had complete resolution of previous abnormal findings on chest x-ray. A positive correlation was found between diameter of the pre-stent RVOT and days of ventilation (r 0.851, p 0.032). Similarly, positive correlation was found between post-stent RVOT diameter (mm) and days of hospital stay (r 0.683 p 0.014).
Conclusion: Transient PRI is present after RVOT stenting. Degree of pre-stent RVOT stenosis is reflected by longer duration of ventilation and length of hospital stay.

Initial experience in percutaneous cryoablation for breast cancer
C. Pusceddu; *Cagliari/IT (clapusceddu@gmail.com)*

Purpose: To evaluate the safety and efficacy of breast cryoablation (CRA) as local therapy for patient with metastatic breast cancer.
Methods and Materials: thirty-nine breast lesions, mean size 2,1 (range 1 - 6,7 cm) in twenty-nine consecutive patients, mean age 51 (36-81) with core-needle biopsy-proven breast carcinoma and metastases were included in this study. Twenty-three patients had one lesion, 4 patients two lesions, 1 patient three lesions and 1 patient five lesions. Under local anaesthesia the tumour and surrounding breast tissue were ablated with percutaneous CT-guided CRA. Cryoablation consisted of 2 cycles each of 10 minutes of freezing followed by a 4-min active and 4-min passive thawing phase for each one. Twenty-four patients underwent one CRA session, four patients 2 CRA sessions and one patient underwent 3 CRA sessions.
Results: All CRA sessions were successfully completed and all breast tumours were ablated. Morbidity consisted in transient and mild ecchymotic changes and post-procedural oedema seen in ten cases. The therapeutic outcomes were evaluated by contrast-enhanced TC or MRI at 2-, 6-, 12-, and 18-month intervals. The absence of tumour enhancement TC or MR image was considered as indicating complete tumour necrosis. During the mean follow-up of 15 months (6- 28 months) 26 patients had shown complete response to the treatment. Only 3 patients out 29 (10%) showed relapse close to the treated lesion. These patients were treated with a second CRA procedure.
Conclusion: CRA of metastatic breast cancer is a safe and effective method which allows local control of the disease.

B-1381 14:17

Breast cancer cryotherapy in elderly patients
C. de Bazelaire[1], C. Jousset[1], R. Cazzato[2], X. Buy[2], S. Ferron[2], E. de Kerviler[1], J. Palussière[2]; [1]*Paris/FR*, [2]*Bordeaux/FR (cedric.de-bazelaire@aphp.fr)*

Purpose: Some elderly patients with breast cancer do not undergo operation despite a theoretical indication for this therapy because of contraindications or refusal. In such cases, cryotherapy could serve as an alternative therapy. The objective of this study was to evaluate the feasibility, tolerance, and effectiveness of cryotherapy for malignant breast lesions.
Methods and Materials: This was a retrospective two-center study. Between February 2012 and January 2016, tumour treatment via cryotherapy under CT and ultrasound guidance was proposed to 40 patients with malignant breast lesions less than 35mm in diameter. All procedures were performed under local anaesthesia. The patients received follow-up by their oncologist and underwent biannual MRI for an average of 18 months (range 3-48 months). The evolution of the disease was compared between the group of patients treated with primary surgery and the group treated with neoadjuvant hormone therapy and subsequent surgery.
Results: A total of 34 patients were disease-free at 24 months. After cryotherapy, two patients had skin necrosis or erythema. Two patients experienced local recurrence. Among this cohort of patients with the same cancer and comorbidities, the frequencies of complications and recurrence after 24 months were not different between patients who received cryotherapy and patients who received either primary surgery or neoadjuvant hormone therapy with subsequent surgery.
Conclusion: When surgery was not feasible, cryotherapy appeared to be an effective alternative to local treatment of breast lesions without major side effects.

B-1382 14:25

Dosimetric and clinical detail detectability performance of a new dedicated tomosynthesis-guided prone breast biopsy system
S. Grisotto, M. Borroni, E. Mazzarella, T. Giandini, C. Tenconi, A. Primolevo, F. Cartia, C. Ferranti, G. Scaperrotta; *Milan/IT (simone.grisotto@istitutotumori.mi.it)*

Purpose: To evaluate the main parameters affecting clinical practice of the first dedicated tomosynthesis-guided prone breast biopsy system Affirm™ Prone (Hologic, Danbury, USA) and to compare it with prone stereotactic system MultiCare Platinum™ (Hologic, Danbury, USA).
Methods and Materials: Average glandular dose (AGD) for breasts of different compressed thicknesses (21-90mm) was calculated according to Dance et al. (2011) exposing suitable polymethyl methacrylate slabs. AGD_{std}, i.e. the total AGD absorbed after a standard biopsy procedure which differs from one system to the other, was estimated. Detectability of different size lesions was semiquantitatively quantified by 9 operators of our institution evaluating images of 3 different thicknesses of a heterogeneous breast imaging phantom provided with 6 clusters of microcalcifications, 7 fibrils and 6 masses (CIRS 020 BR3D). Particularly, for every image, a detectability score (0, 0.5 or 1) relative to each lesion was independently assigned by all operators.
Results: AGD_{std} for MultiCare Platinum™ resulted 47%, 80% and 3% higher than for Affirm™ Prone, for small (21mm), medium (45mm) and large (75mm) breast sizes, respectively. For the first system, masses and fibrils detectability respectively decreased of about 50% and 85% with increasing phantom thickness. Affirm™ Prone detectability of all types of lesions remained almost constant at the different investigated thicknesses.
Conclusion: The new Affirm™ Prone system enables to perfom breast biopsy procedures with a limited amount of radiation dose, particularly with small and medium breast thicknesses. It also allows a much better visibility of clinical details, particularly fibrils and masses.

B-1383 14:33

Role of tomosynthesis-guided biopsy (3D VAB) in reducing uncertain biological potential lesions (B3) overtreatment, detected with tomosynthesis as architectural distortions
G. Romanucci[1], S. Brunelli[1], P. Bricolo[1], L. Cugola[1], A. Caneva[2], F. Caumo[1]; [1]*Verona/IT*, [2]*San Bonifacio/IT (giovi.romanucci@libero.it)*

Purpose: To evaluate the accuracy of tomosynthesis-guided biopsy in the characterisation of distortions detected with Synthetic 2D + tomosynthesis and in reducing lesions of uncertain malignant potential (B3) overtreatment.
Methods and Materials: Since April 1, 2015 we performed 102 3D VAB procedures on distortion (37%), 7.5% of which detected only with tomosynthesis, using a 9G needle with 20 mm aperture. All the 3D VAB procedures were performed with a double round the clock sampling, collecting 24 tissue samples instead of 12 samples (with an average weight of 3.4 g). The assessment of the post-biopsy residue was performed with tomosynthesis and a residue <10% was classified as complete removal of the lesions. All RS and PL (smaller than 15 mm) completely removed were classified as B2. Each histologic result has been subjected to multidisciplinary discussion for the therapeutic continuation and/or follow-up.
Results: B5 27 (25%), of which 9 detected only in 3D. B2 (55.9%): 42 RS, 2 PL, 13 benign lesions. RS and PL went to annual follow-up for 5 years. B3 (17.6%): 3 RS, 7 SR + ADH, 1 RS + LIN1, 1 RS FEA + ADH + 5 LIN. 66.7% were sent to therapeutic open surgical excision (50% were classified carcinomas at definitive histology), 33.3% were sent to follow-up.
Conclusion: 3D VAB procedures with 9G and 20 mm aperture needle allowed a more substantial and accurate biopsy thus avoiding overtreatment of low-risk malignant transformation lesions (RS and PL).

B-1384 14:41

Outcomes of vacuum-assisted biopsy for B3 breast lesions
N. Larkman, N. Sharma; *Leeds/UK (nisha.sharma2@nhs.net)*

Purpose: Management difficulties arise from the heterogeneous pathologies comprising B3 lesions. Vacuum assisted biopsy's (VAB) larger sampling compared to core biopsy means diagnostic surgery may be avoided. Our retrospective study looked at the grade of malignancies arising from B3 pathology.
Methods and Materials: A retrospective study from 2009 to 2014. Patients with B3 lesions on core biopsy from screening or symptomatic settings and a vacuum-assisted biopsy with pathology results were included. Upgrade rate at vacuum biopsy and surgery was reviewed.
Results: 735 B3 lesions on core biopsy. Of these 439 underwent VAB and 230 surgery. 95 had a VAB and surgery. Following VAB 89% (389) remained B3 or benign and 11% (50) were upgraded: 36 (72%) upgraded to B5a - 4 (8%) high grade in-situ disease, 12 (24%) upgraded to invasive B5b disease and 1 to B4. Of the VAB and surgery specimens; 6 (6%) downgraded from B5a to B3 following surgery. In these cases the DCIS was wholly removed by the VAB.

One B5b downgraded to B5a (invasive component excised in VAB), 7 (7%) upgraded from B3 to B5a, 1 (1%) was a B5a upgraded to a B5b - HGDCIS to ductal grade 1. One(1%) was a B3 upgraded to B5b - LCIS to ILC grade 2.
Conclusion: The reticence to use vacuum biopsy to manage B3 lesions is contributing to over diagnosis and treatment. If B3 lesions are upgraded the majority are low grade malignancies that will not have a negative impact on the women's life.

B-1385 14:49

Prospective follow-up of patients with B3 lesions over a 4-year period
N.D. Forester, N. Altaf; *Leeds/UK (nerysforester@mac.com)*

Purpose: Following introduction of large-bore vacuum-assisted biopsy (LVB) for diagnosis and management of B3 lesions in 2011, a prospective database of patients was developed. Following B3 lesion diagnosis on core biopsy, patients underwent LVB. If B5, patients had surgery; if B3 patients underwent 5 years annual surveillance mammography (ASM) or were discharged/returned to routine recall, depending on the presence of epithelial atypia. Patient outcomes were prospectively audited.
Methods and Materials: B3 lesion database analysed to ascertain number of ASMs performed, recall rate, symptomatic episodes and subsequent malignancy following B3 diagnosis.
Results: Between October 2011 and December 2015, 396 B3 lesions identified. 305 underwent second line LVB. 27 patients diagnosed with malignancy following LVB and 17 patients upgraded to malignancy following excision biopsy (unsuitable for LVB/pathology request). 352 patients had ASM/routine recall, together having 410 mammograms performed over 4 years. 9 patients were recalled from ASM (recall rate 2%). 20 underwent further breast investigations (19 presented symptomatically, 1 recalled from MRI high-risk surveillance). From additional investigations 3 cancers diagnosed (1 following high-risk surveillance MRI; 1 symptomatic presentation, 1 recall from ASM). There were also 4 further B3 lesions and 22 benign diagnoses.
Conclusion: LVB for B3 lesions is an excellent alternative to excision biopsy. However, ASM has a low recall rate and cancer detection rate, with only 1 of the 3 subsequent cancers detected by mammographic surveillance. This questions whether ASM is really necessary in this group of patients. Could they be safely returned to routine recall within the screening program?

B-1386 14:57

Non-surgical complete excision of small suspicious breast lesions using the breast lesion excision system BLES
N.M. Abdel Razek; *Cairo/EG (naglaabdelrazek@yahoo.com)*

Purpose: To assess the diagnostic efficiency of BLES in comparison to OB in diagnosis of small suspicious breast lesions.
Methods and Materials: The study included 435 patients with small suspicious non-palpable breast lesions. We included lesions categorised as BIRADS 4 & BIRADS 3 with positive family history for breast cancer.
Results: 435 suspicious lesions were successfully removed using the BLES,19.3 % (84/435) were diagnosed after histopathology as benign including fibrocystic disease, sclerosing adenosis, radial scars and papillomas without atypia. 38.2% (166/435) were diagnosed as high-risk lesions including, papillomas with atypia, ALH, ADH & 48.4% (142/435) were diagnosed as malignant including DCIS, LCIS,IDC&ILC. The maximum size removed was 12mm there was no underestimation encountered by the BLES. The margin was free in 40/142 (28.2%) and the margin was close in 45/142 (31.7%) and the margin was involved in 57/142 (40.1%) of the malignant cases.122/142 histopathologically proven malignant lesions were exposed to re-surgery and in 20/142, no surgery after BLES, only radiotherapy and sentinel node diagnosis. BLES outperforms the VAB in high-risk and malignant lesions. BLES is 100% as sensitive as the OB regarding the concordance and sensitivity with no underestimation. In 20/40 margin-free lesions, BLES excision was not followed by surgery, only sentinel node and radiotherapy.
Conclusion: BLES could be an efficient management for small carcinomas less than 8mm diameter if complete excision with free margin was achieved yet still it is the decision of the MDT and should be associated with sentinel node biopsy and focal radiotherapy.

B-1387 15:05

Gene expression profiling of breast cancer: associations among mammographic microcalcifications, ERBB2 and immunity
S. Shin, A. Chu, S. Song, W. Han, J. Kim, W. Moon; *Seoul/KR (shinsungui@gmail.com)*

Purpose: To investigate the associations between mammographic microcalcifications and breast cancer gene expression profiles using microarray analysis.
Methods and Materials: Gene expression analysis was performed using Affymetrix GeneChip® Human Gene 2.0 ST arrays in 168 breast cancer patients. Mammographic microcalcifications of these patients were reviewed by three radiologists and grouped into three groups: no microcalcifications (n=99); low-to-intermediate microcalcifications (n=37); and highly suspicious microcalcifications (n=32). To identify differentially expressed genes (DEGs) between these three groups, a one-way analysis of variance was performed with post hoc comparisons with Tukey's honest significant difference test, and a P value <0.05 was applied as the threshold for statistical significance. To explore the biological significance of DEGs, we used DAVID for gene ontology analysis and BioLattice for clustering analysis.
Results: Total 2551 genes showed differential expression among the three groups. Of these, 1838 DEGs were detected for the highly suspicious/no microcalcifications comparison, 484 DEGs for the highly suspicious/low-to-intermediate microcalcifications comparison, and 457 DEGs for the low-to-intermediate/no microcalcifications comparison. ERBB2 genes are up-regulated in highly suspicious microcalcifications group (P<0.001, fold change 2.474) . Both gene ontology and clustering analyses revealed that the immune, defense and inflammatory responses were decreased in the highly suspicious-microcalcifications group compared with the no-microcalcifications group (P<0.001).
Conclusion: Gene expression patterns are different according to the status of mammographic microcalcifications in breast cancer. Breast cancers with mammographic microcalcifications are associated with high levels of mRNA expression of ERBB2 and decreased immune system activity.

Triple-negative breast cancer: MR imaging findings associated with clinical-pathologic factors
K. Lee, S. Kim, B. Kang, I. Youn; *Seoul/KR*

Purpose: To compare the magnetic resonance imaging (MRI) findings and clinical-pathologic characteristics in patients with triple-negative cancer (TNC) with recurrence or advanced stage.
Methods and Materials: This study was approved by institutional review board. The informed consent for patients was waived. Two hundred eighty one patients with TNC between January 2009 and March 2016 who underwent preoperative MRI were included. Visual assessment of central T2 high signal intensity, rim-enhancement, DWI peripheral high signal intensity were performed by two radiologists. Measurement of ADC values of entire tumour, central and peripheral portion of the tumour was performed for 101 lesions. Clinical-pathologic data were collected including age, recurrence, stage, resection margin, histologic grade, tumour size, multiplicity, lymphovascular invasion (LVI), nodal involvement. Statistics for hazard ratio of recurrence performed using Cox proportional hazards model. Logistic regression analysis was performed to evaluate risk factors associated with advanced stage. The inter-observer reliability of ADC measurements was assessed using intra-class correlation coefficient.
Results: Of the 288 lesions, 36 (12.5%) lesions were recurred after a median follow-up of 18.0 months. Hazard ratio for recurrence was increased with LVI, tumour size, nodal involvement, advanced stage, rim-enhancement (p<0.05). Odds ratio for advanced stage was increased with LVI, tumour size, nodal involvement and recurrence (p<0.05). Intra-class correlation coefficient for ADC value of the whole tumour exceeded 0.80, indicating good agreement, but ADC values were not significantly associated with recurrence or advanced stage.
Conclusion: Rim-enhancement and several clinical-pathologic factors can be prognostic factors for recurrence and advanced stage in patients with TNC.

B-1389 15:21

Systematic review of breast lesions of uncertain malignant potential (B3 lesions) and their risk of malignancy
N.D. Forester, S. Lowes; *Newcastle/UK (nerysforester@mac.com)*

Purpose: Borderline breast lesions (B3 lesions) can coexist with malignancy. The magnitude of this risk varies between studies and lesion subtypes. This systematic review will determine an accurate estimate of the risk of invasive in-situ malignancy identified by surgical excision biopsy, following diagnosis of a B3 lesion at core biopsy, within each B3 lesion subtype, to guide risk stratification and improve management strategies.
Methods and Materials: Literature searches (MEDLINE, Embase, HMIC, Scopus and Web of Knowledge) identified relevant studies between 1980 and 2015. Literature appraisal, meta-analysis and subgroup analysis performed to determine malignancy risk for all subgroups of B3 lesions (Papilloma, Radial Scar, AIDP, Lobular Neoplasia and FEA).
Results: Searches returned 2289 citations, with 11 identified from other sources. Duplicates, unsuitable articles and abstracts/posters/reviews were excluded leaving 183 records. From these, 54 full-text articles did not meet inclusion criteria. Meta-analysis was performed from 129 studies. Rates of malignancy varied from 6% in a radial scar with no atypia, to 32% for a

papilloma with atypia. Differences in malignancy upgrade rates between atypical and non-atypical lesions were statistically significant (p<0.05). Study heterogeneity could not be explained by differences in core biopsy size or year of publication, however, a significant difference in upgrade rates to malignancy was observed between the US and non-US literature.
Conclusion: Studies have assessed the risk of malignancy following diagnosis of B3 lesions, but are often small and lack statistical power. This study is a comprehensive, inclusive assessment of the available literature, on which to base tailored management strategies.

Integrated FDG-PET/MRI in patients with drug resistant epilepsy
C. Deuschl[1], T. Rüber[2], L. Ernst[2], J. Kirchner[3], V. Ruhlmann[1], T. Pöppel[1], M. Forsting[1], C. Elger[2], L. Umutlu[1]; [1]*Essen/DE*, [2]*Bonn/DE*, [3]*Düsseldorf/DE (cornelius.deuschl@uk-essen.de)*

Purpose: The aim of this study is to evaluate the diagnostic impact of simultaneous 18F-FDG PET/MRI for the detection of epileptogenic lesions in patients with drug resistant epilepsy.
Methods and Materials: Twelve patients with drug resistant epilepsy were enrolled in this ongoing prospective study (mean age: 40,1 years, range: 19-75 years, 6 female). All patients underwent a simultaneous 18F-FDG PET/MRI of the brain, comprising the following sequences: (1) non-enhanced MPRAGE, (2) 3D FLAIR, (3) STIR cor, (4) T2 ax, (5) SWI. Image analysis was performed by a neuroradiologist and a nuclear medicine specialist during consensus reading with subsequent reading of the (1)MRI, (2)PET and (3) fused PET/MR datasets regarding (a) lesion detection and (b) diagnostic confidence.
Results: All examinations were obtained successfully without any relevant (misregistration) artifacts. Based on morphologic MR readings, 8/12 patients were found to show suspicious lesions. Out of these 8 morphologically suspicious lesions, 5 lesions showed a corresponding lesion in FDG-PET (4 showed hypo- and one hypermetabolism). Based on the fused image analysis the diagnostic confidence was rated higher (mean 3,1) for PET/MRI when compared to sole morphologic reading (2.7). 4/12 patients did not show any pathologic findings in MRI and / or PET/MRI.
Conclusion: Our preliminary study results show an added diagnostic value of simultaneous 18-F-FDG PET/MRI in improving the diagnostic confidence for the detection of epileptogenic lesions, particularly for diagnosing temporal lobe epilepsy.

B-1391 14:08

Task specific alterations of the functional language connectome in patients with temporal lobe epilepsy
K.-H. Nenning, O. Fösleitner, C. Widmann, D. Prayer, C. Baumgartner, E. Pataraia, G. Langs, S.B. Bonelli, G. Kasprian; *Vienna/AT*

Purpose: Temporal lobe epilepsy (TLE) in the language dominant hemisphere may impair language function. In this study, we used functional MRI (fMRI) to 1. analyse the functional language connectome (LC) in healthy controls and 2. how it may be disrupted due to the underlying disease during two distinct language tasks in patients with left-sided TLE due to hippocampal sclerosis.
Methods and Materials: The functional LC was calculated on the basis of preoperatively acquired fMRI data (3 Tesla) during a verb-generation and a phrases task. A reference LC was established in 14 healthy controls and compared to the LC of 14 left TLE patients. The LC was calculated via task-regressed functional connectivity analysis (SPM12b, CONN toolbox), and differences in the connectome were quantified using Network Based Statistics (age and duration of disease were used as covariates).
Results: Analysis revealed widespread impairment of the LC in patients during verb-generation, involving frontal and temporal regions on the left hemisphere and regions in the contralateral cerebellum. The functional LC during the phrases task showed significantly decreased interhemispheric connectivity between the temporal lobes.
Conclusion: Analysis of the functional LC showed task-specific impairment of active language networks in left TLE, revealing that the left frontal language network within the ipsi- and to the contralateral hemisphere was impaired. This suggests a critical role for the left medial temporal lobe in language tasks.

B-1392 14:16

Correlation of language lateralisation with resting state hippocampal connectivity in temporal lobe epilepsy patients
A.M. Koc[1], A.Y. Oner[2], H. Ozer[2], M. Guryildirim[3], E.T. Tali[2]; [1]*Izmir/TR*, [2]*Ankara/TR*, [3]*Chicago, IL/US (alimuratcoach@yahoo.com)*

Purpose: Task-based fMRI allows easy calculation of language lateralisation index (LI) which is essential in preoperative evaluation of temporal lobe epilepsy (TLE) patients. Resting state (rs-) fMRI also can reveal brain connectivity networks. A method correlating resting state connectivity values with language lateralisation indices on single subject basis is introduced.
Methods and Materials: Task based and resting state fMRI data were gathered from a total of 45 subjects (15 subjects per Right-TLE, Left-TLE, healthy control groups) in 3T scanner. Brainvoyager QX, SPM and CONN softwares were used for preprocessing and functional data analysis. LI score of each subject was calculated and converted into normalised LI score (nLI). Intrahemispheric rs-connectivity analysis was performed between hippocampus and Broca regions on both sides. Correlation analysis was performed between these variables using SPSS software.
Results: Left intrahemispheric connectivity values showed moderate positive correlation with nLI values in Left-TLE patients (Rho=0,580; p:0,048) and whole subjects (Rho=0,560; p:0,001); strong positive correlation in Right-TLE patients (Rho=0,610; p:0,035) and control subjects (Rho=0,697; p:0,025). There were no positive or negative significant correlation between right intrahemispheric connectivity values and cLI scores in Left-TLE, Right-TLE patients, control and whole subjects (p:0,533; p:0,404; p:0,229; p:0,252 respectively).
Conclusion: Language LI estimation from rs-connectivity analysis in TLE patients could be a very useful tool eliminating the need for task based fMRI. This method seems to depict the correlation between hippocampal FC and nLI in epilepsy patients and healthy controls but further studies with increased sample sizes may demonstrate better outcomes covering all patients.

B-1393 14:24

Dynamic changes in internetwork functional connectivity of resting state networks in intractable mesial temporal lobe epilepsy
C. Zhang, K. Li, N. Chen, H. Yang; *Beijing/CN (chaozhang0328@hotmail.com)*

Purpose: To investigate the dynamic changes in functional connectivity (FC) between each resting-state networks (RSNs) in temporal lobe epilepsy (MTLE) patients before and after surgical treatment.
Methods and Materials: Resting-state fMRI data were acquired from 7 intractable unilateral MTLE patients and all this 7 patients received surgical treatment. The control group included 18 healthy volunteers. Subject-specific RSNs were estimated for three groups through group-information guided ICA. Nine meaningfull RSNs were identified via visual inspection. One-way ANOVA was used for analysing internetwork FC (iFC) differences among three groups. p<0.05 was considered statistically significant.
Results: Preoperative MTLE patients showed significantly increased iFC between pDMN (posterior default mode work) and AN (auditory network), CN (central network) and SMN (sensorimotor network) when compared with healthy volunteers, the significantly decreased iFC was found among AN, mVN (medial visual network) and SMN ($p < 0.05$). Posttreatment patients exhibited deceased iFC between DMN and SMN, CN and SMN, CN and parietal network, on the contrary, iFC between DMN and lVN (lateral visual network) increased when compared with preoperative patients ($p < 0.05$). However, there was no significantly change of iFC in posttreatment patients when compared with healthy volunteers.
Conclusion: Our study suggested that abnormal iFC in RSNs may reflect the characteristics of epileptic network. Furthermore, the dynamical changes of this functional organisation before and after surgical treatment may provide valuable information for further understanding of the pathophysiological mechanisms of intractable MTLE.

B-1394 14:32

Localisation of the epileptogenic neural network by the resting state fMRI in patients with temporal lobe epilepsy
O. Omelchenko, M. Makarchuk; *Kiev/UA (ol.omelchenko@gmail.com)*

Purpose: Temporal lobe epilepsy (TLE) exhibits recurrent seizures and has its epileptogenic zone. Hippocampus plays important role in seizure origin as it possesses large number of epileptogenic potassium ion channels. Localisation of epileptogenic zone and its delineation from eloquent cortex are crucial for successful surgery. We propose analysis of brain neural networks connectivity in the resting state (RS) and during movement execution in patients with TLE for the epileptogenic neural network localisation and motor cortex mapping.
Methods and Materials: Group of 8 patients (4M, 4F, age 19-49 y) was studied with the functional MRI. TLE was diagnosed by neurologist with the EEG. We used 1.5T SIGNA (GE) for routine MRI and fMRI. Finger tapping and RS acquisition was used for the fMRI. EPI was used for BOLD imaging

(TR/TE=3000/71 ms, voxel 4x4x5mm). FMRI data processing was carried out using FSL (Oxford, GB).
Results: FMRI data analysis revealed activation of the intact motor neural network of the brain: contralateral sensorimotor cortex, supplementary motor area and ipsilateral hemisphere of cerebellum. Deactivation of the left hippocampus was found. RS fMRI revealed increased functional connectivity of the anterior pole of the inferior temporal gyrus, posterior pole of the middle temporal gyrus, hippocampus and parahippocampal gyrus of the left hemisphere. This potentially depicts the epileptogenic neural network as it topographically coincides with the localisation of the EEG epileptiform activity.
Conclusion: RS fMRI could potentially depict epileptogenic neural network in TLE which includes regions of temporal lobe and hippocampus.

B-1395 14:40

Disrupted fronto-hippocampal language network in patients with temporal lobe epilepsy

K.-H. Nenning, O. Fösleitner, C. Widmann, D. Prayer, C. Baumgartner, E. Pataraia, G. Langs, S.B. Bonelli, G. Kasprian; *Vienna/AT*

Purpose: Temporal lobe epilepsy (TLE) in the language dominant hemisphere may impair language function. We used fMRI to study hippocampal and frontal language networks in patients with TLE and how it may be disrupted due to the underlying disease.
Methods and Materials: Functional connectivity (FC) analysis was based on preoperative fMRI data (3T, verb-generation task) of 27 patients with TLE (12 left) due to hippocampal sclerosis and 14 healthy controls. Data preprocessing was performed using Freesurfer and FSL, including the measurement of hippocampal volume (HV). For FC analysis the average time-series of 150 regions of interest (ROIs) were used (Freesurfer cortical parcellation), including 2 additional ROIs for the left and right hippocampus.
Results: Compared to right-TLE and controls, patients with left-TLE showed decreased FC within the language dominant network, and decreased FC from the left hippocampal ROI primary to frontal regions on both hemispheres. FC from Broca's region was reduced in left-TLE patients, within the left but also to the right hemisphere, which was not observed in right-TLE who showed a similar FC pattern as controls. Regression analysis revealed a relationship between HV and FC to frontal regions. These findings were corroborated by graph-based network analysis (efficiency, density), demonstrating impaired network structure in left-TLE.
Conclusion: FC analysis revealed that in left-TLE the left fronto-hippocampal language network was disrupted. Results indicated that the hippocampal integration in the frontal default mode network was disturbed, suggesting a critical role for the integration of the left hippocampus in the DMN during language tasks.

B-1396 14:48

Arterial spin labeling (ASL) in acute seizure

B. Law-Ye, M. Schertz, N. Pyatigorskaya, S. Belkacem, D. Dormont, D. Leclercq; *Paris/FR (brunolawye@hotmail.fr)*

Purpose: Seizure activity can mimic acute stroke. Arterial spin labeling (ASL) is a noninvasive method to measure cerebral blood flow. The objective of this study was to evaluate the characteristics of ASL imaging in acute seizure.
Methods and Materials: Among a cohort of patients presenting with a brutal neurological deficit in a national specialised stroke center, we retrospectively reviewed 24 cases of proven seizures who underwent magnetic resonance imaging (MRI) with ASL sequence at acute phase. We compared these data with electro-encephalographic findings.
Results: Hyperperfusion (high relative cerebral blood flow) was found in the cortical epileptogenic zone in all patients with a good correlation with clinical and electroencephalographic data. Additionally, 7 patients had a hyperperfused area in the homolateral pulvinar, and 5 patient had a hyperperfused area related to cerebellar diaschisis. Underlying causing lesions were found in 19 cases (ischemic sequelae n = 3, brain tumour n = 6, surgical scar n = 2, cortical dysplasia n = 2, haemorrhage n = 1, others n = 5). Associated diffusion abnormalities were found in 15 cases.
Conclusion: High cerebral blood flow in ASL can be observed in the cortical epileptogenic zone, in the homolateral pulvinar and in contralateral cerebellum (cerebellar diaschisis) of patients with acute seizure. The mechanism of hyperperfusion due to seizure activity may be related to transient loss of autoregulatory function in the surrounding vasculature. Arterial spin labeling is useful in the differential diagnosis of acute neurologic deficits. This sequence complements the traditional evaluation with electroencephalography (EEG).

Does radiation therapy increase gadolinium accumulation in the brain: quantitative analysis of T1 shortening using R1 relaxometry in glioblastoma multiforme patients

W. Lim, S. Choi; *Seoul/KR (smtwh89@gmail.com)*

Purpose: To evaluate association between gadolinium accumulation in the brain and radiation therapy in glioblastoma multiforme (GBM).
Methods and Materials: From January 2010 to June 2015, 44 patients with supratentorial GBM were retrospectively identified, who completed standard treatment for GBM, and underwent pre- and post-radiation brain MR imaging including R1 map. All MR imagings were performed using gadobutrol (Gadovist, Bayer, Germany). Mean dose of used gadobutrol was 5.1 vials. Region of interests (ROIs) were drawn around primary tumours, which were located within 50-100% iso-dose lines of maximum radiation dose. ROIs were also drawn globus pallidus, thalamus, and cerebral white matters. Averages of R1 values (unit: sec^{-1}) before and after radiation therapy were compared using t-test or rank sum test as appropriate. R1 ratio (post-radiation R1 value / pre-radiation R1 value) was also calculated and compared according to radiation dose and radiation therapy type. Multiple regression analysis was examined to evaluate independent association factor for R1 increase.
Results: R1 value at peri-tumoural areas was significantly increased after radiation therapy (0.7901±0.0977 vs. 0.8146±0.1064; P=.0066). R1 ratio at high dose area was significantly higher than that of low dose area (1.0055±0.06539 vs. 0.9882±0.06419; P=.0003). R1 ratio of whom underwent hypofractionated radiation therapy was lower than that of whom underwent routine radiation therapy (1.0463±0.0633 vs. 0.9913±0.0740; P=.0758). Multiple regression analysis revealed only radiation type was significantly associated with R1 increase (P=.0212) around primary tumours.
Conclusion: Radiation therapy can enhance gadolinium accumulation in the brain, which can be explained by damaged blood-brain barrier.

B-1398 15:04

Evaluation of gadolinium brain deposits in melanoma patients: a retrospective study

J.L. Moreno Negrete, J.C. Soler, N. Borges Ribeiro Vaz, S. Podlipnik, L. Oleaga Zufiria; *Barcelona/ES (JLMORENO@clinic.ub.es)*

Purpose: The aim of the study is to retrospectively evaluate gadolinium brain deposits on MRI in the follow-up studies of patients with melanoma.
Methods and Materials: We performed a retrospective analysis of the contrast-MRI studies in 139 patients with localised melanoma. Mean age 52 years, all patients underwent more than 4 contrast-enhanced MRIs on the follow-up. Patients did not receive chemotherapy. A total of 1109 SE-T1W MRIs were evaluated, 92.24% of them were performed in three different 1,5T scanners and 6.67% in a 3.0T scanner. 87% of the patients underwent an average of 8 contrast-MRIs. Contrast agent used was gadobutrol at 0.1 mmol/kg dose. The variables recorded were creatinine, qualitative visualisation of the basal hyperintensity of the dens nucleus and globus pallidus on SE-T1W images, quantitative evaluation drawing ROIs on SE-T1W images of the dens and pallidum normalised with pons and thalamus respectively.
Results: Hyperintensity in the dens nucleus and globus pallidus was observed in 41% of the sample at the last MRI recorded. 12% of them at the 4th MRI and 54% between the 6th and 10th MRI. All cases visualised in a 1.5T scanner were positive on the 3.0T scanner. In contrast, some positive cases on the 3.0T scanner were not visualised in the immediate-next 1.5T study. All patients had normal renal function at first visit.
Conclusion: There is a significant association between dens nucleus and basal ganglia hyperintensity and the administration of cyclic-chelated gadolinium.

Minimising the confounding effect of gadolinium contrast on subsequent ferumoxytol MRI in the brain

C.G. Varallyay, G. Toth, A. Horvath, L. Szidonya, E. Youngers, E.A. Neuwelt; *Portland, OR/US (varallyc@ohsu.edu)*

Purpose: Gadolinium enhanced MRI is the standard of care for various CNS pathologies. Ferumoxytol, used off label as an MRI contrast agent can visualize abnormal vascularity and can be used to create high resolution steady state CBV maps, which is not feasible with standard gadolinium. Clinically, it would be beneficial to extend gadolinium with subsequent ferumoxytol imaging, without confounding effects between the two contrast agents. The purpose of this study was to test if gadolinium administration alters the signal on T2*-weighted images, which are used for steady state CBV calculation with ferumoxytol.
Methods and Materials: Fifteen cases of 9 subjects with glioblastoma, enrolled in an ongoing imaging trial were analyzed. Two types of T2*-weighted acquisition techniques were tested: 3D gradient echo (the magnitude images of susceptibility-weighted imaging), and 2D gradient multiecho. Signal intensity

changes within the enhancing tumour were evaluated between pre and post standard gadolinium, as well as pre and post 7mg/kg ferumoxytol.
Results: Signal intensities post gadolinium (normalized to precontrast scan) increased substantially on the 3D T2*-weighted scans to 1.62±1.3 (Mean ± SD), while only minimally on the 2D T2*-weighted scans (to 1.1±0.08). Ferumoxytol caused signal drop on both sequences similarly, to 0.63±0.27 on the 3D and 0.64±0.14 on the 2D acquisitions.
Conclusion: Given the predominant T1 relaxation time shortening effect of gadolinium and T2* shortening effect of ferumoxytol early after injection, 2D T2*-weighted acquisition lacking substantial T1 effects is the best choice to image the intravascular space with ferumoxytol when added to standard of care gadolinium MRI.

Gadolinium brain retention: detection and quantification of gadolinium based contrast agents in the cerebrospinal fluid in rats

G. Jost, J. Lohrke, T. Frenzel, H. Pietsch; *Berlin/DE (gregor.jost@bayer.com)*

Purpose: Increased signal (SI) intensity on unenhanced MRI in certain brain regions has been reported after repeated administrations of some gadolinium-based contrast agents (GBCAs). The pathway of GBCA entry into the brain and its distribution are unknown. One potential pathway, the infiltration of GBCAs from blood into the cerebrospinal fluid (CSF), was systematically evaluated in this rat study.
Methods and Materials: The infiltration and distribution of six marketed, multi-purpose GBCAs (three linear and three macrocyclic agents) in the CSF were investigated in healthy rats using repeated fluid-attenuated MRI after a single administration of 1.8 mmolGd/kg. Additionally, gadolinium in CSF and blood samples (obtained after 4.5 and 24 hours) was quantified by inductively coupled plasma mass spectrometry.
Results: Enhanced SI in the CSF spaces with similar kinetics was observed for all GBCAs. The SI time course suggests a GBCA entry from blood into the CSF via the choroid plexus and a further distribution with the CSF flow. No substantial differences in the gadolinium concentrations among the GBCAs were found in CSF and blood. After 4.5 hours, the concentration in the CSF (18.8-27.4 µM) was clearly higher than in blood (2.0-4.7 µM). After 24 hours CSF was almost completely cleared (0.08-0.28 µM) and the gadolinium concentration was lower than in blood (0.29-0.76 µM).
Conclusion: In contrast to the increased SI in some brain areas, no differences in infiltration and distribution into the CSF of healthy rats among the GBCAs were observed. After 24 hours an almost complete clearance from CSF was found.

Sardanelli[1]; [1]*San Donato Milanese/IT*, [2]*Turin/IT*, [3]*Cordoba/ES*, [4]*Nijmegen/NL*, [5]*Erlangen/DE*, [6]*Milan/IT*, [7]*Maastricht/NL*, [8]*Vienna/AT*, [9]*Almelo/NL*, [10]*Tübingen/DE*, [11]*Udine/IT*, [12]*Rotterdam/NL*, [13]*Villejuif/FR*, [14]*Istanbul/TR*, [15]*Sao Paolo/BR*, [16]*Rome/IT*, [17]*Münster/DE*, [18]*Perth/AU*, [19]*Alzira/ES*, [20]*Genoa/IT*, [21]*Palermo/IT*, [22]*Fayetteville, AR/US*, [23]*Antwerp/BE*, [24]*Budapest/HU*, [25]*Cambridge/UK*, [26]*Sydney/AU (trimboli.rm@gmail.com)*

Purpose: To show midterm results of the MIPA study.
Methods and Materials: Two concurrent groups of patients with newly diagnosed breast cancer, not candidate to neoadjuvant therapy, receiving or not receiving MRI, were prospectively enrolled in 28 centres. Data retrieval from clinical records. Statistics: McNemar, χ^2.
Results: Up to July 2016, 4944 patients were recruited, 2425 having data for analysis: 1201 (49.5%) without and 1224 (50.5%) with MRI. Of these 1224 MRIs, 210 (17%) were performed for screening (4%) or diagnostic purposes (13%). Of 1014 preoperative MRIs, 595 (59%) were ordered by radiologists alone (59%), 321 (32%) by surgeons alone; radiologist and surgeons were anyway involved in ordering MRI in 68% and 40% of the cases, respectively. Mastectomy rate planned at mammography/ultrasound was 185/1201 (15.4%) for non-MRI-group and 245/1224 (20.0%) for MRI-group (p<0.001). In MRI-group, 21 additional mastectomies (1.7%) were planned after MRI compared to those planned before MRI, while 25 patients planned with mastectomy shifted to conservative treatment (p=0.026). Of the 1004 patients planned for conservative treatment after MRI, MRI did not change surgery in 733 (73%), while prompted a wider surgery in 143 (12.5%), a less extensive surgery in 128 (12.7%). Mastectomy rate was 192/1201 patients (16%) in non-MRI-group and 257/1224 (21%) in MRI-group (p<0.001). Per-patient reoperation rate for close/positive margins were 135/1009 (13.4%) in non-MRI-group and 80/967 (8%) in MRI-group (p<0.001).
Limitations: Observational, non-randomised.
Conclusion: More than 1/6 (17%) of MRIs were performed for screening or diagnosis. Surgeons ordered MRI in 40% of cases but MRI prompted only 1.7% increase in mastectomy. MRI was frequently used as confirmation tool for an already planned mastectomy. MRI may allow a more tailored conservative surgery.

The MICRA trial: Minimally Invasive Complete Response Assessment of the breast after neoadjuvant systemic therapy

M.E.M. van der Noordaa[1], F.H. van Duijnhoven[1], C.E. Loo[1], I. de Zwart[1], K. van den Vijver[1], G. Sonke[1], C.C. van der Pol[2], A. Francken[1], M.-J.T.F.D. Vrancken Peeters[1]; [1]*Amsterdam/NL*, [2]*Utrecht/NL (m.vd.noordaa@nki.nl)*

Purpose: We aim to omit surgery in breast cancer patients achieving pathologic complete response (pCR) after neoadjuvant systemic therapy (NST), thus preventing overtreatment and improving quality of life.
Methods and Materials: The MICRA-trial is a multicentre prospective cohort study. 440 breast cancer patients with a radiologic complete response on MRI after NST will be included. Prior to NST, a radioactive iodine seed is placed in the tumour. After NST, 8 ultrasound-guided biopsies are obtained from the region surrounding the iodine seed, while the patient is under general anesthesia. Immediately hereafter, breast surgery is performed. Pathology results of the biopsies and resected specimens are compared.
Results: Preliminary results: Until now, 39 patients have been included. The procedure was successful in 35/39 patients. Of these 35 patients, 46% had Her2+, 37% had TN tumours and 17% had HR+ tumours. Overall pCR (ypT0) was 63%. Our preliminary results show that out of 24 patients with pCR in biopsies, 4 patients had residual disease in the specimen (2 patients with near-pCR and 2 patients with ductal carcinoma in situ). All patients with residual disease in biopsies had residual disease in the specimen.
Limitations: Since biopsies are obtained in the operating room while the patient is under general anesthesia, identification of the iodine seed is more challenging for the radiologist.
Conclusion: With the MICRA-trial we aim to select a group of breast cancer patients in whom surgery of the breast after NST can be omitted, by predicting the presence of a pCR solely on biopsies.

The MULTIPROS study - Multiparametric MRI with subsequent randomisation to MRI/US fusion guided biopsy vs TRUS biopsy in the diagnosis of prostate cancer

M.J. Szewczyk-Bieda, C. Wei, S. Vinnicombe, S. Lang, G. Nabi; *Dundee/UK (m.szewczyk-bieda@nhs.net)*

Purpose: To assess the reliability of pre-biopsy multiparametric MRI (MP MRI) in prediction of significant prostate cancer (PCa) and whether targeted US/MRI fusion-guided biopsies (FGB) allow accurate targeting of suspicious foci.
Methods and Materials: A prospective, multicentre study with subgroup randomisation. All patients with suspicion of localised PCa were considered. All enrolled participants underwent pre-biopsy MP MRI. In the positive MP MRI subgroup, (PIRADS v.2 score ≥3), patients were randomised to intervention (US/MRI FGB +TRUS) or TRUS biopsies alone. Patients diagnosed with PCa were offered standard stage-dependent treatment options. In the subgroup undergoing radical prostatectomy (RP) the specimen was sectioned using customised 3D printed molds, to allow slice-by-slice comparison with MP MRI.
Results: To date 107/600 participants have been recruited with 82 positive MP MRI, 39 randomised to US/MRI FGB (intervention group) and 43 to SC TRUS biopsy. In the intervention group, US/MRI FGB diagnosed 25 PCa and TRUS diagnosed 19 PCa; fusion biopsy targeted 22% more significant cancers than TRUS biopsy (p<0.05). A total of 46 MP MRI positive lesions were targeted in US/MRI FGB. Significantly more Gleason score ≥7 PCa were diagnosed in PIRADS 5 lesions (p=0.04). Preliminary data from 18 RP performed, suggest that performance of MP MRI was better for lesions larger than 10mm and situated in the peripheral zone.
Limitations: Health economics was not included in the study.
Conclusion: Preliminary results suggest that US/MRI FGB performs better than TRUS biopsy in patients with positive MP MRI.

Study design and inclusion ROBINSCA trial: large-scaled population based (CT) screening trial for cardiovascular disease

C. van der Aalst[1], M. Vonder[2], J. Gratama[3], M.A. van Aerde[1], D. Kuijpers[4], H. de Koning[1], M. Oudkerk[2]; [1]*Rotterdam/NL*, [2]*Groningen/NL*, [3]*Apeldoorn/NL*, [4]*The Hague/NL (m.vonder@umcg.nl)*

Purpose: To give an overview of the study design and the first recruitment results of the ROBINSCA trial.
Methods and Materials: In three regions of the Netherlands, 400,000 people (age: 45-74 years) were invited to complete a questionnaire to assess eligibility. Eventually, 39,000 responders with elevated cardiovascular risk will be included and randomised (1:1:1) into either: 1) control group, 2) screening by SCORE method group, or 3) screening by coronary calcium CT scan group. Participants of group 2 and 3 will be stratified into risk categories and receive medical treatment according to their risk category. Risk categorisation for group 3 is based on the Agatston score, with low: 0-99, high: 100-399 and very high risk: ≥400.
Results: In the first phase, 135,862 persons were invited of which 33,918 (25%) responded of which 17,500 (51%) were eligible for randomisation, as expected. So far, 3140 participants (52% male, mean age 61.8 (SD 7.3)) were randomised to the CT screening group. Of these participants, 59.9% had a positive calcium score with a median Agatston score of 53.6 (range:1-7678). Percentage of participants per risk category was: low: 77.7%, high: 14.7%, very high: 7.5%.
Limitations: Only results of the first phase were included.
Conclusion: The inclusion of the first phase of the ROBINSCA trial shows optimal fulfilling of the parameters of the study design. Currently, participants at (very) high risk are treated with medication and in forthcoming years, results should show if population-based CT screening for CVD is more (cost) effective than screening by conventional risk factors or no screening.

Non-invasive treatment of osteoid osteoma with MRgFUS in paediatric patients only: a retrospective multicentre study
F. Arrigoni[1], A. Napoli[2], L. Zugaro[1], R. Scipione[2], A. Barile[1], C. Catalano[2], C. Masciocchi[1]; [1]*L'Aquila/IT*, [2]*Rome/IT (arrigoni.francesco@gmail.com)*

Purpose: To retrospectively evaluate in a multicentre study (two university hospitals), the effectiveness and safety of magnetic resonance-guided focused ultrasound (MRgFUS) as a definitive treatment for Osteoid Osteoma in paediatric patients. This pathology mostly affects patients in paediatric age: it is therefore crucial, to use the least invasive techniques.
Methods and Materials: Over a period of 4 years, we treated 27 patients (age <18 years, mean 11.7) affected by symptomatic non-spinal osteoid osteoma. Pretreatment pain, measured with visual analogue scale (VAS no pain: 0; the strongest imaginable pain 10) was 7.3 (CI: 4-10). Each lesion was treated in a single session. The outcome was evaluated with clinical and imaging follow-up over 5 years.
Results: After treatment, 25 patients reported no pain (93% of complete success, VAS:0), confirming the effectiveness of the procedure; 1 patient required another session for persistent pain (the VAS value dropped from 9 to 5) that finally completely resolved the symptoms; another patient reported VAS 1 during follow-up without requiring additional treatment. During follow-up, not disease relapse or complications occurred. The long-term imaging control showed a progressive "restitutio ad integrum" of the bone segments without signs of alteration of bone growth.
Limitations: No control group with alternative interventional radiology techniques.
Conclusion: MRgFUS is a safe and effective therapy. It may become the first line of treatment for paediatric patients with osteod osteoma.

Iodixanol versus iopromide in contemporary coronary CT angiography: lumen opacification and effect on heart rhythm in the randomised IsoCOR trial
M.M. Lubbers[1], A. Coenen[1], A. Niezen[1], M. Kock[2], T. Galema[1], M. Kofflard[2], T. Bruning[1], S. Kooij[2], F. Nous[1], H. van Valen[1], M. Dijkshoorn[1], R. Booij[1], R. Budde[1], K. Nieman[1]; [1]*Rotterdam/NL*, [2]*Dordrecht/NL (m.m.lubbers@erasmusmc.nl)*

Purpose: To demonstrate that using contemporary cardiac-CT protocols equal coronary lumen opacification can be achieved with iso-osmolar and low-osmolar contrast media, when injected at the same iodine delivery rate. In addition, we investigate the effect on heart rate.
Methods and Materials: Between November 2015 and August 2016, 306 patients who were clinically referred to cardiac CT and were at least 18years old and had a weight between 50-125 kg, were prospectively randomised to iso-osmolar iodixanol-270 (Visipaque) or low-osmolar iopromide-300 (Ultravist). Contrast media were injected to achieve a net iodine delivery rate of 1.5 gI/s (bodyweight 50-100 kg), or 1.75g I/s for larger patients (bodyweight 100-125 kg). All coronary segments were assessed for intraluminal opacification and image quality and compared using a student T-test. Heart rate, arrhythmia, patients discomfort and adverse events were also monitored.
Results: Measured coronary attenuation values were comparable between both contrast media (476 ± 160 HU vs 454 ± 158 HU, p=0.227). Adjusted for the lower iodine concentration, the mean iodixanol-270 bolus was larger compared to iopromide-300 (76.8 ± 11.6 ml vs. 69.7 ± 10.8 ml, p<0.001). The higher injection rate was associated with a higher injection pressure (111 ± 44 PSI vs 90 ± 36 PSI, p<0.001) while there were no differences in heart rate or rhythm between groups.
Limitations: While CT readers were blinded for randomisation, it was impossible to blind the CT technicians because of the different injection rates which resulted in similar iodine delivery rates.
Conclusion: If injected at comparable iodine delivery rates, the iso-osmolar contrast medium iodixanol-270 is not inferior to low-osmolar contrast medium iopromide-300 in terms of coronary opacification. Iodixanol-270 was associated with less heat discomfort, but did not affect heart rate differently compared to iopromide-300. The study was supported by an unrestricted grant from GE Healthcare.

Comparison of Pretest Probability with Prevalence of Obstructive Coronary Artery Disease Using Invasive Coronary Angiography or Computed Tomography Angiography
S. Feger, M. Dewey, on behalf of the DISCHARGE consortium; *Berlin/DE (sarah.feger@charite.de)*

Purpose: To compare pretest probability of obstructive coronary artery disease (CAD) determined by using the pragmatic Diamond-Forrester (D+F) prediction models with prevalence of obstructive CAD by invasive coronary angiography (ICA) or computed tomography (CT).
Methods and Materials: Patients with suspected CAD and stable chest pain who were clinically referred for ICA or CT were prospectively included by clinical sites participating in the pilot study of the European multicentre DISCHARGE trial (www.dischargetrial.eu/EC-GA603266). Pretest probability of CAD was compared between the initial D+F model (1979) and the updated D+F model (2011).
Results: Overall, 1368 patients (611 female, 757 male) were included in 23 clinical sites from May, 2014 until July, 2016. Of these patients, 689 patients underwent CT (334 female, 355 male), while 679 underwent ICA (277 female, 402 male). The discriminative ability was higher for the updated D+F with an area under the receiver operating curve of 0.72 (AUC; 95% confidence interval 0.69-0.75), compared with an AUC of 0.64 for the initial D+F (0.62-0.68; P<0.001). The prevalence of obstructive CAD identified by using ICA and CT (32.0%, 443 of 1368 patients) was relevantly overestimated by both prediction models (pretest probabilities: initial D+F 57.8±25.3%, updated D+F 48.0±16.6%, P<0.001 respectively). However, overestimation of disease prevalence was less for the updated D+F compared with the initial version (P<0.001).
Limitations: Prevalence and pretest probabilities differ between both groups due to the non-randomised design.
Conclusion: Pragmatic pretest probability calculation relevantly overestimates the actual prevalence of obstructive CAD in patients with stable chest pain. To improve individually tailored decision-making according to chest pain guidelines for patients suspected having obstructive CAD, more accurate models to calculate pretest probability of CAD are needed. For the appropriate use of diagnostic tests further aspects should be considered, including cost-effectiveness and health related quality of life.

Beets-Tan[2]; [1]*Amsterdam/NL*, [2]*Amsterdam/Maastricht/NL*, [3]*Maastricht/NL*, [4]*Heerlen/Sittard/NL*, [5]*Breda/NL*, [6]*Veldhoven/NL*, [7]*Eindhoven/NL*, [8]*Hengelo/Almelo/NL (doenja.lambregts@gmail.com)*

Purpose: To evaluate the performance of diffusion-weighted imaging (DWI) and lymph node contrast-enhanced MRI for rectal cancer (re-)staging.
Methods and Materials: Multicentre study of n=307 patients undergoing MRI including T2-weighted (='routine') plus additional DWI and (in n=125) lymph node (gadofosveset trisodium) contrast-enhanced (CE) sequences (='novel'). 145 patients were stratified for chemoradiotherapy (CRT) and underwent the same protocol again for restaging. Scans were evaluated by site radiologists (non-experts) and then re-assessed by a central expert radiologist. Main outcomes were defined as [1] discrimination between residual tumour (yT+) vs complete response (yT0) after CRT, and [2] discrimination between N0 vs N+ stage (both for primary staging and restaging after CRT). (Re-)staging results for experts and non-experts respectively were compared between 'routine' vs 'novel' MRI-methods using area under the receiver operating characteristics curve (AUCs)).
Results: AUC to predict tumour vs complete response for the non-expert was 0.81 on T2W MRI vs 0.79 on DWI (P=0.35); for the expert AUC was 0.80 on T2W-MRI vs 0.80 on DWI (P=0.61). AUC to predict N0 vs N+ stage for the

non-expert was 0.69 on T2W-MRI vs 0.74 on CE-MRI (P=0.70); for the expert AUC was 0.70 on T2W-MRI vs 0.81 on CE-MRI (P=0.05). AUC to predict yN0 vs yN+ stage after CRT for the non-expert was 0.82 on T2W-MRI vs 0.86 on CE-MRI (P=0.31); for the expert AUC was 0.80 on T2W-MRI vs 0.80 on CE-MRI (P=0.45).
Limitations: Not all patients received contrast agent.
Conclusion: Lymph node contrast may improve the performance of MRI for nodal staging; no significant effect was observed for addition of DWI on tumour restaging.

Breast MRI: Current challenges and new trends

Moderator:
J. Barkhausen; Lübeck/DE

Preoperative breast MRI: first results from the MIPA study
F. Sardanelli; *San Donato Milanese/IT*

MIPA is an ongoing prospective observational multicenter study sponsored by Bayer, endorsed by EUSOBI and run by EIBIR/EuroAIM. Study was designed as an individual data analysis of two concurrent groups of women with a newly diagnosed first breast cancer, not candidate to neoadjuvant therapy, receiving or not receiving MRI before surgery. In 2012, after an web-based call, 96 centres applied and 34 (19 academic) were selected from 14 countries; 28 started the enrolment. Up to July 2016, 4,944 patients were enrolled, 2,425 with complete eCRF: 1,201 (49.5%) without and 1,224 (50.5%) with MRI. Gadobutrol (0.1 mmol/kg) was used in 70% patients; 84% had also DWI. A radiologist was involved in the MRI order in 68% of cases, a surgeon in 40%. Mastectomy rate planned after mammography/US was 185/1201 (15.4%) for non-MRI and 245/1224 (20.0%) for MRI-group (p<0.001). In MRI-group, 21 additional mastectomies (1.7%) were planned after MRI; bilateral surgery instead of bilateral was performed 13 (1.1%); of 1004 breasts conservatively treated after MRI, surgery was unchanged in 733 (73%), while a wider surgery or >1 excision wad done in 143 (12.5%) and a less extensive surgery was done in 128 (12.7%). Actual mastectomy rate was 192/1201 (16%) in non-MRI-group and 257/1224 (21%) in MRI-group (p<0.001; age/density-adjusted OR 1.4, 95% CI 1.3-1.6). Per-patient re-operation rate for close/positive margins was 135/1009 (13.4%) in non-MRI-group and 80/967 (8%) in MRI-group (p<0.001). These results show that already planned mastectomies prompt MRI, used as a confirmation tool, not vice versa and that MRI allows for tailoring conservative treatment.

First clinical experiences with a new 7ch breast imaging and biopsy coil
E. Wenkel; *Erlangen/DE*

A new coil for high-resolution imaging of the breast at 3T is presented. Whereas most breast coils have a high number of coil elements for diagnostic purposes but only a subset can be used during biopsy, the 7ch BI Breast Coil has a special design to facilitate imaging with the full number of elements in the biopsy scenario, thereby offering comparable image quality to the imaging scenario. Due to its open design, the coil is well suited for breast biopsy with lateral, medial and cranio-caudal access. Additional features like LED-lighting of the biopsy site simplify the workflow. During the presentation, first clinical cases and workflow experience with the new device are reported.

Gadolinium retention: impact on breast MRI?
J. Barkhausen; *Lübeck/DE*

Normal 0 false false false EN-GB X-NONE X-NONE /* Style Definitions */ table.MsoNormalTable {mso-style-name:"Normale Tabelle"; mso-tstyle-rowband-size:0; mso-tstyle-colband-size:0; mso-style-noshow:yes; mso-style-priority:99; mso-style-parent:""; mso-padding-alt:0cm 5.4pt 0cm 5.4pt; mso-para-margin-top:0cm; mso-para-margin-right:0cm; mso-para-margin-bottom:10.0pt; mso-para-margin-left:0cm; line-height:115%; mso-pagination:widow-orphan; font-size:11.0pt; font-family:"Calibri","sans-serif"; mso-ascii-font-family:Calibri; mso-ascii-theme-font:minor-latin; mso-hansi-font-family:Calibri; mso-hansi-theme-font:minor-latin; mso-fareast-language:EN-US;} More than 30 years ago, contrast-enhanced MRI emerged as a new technique in clinical breast imaging and over the last three decades numerous clinical studies have shown excellent results for the detection and characterization of breast lesions. Despite the most recent improvement of high-resolution and diffusion-weighted MRI, dynamic contrast-enhanced sequences are still considered as key component of any breast MRI examination. The applied gadolinium-based contrast agents (GBCAs) were considered as very safe compounds until the association between nephrogenic systemic fibrosis and GBCAs was suspected in 2006. Additionally, in late 2013 Kanda and colleagues described increased signal intensity in the dentate nucleus on unenhanced T1-weighted MR images as a consequence of repetitive previous GBCA administrations. Although no clinically relevant adverse events have yet been associated with the detection of gadolinium in the brain, the results of these studies must be taken seriously. With respect to breast MRI, these issues are especially important for repetitive breast cancer screening in high-risk patients, for example, with BRCA mutations. In this lecture, the results of the most recent clinical trials addressing these topics will be presented in a comprehensive manner and the impact of these studies on daily clinical routine will be discussed.
Learning Objectives:
1. To gain knowledge on the pharmacokinetics of different MR contrast agents.
2. To discuss the potential risks of gadolinium based contrast agents.
3. To learn about the most recent recommendations and guidelines.

Multimodality lunch symposium: Dense breast and how to overcome the radiologist's "problem child"

Moderator:
L.J. Pina Instausti; Pamplona/ES

Dense breast and how to overcome the radiologist's "problem child"
L.J. Pina Insausti; *Pamplona/ES*

In BI-RADS 2003, the composition was based on the overall density resulting in ACR category 1 (<25% fibroglandular tissue), category 2 (25-50%), category 3 (50-75%) and category 4 (>75%). In BI-RADS 2013, the use of percentages is discouraged, because in individual cases it is more important to take into account the chance that a mass can be obscured by fibroglandular tissue than the percentage of breast density as an indicator for breast cancer risk. Four groups are used: a,b, c and d. The patterns c and d are considered as “dense”. Dense breasts reduce the sensitivity of mammography up to 50%. This is the main limitation of mammography. Fortunately, tomosynthesis can significantly increase the sensitivity of mammography, especially if wide angle is used (increment of detection rate up to +43%). Tomosynthesis is able to reduce the superimposition of tissue and the anatomic noise, allowing the detection of occult lesions. However, at least a small amount of fat surrounding the lesion is needed to be detected. Breast US is widely used as an adjunct to mammography and it improves the sensitivity in dense breasts. But US is a time-consuming, operator-dependent technique that detects too many benign lesions (false-positive results). This is why US cannot be used for population-based screening. MRI is not routinely used for the evaluation of dense breasts, although it can be very useful in some particular cases (preoperative planning, high-risk patients, etc.).
Learning Objectives:
1. To become familiar with the limitations of mammography in dense breasts.
2. To learn the role of Tomosynthesis to overcome the limitations of mammography in dense breasts.
3. To understand the role of breast US in dense breasts.

Volumetric breast density analysis in mammography and tomosynthesis: brief overview
H. Sartor; *Lund/SE*

High breast density is associated with an increased risk of breast cancer. However, qualitative measurements of breast density by radiologists may vary and be subjective. Automated VBDA, which is also associated with an increased risk of breast cancer, was developed to provide objective and reproducible measurements. To explore the possibilities and clinical use of VBDA, previous studies have described the agreement between different methods of measuring volumetric density (e.g. by software such as Volpara and Quantra) and radiologists' assessments in mammography (e.g. qualitative measurements such as BI-RADS and a visual analogue scale) with varying results. DBT is a promising technique and a potential screening modality and the possibility to measure breast density on DBT images is important. Our group has previously compared breast density that was measured by radiologists to measurements obtained from an automated VBDA tool from Siemens using the central projection image in DBT. The results suggested that VBDA could be used in DBT in addition to mammography. Taken together, the use of a robust VBDA is important and seems possible in both mammography and DBT, enabling it to be used in individualised screening programs and in breast cancer risk scores.
Learning Objectives:
1. To understand the clinical basics of volumetric breast density analysis (VBDA) based on previous studies.
2. To acknowledge the difference between radiologists' assessment of breast density and software measurements.
3. To discuss VBDA's potential use for mammography and digital breast tomosynthesis (DBT) in clinical practice.

Current role of MRI in imaging of dense breast tissue
C. Van Gils; *Utrecht/NL*

MRI is the most sensitive breast cancer imaging technique currently available and recommended for screening women with high breast cancer risk. Women with dense breasts have a moderately increased breast cancer risk. In addition, their dense tissue limits the detection of a tumour with mammography and, therefore, additional screening with MRI could provide a solution for these women as well. However, MRI is not included in screening recommendations for women with dense breasts. The effects of MRI, and also those of other supplemental imaging methods, on breast cancer outcomes remain as yet unclear due to a lack of comparative studies with interval breast cancer rates, stage at diagnosis or breast cancer mortality as the outcome. In this presentation I will outline the present evidence for MRI screening in women with dense breasts, and indicate which type of evidence is still needed to proove its additional value. DENSE, a large randomised controlled trial, that we are currently conducting, has been designed to deliver this proof. It investigates the value of additional MRI compared to usual screening practice, in women with extremely dense breasts and a negative digital mammography. Women are included solely on the basis of their breast density. A fully automatic and validated method is used to estimate mammographic density. The primary outcome is a difference in interval cancer rates between the two arms, the best proxy for a difference in breast cancer mortality.
Learning Objectives:
1. To understand the current evidence for MRI screening in women with dense breasts.
2. To learn what type of studies are needed to fully appreciate and weigh the benefits and harms of supplemental MRI screening in women with dense breasts.

The future of breast cancer screening: where can it help the dense breast?
M. Golatta; *Heidelberg/DE*

In most countries breast cancer screening is offered to women between (40)50 and 70(75). The organisation of the screening programs differ from country to country, but in general every two or three years mammography is offered to the participating women. In the past years, several breast imaging techniques have been developed which have the potential to improve breast cancer screening. Digital breast tomosynthesis is one method that has been developed. Multiple low-dose images are obtained and digitally edited and reconstructed as a 3D-image of a breast. The reconstructed 3D-image overcomes the weakness of standard mammography and enables reduction in false-positive findings as results of overlapping tissue. On the other hand, it also enables reduction in the false-negative findings in women with dense breast tissue. Studies have shown that combining ultrasound with mammography in screening settings can significantly improve the rate of found lesions. By adding US to the screening work flow the sensitivity can be improved especially in the dense breast. But US is very time consuming and the specificity goes down (more biopsies are necessary). To overcome these two weaknesses, an "automated breast volume scanner (ABVS)" and elastography can be used. Strain imaging ultrasound technology as Virtual Touch IQ(VTIQ) is a new method being used in breast ultrasound. Various studies have been able to show an increase of the diagnostic specificity without loss of sensitivity when combining the standard ultrasound BIRADS® classification with elastography. The improvement of the specificity will help to eliminate unnecessary breast biopsies in the future.
Learning Objectives:
1. To become familiar with new breast imaging techniques.
2. To understand that breast cancer screening could be improved by embedding new breast imaging techniques like tomosynthesis, US, elastography, ABVS.

Breast tomosynthesis symposium: Is digital breast tomosynthesis ready for mammo screening?

Moderator:
S.H. Heywang-Köbrunner; Munich/DE

Is digital breast tomosynthesis ready for mammo screening?
S.H. Heywang-Köbrunner; *Munich/DE*

For DBT, first systematic reviews of screening trials and of mostly retrospective data from the US confirm that DBT is clearly superior to mammography allowing significantly improved sensitivity. DBT leads to a slightly increased biopsy rate with comparable PPV compared to mammography screening with double reading. Unfortunately for a screening procedure, increased detection is not equivalent to mortality reduction, since increased detection could as well be caused by overdetection of "harmless" malignancy (overdiagnosis). So far no data on overdetection or mortality reduction exist for DBT. Even though important, they are generally difficult to obtain and require long-term follow-up. First indicators of effectiveness could include a significant reduction of interval cancers or an improved stage distribution of cancers detected during the follow-up round(s). Initial data on interval carcinomas are being published. However, first analyses show that evaluation of follow-up rounds remains essential. Thus, to date DBT remains the most promising new modality for screening. Further data allowing estimates of effectiveness and potential overdiagnoses are needed and are gradually expected. Logistic problems (longer reading time, fatigue, optimised hanging protocols, comparison with DM or DBT priors, etc.) should be investigated as well as the potential of stratified DBT vs mammography screening.
Learning Objectives:
1. To understand true benefits and risks of screening procedures.
2. To understand present data on diagnostic accuracy and the gap concerning data on screening effectiveness and potential overdiagnosis.
3. To understand logistic demands associated with future DBT screening.

Experiences from the Malmö breast tomosynthesis screening trial
K. Lang; *Malmö/SE*

The Malmö breast tomosynthesis screening trial is a prospective population-based single-arm study including randomly invited women 40-74 years old eligible for the screening programme in the city of Malmö, Sweden. Women underwent one-view BT and two-view DM. The images were read and scored separately in a blinded double-reading procedure. Interim results of 7,500 women showed a significant increase in cancer detection rate (6.3 to 8.9/1,000) and recall rate (2.6% to 3.8%). The additionally detected cancers were mainly invasive, with a tendency of downstaging (Lång 2015). Findings of stellate distortions simulating malignancy increased the false-positive rate with BT. The FP rate was reduced over time, suggesting a learning curve (Lång 2016). The BT images were acquired with reduced compression force which would be a great advantage for a new screening modality. Slabbing and reconstruction methods can be used to reduce the reading time and increase the image quality. The main challenge of implementing BT in screening is the reading time (x 2-4) (Bernardi 2012, Skaane 2013). CAD and AI could provide a solution. Hopefully, attempts to implement BT in screening could be a catalyst towards the development of individualised screening programmes.
Learning Objectives:
1. To describe the Malmö breast tomosynthesis screening trial.
2. To illustrate technical aspects of BT as a screening tool.
3. To recognise the challenges of implementing BT in screening.

Clinical performance of a synthetic mammogram (Insight 2D) and its role for screening procedures

Practical challenges in screening with digital breast tomosynthesis
C. Van Ongeval; *Leuven/BE*

Learning Objectives:
1. To evaluate the impact of the reading time on the use of digital breast tomosynthesis (DBT) in breast cancer screening.
2. To discuss the requirements of image transfer and data storage in breast cancer screening with DBT.
3. To evaluate additional tools in improving accuracy in reading of DBT in screening.

New tomo reconstruction algorithms: clinical experiences
D.F.P. Uhlenbrock; *Dortmund/DE*

Technical aspects of digital breast tomosynthesis
W. Lemish; *Melbourne/AU*

There are a number of digital breast tomosynthesis (DBT) systems in the market that have applied differing technologies to acquire the data necessary for tomosynthesis image reconstruction. The various techniques all have advantages and some potential limitations. These differences could potentially produce different clinical outcomes and the lack of uniformity may make the comparisons between clinical trials difficult. We will review the principles of DBT and discuss the likely advantages and possible limitations of different methods available.
Learning Objectives:
1. To review the physical principles of digital breast tomosynthesis.
2. To become familiar with the strengths and limitations of different technologies used in digital breast tomosynthesis.

Getting it right: radiation dose management

Moderator:
S. Ulzheimer; Forchheim/DE

Dose in breast tomosynthesis: where are we, where are we going, and what does it mean?
I. Sechopoulos; *Nijmegen/NL*

The introduction of digital tomosynthesis to breast imaging has brought about many questions regarding the dose involved in this new imaging modality. Questions on dose are especially important when the modality is or has the potential to be used for screening of asymptomatic patients. In addition, the uncertainty on how digital tomosynthesis will be incorporated into the clinic in the long term, i.e. as a replacement, adjunct, or some combination thereof of mammography, makes the dosimetric concerns more complicated. We will review the basic concepts of breast dosimetry, how they have changed for breast tomosynthesis, and the current levels used for dose from mammography and tomosynthesis. We will discuss the implications for patient breast dose that the different clinical implementations of tomosynthesis might result in.

CT dose reduction innovations and their impact on dose management
H. Alkadhi; *Zurich/CH*

The introduction of dual-source CT technology has revolutionised clinical CT imaging by enabling the radiologist to apply and combine a multitude of patient-tailored different dose reduction strategies. These include the technique for automated, attenuation-based tube potential selection, the tin filter technology for single-energy CT, high-pitch scanning and advanced iterative reconstruction algorithms. Combined application of these many options must be done carefully for fully exploiting the potential of the techniques for each individual patient. Optimal use of the techniques also allows for an individually tailored reduction of the amount of required contrast media for achieving a good image quality. This presentation will review the effect of these options on radiation dose, image quality and contrast media protocols and their impact on patient management and clinical decision making.
Learning Objectives:
1. To learn about the various individual and combined techniques for lowering and optimising the radiation dose of modern CT machines.

Radiation dose management made easy
F. Schellhammer; *Cologne/DE*

In modern radiology departments dose monitoring is gaining more and more interest. Based on regulations, legislation and recommendations from different associations, radiology departments commence to monitor the applied radiation. Team play provides the ability to gather all the information on the applied radiation dose and creates transparency in performance. By analysing dose values you gain knowledge and understanding what might cause dose outliers. As objectivity in dose monitoring and reporting is a must, team play helps to achieve this. In addition, team play supports to map customised scan protocols with the RADLEX Playbook coding that is created by the RSNA. We will experience how team play supports dose monitoring and how it is the base
