A. Brain trauma
M. Smits; *Rotterdam/NL (marion.smits@erasmusmc.nl)*

Neurotrauma is a major cause of death and disability and accounts for up to 10% of all emergency department visits. Most patients with head trauma are classified as having minor head injury, defined as no or brief loss of consciousness, amnesia and a Glasgow Coma Score (GCS) of 13-15. Brain injury is, however, fatal in 10% of all head injury patients, while 5-10% suffer permanent serious neurological deficits. A further 20-40% of patients are left moderately disabled. CT is the modality of choice for assessment of brain injury in the acute setting, while MRI is more commonly used as a secondary modality in the subacute or chronic stage. Direct consequences of brain injury include fracture, contusion, haematoma and vascular injury, which are generally well known and easily appreciated. Findings of indirect consequences, however, such as herniation, brain swelling and vascular complications, are sometimes subtle and easy to overlook. In this case-based presentation, I will outline the common findings of direct brain injury consequences and specifically focus on the less common findings of indirect consequences.

Learning Objectives:
1. To understand the different types of brain trauma.
2. To become familiar with the differential diagnosis.

A-002 09:15
B. Peripheral vascular injury
J. Ferda; *Plzen/CZ (ferda@fnplzen.cz)*

Penetrating vascular trauma is caused by direct vessel damage, which exhibits visible bleeding with an extensive blood loss. Blunt trauma injures vessels by crushing, distraction or shearing which leads to dissection, thrombosis and consequent ischaemia and/or invisible bleeding. Unrecognised and uncontrolled haemorrhage can rapidly lead to the demise of the trauma patient. Unrecognised and untreated ischaemia can lead to limb loss, stroke and multiple organ failure. Proper imaging has to be done to recognise the vascular injury and to decide if surgical or endovascular repair should be used. In injuries caused by high energy and/or high velocity, CT angiography is the method of choice to determine the site of active extravasation or the vessel occlusion even if the patient is in the condition of centralised circulation. Some bleedings are delayed after restoration of systemic blood pressure, especially in pelvic region. In low-energy low-velocity trauma, the development of the signs of vascular trauma could be hidden - ultrasound aims to detect the pseudoaneurysms as well as the intramural haematoma or thrombosis. The imaging of the bleeding artery or occluded vessel is crucial to consequent therapy. The injuries with tissue loss and destruction of the skeleton are preferably indicated to surgical treatment. Where it is possible to penetrate the injured segments by the wire, the endovascular approach is preferable, with the exception of the simple embolization to stop bleeding. During the presentation, the illustrative cases of penetrating injury, the blunt injury including the crossroads of imaging and treatment will be shown.

Learning Objectives:
1. To understand the different types of peripheral vascular injury.
2. To become familiar with the different imaging techniques.
3. To become familiar with interventional treatment options.

08:30 - 10:00 **Room B**

GI Tract

RC 101
Assessing inflammation and fibrosis in Crohn's disease

A-003 08:30
Chairman's introduction
A. Laghi; *Latina/IT (andrea.laghi@uniroma1.it)*

Diagnostic imaging plays a major role in the decision-making process of patients affected by Crohn's disease (CD), both at the time of diagnosis and throughout the course of the disease. One of the most relevant clinical problems in current management of patients affected by CD is represented by the assessment of inflammation and fibrosis. The two entities should not be considered separately, since they coexist in most of the patients. A correct quantification of the prevalent entity is extremely important, since the patient should be referred for medical therapy if inflammation predominates, whereas either endoscopic dilatation of the stricture or surgery becomes necessary if fibrosis is prevalent. Cross-sectional imaging (CSI) modalities, including ultrasound (US), multidetector-CT (MDCT) and MR imaging (MRI), can provide useful information, particularly for inflammation, less for fibrosis. Contrast-enhanced US (CEUS) has been shown to correlate with disease activity and severity, in comparison with endoscopic score of severity. Data about CEUS and fibrosis are controversial, although a quantitative data analysis seems the most valuable approach. Very promising results have been recently obtained with US elastography. Current data with MDCT highly correlate with disease activity and severity, but not with fibrosis. Dual-energy analysis might improve MDCT performances. MRI correlates not only with inflammation, but also with fibrosis, particularly if multiparametric analysis is performed. This analysis includes the evaluation of pattern of enhancement, late enhancement and the analysis of T2 signal. In the next future, other MR techniques are under evaluation, such as T1 mapping and magnetization transfer contrast.

A-004 08:35
A. Is sonography (CEUS and elastography) the right tool?
E. Quaia; *Edinburgh/UK (equaia@ex sede.ed.ac.un)*

Crohn's disease (CD) is a chronic transmural inflammatory disease of the gastrointestinal tract which can be assessed by ultrasound. Unenhanced ultrasound may evaluate the localization and the length of the affected intestinal segments and may suggest the presence of mural fibrosis based on the layered appearance of the bowel wall. Contrast-enhanced ultrasound of the bowel is performed by wide-band transducers including the microbubble resonance frequency. Contrast-enhanced ultrasound has become an important imaging modality in patients with CD for the grading of disease activity, the differentiation between small bowel stricture due to inflammation or mural fibrosis, and for the assessment of the response to specific pharmacologic therapy. New dedicated software packages allow the accurate quantification of the enhancement within the small bowel wall after microbubble contrast agent injection to obtain different kinetic parameters - percentage of the maximal enhancement, the time-to-the peak enhancement, and the area under the time-intensity curve - which may differentiate mural inflammation from fibrosis and responders from non-responders to the specific pharmacologic therapy. The main advantage of contrast-enhanced ultrasound in the real-time assessment of the perfusion of the bowel wall but the scan is necessarily limited to one single loop each time. US real-time elastography can be considered an additional tool to complete US assessment of the bowel wall in patients with CD. US real-time elastography allows to assess the bowel wall stiffness to distinguish acute inflammation from fibrosis in patients with CD and increases the diagnostic confidence if compared to contrast-enhanced US alone.

Learning Objectives:
1. To learn about CEUS technique, including imaging acquisition and data post-processing.
2. To become familiar with US elastography, particularly with those techniques useful in the assessment of the small bowel.
3. To understand potential advantages and possible limitations of CEUS and elastography in the assessment of inflammation and fibrosis in Crohn's disease.

B. Is there space for MDCT (spectral imaging, iodine map)?

J. Podgorska; *Warsaw/PL (jpodgo@gmail.com)*

Many aspects of managing patients suffering from Crohn's disease (CD) remain unclear. It is still unknown which factors trigger disease chronicity, and which promote the development of intestinal fibrosis. On the other hand, anti-inflammatory treatment such as steroids, immunosuppressants and anti-TNF-alpha have serious side effects; moreover, the decision for surgical treatment is also difficult. Because of many factors that influence the disease management, there is a strong need for a reliable tool of inflammatory activity and fibrosis assessment. Recently, apart from MR enterography (MRE), CT enterography (CTE) is being used to detect and monitor intestinal inflammation. Bowel wall and mesenteric changes such as mural thickening and hyperenhancement, increased attenuation of perienteric fat, and mesenteric hyperaemia have been reported to indicate CD activity. Recently introduced dual-energy CT modality allows creating monochromatic spectral images at energy levels ranging from 40 to 140 keV and water and iodine-based material decomposition with quantitative analysis. This method has already been applied in abdominal imaging, e.g. urinary stones, renal cell carcinoma and hepatocellular carcinoma. There are also preliminary reports about implementation of spectral imaging in CTE technique for an objective assessment of Crohn's disease activity and coexistent fibrosis. The aim of this lecture is to give an overview of the CTE bowel inflammatory changes, and the possible advantages of spectral imaging for assessing activity and fibrosis in CD.

Learning Objectives:

1. To understand basic principles of spectral imaging, including data post-processing.
2. To appreciate the strengths and limitations of spectral imaging in the abdomen.
3. To learn about advantages and possible limitations of spectral imaging in the assessment of inflammation and fibrosis in Crohn's disease.

A-006 09:21

C. Will MRI (DWI and perfusion) solve the problem?

S.A. Taylor; *London/UK (csytaylor@yahoo.co.uk)*

Crohn's disease (CD) is a relapsing and remitting inflammatory condition of the GI tract. Clinical management essentially resolves around use of immunosuppressive medication and surgery. Crucial to clinical decision making is assessment of the underlying inflammatory activity, those with active inflammatory disease tend to undergo immunosuppressive therapy whereas those with fibrosis may benefit from surgical resection. In reality, however, inflammation and fibrosis tend to coexist. Both DWI and perfusion are abnormal in CD. However, the relationship between both DWI and contrast enhancement and the histopathological phenotype is complex. Whist data suggest active Crohn's disease tends to result in restricted DWI, the balance between increased inflammatory infiltrate and tissue oedema influences ADC values and recent data using surgical resection specimens suggest fibrosis also leads to restricted diffusion. Similarly, whilst perfusion tends to increase in active CD, tissue angiogenesis which increases in chronic disease also affects contrast uptake. Enhancement patterns may help radiologist grade activity. For example, a layered enhancement pattern is reported in active disease, but again overlap with fibrosis is seen. Recent data suggest delayed contrast-enhanced sequences at around 7 minutes can help quantify fibrosis. This presentation will describe clinical protocols used to acquire DWI and perfusion imaging in CD and present the data as to their utility in clinical practice.

Learning Objectives:

1. To understand basic principles of DWI applied to Crohn's disease.
2. To learn about MR-perfusion protocols and data analysis.
3. To learn about advantages and possible limitations of MRI in the assessment of inflammation and fibrosis in Crohn's disease.

RC 104
Pneumonia

A-007 08:30

Chairman's introduction

I.E. Tyurin; *Moscow/RU (igortyurin@gmail.com)*

Pneumonia is a major health care and economic problem because of high morbidity and mortality rate, and due to direct and indirect costs of its management. The most common cause is community-acquired pneumonia, caused by common bacteria like S. Pneumonia as well as different viral agents. Tuberculosis is one of the most important respiratory infections in developing countries and in immune-compromised patients with AIDS everywhere. Tuberculosis pneumonia can easily mimic bacterial CAP and other pulmonary infections. Viral and mycotic infections represent a common course of febrile neutropenia in immune-compromised patients under aggressive therapy. In most of all these patients, a diagnosis is made on the basis of a combination of clinical, radiographic, and laboratory findings. High-resolution CT is usually performed in patients with nonspecific clinical and radiologic findings and in patients with progression of disease despite therapy. A large number of acute and chronic infectious and noninfectious diseases may also result in parenchymal lung disease in both immune-competent and immune-compromised patients. Thin section CT is also performed in patients with noninfectious causes of acute parenchymal lung disease such as organizing pneumonia, acute interstitial pneumonia, hypersensitivity pneumonitis, acute eosinophilic pneumonia, pulmonary oedema and haemorrhage. These diseases often have clinical and functional features similar to one another but obviously requiring different treatment. Therefore, the differential diagnosis of these entities is important in daily clinical practice.

Session Objectives:

1. To review the role of imaging in infectious lung diseases.
2. To become confident in recognising typical patterns.

A-008 08:35

A. Community-acquired pneumonia

I. Hartmann; *Rotterdam/NL (i.j.c.hartmann@gmail.com)*

Community-acquired pneumonia (CAP) refers to pneumonia acquired outside of hospitals or extended-care facilities and is one of the most common infectious diseases. CAP is an important cause of mortality and morbidity worldwide. According to the IDSA/ATS/AAFP guidelines, a chest radiograph is required for the routine evaluation of patients with suspected CAP to exclude conditions that mimic CAP (e.g., acute bronchitis) and to confirm the presence of an infiltrate compatible with the presentation of CAP. Although chest radiography findings usually do not allow identifying the causative organism, they may be helpful in narrowing down the differential diagnosis, prognosis, and detection of associated conditions. Serial chest radiography can be performed to observe the progression of CAP. CT scanning is increasingly used in clinical practice. Performing CT should be considered if any of the abnormalities at presentation or at follow-up are not consistent with the diagnosis of pneumonia, if concomitant disease is suspected such as an underlying bronchogenic carcinoma, for the confirmation of pleural effusion, and for the detection of pulmonary complications. The aim of the presentation is to provide an overview of the imaging findings of the most common aetiologic organisms in patients with CAP. In addition, imaging findings that may help in the differentiation between pneumonia and other common non-infectious causes of abnormal chest radiographs in patients with suspected CAP will be discussed.

Learning Objectives:

1. To appreciate the role of imaging in the management of community-acquired pneumonia.
2. To consolidate knowledge of how to discriminate from noninfectious diseases.

A-009 08:58

B. Tuberculosis

E. Castañer; *Sabadell/ES (ecastaner@tauli.cat)*

Pulmonary tuberculosis (TB) remains a common worldwide infection that produces high mortality and morbidity, especially in developing countries. In 2013, an estimated 9.0 million (360 000 of whom were HIV-positive) people developed TB and 1.5 million died from the disease. Chest radiographs play a major role in the screening, diagnosis and response to treatment of patients with TB. However, the radiographs may be normal or show only mild or nonspecific findings in patients with active disease. We will review the chest

radiograph findings of TB, which vary widely in function of several host factors, age, prior exposure to TB, and underlying immune status. CT is useful, in detecting TB incidentally, in resolving cases with inconclusive findings on chest radiographs and in assessing disease activity. Cavities, centrilobular nodules and tree-in-bud appearance are the most common CT findings of active pulmonary tuberculosis. We will discuss the classic, and some not-so-classic, signs that should suggest the diagnosis of TB.

Learning Objectives:

1. To appreciate typical and atypical tuberculosis manifestations on imaging.
2. To differentiate between acute and chronic tuberculosis infection.

A-010 09:21

C. Fungal pneumonia in immunocompromised hosts

C.P. Heussel; *Heidelberg/DE (heussel@uni-heidelberg.de)*

The radiological characterisation of infiltrates gives a first and rapid hint to differentiate between different types of infectious (e.g. typical bacterial, atypical bacterial, fungal) and non-infectious aetiologies. Follow-up investigations need careful interpretation according to disease, recovery, concomitant treatment and eventually vessel erosion requiring contrast-enhanced angio-CT. Due to a high incidence of fungal infiltrates in immunocompromised hosts, interpretation of the follow-up of an infiltrate must use further parameters besides the lesion size.

Learning Objectives:

1. To learn the patterns of fungal lung infection depending on the type of immune depression.
2. To become familiar with CT signs suggesting angioinvasive fungal infection.

Author Disclosure:

09:44

Panel discussion: What is the role of radiologists in the diagnosis and management of lung infections?

08:30 - 10:00 **Room Z**

ESR Working Group on Ultrasound

WG 1

Ultrasound of the lung parenchyma: a diagnostic tool for the paediatric radiologist or for the clinician?

Moderator:
C. Owens; London/UK

A-011 08:30

How I perform and interpret lung parenchymal ultrasound

M. Riccabona; *Graz/AT (michael.riccabona@medunigraz.at)*

The objective of this presentation is to present and discuss the role, the potential and the limitations of ultrasonography (US) in paediatric lung and chest conditions. The technical equipment, transducer selection and device setting will be listed. Furthermore, the course of the examination is demonstrated. Requirements for standardisation will be discussed, such as sitting position for quantifying potentially associated effusions. Typical queries that can be addressed by US will be listed and normal as well as abnormal findings will be demonstrated. Besides the great potential of US in pleural and lung conditions, limitations have to be respected and artefacts have to be known to avoid pitfalls and mismanagement. Particularly, one needs to accept that US cannot replace plain film or chest CT, despite its huge potential for many queries. Lung (and chest) US have become a valuable tool for addressing chest conditions in childhood both for diagnosis as well as for follow-up. US helps to reduce other irradiating imaging, but restrictions and artefacts have to be acknowledged and other imaging such as plain film and CT need to be considered as additional methods helping to solve sonographically equivocal findings.

Learning Objectives:

1. To define technical requirements and main protocols for use in lung ultrasound.
2. To describe normal and abnormal findings in childhood.
3. To understand artefacts and limitations in lung ultrasound.

A-012 08:55

How does lung parenchymal ultrasound change the clinical management of the sick child: the paediatric radiologists' perspective

P. Tomà; *Rome/IT (paolo.toma@opbg.net)*

The imaging of the chest in paediatrics needs a specific cultural approach planned to integrate and optimise the techniques available. The prevalence of air represents a particular challenge for the radiologist. It limits the intrathoracic ultrasound (interfaces between soft tissue and lung generate very strong echoes due to a large acoustic impedance gradient), is a problem for the MRI (low proton density and the susceptibility differences between tissue and air), determines an excellent contrast resolution for the conventional radiology and CT that remains the gold standard. Technically, CT is conditioned by a cost/benefit ratio that means dose/diagnosis relationship. Risk of chest PA and lateral is negligible. Classical indications for chest US (in the presence of an acoustic window) are opaque hemi-thorax, assessment of vascular abnormalities, evaluation of diaphragmatic motion and juxta-diaphragmatic processes, detection characterisation of a suspected mediastinal disease, evaluation of chest wall lesions, to confirm and characterise pleural effusions guiding for pleural drainage procedures. New extensive use of sonography as clinical portable tool takes information also from physical acoustic phenomena that are not directly convertible into images of the human body. These artefacts are non-anatomical images, which are at best a sensitive but, unfortunately, a very nonspecific sign of lung injury common to many conditions. Young paediatric radiologists can easily learn the traditional chest ultrasound and they should know strengths and weaknesses of “new” imaging.

Learning Objectives:

1. To discuss the appropriate use of US, x-ray, CT and MRI in the management of children presenting with thoracic diseases.
2. To define if and how paediatric radiologists should be trained in chest US.

A-013 09:20

How does lung parenchymal ultrasound change the clinical management of the sick child: the clinicians' perspective

L. Cattarossi; *Udine/IT (luigi.cattarossi@asuiud.sanita.fvg.it)*

In the last two decades, lung ultrasound (LUS) has become popular both in adult and children for the clinical evaluation of pulmonary diseases. In neonatal and paediatric age, LUS has been utilized by the clinician as point of care tool to address the decision making process. LUS features of the most common neonatal respiratory diseases (respiratory distress syndrome, transient tachypnoea of the newborn, meconium aspiration, pneumothorax, pleural effusion, pulmonary haemorrhage) as well as its functional application on the respiratory therapy will be presented.

Learning Objectives:

1. To illustrate the role of bedside lung parenchymal US in comparison with x-ray and CT in management of sick children.
2. To define and discuss the paediatricians perspective.

09:45

Panel discussion

08:30 - 10:00 **Room O**

Special Focus Session

SF 1

Assessing age, based on bone maturation: scientific and ethical aspects

A-014 08:30

Chairman's introduction

K. Rosendahl; *Bergen/NO (karen.rosendahl@helse-bergen.no)*

Age assessment is an important, yet complex and challenging issue that authorities may need to perform to determine whether an individual is an adult or a child in circumstances where their age is unknown. There is currently no method which can identify the exact age of an individual and there are concerns about the invasiveness and accuracy of the methods in use, namely analysis of documentary evidence, interviews, physical or other form of medical examination such as imaging. The main imaging methods include carpal, collar bone and dental examinations. Whilst many countries make use of these methods they do not apply them in the same way and often use different combinations and/or order. One of the main reasons for this is the fact that age assessment procedures remain to a large extent determined by national legislation, with procedures evolving through national jurisprudence (Ref.: European Asylum Support Office (EASO Age Assessment Practice in Europe)). During this session, different methods of bone age assessment, their precision and accuracy will be addressed by experts within the field, followed by a presentation/discussion on ethical and legal aspects of using bone age to determine age.

Session Objectives:

1. To become familiar with current indications for bone age assessment.
2. To learn about the methods' precision and accuracy.
3. To appreciate the caveats in using bone maturation to determine chronological age.

A-015 08:35

Bone age assessment: indications and methods

F. Dedouit, P. Baumann, T. Uldin, S. Grabherr; *Lausanne/CH (fabded2@hotmail.com)*

The use of appropriate methods for determining the age is necessary for medical, medico-legal, and sporting contexts. Paediatric endocrinologists have an important interest for bone maturation to evaluate children for advanced or delayed growth and physical development. The developmental status of a child can be assessed by analysing various parameters such as height, weight, secondary sexual characteristics, bone age (BA) and dental age. The factors determining a normal skeletal maturational pattern are not clearly defined; however, genetic, nutritional, metabolic, social and emotional as well as environmental factors and hormones have an impact on bone development. BA assessment is a common procedure used in the management of children with various endocrinopathies and growth disorders. A significant discrepancy between BA and chronological age (CA) indicates abnormalities in skeletal development. When integrated with other clinical findings, clinicians can separate the normal from the relatively advanced or retarded physical development. The literature concerning age assessment, especially hand and wrist radiographies is oversized. Besides chronological methods, some morphological methods can be performed with a citation method (Tanner-Whitehouse, Fels, Sempé, Fishman) or with an atlas (Greulich and Pyle [GP], Gilzang-Ratib, Thiemann-Nitz-Schmeling). Different automated software have been developed for this purpose. The future seems to be represented by non-ionizing techniques like MRI. Nevertheless, the GP atlas, published in the 1950s, is still the most world-wide used method, although the reference sample compared to contemporary European population presents a different socio-economic status and a different ethnics.

Learning Objectives:

1. To learn about current medical indications for bone-age assessment.
2. To become familiar with the different methods.
3. To understand the differences between the different methods.

A-016 08:50

Precision and accuracy of an automated radiographic method

H.H. Thodberg; *Holte/DK (thodberg@visiana.com)*

The automated method for assessing bone age from radiographs has recently been extended up to 19 years of bone age for boys. The precision of the automated method is defined as its ability to give the same results on repeated x-rays of the hand, and it is reported as the SD = 0.18 years of such repeated determinations. Manual reading by different rater has a precision error of SD = 0.58 years. The accuracy of the automated method is defined as the SD error when compared to manual rating and it has been determined to be 0.75 years, when comparing to a single rater and to 0.52 years when compared to the average of many raters. When the automated method is used to predict the age, the accuracy is larger, with SD approx. 1 years. This holds for Caucasians in Western Europe; for other populations, the age assessment is biased to the extent that maturation proceeds differently in these populations. This has been studied by the automated method by presenting bone age reference curves, where the average bone age advancement (i.e. average BA-CA, BA = bone age, CA = chronological age) is shown versus CA. Such curves have been established for eight populations. The magnitude of BA-CA can be up to 1 year, in particular at the end of puberty. Such differences should be taken into account when using bone age to estimate age, so new studies need to be performed in countries wherefrom asylum seekers originate.

Learning Objectives:

1. To learn about an automated radiographic method.
2. To understand the difference between the method's precision and its accuracy.
3. To acknowledge the need for different reference standards by ethnicity.

Author Disclosure:

H.H. Thodberg: Owner; Owner of Visiana, which develops and markets the BoneXpert method.

A-017 09:10

Precision and accuracy of MRI

S. Diaz; *Stockholm/SE (sandra.diaz@med.lu.se)*

Magnetic resonance imaging (MRI) emerged as a potential technique in the assessment of bone age maturity in the context of international football competitions supported by the Fédération Internationale de Football Association - FIFA - due to the need to estimate the 'real' age of healthy adolescent football players. Meanwhile, the clinical use of MRI in the assessment of bone age is limited to the field of endocrine disorders related to alterations in developmental age. Lately, and due to war situation in different countries, MRI has been proposed as a forensic tool to establish the age of migrant unaccompanied children without official documents evidencing their 'real' age. MRI technique not only avoids the radiation that conventional radiography leads to but also provides detailed image of the growth plate. With this purpose, several groups in the world have been working with different magnetic fields (0.2, 0.3, 1.5, 3T), sequences and gradients (T1 tse, ge, vibe/flash, T2, PD, FFE), body areas (wrist, hand, clavicle, knee, ankle), grade scales and consequently with different results. The majority of the studies have been conducted with males and Caucasians. No consideration regarding other potential factors of influence such as ethnicity, gender, height and weight, nutritional level and socioeconomic factors was taken into account. Whatever the purpose to use MRI for assessment of bone age, there is a pressing need to coordinate our efforts to get consensus not only elaborating standard MRI protocols and grade scales to use, but also in other influencing factors.

Learning Objectives:

1. To learn about MRI in the assessment of bone age.
2. To become familiar with the method's precision and accuracy.
3. To appreciate potential pitfalls.

A-018 09:30

Ethical and legal aspects of using bone age to determine age

K. Chaumoitre; *Marseille/FR (kathia.chaumoitre@ap-hm.fr)*

Numerous bone age (BA) methods have been used by clinical practitioners in assessing growth or developmental disorders. BA does not reflect the child's chronological age, which is an objective element that does not take account of individual variability. Many studies carried out in diverse populations have not always yielded concordant results, but one constant finding emerges: large individual variability exists whatever the method. A princeps study, revealed a link between socioeconomic, health level and BA. The existence in the Greulich and Pyle (GP) atlas of age categories of up to 19 years in boys may perpetuate the illusion that the GP atlas enables classification of individuals aged under or over 18 years. It appears indispensable to apply the recommendations of the Study Group for Forensic Age Estimation. To assess the age of persons who are assumed to be at least 18 years, an additional CT examination of the clavicles is possible. The use of methods of BA estimation in a judicial context raises a number of ethical problems, especially for a delinquent minor. The width of the prediction intervals and the limits of agreement make it possible to emphasize some restrictions when a BA method is used to estimate the age of an individual in a judicial context. In individuals with a bone age of more than 10 years, the prediction interval is nearly 4 years. This raises the question of whether it is relevant to use bone age in judicial context.

Learning Objectives:

1. To understand the difference between bone age as "a marker of disease", and "a substitute for age".
2. To become familiar with ethical aspects.
3. To appreciate legal aspects.

09:50

Panel discussion: Should bone age be used to estimate chronological age - alone or in combination with additional methods?

08:30 - 10:00 **Room N**

Head and Neck

RC 108

Head and neck imaging: don't sell your ultrasound yet!

Moderator:
D.W. Tshering Vogel; Berne/CH

A-019 08:30

A. Salivary gland imaging with ultrasound

P. Gołofit; Koszalin/*PL (piotrgolofit@gmail.com)*

Ultrasound examination is often the first-line modality for imaging patients suspected of having salivary gland disease. Indications for this procedure include swelling with suspected sialadenitis or obstructing calculus, autoimmune diseases, palpable solitary or multiple masses suggestive of a benign or malignant neoplasm or floor of the mouth lesion. A thorough knowledge of the anatomy is crucial for reliable diagnosis of the pathology in this area. Although having considerable limitations (e.g. limited visualization of the deep lobe of the parotid gland) ultrasound can be very useful in selecting patients who require CT or MR imaging, provide biopsy guidance and, in some cases, gives the final diagnosis.

Learning Objectives:

1. To understand the limitations of clinical examination.
2. To learn about the diagnostic approach to salivary glands.
3. To appreciate how to differentiate salivary gland pathology.

A-020 09:00

B. Masses of the soft parts of the neck

P.K. Srivastava; *Lucknow/IN (yashdeep.pks@gmail.com)*

The neck constitutes a broad anatomic region, which has many aero-digestive, salivary glands, lymphatic, endocrine, neural and vascular structures. A good number of pathological conditions affecting these organs system are very well evaluated on high-resolution ultrasound. It is also very useful for ultrasound-guided needle aspiration for cytology, culture and hormone assay, ultrasound-guided core biopsy and molecular markers. The excellent tissue details and anatomical landmarks in the neck such as thyroid cartilage, trachea, strep muscles and neck vessels have made assessment of the neck masses a practical proposition. The neck masses are divided into two major groups: 1. thyroid neck masses; 2. non-thyroid neck masses. The non-thyroid neck masses include congenital masses, cervical masses, lymph node mass, salivary gland masses, nerve tumours, vascular masses, inflammatory masses, parasitic infestations, foreign body, benign and malignant neck tumours. High-resolution ultrasound is a multi-planner, non-invasive, cost-effective imaging modality which is having advantage of CT scan and MRI as the spatial resolution of ultrasound is much better than CT and MRI. The biggest advantage is that it is a dynamic modality which does not require any sedation or special preparation for evaluation of neck masses. The excellent tissue characterization of various structures in the neck on ultrasound clearly differentiate different pathology. The 3D ultrasound with multi-planner, panoramic and colour flow imaging increases the diagnostic accuracy.

Learning Objectives:

1. To become familiar with cervical ultrasound anatomy.
2. To learn about benign neck masses.

A-021 09:30

C. Lymph nodes: differential diagnosis and fine-needle aspiration

R. Maroldi; *Brescia/IT (roberto.maroldi@unibs.it)*

There are several clinical scenarios where imaging is required to investigate the neck lymph nodes. 1. Imaging is indicated to integrate the clinical examination in the evaluation of unknown neck masses. In this clinical setting, the first task of imaging is to differentiate between non-nodal lesions and adenopathies. If the clinical examination cannot detect a primary neoplasm in the head and neck area, fine-needle aspiration (FNAC) is indicated. Ultrasound (US) is the technique of choice for the initial evaluation and for FNAC. 2. In case of acute/subacute neck infection with enlarged adenopathies, imaging is required to assess nodal changes (abscess), spread outside the lymph node capsule, potential extent into deep neck spaces, with great risk of mediastinal involvement. While US can be accurate in assessing superficial cervical node changes, CT with contrast agent is indicated to survey the deep spread of infections. 3. If a malignant neoplasm arising from the mucosa of the upper aerodigestive tract (UADT) is identified at clinical examination, imaging techniques are required to detect nodal metastases in the ipsilateral (if the primary tumour arises far from midline) and the contralateral neck. Besides detecting the abnormal node, extra-nodal spread and key vessels invasion (carotid, jugular vein) are key information to be acquired by imaging. US, MDCT and MR can be used: their greatest limitation is the low sensitivity for non-enlarged metastatic nodes. A different setting is the assessment of thyroid papillary carcinoma where microcalcifications inside even very small metastatic nodes can be detected by US.

Learning Objectives:

1. To get acquainted with normal and abnormal findings.
2. To understand the patterns of nodal involvement.
3. To learn about technique of fine-needle aspiration.

Will emerging technology replace the radiologist?

A-022 08:30

Chairman's introduction

L. Donoso; *Barcelona/ES (ldonoso@clinic.ub.es)*

Call it artificial intelligence, deep learning, cognitive computing; whatever its name, it is the same thing, machines recognizing clinical problems in digital images ahead of the radiologists charged with making the diagnosis. Regardless of whether machine- or human-based aids are leveraged, radiology needs such aids. Never has improving performance been so important to its future. The liquid biopsy as a test is done on a sample of blood to look for cancer cells from a tumour that are circulating in the blood or for pieces of DNA from tumour cells that are in the blood. A liquid biopsy may be used to help find cancer at an early stage. It may also be used to help plan treatment or to find out how well treatment is working or if cancer has come back. The clinical impact of these developments together with the ones in molecular imaging, quantification and biomarkers will be discussed in this session.

Session Objectives:

1. To become familiar with the emerging technologies in the imaging field.
2. To learn about the new concepts behind the computerised image analysis and diagnosis.
3. To understand the potential benefits and threats related to its implementation.

A-023 08:35

Computer-aided and computer-determined diagnosis

K.J. Dreyer; *Boston, MA/US*

As computers outperform humans at complex cognitive tasks, disruptive innovation will increasingly remap the familiarity with waves of creative destruction. In healthcare, nowhere is this more apparent or imminent than at the crossroads of radiology and the emerging field of clinical data science. As leaders in our field, we must shepherd the innovations of cognitive computing by defining its role within diagnostic imaging, while first and foremost ensuring the continued safety of our patients. If we are dismissive, defensive or self-motivated, industry, payers and provider entities will innovate around us achieving different forms of disruption, optimized to serve their own needs. To maintain our leadership position, as we enter the era of machine learning, it is essential that we serve our patients by directly managing the use of clinical data science towards the improvement of care. In this session, we will explore the state of clinical data science in medical imaging and its potential to improve the quality and relevance of radiology as well as the lives of our patients. Attendees will learn the basics of clinical data science, understand the potential impact of data science on the field of radiology, understand the transition of radiology from visualization to quantification in preparation for precision healthcare, and understand the value of deep learning in the era of MACRA and MIPS payment reform policies.

Learning Objectives:

1. To lean about the different tools related with "computer assisted" diagnosis.
2. To understand the challenges in management and radiologist practice of introducing these technologies.
3. To become familiar with "real-life" implementations.

A-024 08:50

Liquid biopsy: a new kid on the block

M. Ignatiadis; *Brussels/BE (michail.ignatiadis@bordet.be)*

Circulating tumour cells and circulating tumour DNA often referred as a 'liquid biopsy' are promising tools that have the potential to improve cancer diagnosis, prognosis assessment and real-time monitoring of treatment efficacy. In June 2016, the Food and Drug Administration (FDA) approved a test to screen for EGFR mutations in plasma samples to identify patients with metastatic non-small cell lung cancer that are eligible for treatment with erlotinib. In the future, more liquid biopsy tests are expected to complement other approaches used today for the prediction of treatment efficacy towards precision medicine.

Learning Objectives:

1. To understand the concept of liquid biopsy.
2. To learn about the advantages of liquid biopsy in the diagnostic process.
3. To understand the impact that these techniques will have on clinical practice.

Novelties in molecular imaging

K. Riklund; *Umea/SE (katrine.riklund@umu.se)*

Molecular imaging with hybrid imaging such as PET/CT is integrated in many clinical pathways. The selected tracer for the PET part will determine which biochemical or molecular information the examination with the PET part will return. On the other hand, the section of study protocol for the CT or MR on the case of PET/MR imaging will decide which information that part of the examination will return. The major role for PET/CT or PET/MR is staging of oncologist diseases but applications in cardiac and neuro-imaging are emerging. There are also non-oncologic applications for these modalities. In the field of oncology, we are aware of several hallmarks in cancer that are involved in disease development as well as in treatment strategies and treatment response. A major challenge is to develop imaging so we can visualize the behaviour of these hallmarks and during the talk the possibility of using hybrid imaging to do this will be discussed. The interest and attempts to quantifying biomarkers is higher than ever; however, there are many challenges in this field. Quantification and how it can be used will be briefly discussed.

Learning Objectives:

1. To understand the role of hybrid imaging in the current clinical practice.
2. To become familiar with the new hybrid imaging applications in relationship to disease presentations.
3. To learn about quantification in hybrid imaging: its benefits and limitations.

A-026 09:20

Deep learning and biomarkers: the engineer's view

A. Alberich-Bayarri; *Valencia/ES (alberich_ang@gva.es)*

Quantitative imaging biomarkers are driving the paradigm shift in radiology towards precision medicine. Although the lack of standardization can hinder their appropriate use in clinical practice and drug development trials, alliances like QIBA and EIBALL allow for arriving to a consensus in image acquisition and image processing algorithms, which are the main current sources of uncertainty. The adoption of quantitative imaging solutions in the clinical setting requires, however, from the synthesis of the most relevant information, moving from redundancy to relevancy in the data evaluated by the radiologist and the clinical specialist, avoiding information overload. Therefore, data clustering and data reduction techniques, consisting of machine learning approaches have to be implemented. One of the most promising artificial intelligence techniques in the field of medical imaging is deep learning, which allows for the supervised (based on given features like imaging biomarkers) or non-supervised (learning features from data) by means of convolutional neural networks (CNN). Such networks have been applied for the automated classification of medical images as computer-aided detection (CAD) systems; however, the high number of data (millions of cases) required to train the CNNs and obtain efficacy is influencing the research evolution to new network configurations such as generative adversarial nets (GAN), which are expected to have a highly significant impact in the field of artificial intelligence and medical imaging.

Learning Objectives:

1. To learn about the specific engineering challenges of developing new quantification methods.
2. To become familiar with the process of adapting the use of biomarkers in the clinical setting.
3. To understand the impact of deep learning on these diagnostic tools.

Management of acute stroke

Moderator:
P. Vilela; Almada/PT

A-027 08:30

A. A critical appraisal of the current literature

W. van Zwam; *Maastricht/NL (w.van.zwam@mumc.nl)*

In 2015 and 2016, eight randomised controlled trials were published, reporting a clear benefit of endovascular treatment over standard care for patients with an acute ischaemic stroke caused by a large vessel occlusion of the anterior intracranial circulation. Individual patient data from five of these trials were pooled in the HERMES collaboration project and first results were published in 2016. After publication of the first positive trial, MRCLEAN, stroke treatment underwent a revolutionary change since the introduction of intravenous therapy with thrombolytics more than twenty years before. The different trials used different inclusion criteria and showed differences in outcome. In this lecture, a short history of acute stroke treatment trials, an overview of the differences between the 2015 and 2016 trials, new studies with subgroup analyses, and the pooled data from the HERMES collaboration will be presented and discussed.

Learning Objectives:

1. To understand the strengths and shortcomings of the relevant multicentre trials assessing the role of endovascular treatment in patients with acute ischaemic stroke.
2. To understand the outcomes of these trials, the context in which they were achieved and how they can be ensured in a different environment.
3. To appreciate potential differences in management of patients with anterior vs posterior circulation strokes.

W. van Zwam: Grant Recipient; Dutch Brain Council, Dutch Heart Foundation. Speaker; Codman, Stryker.

A-028 09:00

B. Which techniques can we use to reopen an occluded cerebral blood vessel?

T. van der Zijden; *Edegem/BE (thijsvanderzijden@hotmail.com)*

Since the 90s, the mainstay of primary stroke treatment is the use of clot-dissolving medication. Nowadays, mechanical thrombectomy has established itself as a very powerful tool in the management of acute ischaemic stroke in the (hyper)acute setting. The number of mechanical thrombectomy procedures has increased considerably in the last few years. An occluded cerebral blood vessel can be reopened in a swift and efficient way with quite acceptable complication risk rates using stent retrievers and/or thrombosuction catheters. In this presentation, not only an illustration of different mechanical thrombectomy techniques will be provided, but, next to an introduction to intra-arterial primary stroke treatment, also an overview of several accessory matters, such as tandem lesions, stenting and complications, will be discussed.

Learning Objectives:

1. To understand the principles underlying endovascular clot aspiration.
2. To become familiar with the different materials available for mechanical clot retrieval.
3. To understand the circumstances in which stenting of an intracranial blood vessel is needed.

A-029 09:30

C. Endovascular stroke treatment: ethical and economical concerns

K.-O. Løvblad; *Geneva/CH (karl-olof.lovblad@hcuge.ch)*

While stroke has known advances both in imaging and treatment since the 1990s, it has been the breakthrough with the use of stentrievers that has caused the most response. We have seen that with these methods, it is now possible to on the one hand extract safely and quickly the thrombus without the adverse effects of secondary haemorrhage. While this is extremely encouraging, a few things need to be considered: on the one hand, there will be an enormous demand in a very strictly organized stroke treatment system based on stroke units and stroke centres. Some that will carry out the initial examination and maybe treatment while the patients that need endovascular treatment may be referred to centres that dispose of 24/7 state-of-the-art imaging and post-treatment setups. The costs incurred will be caused on the one hand by and increase in treated patients, then an increase in the management and treatment costs themselves due to the stents. However, this should be counterbalanced by a decrease in morbidity and mortality with decreased readaptation costs. One major concern is the case of the increased need for improved informed consent ways for these patients that may not be initially be able to agree or disagree to the treatment, which is critical due to the short time-window available. Also while the industry is necessary to continue to support the needed R&D in this field, it should allow physicians freedom to provide the best choice of materials adapted to the patient.

Learning Objectives:

1. To appreciate the structure that is necessary to organise interventional stroke treatment for a large population.
2. To understand the cost implications and their mitigation.
3. To become familiar with the associated ethical concerns (such as informed consent) and the different ways of addressing them.

White matter disorders

A. Rovira-Cañellas; *Barcelona/ES (alex.rovira@idi.gencat.cat)*

MR imaging is highly sensitive for the detection of white matter signal abnormalities, which can be identified in 5-10% of the adult population. Evaluation of this focal white matter hyperintensities (WMHs) on MR imaging, particularly in young adults, is always challenging since clinical and imaging features are commonly non-specific. Although most of these signal abnormalities are incidental and age related, or secondary to different types of vascular disorders, they also may be caused by a wide variety of infectious, inflammatory, neoplastic, and demyelinating disorders. In this regard, the most common difficulty, by far, is to distinguish multiple sclerosis from acquired hypoxic/ischaemic small-vessel disease, due to the high prevalence of this last group of disorders even in young adults. While it is recognized that a combination of findings from clinical history, physical examination, and laboratory tests is commonly required to correctly establish a firm and clear aetiological diagnosis, a detailed analysis of different MR imaging features should also be considered essential, e.g. lesions shape, size, and distribution; contrast-uptake; associated structural lesions (microbleeds, infarctions, etc.). Knowledge of these features, will assist the diagnostic workup of patients presenting with WMHs, and should be considered a first step to take full advantage of the potential of MRI, and in doing so should result in a reduced chance of misdiagnoses and facilitate the correct diagnosis of sometimes treatable disorders.

Learning Objectives:

1. To have a basic understanding of classification of white matter disorders.
2. To describe the typical imaging features of noninfectious, noninflammatory disorders.
3. To identify and describe the imaging features of brain infectious-inflammatory disorders.

A-031 09:00

Brain tumours

J. Walecki; *Warsaw/PL (jerzywalecki@o2.pl)*

Neuroimaging techniques are essential tools for the diagnostic process and management of brain tumours. Early and accurate diagnosis is usually possible using various brain imaging techniques. Brain tumours are classified by cell origin and how the cells behave, from the least aggressive (benign) to the most aggressive (malignant). Malignant tumours can be divided into two categories: primary and metastatic. A malignant tumour usually grows rapidly and often invades or crowds healthy areas of the brain, where most benign brain tumours are characterised by slow growth. Based on analysis of all imaging features/imaging biomarkers/tumours are rated or graded by their level of malignancy. Many factors which determine tumour grade include how fast the tumour is growing, how much blood is supplying the tumour's tissue, the presence of the tumour necrosis and peritumoural oedema leading to high intracranial pressure/mass effect. Brain tumours are one of the most challenging disorders encountered; however, experiences of numerous authors as well as my own affirm the highest efficacy in the diagnostic process using multiparametric MR imaging: DWI, PWI or MRS. Lecture will present most common brain tumours and selected imaging modalities to their detection as well as postoperative follow-up and/or tumour's recurrence.

Learning Objectives:

1. To identify and describe the imaging appearance of malignant tumours.
2. To identify and describe the imaging features of benign tumours.
3. To have a basic knowledge of postsurgical evaluation of brain.

A-032 09:30

Stroke

E.T. Tali; *Ankara/TR (turgut.tali@gmail.com)*

Ischaemic stroke results from a sudden cessation of adequate amounts of blood reaching the brain. Imaging workup should be fast, readily available and reliable to detect early and subtle abnormal findings to suggest parenchymal hypoperfusion and, therefore, facilitate early diagnosis and intervention. Initial ischaemic stroke imaging using non-contrast CT has been effectively applied to exclude haemorrhage, estimate parenchymal abnormality and other intracranial pathologies that may mimic stroke. Even though non-contrast CT remains the mainstay of imaging, it has limited sensitivity in the acute setting of the ischaemic changes. Detection depends on the territory, time of the examination from onset of symptoms and experience of the interpreting radiologist. CT perfusion and angiography as a second step is a critical tool in increasing the accurate diagnosis. CT perfusion shows both the core of the infarct and the surrounding penumbra, the region which can be salvaged. CT angiography may be helpful to identify the thrombus within an intracranial vessel, establishing the stroke aetiology and also may guide treatment planning. MRI has significantly higher sensitivity and specificity in the diagnosis of hyperacute stage of ischaemic stroke. However, MRI is more time-consuming and less available than CT particularly in the emergency departments. Diffusion-weighted MR imaging shows infarct core within minutes following the onset of ischaemia. MR perfusion imaging also provides information almost similar to the CT perfusion. Treatment planning can be done under the guidance of the imaging findings and can be performed as various reperfusion techniques (intravenous or intra-arterial thrombolysis, mechanical thrombectomy, etc.).

Learning Objectives:

1. To learn about typical imaging features of haemorrhagic stroke.
2. To discuss current imaging techniques for evaluation of ischaemic stroke.
3. To have a basic knowledge of neuroradiological interventions - revascularisation in stroke.

Oncologic imaging in the age of precision medicine

Moderator:
H. Hricak; New York, NY/US

A-033 08:30

A. Precision medicine
G. Frija; *Paris/FR (guy.frija@egp.aphp.fr)*

According to the National Institutes of Health (NIH), precision medicine (PM) is "an emerging approach for disease treatment and prevention that takes into account individual variability in genes, environment, and lifestyle for each person". Its development is stimulated by the progresses in data intensive basic science, and is characterized by a high level of complexity. The key pillars of PM are: to develop a new taxonomy of diseases based on biological mechanisms, to develop correlations of phenotyping with genotyping, to increase the statistical power of research in developing networking and integrated databases. The main national plans or programmes, which are currently being developed, will be briefly presented in order to highlight the cost and the complexity of this concept. Imaging has certainly an important role in this framework: the development of reliable quantitative biomarkers and the delivery of structured data are crucial. Correlations between phenotype and genotype through radiogenomic approaches appear promising. Concrete examples will be presented to illustrate the potential of imaging in this context mostly in oncology (tumour heterogeneity mapping). The importance of companion diagnostics will be discussed as well as liquid biopsy, which potentially is a strong competitor as well.
Learning Objectives:
1. To understand the meaning of precision medicine.
2. To document the role of radiologists in precision medicine.
3. To understand how precision imaging will have an influence on the practice of radiology.

A-034 08:55

B. Radiomics: the role of imaging in precision medicine
R. Kikinis; *Boston, MA/US (kikinis@bwh.harvard.edu)*

Radiogenomics is the correlation between image-derived features and gene expression. Recent scientific progress has enabled the treatment of cancer based on targeting of specific mutations. Imaging, in contrast to biopsies, allows the assessment of the entire tumour volume. The presentation will explain the state of the art in the field and discuss the contributions that radiology can make.
Learning Objectives:
1. To review how radiologists can contribute to radiomics investigation.
2. To explain state-of-the-art of radiomics, from science to practise.
3. To learn about the idea of radiomics.

A-035 09:20

C. Precision medicine and imaging-guided interventions
S.B. Solomon; *New York, NY/US (SolomonS@mskcc.org)*

Modern oncologic care is centred on the molecular characteristics of an individual's cancer in what is termed precision medicine. The image-guided needle biopsy has been the key tool used to access the cancer for molecular analysis. Radiologists as central players in needle biopsy, thus, play a critical role in precision medicine. Recent data show that many specimens are insufficient to provide enough material for molecular analysis. This lecture will focus on optimising biopsies through improved techniques, tools and work flow. In addition, we will see how radiologists can use molecular status to help distinguish between responders and non-responders of locoregional therapies.
Learning Objectives:
1. To explain what is the present and the future of imaging-guided interventions.
2. To learn about current concepts for precise imaging guidance during IR procedures.
3. To understand the practical implementation of such tools.
Author Disclosure:
S.B. Solomon: Consultant; AstraZeneca, Medtronic, Aperture, Innoblative. Research/Grant Support; GE Healthcare.

Musculoskeletal

RC 110

The elbow: a comprehensive approach

A-036 08:30

Chairman's introduction
A. Alcalá-Galiano; *Madrid/ES (aalcalagaliano@gmail.com)*

The elbow is a complex hinge joint commonly injured in trauma and subject to chronic overuse syndromes in both athletic and non-athletic individuals. Understanding of the anatomy, systematic image evaluation as well as structured reporting are crucial for accurate diagnosis and to assist in surgical decision making. Recognised pitfalls and normal variants should not be confounded with pathology. Chronic overuse injuries or instability may have subtle imaging manifestations and some injuries may clinically emulate or exacerbate other entities; therefore, imaging prior to intervention is essential. Relevant parameters of tendon injury for treatment planning and the imaging appearance of the different instability patterns of the elbow joint due to lesion of the valgus/varus stabilizers need to be identified. Ulnar neuropathy at the elbow is the most common and best recognised, but there are other nerve entrapment syndromes that should not be missed. The choice of imaging modality for soft tissue derangement at the elbow includes MR and US, whereas CT is usually reserved for osteoarticular evaluation. US allows dynamic evaluation and may demonstrate findings which would otherwise be missed at static examinations. This session will provide a profound review of the imaging appearance of tendon anatomy and pathology, ligament injury and instability and nerve entrapment syndromes at the elbow with different imaging modalities. Interventional techniques for treating elbow tendon disease will also be discussed
Session Objectives:
1. To understand that assessing this joint requires a multimodality approach with careful attention to technique, imaging protocol, choice of coils and sequences.
2. To learn about the pivotal role of the radiologist in evaluating elbow imaging to provide relevant information to the arthroscopist.

A-037 08:35

A. The tendons: anatomy, pathology and intervention
P. Peetrons; *Brussels/BE*

"no abstract submitted"
Learning Objectives:
1. To become familiar with the normal imaging anatomy and pathological appearances of the elbow tendons.
2. To learn about interventional radiological techniques for treating elbow tendon disease.

A-038 08:58

B. Ligament injury and instability: what to look for and what to say
M.C. De Jonge; *Amsterdam/NL (mdjonge@zuwehofpoort.nl)*

The elbow joint is an intrinsic very unstable joint. It derives its stability from the capsula, joint crossing muscles, tendons and ligaments. Ligament injuries are not frequent although it depends upon the patient population. In sports people, e.g. throwing sports like baseball, it is quite common. The most common stabilising ligaments are on the ulnar and radial side. On the ulnar side, the ulnar collateral ligament (UCL) is the most important one often injured in situations where acute (severe) valgus stress is applied to the elbow. The most common chronic instability due to a ligament injury of the elbow, however, is the posterolateral instability. The most important structure on the radial side involved in this type of instability is the lateral ulnar collateral ligament (LUCL). At the same time this is also one of the most challenging ligaments to visualise for the radiologist. After a brief introduction of the anatomy, the mechanisms of injury to the medial and lateral ligaments will be discussed. Optimisation of the imaging protocol will be reviewed with the respective values of ultrasound and MRI.
Learning Objectives:
1. To become familiar with patterns of abnormality seen in elbow instability.
2. To learn about the imaging findings of elbow instability.

A-039 09:21

C. Nerve entrapment at the elbow

L.M. Sconfienza; *San Donato Milanese/IT (io@lucasconfienza.it)*

The most common condition around the elbow is the cubital tunnel syndrome. It is a compression neuropathy that can occur either at the condylar groove or at the edge of the arcuate ligament. Causes of compression include direct extrinsic compression on the condylar groove, bone abnormalities, and soft tissue lesions. Clinical findings include elbow pain and sensory symptoms in the innervated area. Diagnosis is mainly based on electrophysiological studies but US may demonstrate the presence of nerve thinning/thickening and associated abnormalities. Ulnar nerve instability at the cubital tunnel is also common but is asymptomatic in up to 47% of patients. When symptoms are present, US may demonstrate nerve thickening with hypervascularisation. The median nerve is infrequently impinged around the elbow. Anterior interosseous neuropathy occurs where nerve branches off the median nerve, in proximity to the pronator teres and the tendinous bridge connecting the heads of the flexor digitorum superficialis. When this syndrome is clinically suspected, US evaluation is usually inconclusive. However, abnormal reflectivity of innervated muscles can be seen. The median nerve may also be impinged as passing the pronator teres muscle. Posterior interosseous neuropathy is an uncommon condition of impingement at three different locations around the elbow, but more typically near or behind the supinator muscle at the proximal third of the forearm, where the nerve enters a strong fibrous arcade (i.e. arcade of Frohse). Clinical presentation is typical and US is able to identify the thickened nerve impinging in the arcade of Frohse.

Learning Objectives:

1. To understand the radiological anatomy of the peripheral nerves at the elbow.
2. To learn about the imaging findings of nerve entrapments at the elbow.

Author Disclosure:

Physics in Medical Imaging

RC 113

Single-dual-multi-energy CT

A-040 08:30

Chairman's introduction

J. Damilakis; *Iraklion/GR*

Dual-energy CT acquisition is possible using either single-source CT or dual-source CT. In single-source CT units, a generator switches x-ray tube potential from 80 kVp to 140 kVp corresponding to photon energies from about 40 keV to 140 keV. For each exposure, the exposure time is only 0.5 msec, allowing simultaneous acquisition of low-kVp and high-kVp images. Dual-source CT scanners are composed of 2 tubes and 2 detector arrays. The 2 tubes are positioned at 90 degrees from each other. For dual-energy CT the potential applied across the 2 tubes is 80 kVp to 140 kVp. The tube load (mAs) is adjusted accordingly to 50 mAs for the high-kVp tube and 200 mAs for the low-kVp tube. Other approaches have been introduced through energy-sensitive detectors and photon counting detectors. All CT examinations should be optimised to achieve diagnostic image quality with the lowest radiation dose possible. Dose optimisation of dual-energy examinations is an area of great interest for both medical physicists and radiologists. The replacement of pre-contrast imaging by virtual non-contrast-enhanced imaging provides a great opportunity of radiation dose reduction. Moreover, several techniques and tools have been developed for CT dose optimisation and these methods are also applicable for dual-energy CT studies. For example, application of new iterative reconstruction algorithms, use of automatic exposure control and other dose saving tools may help to reduce patient doses considerably.

Session Objectives:

1. To learn about the basics of dual-energy CT (DECT).
2. To understand today's photon counting detector technology.
3. To learn how DECT is applied in clinical practice.

A-041 08:35

A. Basics of diagnostic dual-energy CT

T. Klinder; *Hamburg/DE (tobias.klinder@philips.com)*

Although the first applications of dual-energy CT (DECT) were already introduced in the 1980s, they were not adopted in clinical practice. However, with advancements in the CT systems, DECT experienced its comeback and is now clinically emerging. In this talk, we will explain the technological basics of diagnostic DECT and show its clinical potential. First, the general idea of CT acquisition is reviewed to acknowledge the spectral information that DECT provides. The fundamental underlying physics of DECT is explained. In particular, it is derived how spectral acquisition allows to parameterise the energy-dependent attenuation coefficient inaccessible to single-energy CT. The different techniques for acquisition of DECT will be shortly compared. Dual-energy data can be post-processed and presented in various ways (e.g. monochromatic images, iodine maps or virtual non-contrast images). The individual possibilities are thereby described on the basis of the introduced physical principles. Finally, an overview of main clinical applications of DECT is given including the detailed review of different clinical example cases. Where appropriate, a comparison to single-energy CT is given to fully appreciate the additional value of DECT.

Learning Objectives:

1. To learn about the underlying physics and today's technology.
2. To see potential advantages compared to single-energy CT.
3. To appreciate the rationale behind clinical applications.

A-042 08:58

B. Photon counting detector technology for diagnostic CT

I. Blevis; *Haifa/IL (ira.blevis@philips.com)*

Medical CT imaging has recently advanced due to the introduction of dual-energy techniques. Material composition and density in the body are disentangled using the energy information in the x-rays traversing the body. The added information can be combined with the conventional image using colours or other techniques. Realizing the full potential of the newly tapped energy information will require a major technological change from the scintillating crystals and light sensing electronics in current use to semiconductor detectors and electronics sensitive to each photon and its energy, individually. The current technology is called indirect and integrating detection, and the new and emergent technology is called direct conversion photon counting. Photons are absorbed in high Z, high band gap, high crystallinity, thick semiconductors, notably Cd(Zn)Te, producing a very compact ball of electric charge that is transferred to external electronics by a fine grid of contact electrodes on the semiconductor surface. The small size of the charge ball also permits a high resolution and contrast improvement in CT, potentially without an increase of patient dose. The new technology has been introduced commercially in the past decade in less demanding SPECT imaging at 10^{-1}photons/s/mm^2 and now in our CT research prototypes the detector development has permitted close to the 10^{9}photons/s/mm^2 needed for CT. Verification images from phantoms and preclinical trials, including resolution tests, and high Z contrast agents will be shown.

Learning Objectives:

1. To learn about the underlying physics and technological solutions.
2. To understand the potential advantages compared to dual-energy CT.
3. To appreciate how mature today's photon counting technology is.

Author Disclosure:

A-043 09:21

C. Do we really need multi-energy CT?

S.T. Schindera; *Aarau/CH (sschindera@aol.com)*

Dual-energy CT has been introduced more than ten years ago and since then various clinical applications from head to toe have been described in the scientific literature. A clear added value of each clinical application needs to be proven to transfer them into clinical routine. Besides optimization of the clinical workflow of dual-energy CT, including post-processing of the additional datasets, the radiation exposure to the patient is an important aspect which decides if dual energy maintains a success story. To promote the wide-spread use of dual-energy CT, there is a definite need for future investigations on the outcome of dual-energy CT, such as patient care, costs and workflow.

Learning Objectives:
1. To learn about medical applications and potential benefits.
2. To see which single energy applications should be replaced by dual-energy applications, and why.
3. To find out what additional multi-energy CT applications would be nice to have.

Author Disclosure:
S.T. Schindera: Advisory Board; Bayer Healthcare.

A. Recent developments in structural and quantitative spinal cord imaging at 3T
M.C. Yiannakas; *London/UK*

In this presentation I would be discussing new developments in acquisition and analysis protocols for spinal cord imaging using a clinical 3T MR system, which are suitable for use in a number of neurological diseases, such as multiple sclerosis (MS), spinal cord injury (SCI), amyotrophic lateral sclerosis (ALS), neuromyelitis optica (NMO) and multiple system atrophy (MSA). In terms of acquisition, protocols which allow depiction of grey matter (GM) and white matter (WM) within the cord will be presented along with examples on how these may facilitate further tissue-specific (i.e. GM/WM) quantitative investigations such as the estimation of tissue volume, diffusion tensor imaging (DTI) metrics and magnetisation transfer ratio (MTR). In terms of analysis methods, recent advances in semi- and fully-automated image segmentation will be presented and discussed.

Learning Objectives:
1. To understand the technical challenges associated with spinal cord imaging.
2. To learn about new structural and quantitative spinal cord acquisition and analysis protocols.
3. To discuss some of the clinical applications in neurological disease.

A-045 08:55
B. RF-related heating in clinical MRI
T. Owman; *Lund/SE (Titti.Owman@gmail.com)*

Magnetic resonance is a frequently used diagnostic tool and considered a fairly safe modality. It is well known that MR is not only exclusively used for diagnostic purposes but also used in interventional care, research and functional studies of various kinds. Clinical demands for faster examinations and higher resolution, and in combination with advanced research has resulted in a development toward stronger magnetic fields and a more powerful and complex technology. This with the consequence that clinical MR of today uses higher frequencies and increased energy deposition in patients and volunteers. There are several known risks in MR and the radiofrequency (rf)-induced heating problem in patients has increased significantly parallel to the fast technological development. Several efforts are made to improve the situation since MR-related rf-burns occur more and more frequent in clinical practice. The rf-heating problem is relatively difficult to predict and may even cause various degrees of burns during regular clinical MR scanning. Improved knowledge and better understanding of this hazard is necessary to minimize risks and avoid unnecessary damage. Heat-related accidents (rf) can be reduced and the situation considerably improved by careful patient preparations and good safety routines prior to MR examinations.

Learning Objectives:
1. To learn about b1-related problems in clinical MRI.
2. To understand RF-related heating and current efforts to improve the situation.
3. To discuss how to avoid RF-burns in clinical practice.

A-046 09:20
C. The benefits of diffusion imaging
J. Castillo; *Msida/MT (josecast@melita.com)*

Diffusion-weighted magnetic resonance imaging (DWI) derives its image contrast from differences in the motion of water molecules between tissues. Such imaging can be performed very quickly without the need for exogenous contrast medium administration. A series of technological advances have made it feasible to translate DWI measurements to extra-cranial sites, such as the abdomen and pelvis. The application of DWI in oncology has been widely explored. DWI for tumour detection has been shown for a variety of tumour types in adult and paediatric oncology. Used together with other MR imaging techniques, DWI can aid tumour characterization and in distinguishing tumour from non-tumour tissues. DWI is usually performed using an echo-planar imaging technique, in breath-hold, free-breathing or with the use of respiratory and/or cardiac gating. Meticulous attention to technique is important to ensure high-quality images can be consistently obtained. This is one of the key competence of MR radiographers. There is now considerable interest in using DWI for the monitoring of treatment response. Several studies have already shown that the apparent diffusion coefficient (ADC) of tumour in response to successful chemotherapy, radiotherapy and other minimally invasive interventional procedures. Diffusion-weighted MRI is being increasingly used in paediatric body imaging. Its role is still emerging. It holds great promise in the assessment of therapy response in body tumours, with ADC value as a potential biomarker. Body DWI is a technique that can be quickly performed on clinical MR systems, and can be incorporated into existing clinical protocols.

Learning Objectives:
1. To appreciate the role of diffusion imaging in oncology imaging.
2. To discuss the responsibility of radiographers in the application of DWI.
3. To discuss the clinical application of diffusion imaging in MR enterography and paediatric imaging.

09:45
Discussion and questions: How is patient care affected by MRI technology and techniques?

Vascular

RC 115
Peripheral vascular malformations: light after darkness

A-047 08:30
Chairman's introduction
J.A. Reekers; *Amsterdam/NL (j.a.reekers@amc.uva.nl)*

Treatment of peripheral vascular malformations is a combination of diagnostics, skills and experience. This treatment is done by specialised interventional radiologists in dedicated centres. Treatment is always a team effort. There is a wide variety of diagnostic pathways used to establish the final diagnosis and to plan treatment. These pathways will be discussed. Based on the clinical diagnosis specific imaging algorithms can be used. In the workshop this will be discussed. Treatment of peripheral vascular malformations is often not a medical necessity but mainly closely related to the wishes and expectations of the patients. Every procedure is tailored by this “shared dissection making” and, therefore, planning of a treatment procedure should also be patient tailored. How to define success is, therefore, sometimes difficult. This planning of treatment will also be discussed. Children are a specific entity within the spectrum of vascular malformations and special knowledge is needed not only to treat but also to support these patients and their family. Also in children interventional techniques are tailored and this will be discussed in the session.

Session Objectives:
1. To review classification and description.
2. To identify the role of imaging modalities.
3. To understand the role of interventional radiologist in management and treatment.

A-048 08:35
A. The diagnostic assessment
M. Köcher; *Olomouc/CZ (martin.kocher@seznam.cz)*

Vascular malformations are categorized into the low-flow malformations and high-flow malformations. From imaging methods it is expected to distinguish between the low-flow lesions and high-flow lesions, localisation, volume and range of lesion and relationship to the surrounding tissues and organs. Colour

Doppler ultrasonography (DUS) can offer good differentiation between high-flow and low-flow lesions. Magnetic resonance (MR) offers good differentiation between high-flow and low-flow lesions also and, moreover, good evaluation of volume and extent of lesion, good interpretation of anatomical relationship to the surrounding tissues and organs. On DUS the low-flow malformations are demonstrated as hypoechogenic or heterogenous lesions with minimal flow inside, flow during augmentation and normal arterial flow volumes and normal high arterial resistance flow. The high-flow malformations are heterogeneous lesions with tortuous feeding arteries, high-velocity and low-resistance flow in feeding arteries, multiple arteriovenous shunts and pulsatile flow in draining veins. On MR, the low-flow malformations typically have low signal intensity in T1-weighted images in abnormal vascular structures and high signal intensity in T2-weighted images whereas the high-flow lesions usually demonstrate signal voids in abnormal vascular structures on most sequences. At follow-up, DUS demonstrates thrombosis and fibrosis of the low-flow lesion. In the high-flow lesion, the waveform will normalised and the resistive indexes and the flow volumes will become normalized as well. MR demonstrates thrombosis and fibrosis of low-flow malformation by the loss of high signal in T2-weighted images and loss of signal voids in high-flow lesions.

Learning Objectives:

1. To learn about classification and terminology.
2. To understand the role of US, CT and MRA in diagnostic assessment.
3. To learn the optimal imaging algorithm for diagnosis and follow-up.

A-049 08:58

B. Percutaneous or endovascular treatment: when and how?

B. Peynircioglu; *Ankara/TR (borapeynir@gmail.com)*

Vascular anomalies are divided into two different categories which carry different prognosis and management: "vascular tumours" and "vascular malformations" (VM). Their precise identification is crucial and involves a good knowledge of the biological classification published by Mulliken and Glowacki and that has recently been updated by the International Society for the Study of Vascular Anomalies (ISSVA). Vascular malformations are always congenital and growth with the child. They can involve type of vessels solely or combined with others. A rheologic differentiation between low and high flow malformations is essential to characterize the seriousness of the lesion. Interventional radiology (IR) plays major role in both curative and palliative treatments of these VM. Transcatheter/endovascular (transarterial or transvenous) or direct percutaneous puncture under imaging guidance are the 2 main techniques for treating these lesions. Depending on the type, nature, location and surroundings of the VM, one should decide the best strategy for treatment. Another key point is to decide whether to use embolization or sclerotherapy. Again, the type, location of the VM is vital and the patient-based decision is to be made carefully by a multidisciplinary team. Operator's experience is of most importance in determining all of the above variables, together with the local circumstances. There are many different types of embolic and sclerotherapy agents available around the world.

Learning Objectives:

1. To recognise the indications and the real need for treatment.
2. To learn about technical approach - how to plan the intervention?
3. To understand possible limitations and the final result prediction.

A-050 09:21

C. Paediatric vascular malformations: diagnosis and treatment

S. Stuart, D. Roebuck; *London/UK (derek.roebuck@gosh.nhs.uk)*

The current accepted method for classification of vascular malformations is straightforward and clinically relevant. Vascular malformations can be divided into high flow lesions such as arteriovenous malformation (AVM) or low flow lesions such as venous or lymphatic malformations. In children, 90% of vascular anomalies can be diagnosed by clinical history and examination alone. Imaging predominantly with US or MRI can confirm the diagnosis, evaluate extent of a lesion or flow within it. In children ultrasound is particularly useful for aiding the diagnosis. Many vascular malformations require no treatment, if they are not causing symptoms. A multidisciplinary team approach to the management of these conditions is vital. Non-interventional treatments such as physiotherapy and occupational therapy are vital. The use of compression garments can help symptomatically in venous malformations. Interventional radiology plays a role in treatment principally with injection sclerotherapy of low flow lesions and embolization of the much rarer AVM. Many sclerotherapy agents are available with sodium tetradecyl sulphate the most commonly used for venous malformations and doxycycline commonly used for lymphatic malformations. Different sclerotherapy agents have different characteristics and uses which will be covered. Symptomatic relief is often achieved with treatment but multiple treatment episode may be needed to achieve the wanted outcome. Ensuring the child and family understand this is vital to ensure they are satisfied with the management of the condition.

Learning Objectives:

1. To understand the specifics of vascular malformations in children.
2. To recognise when to observe and when to intervene?
3. To learn about interventional techniques used and results of treatment.

09:44

Panel discussion: How could we improve diagnosis and optimise the results of our interventions?

Interventional Radiology

RC 109

Musculoskeletal interventions: what's new?

Moderator:
A. Gangi; Strasbourg/FR

A-051 08:30

A. Musculoskeletal ablation and embolisation

A. Basile; *Catania/IT (basile.antonello73@gmail.com)*

In a modern era of interventional strategies, ablation and embolization use is not anymore limited to usual target organs but these techniques are finding new rooms, remarkably in MSK tumours. In the literature, the most encountered benign tumours treated via ablation and/or embolization are osteoid osteoma, osteoblastoma, chondroblastoma and osteochondroma, giant cell tumour, aneurysmal bone cyst, eosinophilic granuloma, vertebral haemangioma and fibrous dysplasia. In turn, malignancies of the soft tissue and bones (primary sarcomas) are rare, likely spinal metastases are the most common (derived by carcinomas of the breast, lung, prostate, kidney and uterus). Shall be underlined that in most cases palliative measures are related to malignant cancer and patient's quality of life and motility are the priority. Among first weapon such as thermal ablation (both MW, RF and Laser) cryotherapy is raising the interest of the IR's community due to the powerful pain management feature and the possibility of an instant check of the ice ball, preserving nervous tissues, specially for vertebral metastases use. Nevertheless, ablation may be applied both for curative and palliative strategies when combined with cement injection, allowing a precise patient's selection to be made. Embolization has a strong importance applied to hypervascular lesions, may also reduce recurrence rate and potentially extend survival one. New heroes of oncologic interventions and probably future fashion are MR-guided HIFU and irreversible electroporation (IRE), even though bringing higher cost. Improved research of the field is strongly needed to assess a proper cost-benefit analysis and limits of these approaches.

Learning Objectives:

1. To appreciate the indications for ablations and embolisation.
2. To learn about different techniques and combination of them.
3. To discuss the results and literature data of interventional radiology procedures.

A-052 09:00

B. Vertebral augmentation and discectomy techniques: can we challenge surgery?

D. Filippiadis; *Athens/GR (dfilippiadis@yahoo.gr)*

Vertebral augmentation techniques include standard vertebroplasty, balloon kyphoplasty and percutaneous implant insertion combined to PMMA injection. Indications include osteoporotic, traumatic, pathologic and cancer-related fractures as well as benign (e.g. symptomatic atypical aggressive haemangiomas) or malignant (e.g. metastatic) lesions. Under proper patient selection, these techniques provide pain relief and functional improvement along with spine alignment height restoration and endplate reduction. Additionally, kyphotic angle restoration or maintenance seems to prevent future vertebral fracture in the adjacent levels and improved sagittal balance. Studies in the literature report that load distribution in patients with vertebral fractures post-vertebroplasty returns to values of normal population. Variety in the morphology, location, and aetiology of vertebral fractures demands a tailored patient-centred approach. Percutaneous technique for intervertebral disc herniation and discogenic pain can be either decompression or biomaterial implantation techniques. The former can be classified into mechanical (discectomy), thermal (RF, laser, coblation, IDET) or chemical (Discogel, ozone) methods whilst the latter includes hydrogel, PRP and stem cell therapies. Decompression techniques are indicated for small- to medium-sized symptomatic contained hernias. Percutaneous techniques are performed as outpatient, low-cost procedures and are governed by good patient compliance, high success (75-85%) and low complication rates (<1-2%). In case of treatment failure, percutaneous techniques can be repeated without interfering

with surgery at a later stage. Percutaneous vertebral augmentation and discectomy techniques compared to surgical approaches are favoured in terms of reduced blood loss and operating time, shorter hospital stay, fewer complications and less postoperative pain.

Learning Objectives:

1. To appreciate the rationale for the using of interventional radiology procedures.
2. To learn about different techniques and treatment strategy.
3. To discuss results and literature data in comparison with other treatments.

A-053 09:30

C. Bone biopsy and pain treatment using cone-beam CT (CBCT)

L. Tselikas; *Villejuif/FR (lambros.tselikas@gustaveroussy.fr)*

Cone beam-CT imaging (CB-CT) is actually widely available and allows, because of high-quality multiplanar reconstructions and using dedicated guiding software, to perform various bone interventions. Bone biopsies are feasible using CB-CT guidance with the same accuracy as CT-scan guidance and requiring less radiation exposure for patients and operators. Furthermore, pain palliation procedures such as cementoplasty and percutaneous osteosynthesis are actually possible with very high accuracy and technical success rates. New techniques and software are under development to decrease radiation dose, improve guidance for in case where CB-CT acquisition can be complicated and be easily integrated in an everyday workflow.

Learning Objectives:

1. To appreciate the high imaging quality and guidance accuracy using CBCT for biopsy and pain treatment.
2. To learn about the advantages of CBCT guided interventions, reconstruction algorithms, image enhancement and dose reduction.
3. To discuss about techniques, limitations of CBCT and future applications.

Author Disclosure:

E³ - ECR Academies: Tips and Tricks in Liver, Bile Ducts and Pancreas Imaging

E³ 118

Liver, bile ducts and pancreas: improving your technique with advanced tools

A-054 08:30

Chairman's introduction

Y. Menu; *Paris/FR (yves.menu@sat.aphp.fr)*

Optimal imaging technique is absolutely critical in abdominal studies, as many parameters may interfere in the production of final images. Despite technical advances, or may be as a consequence, settings and fine-tuning of machines is the only way to reach clinical relevance of images. The radiologist has to be familiar with the most important parameters that may influence image quality and relevance. In this session, the purpose is to learn the best and the most simple way to obtain optimized results with recent and advanced imaging technique, with a special interest on how to integrate it while driving these machines for clinical practice.

A-055 08:35

A. Liver specific contrast: how, why, when?

E. Neri; *Pisa/IT*

The so-called liver-specific (or hepatobiliary) contrast agents (gadobenate dimeglumine, Gd-BOPTA, and gadoxetic acid, Gd-EOB-DTPA), are characterised by a dual behaviour by exhibiting elimination through both renal and hepatic excretion pathways and thereby possessing both early perfusion information (renal elimination pathway) and, later, hepatocyte-selective information (hepatic excretion pathway) mediated through protein transporters, located in the canalicular or sinusoidal pole of the hepatocytes. As a basic rule of MR technique all non-blood pool gadolinium chelate-based contrast agents are suitable for dynamic liver MRI, but the use of liver-specific contrast agents is mandatory to obtain the hepatobiliary phase in addition to the dynamic phase. The workup of solid focal liver lesions should include: axial breath-hold heavily T2-weighted half-Fourier single-shot turbo spin-echo sequences; navigator triggered intermediate T2-weighted turbo spin-echo sequences, breath-hold T1-weighted two-dimensional dual gradient-echo in-phase and opposed-phase sequences, and dynamic contrast enhanced fat-suppressed three-dimensional spoiled gradient-echo breath-hold sequence, acquired before and during the late arterial, portal venous and late dynamic phase. Hepatocyte phase can be considered adequate when Gd-EOB is detected in the intrahepatic bile ducts and the vessels are definitely hypointense in comparison to the background parenchyma. Liver specific contrast agents improves the characterisation of benign liver lesions, malignant liver lesions in non-cirrhotic, focal lesions in cirrhotic patients; they are also helpful to to depict the degree of fibrotic changes in liver fibrosis.

Learning Objectives:

1. To learn about physiology of liver specific contrast media physiology, and to be able to optimise liver MRI protocols.
2. To understand why they are useful for the detection and characterisation of liver masses.
3. To learn and understand the limitations.

A-056 09:03

B. Diffusion-weighted imaging (DWI): how, why, when?

D.-M. Koh; *Sutton/UK*

Diffusion-weighted MRI (DWI) is now routinely applied for the evaluation of abdominal diseases. The principles of optimising DWI are similar on both 1.5T and 3.0T, which includes maximising image signal to noise and minimising artefacts. In this regard, free-breathing DWI acquisition is most widely used to achieve the best image quality. DWI can be used to improve disease detection in the liver, hepatobiliary tract and the pancreas. It can be applied to support disease characterisation, but potential pitfalls should be appreciated. There is an increasing role for its deployment for the early evaluation of tumour response to treatment. Monoexponential DWI model to derive the apparent diffusion coefficient (ADC) of tissue is still the most widely used approach in the clinical setting. However, there is interest in applying non-monoexponential approaches including IVIM (intravoxel incoherent motion) and DKI (diffusion kurtosis imaging). These approaches should be utilised with full knowledge of their measurement repeatability so that it allows for meaningful data interpretation.

Learning Objectives:

1. To become familiar with the different acquisition techniques and to be able to adapt to a specific machine, including field strength.
2. To understand the role of DWI in the detection and characterisation of hepatobiliary and pancreatic diseases.
3. To learn about the potential technical future developments.

A-057 09:31

C. Advances in hybrid imaging: new tracers and MR/PET

E.J. Rummeny; *Munich/DE (rummeny@roe.med.tu-muenchen.de)*

In both PET/CT and MR/PET, radioactive tracers are used to detect primary tumours and metastases. During the lecture, we will discuss those tracers which are used for PET imaging of the abdomen and pelvis. By far the most commonly applied tracer is 18F-FDG which is used to study glucose metabolism in tumours and metastases. Increasingly, other more specific tracers, primarily marked with 68 Ga, are used for abdominal tumours such as DOTA-TATE and DOTA TOC. These tracers exhibit high affinity to somatostatin receptors and can be used to detect endocrine tumours (NET) with low or moderate proliferation rate (G1 and G2). To quantify tumour response to therapy, standard uptake values (SUV) can be calculated. Newer tracers like 68 Ga-PSMA-ligand are primarily used to diagnose prostate cancer (PCa) and its metastases to lymph nodes and bones. Furthermore, this tracer may be also useful to diagnose other tumours of the urinary tract. Bound to 90 Yttrium or 177 Lutetium, these carriers, i.e. DOTA-NOC and PSMA-ligand, can be used as so-called theranostics which are employed successfully to treat tumour metastases of certain cancers. All those markers can be used for PET/CT and MR/PET. While PET/CT is in clinical use already, MR/PET systems are still under evaluation. MR has better soft tissue contrast and radiation dose from MR/PET is substantially less than PET/CT. However, MR/PET takes longer than PET/CT and is only feasible in certain patients. Therefore, MR/PET is currently available for patients with selected indications and primarily used for clinical research studies.

Learning Objectives:

1. To understand why alternative tracers to FDG may be useful in exploring liver and pancreatic diseases.
2. To learn about the role of PET in the follow-up of tumours and quantification of tumour response.
3. To become familiar with the specific advantages of MR/PET over PET/CT in abdominal diseases.

E³ - ECR Master Class (Genitourinary)

E³ 126b

Functional MRI of the kidneys: ready for prime time?

Moderator:
H.C. Thoeny; Berne/CH

A-058 08:30

A. Diffusion-weighted MRI
N. Grenier; *Bordeaux/FR (nicolas.grenier@chu-bordeaux.fr)*

Diffusion-weighted MRI of the kidney has multiple applications in morphological renal imaging. Its applications in the functional field of parenchymal renal diseases are still to be defined. For morphological applications such as renal tumours or infections, 3 b-values are enough with calculation of an ADC-map based on a mono-exponential fit. For functional applications, the tendency goes toward more sophisticated approaches such as the IVIM technique with more b-values and a bi-exponential fit or characterisation of the diffusion tensor, based on acquisition of at least 6 directions, of diffusion encoding. All functional and tissue changes decreasing water movements or increasing the cell density in renal parenchyma can decrease diffusion coefficients. Renal ADC decrease is correlated with the degree of renal dysfunction in parenchymal diseases. Urinary obstruction and parenchymal processes such as inflammation or fibrosis also decrease the diffusion coefficients. In chronic diseases, tissue changes and fibrosis induce changes of the microarchitecture responsible for a decrease of renal anisotropy shown by diffusion tensor imaging.

Learning Objectives:
1. To learn about the technical issues of DWI.
2. To understand the physiological determinants of diffusion measurements.
3. To assess the role of DWI in clinical practice.

Author Disclosure:
N. Grenier: Advisory Board; Supersonic Imagine.

A-059 09:00

B. Perfusion MRI
M. Claudon; *Vandoeuvre-les-Nancy/FR (m.claudon@chu-nancy.fr)*

Because of its high spatial resolution, magnetic resonance urography has demonstrated high accuracy in the morphologic assessment of urinary tract. More recently, functional MRU (fMRU) has shown feasibility in adults and children, using dynamic pulse sequences performed after injection of an intravenous bolus of gadolinium chelates (DCE-MRU), which allow calculating the split renal function (SRF) from time-intensity curves, where the Patlak method should be preferred to the area under the curve method. Using MRU to obtain both anatomical and functional information in a single examination without radiation would be beneficial, especially for follow-up in young patients. Complementary medico-economic analysis confirms the interest of a potential substitution of nuclear renal scintigraphy by fMRU as an adjunct to morphological MRU.

Learning Objectives:
1. To learn about the clinical indications for kidney perfusion imaging.
2. To become familiar with perfusion protocols for kidney perfusion imaging.
3. To learn about difficulties in kidney perfusion imaging.

A-060 09:30

C. BOLD and ASL
A. Boss; *Zurich/CH (andreas.boss@usz.ch)*

In functional renal magnetic resonance imaging (MRI) advanced techniques are used to obtain functional and molecular information from the state of the kidney. In blood oxygenation level-dependent (BOLD) MRI, the susceptibility difference between oxyhaemoglobin (diamagnetic) and deoxyhaemoglobin (paramagnetic) is used to extract information on tissue oxygenation, which is interesting because of the physiological hypoxia in the renal medulla. BOLD MRI, therefore, may be applied to non-invasively assess renal oxygenation and the oxygen metabolism of the kidneys. Arterial spin labelling (ASL) is a non-invasive technique, which uses radiofrequency-labelled blood water as endogenous tracer to visualize and quantify renal perfusion. Using the extended Bloch equations, quantitative perfusion values in ml/100 g/min can be calculated.

Learning Objectives:
1. To understand the physiological and technical basis of blood oxygen level-dependent (BOLD) imaging of the kidneys.
2. To learn typical findings of BOLD-MRI in patients with kidney disease.
3. To review the physics and technique of arterial spin labelling (ASL) perfusion measurements of the kidneys.
4. To see typical findings of ASL measurements in patients with kidney diseases.

MR imaging in sports medicine I

A-061 10:30

A. Muscle injury in sports
M.G. Mack; *Munich/DE (m.mack@radiologie-muenchen.de)*

According to the UEFA injury study 2014, almost 50% of all injuries in professional soccer players are related to muscles, tendon and the musculotendinous junction. During this lecture, you will learn how normal and injured muscle will look like. The standard imaging protocol is including axial T1- and fsPD sequences, angulated coronal and sagittal fsPD sequences with a slice thickness between 1 and 6 mm. You will learn to differentiate between functional muscle disorders without structural injuries (like fatigue-induced muscle disorder (Type 1a), delayed-onset muscle soreness (Type 1b) and spine (Type 2a) or muscle-related neuromuscular disorder (Type 2b)) and structural injuries (minor partial tear (Type 3a), moderate partial tear (Type 3b) and total/subtotal tear (Type 4) of the muscle, the musculotendinous junction and tendinous avulsion). Most structural injuries are stretch-induced injuries and have to be differentiated from contusion injury and distraction injury. In soccer, 92% of all muscle injuries affect the four major muscle groups of the lower limbs (hamstrings, adductors, quadriceps and calf muscles) and occur mainly in non-contact situations.

Learning Objectives:
1. To understand the anatomy of the most common injured muscles.
2. To learn the evaluation of muscle injuries and the impact regarding recover.

A-062 11:15

B. Knee trauma
M. Shahabpour; *Brussels/BE*

"no abstract submitted"

Learning Objectives:
1. To learn the anatomy of the most common injured structures.
2. To recognise typical combinations of injuries.

10:30 - 12:00 **Room F1**

E³ - Rising Stars Programme: Basic Session

BS 2

Lungs

Moderator:
T. Franquet; Barcelona/ES

A-063 10:30

Congenital anomalies
J. Ley-Zaporozhan; *Munich/DE*

Imaging in lung anomalies is usually started off by plain film radiography. This projection technique gives a first overview of the anatomical situs and allows for a first assessment of expected anomaly. Depending on the individual setting an ultrasound of the chest can be added for further assessment of the vascular structures or cystic components. A more sophisticated imaging technique like computed tomography or magnetic resonance imaging will allow for definite classification of the anomaly. The different imaging techniques and especially CT and MRI protocols used will be covered. Anatomical variants are most often detected within the tracheobronchial tree, namely with anomalous branching pattern of the upper lobe bronchi. Congenital lung anomalies are a heterogeneous group of developmental disorders with a wide distribution in imaging appearance and clinical manifestations. The most frequent ones are: congenital pulmonary airway malformation (CPAM), congenital lobar hyperinflation, bronchial atresia, bronchiogenic cyst and pulmonary

sequestration. For these anomalies, the embryologic background, clinical presentation and imaging findings will be demonstrated.
Learning Objectives:
1. To discuss current imaging techniques for evaluation of normal lung anatomy.
2. To learn and understand possible anatomical variants.
3. To describe the typical imaging features of the most common anatomical anomalies.

A-064 11:00

Infection

T. Franquet; *Barcelona/ES (tfranquet@santpau.cat)*

Inflammation is a response of vascularised tissues to infections to eliminate the offending agents. Pneumonia occurs when the host mounts an inflammatory response, centred on the lung parenchyma, usually against a microorganism which has reached this normally sterile site. Bacteria are the most common causative microorganisms. Pneumococci usually spare alveolar walls and cause lobar pneumonia that resolves completely, whereas Staphylococci and Klebsiella species destroy alveolar walls and form abscesses that heal with scar formation. Combination of pattern recognition with knowledge of the clinical setting is the best approach to pulmonary infectious processes. When pulmonary infection is suspected, knowledge of the varied radiographic manifestations will narrow the differential diagnosis, helping to direct additional diagnostic measures, and serving as an ideal tool for follow-up examinations. Management of immunocompromised patients is challenging and difficult because of the diversity of causative organisms. Although diagnostic information may also be obtained by means of bronchoalveolar lavage and transbronchial needle aspiration, the radiologist plays an important role in the diagnosis and management of patients with suspected pneumonia.
Learning Objectives:
1. To recognise the most common imaging patterns of lung infections.
2. To understand the temporal relationship between the immune status and diverse lung infections.
3. To have a basic knowledge of CT-path correlation of some pulmonary infectious diseases.

A-065 11:30

Tumours

I. Hartmann; *Rotterdam/NL (i.j.c.hartmann@gmail.com)*

Non-small cell lung carcinoma (NSCLC) comprises the largest group of which the imaging appearance can be variable. It can present as centrally or peripherally located nodule or mass that may invade mediastinal structures or the chest wall. Tumour margins may be smooth, lobulated, ill defined, irregular or spiculated. Other findings include cavitation, consolidation and ground glass opacity (GGO). Accompanying post-obstructive pneumonia and/or lung collapse can be seen in central tumours. Small cell lung carcinoma (SCLC) is the most common primary pulmonary neuroendocrine tumour. Most SCLCs are a centrally located large mass invading or metastasising to regional lymph nodes. 5-10% of SCLCs present as a peripherally located spiculated nodule without associated lymphadenopathy. Pulmonary metastasis: the lung is frequently involved in metastatic disease. Typical radiological features include multiple round nodules with variable size, peripherally located (haematogenous metastasis) and diffuse thickening of the interstitium (lymphangitic carcinomatosis). Atypical features such as cavitation, calcification, air bronchogram and GGO are often encountered. Pulmonary lymphoma imaging findings of parenchymal disease in both primary (rare entity) and more frequently occurring secondary pulmonary lymphoma are variable and non-specific. They include single or multiple nodules, masses or consolidations, cavitation and air bronchogram. Ancillary findings include lymphadenopathy, bronchial wall thickening, interlobular septal thickening and pleural effusion. CT is the workhorse of imaging in bronchogenic carcinoma, metastasis and lymphoma, and plays together with PET/CT a crucial role in staging bronchogenic carcinoma and lymphoma. Due to the variety in CT imaging appearances, tissue confirmation is usually warranted to confirm the diagnosis.
Learning Objectives:
1. To describe the typical imaging appearance of bronchogenic carcinoma.
2. To describe the typical imaging features of pulmonary metastases.
3. To describe the manifestations and the role of imaging in pulmonary lymphoma.

Benign liver tumours: daily questions

A-066 10:30

Chairman's introduction

S.M. Ertürk; *Istanbul/TR (smerturk@gmail.com)*

The session will focus on the imaging features of the cystic and solid liver lesions. The new classification system of the hepatic adenomas will be discussed in detail. Sample cases of haemangiomas and FNHs will be another focus of the session since these lesions are very frequently encountered in imaging studies of the liver. Imaging strategies to increase accuracy regarding the detection and characterisation of focal hepatic lesions will be summarised.
Author Disclosure:
S.M. Ertürk: Speaker; General Electric, Siemens, Bayer, Guerbet.

A-067 10:35

A. Cystic lesions: always biliary cysts?

O. Benjaminov; *Petach Tikva/IL (obenjaminov@gmail.com)*

Liver cysts are increasingly found on abdominal imaging studies. They cause a diagnostic challenge. There are no current management guidelines that help in their management. In most cases they are asymptomatic and follow a benign course. However, it is essential to differentiate between benign and malignant liver cysts. The majority are of a biliary origin. Others are non-biliary and include hydatid and other infectious cystic lesions, cystic neuroendocrine lesions and cystic metastases. Other lesions which contain a fluid attenuation component may mimic liver cysts such as necrotic changes within lesions following chemotherapeutic treatment. Clinical history, laboratory findings and previous imaging may help in reaching an accurate diagnosis. An important step in narrowing the differential diagnosis is in determining the presence of complex structures within the lesions.
Learning Objectives:
1. To be able to list the different conditions that may present as cystic liver masses.
2. To understand the diagnostic multimodality strategy.
3. To become familiar with assessment challenges.

A-068 11:03

B. Solid benign lesions: how to solve the conundrum?

F. Caseiro-Alves; *Coimbra/PT (caseiroalves@gmail.com)*

Benign hepatocellular neoplasms are being recognized with increased frequency using cross-sectional imaging. One of the main goals is to be able to make a clear-cut differential diagnosis between focal nodular hyperplasia (FNH) and hepatocellular adenoma (HCA) since patient management is substantially different. Despite the sound knowledge acquired in the last few years about the morphological features of FNH using various cross-sectional imaging techniques, new players in the field have arisen such as diffusion-weighted MR imaging (DWI) and use of hepatobiliary contrast agents. These new biomarkers offer a different view over FNH and allow a more accurate characterization even in more atypical cases. Concerning HCA, current knowledge implies that the sub-types of this neoplasm should be known since, again, patient management differs and these patients are no longer seen as compulsory surgical candidates. These sub-types will be further discussed and the role of imaging for risk stratification (haemorrhage and malignant transformation) will be addressed. Further, illustrative cases of combined FNH/HCA cases will be demonstrated along with the main imaging clues for a successful differential diagnosis.
Learning Objectives:
1. To become familiar with the recent classification of liver cell adenoma and its justification.
2. To learn about the typical and atypical appearance of focal nodular hyperplasia.
3. To understand the treatment strategy and the modalities of follow-up when appropriate.

A-069 11:31

C. From images to strategy: tough cases of benign liver tumours

M. Nadrljanski; *Belgrade/RS (dr.m.nadrljanski@gmail.com)*

Benign liver tumours are often diagnosed incidentally. The most common lesions include haemangioma, focal nodular hyperplasia (FNH) and hepatocellular adenoma (HCA). Liver nodule(s), often detected on the initial abdominal ultrasound (US), are characterized by contrast-enhanced imaging studies: contrast-enhanced US (CEUS), computed tomography (CT) and magnetic resonance imaging (MRI). Clinical context determines the association with the development of liver disease. Lesions with atypical features ("tough cases") require additional attention. The most common atypical findings in haemangioma - rapidly filling and giant haemangiomas - may be diagnosed on MRI. In case of the slow-filling and calcified lesions - sclerosing haemangiomas - the diagnostic imaging is less reliable. In case of the growing lesions, the lesion management is made according to multidisciplinary team (MDT). The diagnosis of FNH is based on the combined radiological features, not considered as lesion specific. Atypical forms (FNH without a central scar, FNH with significant steatosis) require particular attention, as the sensitivity of MRI is lower, especially in the absence of the central scar. The use of the specific hepatobiliary contrast agents may contribute to the increase of MRI sensitivity. HCA, not considered the unique entity, reflects the subtype radiological features. The presence of fat and telangiectatic features requires the appropriate imaging technique(s) - MRI for fat and dilated vascular spaces visualization. MRI lesion subtyping is important, as MRI is considered superior to other modalities. In case of atypical benign lesions, MDT will decide on the patient management, including the indication for biopsy/resection.

Learning Objectives:

1. To be able to define a diagnostic strategy when facing an unknown case of solid liver lesion, likely to be benign.
2. To become familiar with the unusual appearance of common lesions like focal nodular hyperplasia or haemangioma.

Imaging findings in Zika virus infection

M. Vasco Aragao; *Recife/BR (fatima.vascoaragao@gmail.com)*

Zika virus (ZIKV) was discovered in 1947 in monkeys (Zika forest) and human infection was identified in 1952. The first epidemic happened in 2007, at Micronesia and Yap Islands and the second in 2013, at French Polynesia. In Brazil (March 2015) begun the third epidemic and, surprisingly, in the second half of 2015, a microcephaly epidemic was identified. The relationship between the two epidemics is established. The diagnosis is based on clinical and radiological findings, associated with laboratory exclusion of other congenital infections or hereditary conditions. The imaging abnormalities are subcortical calcifications and malformations of cortical development (frontal predominance), ventriculomegaly, decreased brain volume, enlarged cisterna magna, corpus callosum abnormalities and delayed myelination. In patients with arthrogryposis, the abnormalities are reduced spinal cord thickness and anterior nerve roots. Immunologic tests specific for the ZIKV are in development and not available for clinical routine. Thus, the role of radiologists is extremely important in recognizing the radiological pattern of presumed cases of the congenital Zika syndrome, mainly in mild cases, when the disease is not suspected by the paediatrician. There is a possibility that we have been seeing just the most severe extreme of the disease spectrum. Guillain-Barre syndrome, myelitis and encephalitis have been found in adults. Prevention remains the only way to control the disease. The disease has already spread across the world. Up to October 19th, 2016, 73 countries had reported ZIKV transmission, while 23 countries had reported ZIKV-related microcephaly (WHO). In Brazil, there are 2,033 confirmed cases of microcephaly.

Learning Objective:

1. To describe the neuroimaging findings of the Zika virus (ZIKV) syndrome, the new emerging epidemic that is writing a new chapter in the history of medicine.

12:30 - 13:30 **Room C**

E³ 25A

Useful signs in chest radiology

Moderator:
N. Howarth; Chêne-Bougeries/CH

A-071 12:30

A. Lung parenchyma

G.R. Ferretti; *Grenoble/FR (GFerretti@chu-grenoble.fr)*

CXR remains the keystone for the diagnosis of pulmonary diseases, as it is performed in the vast majority of patients complaining of chest symptoms, because is it largely available, simple to realize, low cost and delivers low radiation dose. However, indications of CXR for imaging the lung parenchyma are challenged by ultra-low-dose HRCT. In this presentation, we will focus on useful signs to detect lung parenchymal abnormalities such as airspace opacities, air bronchogram, silhouette sign, atelectasis and interstitial pattern. Pulmonary distribution of abnormalities such as butterfly-wing distribution, anti-butterfly-wing distribution and migratory consolidations may increase the value of CXR. Difficulties in the interpretation and limitations of CXR will be discussed along with correlations with HRCT results.

Learning Objectives:

1. To review the most useful signs on the chest x-ray.
2. To learn how to interpret the chest x-ray more accurately.
3. To know the appropriate indications of the chest x-ray.

A-072 13:00

B. Mediastinum and chest wall

N. Howarth; *Chêne-Bougeries/CH (nigel.howarth@grangettes.ch)*

The presentation will explain useful signs in chest radiology using side-by-side plain film and CT imaging to help understand the imaging features of common pathologies of the mediastinum and chest wall. Although the clinical value of the chest x-ray remains undiminished, errors of interpretation of the chest x-ray remain one of the most frequent causes of malpractice issues. The skills required for accurate interpretation of imaging of the mediastinum and chest wall will be explored. The objective is to help you improve your performance in plain film interpretation and CT imaging of the chest.

Learning Objectives:

1. To review the most useful signs on the chest x-ray.
2. To learn how to interpret the chest x-ray more accurately.
3. To know the appropriate indications of the chest x-ray.

12:30 - 13:30 **Room D**

E³ - The Beauty of Basic Knowledge: A Survival Guide to Musculoskeletal Imaging

E³ 24A

Degenerative disorders

Moderator:
V.N. Cassar-Pullicino; Oswestry/UK

A-073 12:30

Degenerative disorders

A. Cotten; *Lille/FR (anne.cotten@chru-lille.fr)*

Osteoarthritis is the most common joint disease worldwide. It is a major source of pain, disability, and socioeconomic cost. The epidemiology of the disorder is complex and multifactorial, with genetic, biological and biomechanical components. Conventional x-ray is the standard diagnostic method to confirm the clinical diagnosis, to evaluate the degree of severity of osteoarthritis and to look for predisposing conditions. CT can be performed for the assessment of bone stock, anatomic conditions and bone deformation. MRI can be used to confirm early forms and to clarify possible damage and/or wear and tear, which cannot be seen on x-rays. Finally, intraarticular administration of contrast will be performed in selected cases, when a precise assessment of the cartilage or fibrocartilage is required. This lecture will focus on: the role of imaging in clinical practice, the typical and atypical imaging features of OA, the radiological features which should not be read as OA, the main predisposing factors that have to be known and searched.

Learning Objectives:
1. To appreciate the musculoskeletal imaging manifestations of degenerative disorders.
2. To understand the underlying pathomechanisms involved in these imaging abnormalities.
3. To appreciate the strengths and weaknesses of imaging modalities in assessing these disorders.

14:00 - 15:30 **Room F1**

E³ - Rising Stars Programme: Basic Session

BS 3
Gastrointestinal diseases

Moderator:
N. Papanikolaou; Lisbon/PT

A-074 14:00
Oesophagus
F.-T. Fork; *Malmö/SE (thomas.fork@med.lu.se)*

Double-contrast barium fluoroscopy is today almost substituted for endoscopy, because the oesophageal mucosa is better evaluated and locally treated by therapeutic endoscopy. Single-contrast studies are used for diagnosing swallowing disorders, sometimes in combination with oesophageal manometry, for food impaction, stent function and achalasia. Computed tomography of thorax and abdomen is done for staging malignant diseases. Combined with FDG-PET the number of metastases increases. Magnetic resonance imaging of thorax with diffusion techniques may improve detectability of metastatic deposits. Local tumour spread, TNM-stage 1 to 4, is imaged by endoscopic ultrasound. The majority of benign oesophageal lesions emanate from the mucosal lining, i.e. adenoma, all kinds of inflammatory conditions, be it gastric reflux, overgrowth in immunosuppressive patients, or noxious contact lesions. As with varices these superficial lesions are diagnosed and biopsied and, when appropriate treated endoscopically. However, diverticular disease is best evaluated radiographically. Small neoplastic lesions are vague in symptoms and incidentally found on routine examination for other reasons and seldom diagnosed by radiological means. Local wall thickening and dislocation are suspicious signs, whereas local lymph nodes grown in size and number are ominous. Oesophageal cancer is endemic in Asia and with us seen in individuals with an overconsumption of tobacco and alcohol. Due to anatomy of the lymphatic system with lymph vessels reaching into the mucous membrane, early tumour spread is mostly encountered. Radiology plays an important role in detecting peripheral disease prior to a MDT-meeting but also after surgical resection to document any post-operative complication or recurrent tumour.
Learning Objectives:
1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe the imaging features in most common benign pathologies.
3. To review and illustrate the imaging features of malignant pathologies.

A-075 14:22
Stomach
M. Laniado; *Dresden/DE (michael.laniado@uniklinikum-dresden.de)*

Today, the stomach is well accessible for endoscopic evaluation. Therefore, double-contrast barium studies of the stomach have almost completely disappeared from the armamentarium of imaging studies in radiology. However, abdominal computed tomography (CT) - not so much magnetic resonance imaging (MRI) - has become the number one procedure in many scenarios if ultrasonography fails to provide a conclusive diagnosis. As the stomach is always imaged when abdominal CT is performed knowledge of normal anatomy, incidental findings, and the most often benign and malignant gastric pathologies is mandatory. Depending on the clinical request, imaging techniques are slightly different. If the main focus is on a lesion of the stomach, maximum wall distention should be achieved by oral administration of up to 2 L of water shortly before the study and i.v. administration of a hypotonic agent. In addition, i.v. administration of iodinated contrast material is mandatory. The presentation will cover normal anatomy of the stomach including vascular supply/drainage and loco-regional lymph nodes. Examples of common and uncommon gastric lesions (e.g. carcinoma, lymphoma, GIST, NET, metastases, ulcer, portal gastropathy, pneumatosis, ischaemia) will be shown and discussed. Also examples of postoperative anatomy and potential complications will be part of the presentation.
Learning Objectives:
1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe the imaging features in most common benign pathologies.
3. To review and illustrate the imaging features of malignant pathologies.

A-076 14:45
Small bowel
N. Papanikolaou; *Lisbon/PT (npapan@npapan.com)*

Magnetic resonance imaging (MRI) provides excellent soft tissue contrast without radiation exposure and three-dimensional imaging capabilities, which are important when studying the small intestine. Various sequences and contrast agents have been proposed for MRI examination of the small bowel. The development of high-performance gradient systems improved the performance of ultra-fast sequences and allowed comfortable breath-hold acquisition times. For a more detailed evaluation of small bowel diseases, MRI examination should be performed in conjunction with duodenal intubation and administration of a suitable contrast agent, i.e. iso-osmotic water solution (PEG) for homogeneous lumen opacification and adequate distention. A comprehensive MR enteroclysis imaging protocol should comprise single shot turbo spin echo (SSTSE), diffusion weighted imaging, true FISP, HASTE and fat suppressed T1 FLASH sequences. SSTSE is utilized for monitoring the infusion process and performing MR fluoroscopy while true FISP and HASTE, classified as sequential ultrafast techniques insensitive to motion, are mainly used for anatomic demonstration and detection of the pathology. T1 FLASH sequences after intravenous gadolinium injection may aid tissue characterization. For the assessment of Crohn's disease activity other alternative techniques may be used including perfusion and calculation of the magnetization transfer ratio of the bowel wall. These techniques may be useful for differentiating oedematous or inflammatory bowel thickening from fibrotic thickening but a more extensive evaluation is required to determine the clinical utility of these methods.
Learning Objectives:
1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe the imaging features in most common benign pathologies.
3. To review and illustrate the imaging features of malignant pathologies.

A-077 15:07
Colon
R.G.H. Beets-Tan; *Amsterdam/NL*

CT, US and colonoscopy are the main diagnostic tools for detection of benign and malignant diseases involving the colon. Bowel ischaemia, infectious enterocolitis, diverticulitis and appendicitis are causes of the acute abdomen that often needs prompt diagnosis. This lecture will deal with the typical features on imaging that will lead to the correct diagnosis. CT is part of the staging work up of patients with colonic cancer. It does not only provide information on distant disease but also on the local status. The latter information will help surgeons in choosing the right surgical approach. In this lecture attendees will learn about the current role for CT and potential new role for MRI in the management of colon cancer.
Learning Objectives:
1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe the imaging features in most common benign pathologies.
3. To review and illustrate the imaging features of malignant pathologies.

14:00 - 15:30 **Room M 1**

Professional Challenges Session

PC 3
Excellence and innovation in undergraduate teaching of radiology

A-078 14:00
Chairman's introduction: Innovative approaches to undergraduate teaching, impact on student learning
V. Válek; *Brno/CZ (vlvalek@med.muni.cz)*

Over the past several decades, the practice of radiology has undergone substantial change primarily related to advances in imaging technology, changes in the infrastructure of healthcare delivery, and evolution of reimbursement systems. Rapid technological innovation in radiology has led to continual advances in importance of radiology in clinical praxis. This trend is, however, unfortunately without significant implications for radiology teaching and the educational system has not substantially changed. Radiology training programs around the world face a challenging task in both teaching a common knowledge base across all the imaging modalities and in imparting deep knowledge within each imaging domain. Today medical school teaching of radiology includes anatomy, imaging, interventions and new technology. Cross-sectional and virtual anatomy is extremely important. Clinical procedures performed without such a relevant anatomical knowledge could result in serious harm to patients. Important part of the training programs are

radiological e-learning activities. E-learning has been used recently in dental and general medicine curricula to support traditional learning methods. Effectiveness of e-learning in radiology education when compared with traditional classroom learning methods is very good and the students had positive attitude when using e-learning. Second example is incorporation of ultrasound education into medical school curricula. Even if the ultrasound imaging is incorporated into the curricula of most of medical schools, actual hands-on training is less widespread. It is time for the changes. 80 hours, which is a common duration of medical school teaching of radiology, is insufficient. Radiology must be incorporated into clinical teaching programmes.

Session Objectives:

1. To learn about innovation of didactic and learning strategies in radiology.
2. To evaluate the impact of technology for developing and transforming undergraduates teaching.
3. To analyse student organisation experiences.

A-079 14:05

How to keep students engaged

C. Nyhsen; *Sunderland/UK (nyhsenc@doctors.org.uk)*

When teaching medical students, PowerPoint presentations are often chosen as the preferred lecture format as they can be reliably shown year after year. Although presented material may be of excellent quality, published surveys have shown that students prefer interactive sessions, in particular when real-case scenarios are discussed with close relation to daily medical practice. The objective of this talk is to inspire attendees to try implementing different teaching methods, thus breaking down teaching sessions into smaller elements, engaging students to a higher degree (thereby hopefully improving learning outcomes and retention of information) as well as making it more enjoyable for teachers. The focus will be on "low tech" teaching methods which do not require sophisticated software or hardware facilities. Possibilities of how to integrate quizzes and assessments in a positive way will also be included.

Learning Objectives:

1. To learn about tips and tricks to connect with students.
2. To analyse the learning outcomes of students and specify what they expect as a result of a learning activity.
3. To define the methods to achieve excellence in undergraduate training and usefulness of teaching evidence-based radiology.

A-080 14:23

Excellence in undergraduate teaching

B. Ertl-Wagner; *Munich/DE (Birgit.Ertl-Wagner@med.uni-muenchen.de)*

To attract the best and the brightest medical students into a carrier in radiology, it is important that they become acquainted with the principles of radiology early on in their medical studies, preferentially already during preclinical studies. Cross-sectional and radiographic anatomy, radiation biology, radiation protection and imaging physics can already form an integral part of preclinical training and can be integrated into other teaching modules, e.g. in anatomy. During the clinical part of undergraduate medical education, radiology is a crucial part in almost all clinical aspects - the diagnostic workup and/or image-guided therapeutic principles are highly pertinent for almost all disease entities. In addition, radiology is an integral and important part of many oral and/or written examinations throughout undergraduate medical education. To ascertain that radiology is well represented during undergraduate medical education, it is very important that radiologists become and remain involved in curricular planning. The U-level curriculum of the ESR provides a basis for undergraduate curricular planning. In addition, mentoring programmes can be an important part in undergraduate medical education.

Learning Objectives:

1. To learn about the usefulness of curricula.
2. To discuss how to introduce to the students during the undergraduates teaching programmes radiology as an attractive specialisation.
3. To analyse the importance of mentoring undergraduates.

A-081 14:41

Teaching with technology: a challenging experience

P. Pokieser; *Vienna/AT (peter.pokieser@meduniwien.ac.at)*

Direct communication with the students remains the basis of medical education. The big difference to the past before information technology is the great advantage that the students' self-directed learning process is supported by online information and their new ability to navigate within the free available resources and the journals and other contents, by university access. For radiology training, for example, they can even use eurorad, epos or radiopaedia and other valuable data bases. This paradigmatic change does not mean more or less, that the modern student has most interest to hear, what is not accessible online. First, direct contact and interaction with experienced doctors (teachers, tutors), best near the daily work is and will stay as the most appreciated contribution we can give to our students. Second, doctors' experience, ideally combined with own original case studies; nowadays more and more interdisciplinary (e.g. board cases) represents a good starting point of training. Other new challenges in education are the international new undergraduate curricula, with focus on problem orientation, interdisciplinary perspectives of clinical decisions and dedication to organ systems more than clinical disciplines. Sessions in undergraduate's education are enriched by new tools to allow the students to interact with teachers, communication platforms and webinar applications open the space to include online live and remote blended learning.

Learning Objectives:

1. To emphasise on how to communicate with the students.
2. To evaluate new challenges in education, informatics tools available to encourage education.
3. To analyse the advantages of interactive sessions in undergraduate's education.

A-082 14:59

Evidence-based radiology for diagnostic imaging: do we need to teach the undergraduates?

R. Iezzi; *Rome/IT (roberto.iezzi.md@gmail.com)*

Evidence-based practice (EBP) has been defined as the 'interpretation of the best research evidence with clinical expertise and the patient's unique values and circumstances'. EBP teaching to future healthcare professionals has mainly been documented in medical students. Many different educational interventions of varying duration, frequency, and forma to teach EBP in a variety of settings exist. It showed that educational strategies adopted were found to improve students' overall EBP competence and their EBP knowledge and skills. Students felt more confident to accurately interpret the literature, could better assess the reliability/validity of information on the web and felt more comfortable with the concepts of EBP. It indicated that EBP is a learnable skill and the question is not whether EBP can or should be taught, but how to best teach. The use of technology to promote EBP through mobile devices, simulation, and the web is on the rise and web-based educational platforms have been demonstrated as an effective and desirable mechanism to deliver educational content to health professionals.

Learning Objectives:

1. To analyse the key concepts of teaching evidence-based radiology.
2. To learn about new approaches in teaching and learning radiology.
3. To discuss the importance of teaching evidence-based radiology among students.

15:17

Panel discussion: How do new approaches contribute to excellence in undergraduate teaching?

E³ 318

Chronic liver disease: guidelines for the radiologist

A-083 14:00

Chairman's introduction

B.J. Op de Beeck; *Antwerp/BE (bart.op.de.beeck@uza.be)*

Chronic liver disease is a substantial worldwide problem. Its major consequence is increasing deposition of fat, iron and fibrous tissue within the liver, leading to the development of cirrhosis with its consequences, portal hypertension, hepatic insufficiency and HCC. During this session, the question "how accurate are we in measuring fat and iron with MRI" will be answered. The goal is to become familiar with the different acquisition techniques, to understand the correspondence between MRI evaluation and histological scores and to learn about the limitations of the method. A second problem will be discussed concerning the question "can we reliably identify and quantify liver fibrosis and cirrhosis". It is important to understand the basic principles of fibrosis evaluation with US and MRI, how these methods could be implemented in daily practice, and how to make a radiological report. Fibrosis is independently associated with the viscoelastic parameters and is less associated with the diffusion parameters than is steatosis. There is a need for non-invasive detection and follow-up of these chronic liver diseases. Elastographic techniques are rapidly becoming the method of choice for the assessment of liver fibrosis, replacing liver biopsy for diagnosis, evaluation of disease progression and treatment monitoring. Finally, the problem of a small liver nodule in a patient with chronic liver disease will be discussed with the focus on characterisation and the international guidelines presenting diagnostic

and follow-up strategy. Not only HCC presents as a hypervascular nodule, but also FNH, FNH-like lesions, adenoma, capillary haemangioma and nodular regenerative hyperplasia.

A-084 14:05

A. Measuring fat and iron with MRI: how accurate?

M.M. França; *Porto/PT (mariamanuela.franca@gmail.com)*

Liver steatosis is the hallmark of non-alcoholic fatty liver disease (NAFLD) but is also commonly found in different diffuse liver diseases. Iron overload is found not only in genetic haemochromatosis, transfusional haemosiderosis and iron loading anaemias, but also in chronic liver diseases. Because liver biopsy has several limitations, magnetic resonance (MR) imaging biomarkers have been developed for fat and iron quantification. Liver fat quantification can be accurately performed by MR spectroscopy or using multi-echo chemical shift encoded (MECSE) MR sequences. For precise quantification of proton density fat fraction (PDFF), MECSE MR sequences must be corrected for T1 bias, T2* decay effect, noise and fat spectral complexity. Nowadays, PDFF is being considered as the best imaging biomarker of liver steatosis. Quantification of liver iron using MR imaging can be performed with signal intensity ratio (SIR) methods as well as R2 and R2* relaxometry techniques. As MR imaging does not depict iron itself, but the effect of iron in nearby protons, all these different MR methods require calibration against liver biopsies, to generate empirical calibration curves. Both R2 and R2* values are increasingly being used for quantification of liver iron concentration, either for diagnosis or treatment monitoring, but they must be performed with validated acquisition and analysis protocols. MECSE-MR sequences have the advantage of simultaneously quantifying steatosis and siderosis and are promising as fast non-invasive biomarkers of liver fat and iron, also providing spatial coverage of all liver parenchyma.

Learning Objectives:

1. To become familiar with the different acquisition techniques allowing measurement of fat and iron with MRI.
2. To understand the correspondence between MRI evaluation and histological scores.
3. To learn about the limitations of the method.

A-085 14:33

B. Can we reliably identify/quantify liver fibrosis and cirrhosis

V. Vilgrain; *Clichy/FR (valerie.vilgrain@aphp.fr)*

Diagnosis of cirrhosis on imaging is not difficult as there are striking features, the most common being surface nodularity and morphologic changes of the liver (atrophy of segment 4 and hypertrophy of the caudate lobe). Diagnosis and staging of fibrosis was done on pathologic examination of the liver for years but quantitative imaging has changed the paradigm. First, diffusion-weighted MR has enabled to assess liver fibrosis as the ADC decreases with increasing fibrosis stage. More recently, imaging-based elastography (using ultrasound or MR imaging) has shown high diagnostic performance to stage fibrosis. The principle of these two methods is to measure the speed of shear waves propagating in the organ. The shear-wave speed is related to tissue stiffness and, therefore, to the fibrosis. The first technique that has been extensively validated is the fibroscan (transient elastography). More recently ultrasound-based techniques such as ARFI and shear-wave elastography have shown comparable or even better performance over fibroscan. They are nowadays performed in clinical practice. Some limitations are patient overweight and increased intercostal thickness. There are confounding factors that should be known. MR-based elastography is a very accurate technique that has been recently validated in multicentric studies. Its advantages is the 3D assessment of the liver and the ability to go deeper in tissue characteristics (elasticity and viscosity). MR elastography is performed in many centres nowadays but still more in research than for daily use. Both approaches compare favourably with liver biopsy and are particularly helpful for monitoring patients.

Learning Objectives:

1. To understand the basic principles of fibrosis evaluation (US and MRI), how these methods could be implemented in daily practice, and how to make a radiological report.
2. To learn about the correlation between imaging tools and other methods and to understand the clinical strategy.
3. To become familiar with the necessity for non-invasive detection and follow-up of chronic liver disease.

A-086 15:01

C. The small liver nodule and chronic liver disease

G. Brancatelli; *Palermo/IT (gbranca@yahoo.com)*

The enrolment of patients with chronic liver disease into surveillance programs has determined a steady increase in the number of small hepatic masses being detected. In addition, technological advances have improved the spatial, contrast and temporal resolution of imaging modalities allowing for higher rates of detection. However, detection and characterization of a lesion in a cirrhotic liver is oftentimes a challenging task, due to the intrinsic features of a fibrotic/cirrhotic organ and to a different epidemiology in comparison to the noncirrhotic population. While most lesions in a cirrhotic liver are hepatocellular, a wide array of other observations can be encountered, such as haemangioma, nodule-like arterial phase hyperenhancement, focal fibrosis, cholangiocarcinoma and metastases. Moreover, small HCC frequently present with atypical findings, such as lack of enhancement, lack of washout or no capsule. Furthermore, HCC <1cm grows very slowly; therefore, stability (i.e. lack of growth) over a few months does not entirely rule out malignancy, and a negative biopsy is not helpful due to the high false-negative sampling rate. In these instances, two possible options are 1) further imaging with a different technique or 2) imaging follow-up.

Learning Objectives:

1. To become familiar with the problem of characterisation of liver nodule on cirrhosis/fibrosis.
2. To understand the imaging strategy.
3. To learn about the international guidelines presenting diagnostic and follow-up strategy.

The spleen: the forgotten organ

A-087 16:00

Chairman's introduction

L.H. Ros Mendoza; *Zaragoza/ES (lhrosmendoza@gmail.com)*

The spleen has been considered as the forgotten organ of the abdominal cavity; nevertheless, a wide range of diseases can affect the spleen. The finding of an incidental splenic mass is frequently encountered at imaging studies that are performed on patients for other reasons. Pathologic conditions of the spleen can be classified into the following categories: congenital: accessory spleen, polysplenia and asplenia, true cyst; inflammatory: pyogenic abscess, fungal abscess, hydatid cyst, sarcoidosis; vascular: infarction, peliosis: haematologic: sickle cell disease, extramedullary haematopoiesis; posttraumatic: haematoma, false cyst; neoplastic: benign tumours: haemangioma, hamartoma, lymphangioma; malignant tumours: lymphoma, metastases, angiosarcoma. Other disease processes affect the spleen diffusely: Gaucher disease, portal hypertension and sickle cell disease. The findings in the different imaging techniques (ultrasound, computed tomography and magnetic resonance imaging) of these splenic lesions are reviewed, considering three different scenarios: the incidental lesion, acute and chronic diseases, and malignant tumours, emphasizing the key differences that in many cases can help narrow the differential diagnosis. An imaging algorithm is proposed to ease the diagnostic workup in cases of incidental splenic lesions. In some cases, these radiologic findings could have substantial overlap, which precludes the rendering of a specific diagnosis on the basis of imaging findings alone; in these instances, correlation of radiologic features with clinical and histological findings is needed to confirm the diagnosis.

A-088 16:05

A. Acute and chronic splenic disease

G. Zamboni; *Verona/IT (gzamboni@hotmail.com)*

The spleen can harbour different types of acute and chronic non-malignant disease. The radiologist should be aware of these entities, to recognize them on imaging performed with the specific purpose of evaluating the spleen, or to characterize them when incidentally discovered. Congenital abnormalities range from very common entities, like accessory spleens, to rare conditions like polysplenia and asplenia syndromes. Focal non-malignant diseases include cystic lesions, the different types of haemangioma, sclerosing angiomatous nodular transformation (SANT), hamartoma and abscess, among others. Diffuse non-malignant diseases include granulomatous diseases, such as sarcoidosis, and parenchymal infiltrative diseases such as siderosis. In addition, the spleen can undergo vascular diseases, with resulting infarction, and rupture, both traumatic and spontaneous. Aim of this talk will be to describe the imaging features of the most common diseases, with emphasis on the imaging findings that, coupled with clinical information, can allow a diagnosis.

Learning Objectives:
1. To describe the most common causes of acute and chronic splenic disease, excluding malignant lesions.
2. To define imaging protocols, including functional and metabolic techniques, to apply for the detection and characterisation.

A-089 16:28

B. The incidental splenic lesion

M. Laniado; *Dresden/DE (michael.laniado@uniklinikum-dresden.de)*

Incidental findings are defined as lesions detected by CT, MRI, or another imaging modality performed for an unrelated reason. The overall reported incidence is around 30% for CT, and 25% if the initial diagnosis involved the genitourinary and gastrointestinal tract. About 20% of incidental findings are located in the abdomen. The frequency of either clinical follow-up or clinical confirmation accounts for approximately 65% and 45%, respectively. Compared to other abdominal viscera, incidental findings in the spleen have not been evaluated in great detail. Few available data in the literature report a low incidence of less than 2% for splenic granulomas, haemangiomas, cysts, abscesses, etc. Unfortunately, both incidentally detected and other splenic lesions often show overlapping imaging features. Therefore, differentiation of benign lesions from indeterminate or malignant lesion may be a challenge. On the other hand, most isolated splenic lesions are benign and without clinical relevance. To further characterise incidentalomas of the spleen, clinical correlation (e.g. pain, fever, immunocompromised state, neoplasm, trauma) and other imaging findings (e.g. liver lesions, lymphadenopathy) are often the key to diagnosis. It is essential for the radiologist to know how to deal with splenic incidentalomas, namely what should be written in the report and when additional studies have to be recommended. This issue will also be addressed in the presentation.

Learning Objectives:
1. To describe the most common causes of splenic incidentaloma and their imaging appearance.
2. To define imaging protocols, including functional and metabolic techniques, for the differential diagnosis.
3. To propose an algorithm for the management of incidental splenic lesions.

A-090 16:51

C. Malignant lesions

S. Gourtsoyianni; *London/UK (sgty76@gmail.com)*

Malignant splenic lesions are quite rare; however, incidentally picked up splenic lesions on cross-sectional imaging performed in patients with suspected or known malignancy certainly pose a diagnostic challenge. Most common malignant lesion of the spleen is lymphoma, primary or secondary. In Hodgkin disease, splenic involvement results in up-staging while in non-Hodgkin lymphoma if spleen is the predominant site of involvement therapeutic approach might change, thus degree of splenic involvement influences treatment and prognosis. Imaging appearances of malignant splenic lesions, including besides lymphoma, angiosarcoma, leiomyosarcoma and metastases can overlap and imaging alone is not adequate for accurate characterization in all cases. Percutaneous image-guided biopsy of the spleen using 18-gauge needles or smaller has reported a high diagnostic accuracy and a complication rate similar to that reported for liver and kidney rendering it a better alternative to splenectomy.

Learning Objectives:
1. To describe the clinical presentation and imaging findings for focal and diffuse neoplastic malignant lesions.
2. To discuss the indication of splenic lesion biopsy and its diagnostic contribution.

17:14

Panel discussion: How to manage incidental findings in clinical routine practice

16:00 - 17:30 **Room C**

Chest

RC 404

Pulmonary embolism: persistent controversies

A-091 16:00

Chairman's introduction

M. Rémy-Jardin; *Lille/FR (martine.remy@chru-lille.fr)*

The utility of CT angiography is not questioned as a first-line diagnostic test for pulmonary embolism. However, technological advances and incidental findings on chest CT examinations have raised practical questions regarding the most efficient use of CT in this clinical context. The purpose of this session is to cover some of these issues, emphasizing the diagnostic and prognostic role of CT.

Session Objectives:
1. To review the current controversies regarding PE diagnosis.
2. To appreciate the need for defining a standardised management.

Author Disclosure:
M. Rémy-Jardin: Research/Grant Support; Siemens Healthcare.

A-092 16:05

A. Subsegmental PE, incidental PE: diagnosis and management

C.M. Schaefer-Prokop; *Amersfoort/NL*

Attention to subsegmental PE (SSPE) has increased with the ability of CT pulmonary angiography (CTPA) to show such small emboli. The advent of multi-detector computed tomographic pulmonary angiography (CTPA) allows increased visualization of the peripheral pulmonary arteries. More cases of peripheral PEs, such as isolated subsegmental PE (SSPE) and incidental PE, have thereby been identified. The prevalence of SSPE in patients with suspected PE varies between 0.4% and 18% according to the literature. It is likely that this variability is caused by patient characteristics, reading methodology but last not least by scanner technology used. A systematic review mentions a prevalence of SSPE of 4.7% in a group examined with a single slice scanner, and of 9.4% in a patient group examined with a multi-slice CT scanner. In the PIOPED II trial the positive predictive value (PPV) of CTPA when compared to a composite reference was 98% for central but only 25% for SSPE pointing towards the lower diagnostic accuracy and reader confidence in diagnosing SSPE. Clinical relevance and management of patients with symptomatic SSPE is still controversial. A Cochrane meta-analyses of 2014 and 2015 summarized that there is no randomized controlled trial evidence for the effectiveness and safety of anticoagulation therapy versus no intervention in patients with isolated subsegmental pulmonary embolism (SSPE) or incidental SSPE. More and more publications occur describing outcome of untreated patients with SSPE that have no associated DVT. Recent recommendations from the European Society of Cardiology suggest an individualized approach for the management of patients with newly diagnosed SSPE based on the risk/benefit ratio of anticoagulation and the presence of lower limb DVT. Results of a still ongoing prospective trial (NCT 01455818) are expected to provide more evidence in that respect.

Learning Objectives:
1. To learn about the characteristics of subsegmental and incidental PE.
2. To appreciate an appropriate management in both situations.

A-093 16:28

B. CT not available, contraindicated or inconclusive: what to do?

E.J.R. van Beek; *Edinburgh/UK (edwin-vanbeek@ed.ac.uk)*

The utility of CT pulmonary angiography (CTPA) as a first-line diagnostic test for imaging of pulmonary embolism (PE) is one of the great developments for this commonly encountered disease. It has enabled a fast triage service, allowing safe exclusion and early discharge for patients with symptoms, thus avoiding unnecessary treatment and complications. In approximately 5% of cases, CTPA is inconclusive. In most of these patients, repeat CTPA is an accepted method to detect or rule out PE. In some hospitals, CTPA may not be available around the clock, and in these situations the aim would be to positively diagnose the presence of venous thromboembolic disease using ultrasound or rule out the disease using perfusion scintigraphy. Finally, there are situations where radiation dose is of concern, e.g. in young female patients or during pregnancy. Although the risk-benefit for diagnosis of PE is beyond doubt, alternative approaches such as ultrasound for the detection of DVT or MR angiography for detection or exclusion of PE may be considered. This lecture will describe some potential approaches using a combination of

ultrasonography, perfusion scintigraphy and MR angiography as an alternative to CTPA.

Learning Objectives:

1. To review the role of US and V/Q scan.
2. To learn about the current performance of MR.

Author Disclosure:

E.J.R. van Beek: CEO; QCTIS Ltd. Founder; QCTIS Ltd. Research/Grant Support; Siemens Healthineers.

A-094 16:51

C. Can we predict outcome from imaging?

B. Ghaye; *Brussels/BE (benoit.ghaye@uclouvain.be)*

The mortality risk of unselected patients with proven pulmonary embolism (PE) is around 10%, although it may be superior to 50% in some selected patient categories. Recent international guidelines have refined the stratification of early mortality risk in patient with PE as this may influence the therapeutic strategies and the duration of hospitalization. Clinical findings as cardiogenic shock or persistent arterial hypotension remain the most powerful predictors and identify patients at high risk of mortality. Absence of such findings requires further risk stratification. Clinical prognostic scores, such as the PESI, cardiac biomarkers dosage and signs of right ventricle (RV) dysfunction on an imaging test (echocardiography or CT pulmonary angiography) are used to discriminate patients with intermediate or low risk. Therefore, it is recommended to indicate the ratio between the diameters of RV and left ventricle (RV/LV) on each report of CT pulmonary angiography. Meta-analyses have confirmed RV/LV diameter ratio as measured on CT to be significantly associated with increased risk of mortality. However, taken individually, RV/LV diameter ratio is limited by a 95% NPV and a 5-30% PPV for predicting mortality. RV/LV diameter ratio should be, therefore, combined with other factors, including biomarkers and clinical findings to increase the prognostic value. This lecture will also discuss more recent and potentially more powerful predictor CT findings, including among others RV/LV surface and volume ratios, atrial measurements, severity of "perfusion" defect and cardiac function parameters as calculated from ECG-gated acquisition.

Learning Objectives:

1. To learn how clinical findings influence the selection of the imaging strategy.
2. To learn how imaging may predict the outcome of the patient.
3. To learn about the follow-up.

17:14

Panel discussion: How to optimise patient management?

16:00 - 17:30 **Room Z**

ESR Working Group on Ultrasound

WG 2
Image fusion

A-095 16:00

Chairmen's introduction: Basic principles of image fusion (part 1)

M. Bachmann Nielsen; *Copenhagen/DK (mbn@dadlnet.dk)*

This technique is optional and only available in high-end US machines. It requires a positioning device connected to the US apparatus and corresponding images in DICOM format (CT, MRI, PET/CT). Theoretically also US-US fusion can be performed. Several techniques can be used to align the image data, and not all will be available from all manufacturers. There is probably no distinct advantage of any of these except time consumption. Co-registration should be repeated when scanning at a distance from the primary co-registration area. Using the technique requires good patient cooperation. Training of the doctor is also required to become familiar with the technique and pitfalls. Image fusion will extend the examination time 10-15 minutes and, therefore, used in selected patient cases. When US is used as the modality for patient follow-up the fusion will facilitate comparison with the measurements on the primary imaging modality. Image fusion may also be of help in patients with poor image quality on US, e.g. obese patients and where the target area is partially covered of air in bowels or abscesses. It is also used as assistance for US-guided biopsy of lesions seen by CT, MRI or PET/CT, and to identify lesions which stand out in PET-imaging. However, since the US examination is the only live procedure, care must be taken not to rely fully on the projected needle path on previous recorded datasets. The session will give examples on how the image fusion can be used in the kidney, liver and prostate.

Session Objectives:

1. To become familiar with the technical requirements for performing image fusion.
2. To learn about the technologies used to fuse CT-US, MR-US and PET-MR/CT -US-images.
3. To understand the different option of image registration (point to point, plane, auto registration).
4. To understand how to use them in clinical practice and difficult cases.

A-096 16:07

Chairmen's introduction: Basic principles of image fusion (part 2)

L.E. Derchi; *Genoa/IT (derchi@unige.it)*

Image fusion techniques have gained an important role in clinical practice. Their value is mainly during interventional procedures, to guide more accurately therapeutic manoeuvres; there are, however, also diagnostic situations in which added value is provided by simultaneous co-registered display of US images with those from other techniques. Different technologies can be used to fuse CT-US, MR-US and PET-MR/CT-US images and it is important to understand the main advantages of each of them, the problems that may be encountered and the need for a learning curve to provide good results. This session will demonstrate situations in which image fusion can provide clinical advantage in the use of US in renal, hepatic and prostatic applications.

Session Objectives:

1. To become familiar with the technical requirements for performing image fusion.
2. To learn about the technologies used to fuse CT-US, MR-US and PET-MR/CT -US-images.
3. To understand the different option of image registration (point to point, plane, auto registration).
4. To understand how to use them in clinical practice and difficult cases.

A-097 16:15

Image fusion of the kidney (part 1)

M. Claudon; *Vandoeuvre-les-Nancy/FR (m.claudon@chu-nancy.fr)*

Image fusion of kidney is now more currently used to facilitate the realization of second-row ultrasound (US) examination in complex cases, when contrast-enhanced ultrasound (CEUS), guided biopsy or interventional procedure is required. Fusion is usually obtained using CT series of images, generally after contrast injection, but T2-weighted sequences or post-Gd T1-weighted series are more commonly considered. Fusion can be made using various fusion protocols, which require some training phase. Examples of various pathological cases of complex cystic lesions, tumours, vascular pathologies will be presented to illustrate the interest of the technique.

Learning Objectives:

1. To understand the imaging features of kidney lesions.
2. To become familiar with unclear cystic lesions by using the Bosniak classification.
3. To learn about the differential diagnoses of complex cystic renal masses and compare the modalities by using the image fusion tool.
4. To understand the potential pitfalls in image fusion.

Author Disclosure:

M. Claudon: Speaker; Philips Ultrasound.

A-098 16:25

Image fusion of the kidney (part 2)

D.A. Clevert; *Munich/DE (Dirk.Clevert@med.uni-muenchen.de)*

Ultrasound is a widely accepted imaging technique for the diagnosis and monitoring of cystic renal lesions. The widely used Bosniak classification (I-IV) categorises renal cystic lesions in five distinctive groups by the help of ultrasound and CT image criteria. In unclear cases, contrast-enhanced ultrasound (CEUS) and MRI/CT ultrasound image fusion are able to detect and characterise difficult pathologies. In contrast to multi-slice CT (MS-CT), ultrasound image fusion is a real-time imaging technique that can be used in combination with other cross-sectional imaging techniques. This talk explains the latest possibilities of image fusion with CEUS and MS-CT to detect and characterise unclear renal pathologies.

Learning Objectives:

1. To understand the imaging features of kidney lesions.
2. To become familiar with unclear cystic lesions by using the Bosniak classification.
3. To learn about the differential diagnoses of complex cystic renal masses and compare the modalities by using the image fusion tool.
4. To understand the potential pitfalls in image fusion.

Author Disclosure:

D.A. Clevert: Advisory Board; Samsung, Siemens, Philips, Bracco. Speaker; Samsung, Siemens, Philips, Bracco.

A-099 16:35

Image fusion of the liver

G.H. Mostbeck; *Vienna/AT (gerhard.mostbeck@wienkav.at)*

US image fusion may be defined as overlaying US (real-time US, colour Doppler and CEUS) images with CT, MRT or PET-CT data. Spatial co-registration is needed to make sure that US volume data and CT/MRT/PET-CT data represent the same volume, which is of major importance in the liver. This is obtained by defining standard registration points, either by external fiducials or by defining specific anatomic structures in the specific patient. All US image fusion systems available work based on an electromagnetic tracking system, where sensors and transmitters on the US scan head inform the system about the orientation and position of the current imaging plane. In liver imaging, fusion might be useful in various clinical situations. First, in diagnostic imaging, overlying US with CT/MRT/PET data may be useful to get information on focal lesions not seen by real-time US and/or CEUS. Specifically, small or superficial or lesions deep in the liver might be able to be detected and classified regarding their aetiologies. Second, in patients with contraindications to CT or MR contrast media (especially in renal insufficiency) fusion between CEUS and CT/MRT might gain vascular information and allow lesions classification. Third, in US-guided diagnostic and therapeutic interventions (biopsy and ablation) various studies have demonstrated advantages for fusion-guided procedures regarding lesion conspicuity, needle path safety and ablation evaluation with US and CT/MRT/PET and US/US (pre- and post-intervention) fusion. Needle tracking is another option to improve outcome in diagnostic and therapeutic procedures.

Learning Objectives:

1. To learn about the advanced liver imaging fusion technique.
2. To learn how to optimise scanning protocols by using the image fusion tool.
3. To learn about common benign and malignant lesions and differential diagnosis by using image fusion.
4. To understand how to use fusion imaging of US, CT and MRI for treatment of liver tumour.

A-100 16:55

Image fusion of the prostate

D.A. Clevert; *Munich/DE (Dirk.Clevert@med.uni-muenchen.de)*

Transrectal prostate biopsy is currently performed one million times annually in the USA to diagnose or exclude prostate cancer under ultrasound-guided technique. However, many of the currently performed prostate biopsies yield misleading information. Multiparametric MRI of the prostate is capable of detecting clinically relevant prostate cancer. Image fusion is the process of combining relevant information from MRI and real-time ultrasound into a single image, which provides more information than the separate image. Targeted biopsy through MRI-ultrasound fusion offers a way to localise and sample suspected cancers with precision.

Learning Objectives:

1. To explain the PIRADS system in prostate imaging.
2. To become familiar with the technical requirements for performing image fusion of the prostate.
3. To understand how to detect and biopsy guided suspicious MR-lesions using the ultrasound image fusion technique.
4. To understand the potential pitfalls and discuss the evidence for the use of these technologies in routine clinical practice.

Author Disclosure:

D.A. Clevert: Advisory Board; Siemens, Philips, Samsung. Speaker; Siemens, Philips, Samsung.

Paediatric

RC 412

Chest imaging in paediatrics

Moderator:
B. Ahuja; Agra/IN

A-101 16:00

A. Congenital anomalies of the chest

M. Haliloglu; *Ankara/TR (mithath@hacettepe.edu.tr)*

Advances in both foetal ultrasonography (US) and magnetic resonance (MR) imaging resulted in increased recognition of congenital anomalies of the chest prenatally. Despite the role of US and/or MR imaging in the prenatal diagnosis of congenital lung malformations, chest radiography and computed tomography still have an important role for postnatal diagnosis. Congenital lung anomalies have a broad spectrum ranging from small and asymptomatic to large and symptomatic lesions. They may involve lung parenchyma, bronchi, arterial supply and venous drainage. Currently there is no organizational structure or system of nomenclature to define all lung abnormalities. Congenital lung anomalies can be divided into three categories including isolated bronchopulmonary anomalies, combined lung and vascular abnormalities and vascular anomalies. Congenital thoracic wall anomalies involve sternum, clavicle, rib and scapula anomalies. Malformations of the chest wall can be a manifestation of a syndrome or skeletal dysplasia. The management of congenital lung and thoracic wall anomalies depends on the type of malformation and symptoms. Radiologists should perform individualized proper imaging techniques and should be familiar with characteristic imaging findings in paediatric patients for appropriate patient management.

Learning Objectives:

1. To discuss best imaging techniques when evaluating congenital chest anomalies.
2. To have an overview of antenatal and postnatal appearances of common congenital chest anomalies.
3. To understand the clinical significance and management of congenital lung and thoracic wall anomalies.

A-102 16:30

B. Lung infection and its complications

M.L. Lobo; *Lisbon/PT (mluisalobo@gmail.com)*

Lung infection is one of the most common causes of illness in children, and a leading cause of mortality in developing as well as in developed countries. Chest radiography is the imaging cornerstone in the diagnosis of pneumonia. While most previously healthy children with community acquired pneumonia treated as an outpatient will not clearly benefit from chest radiography, imaging plays an important role in the approach of paediatric patients with more severe lung infection, atypical presentation, complicated clinical course as well as in those with recurrent infections or infection in the immunocompromised children. Radiological findings are usually nonspecific, but in the appropriate clinical setting (including patient's age, immune status, seasonal epidemiology and clinical presentation) some radiological patterns may allow to narrow the differential diagnosis, thus helping to guide treatment. Furthermore, imaging is crucial in the assessment of complicated pneumonia and development of potential late complications. Ultrasound is an invaluable imaging modality in the evaluation of pleural effusion/empyema and peripheral lung consolidations, with chest computed tomography reserved for centrally located complicated pneumonia, bronchopleural fistula and bronchiectasis, as well as unusual infections, infection in the immunocompromised children and suspicion of underlying pulmonary or systemic conditions (e.g. foreign body, congenital malformation, immunodeficiency). Although not routinely used in many places, lung MRI should be considered as a potential alternative to CT for diagnosing at least some complications of infection, particularly in patients with chronic lung diseases (e.g. cystic fibrosis), thus contributing for reduction of radiation exposure from CT.

Learning Objectives:

1. To understand the justification for imaging children with lower respiratory tract infection.
2. To provide tips for accurate diagnosis and to understand differential diagnosis.
3. To become familiar with complications and potential underlying conditions.

A-103 17:00

C. Imaging interstitial lung disease in children: update 2017

E. Alexopoulou[1], A. Pastroma[1], G. Papaioannou[1], M. Raissaki[2]; *[1]Athens/GR, [2]Iraklion/GR (ealex64@hotmail.com)*

Paediatric interstitial lung diseases (ILDs) include a range of diseases, which involve the pulmonary interstitium, causing defective gas exchange. The current classification of paediatric ILDs is based on aetiology, clinical characteristics, genetics, child's lung growth and histology. Some of the diseases are common, or even unique in infants or younger children. The clinical presentation varies from mild, subclinical respiratory symptoms, which may disorientate the initial diagnosis, to severe respiratory failure. Correct diagnosis of ILDs is crucial for early treatment and better prognosis, when possible. Imaging and especially CT scan plays a significant role in this, as for some types of ILDs CT findings are quite specific, while in others laboratory tests or lung biopsy may be needed for definitive diagnosis. CT scan can also suggest a short list of the most likely diagnosis, and guide further investigation including lung biopsy. Child's age is an essential tool to approach the diagnosis as some ILDs have a predisposition in infancy-early childhood (developmental, growth, or genetic disorders). Disorders related to systemic diseases, infections, or environmental exposures are commoner in older children. Additionally, CT scan is helpful for monitoring disease activity and assessing response to therapy. The use of low-dose techniques is mandatory in paediatric population, to minimize patient's radiation exposure. High-resolution computed tomography (HRCT) is a valuable technique to gain information on the pattern and anatomical distribution of lung diseases.

Learning Objectives:

1. To understand optimised protocols.
2. To learn about updated nomenclature of interstitial lung diseases in children.
3. To discuss a systematic approach for the diagnosis of common entities diffusely affecting the paediatric lung.

16:00 - 17:30 **Room N**

Head and Neck

RC 408

Pathways for tumour spread

Moderator:
J. Huyskens; Antwerp/BE

A-104 16:00

A. Pathways for oral cavity and oropharynx tumour spread

A. Borges; *Lisbon/PT*

90% of oral cavity and oropharyngeal malignancies originate from the epithelial lining and spread superficially along the mucosa, deeply into the submucosa, adjacent muscles and bone and along neighbouring cranial nerves used as elevator shafts for tumour spread. There are 8 tumour subsites in the oral cavity each with different patterns of spread and implications on patient's management. Those with direct impact on tumour staging or surgical management are the midline raphe, extrinsic tongue muscles, bone and oropharyngeal spread. Tumours of the retromolar trigone have a complex pattern of spread as they sit on the crossroad between the oral cavity, masticator space and oropharynx. Whereas gingival tumours of the superior alveolar ridge can invade the maxilla and spread along the superior alveolar nerves and V2, tumours of the inferior alveolar ridge can invade the mandible, the inferior alveolar nerve and spread along V3. Invasion of the neurovascular tongue bundle prone tumours to spread along the lingual or hypoglossal nerves. There are 4 different oropharyngeal subsites. The palatine tonsil has the highest association with lymph node metastases. Local spread is through the palatoglossus muscle and transgression of the constrictor muscles and pterygomandibular raphe leads to tumour extent into the retromolar trigone and pterygoid plates. Tongue base tumours can spread anteriorly to the tongue root and floor of the mouth and posteriorly into the supraglottic larynx. Palatal tumours spread inferiorly into the palatine fossa, laterally into the parapharyngeal space and are prone to perineural spread along the greater and lesser palatine nerves.

Learning Objectives:

1. To become familiar with the anatomy of the oral cavity and oropharynx.
2. To learn which imaging technique to use.
3. To understand the typical local and remote spread of oral cavity and oropharynx tumours.

A-105 16:30

B. Pathways for nasopharyngeal tumour spread including perineural spread

V. Chong; *Singapore/SG (vincent_chong@nuhs.edu.sg)*

Most nasopharyngeal carcinomas (NPC) originate in the fossa of Rosenmuller and spread along well-defined routes. Tumours often spread into the nasal and pterygopalatine fossa. From the nasal cavity tumours can infiltrate the pterygopalatine fossa which may lead to perineural infiltration of the maxillary nerve and further extend into the intracranial cavity. Tumours may infiltrate further into the orbital apex and enter the intracranial cavity through the superior orbital fissure. Lateral spread involves the parapharyngeal and masticator spaces. When tumour enters these spaces, there is a risk of perineural infiltration along the mandibular nerve. Perineural spread along the mandibular nerve is a frequent route of intracranial extension. When NPC spreads superiorly, it erodes the skull base with subsequent direct extension into the intracranial cavity. Lesions may also be seen to spread through the foramen lacerum. Cervical nodal metastasis is very common and up to 80% of patients have enlarged nodes at presentation. Nodal metastasis show an orderly inferior spread and the affected nodes are larger in the upper neck. Spread to the supraclavicular nodes has grave prognostic significance. Up to 50% of patients with supraclavicular lymphadenopathy will eventually have distant metastases. NPC shows a high frequency of distant metastasis compared with other tumours of the head and neck. The frequency of distant spread varies between 5% and 41%. Common sites of distant metastases include bone (20%), lung (13%) and liver (9%).

Learning Objectives:

1. To become familiar with the anatomy of the nasopharynx.
2. To learn which imaging technique to use.
3. To understand the typical local and remote spread of nasopharyngeal tumours, including perineural spread.

A-106 17:00

C. Pathway for laryngeal and hypopharyngeal tumour spread

N. Chidambaranathan; *Chennai/IN (drchidam55@gmail.com)*

Supraglottic tumours constitute 30% of laryngeal tumours. Epiglottic tumours primarily invade the pre-epiglottic space (PES), base of tongue and the paraglottic space (PGS) laterally. Tumours from petiole of epiglottis invade the low PES and extend to the glottis/subglottis through the anterior commissure. Tumours originating from the false vocal cord, laryngeal ventricle or aryepiglottic fold primarily infiltrate the PGS. Tumours arising from arytenoids and inter-arytenoid regions tend to infiltrate post-cricoid region of hypopharynx. Lymphatic spread (levels II,III&IV nodes) is common. Glottic tumours (~65%) arise from the anterior half of the true vocal cords and spread anteriorly to the anterior commissure, contralateral cord and thyroid cartilage via Broyle's ligament, or posteriorly into the posterior commissure, arytenoids, cricoarytenoid joint and cricoid cartilage. The tumour can extend superiorly to the PES and PGS or inferiorly to the subglottis. Lymphatic spread is uncommon. Subglottic tumours (~5%) are usually inferior extensions of glottic or supraglottic tumours. Primary subglottic tumours spread to the trachea, thyroid gland and cervical oesophagus. Lymphnode metastases involve pre/para-tracheal nodes. Hypopharynx consists of pyriform sinus, posterior hypopharyngeal wall and post-cricoid region. Pyriform sinus tumours spread to thyroid cartilage laterally, endolarynx medially, post-cricoid region infero-medially, posterior pharyngeal wall posteriorly and base of tongue superiorly. Growths in the posterior pharyngeal wall invade the pre-vertebral fascia, whereas post-cricoid growths spread inferiorly to the cervical oesophagus and antero-laterally to thyroid. CT is the preferred imaging modality for evaluating laryngeal carcinoma, while MRI is useful as a problem-solving adjunct, especially early cartilage involvement.

Learning Objectives:

1. To become familiar with the anatomy of the larynx and hypopharynx.
2. To learn which imaging technique to use.
3. To understand the typical local and remote spread of laryngeal and hypopharyngeal tumours.

16:00 - 17:30 **Room L 8**

Joint Session of the ESR and UEMS

ESR and UEMS: a strong professional partnership

A-107/A-108 16:00

Chairmen's introduction

L. Bonomo; *Rome/IT (lorenzo.bonomo@unicatt.it)*
P. Ricci; *Rome/IT (paolo.ricci@uniroma1.it)*

The UEMS - European Union of Medical Specialists is the oldest European medical organisation representing the interests of more than 50 different medical specialities and involving more than 1.6 million of healthcare professionals. The ESR - European Society of Radiology is the world's biggest radiological society, encompassing 67.500 members from 155 different countries. It was founded in 2005 by merging the European Congress of Radiology and the European Association of Radiology, aiming at establishing a single, powerful and unified voice for European radiologists. Through the section of radiology, UEMS and ESR share the same ambitious objective of promoting the highest quality of care and medical practice in radiology, by serving the needs of patients and general public, harmonizing radiological training and defending free movement and professional interests of European radiologists. This Joint Session will focus in particular on the function of the UEMS section of radiology within EU institutions and legislation, with specific regard to the harmonisation of radiological training, to the definition of clear boundaries towards other specialities and to the competence-based format of European Training Curricula. It will further investigate the value of European Diploma in Radiology, the impact of professional qualifications directive on radiologists and the importance of joint effort for EU lobbying and interest representation. Finally, particular attention will be dedicated to the working methodologies of EACCME (European Accreditation Council for Continuing Medical Education) and ACI (Accreditation Council in Imaging) in the framework of CME - Continuing Medical Education and CPD - Continuing Professional Development programmes.

Session Objectives:

1. To describe the role of the UEMS within the EU.
2. To understand the difference between ESR and UEMS.
3. To understand the importance of cooperation between ESR and UEMS.

Author Disclosure:

P. Ricci: Board Member; UEMS SECTION of RADIOLOGY - PRESIDENT.

A-109 16:05

Structure of the UEMS and position of the UEMS within the EU

B. Maillet; *Brussels/BE (bernie.mail@skynet.be)*

The harmonisation of post graduate training in Europe: a challenge for the medical profession. The diploma in medicine is automatically recognised in the European Union but for the specialities things are different, the European directive on recognition of Professional qualification has an Annex V where the specialities are listed that can be enjoying automatic recognition if the speciality is mentioned as recognised in the home as well as the host country. This is only the case for 19 specialities that are recognised in all the EU Member States while for other specialities it varies from country to country. Until now, the only criterion that is taken into account is the length of training while it would be also good to include competences, and that is the reason why the UEMS is working on the European Training Requirements (ETR) for all the specialities that are mentioned in Annex V. The UEMS is also working for more than ten years now to increase the harmonisation of training by developing European exams in those specialities and this through the Council for European Specialist Medical Assessment (CESMA). Of course being licensed to practice is not the endpoint of the learning process and afterwards, the physician should demonstrate that he or she is working on keeping up to date his or her knowledge, skills and attitudes and here the UEMS has created the European Accreditation Council for Continuous Medical Education (EACCME) to harmonise the process of CME-CPD accreditation also at European level.

Learning Objectives:

1. To understand the structure of the UEMS and the position of the UEMS radiology section within the UEMS.
2. To understand the UEMS political involvement in EU affairs.
3. To understand the influence of EU directives on national legislation and daily practice.

A-110 16:25

Harmonising radiology training in Europe (part I)

P. Ricci; *Rome/IT (paolo.ricci@uniroma1.it)*

Free exchange of persons and services within the European medical sector has been achieved by mutual recognition of basic and specialist medical qualifications brought into effect by the Commission of the European Communities in 1975. The directives have been consolidated in the Directive 93/16/EEC of 5 April 1993, establishing a European training charter for medical specialists. The charter describes the requirements for adequate training, which prepares specialists for practice of their speciality at an appropriate level in any EU member state. The same charter divides the requirements regarding content of training into a general part, defined by the European Union of Medical Specialists (UEMS), and a specific part for each recognized speciality, defined by the UEMS Specialized Sections (Chapter 6). For the speciality of radiology, the charter states radiology involves all aspects of medical imaging which provide information about the anatomy, pathology and function of normal and disease states and interventional techniques for diagnosis and minimally invasive therapy involving image-guided systems. The Council for European Specialist Medical Assessment (CESMA) is an advisory body of the UEMS created in 2007 with an aim to provide recommendation and advice on the organisation of European examinations and improve the quality of European postgraduate training examinations. Its main tasks include: to promote harmonisation of European board assessments, to provide guidelines to the boards on the conduct of assessments, to encourage take up of board assessments as a quality mark, and to offer an alternative to national assessments, where appropriate.

Learning Objectives:

1. To become familiar with Chapter 6 and the current competence-based European Training Curricula.
2. To learn about the Council for European Specialist Medical Assessment (CESMA).

Author Disclosure:

P. Ricci: Board Member; UEMS SECTION of RADIOLOGY - PRESIDENT.

A-111 16:35

Harmonising radiology training in Europe (part II)

L. Oleaga Zufiría; *Barcelona/ES (lauraoleaga@gmail.com)*

The European Training Curriculum (ETC) represents a guide to standardize education and harmonize skills and competencies among radiologists in Europe. The ETC outlines a five-year training period to acquire the knowledge to practice radiology, consisting of Level I training over the first three years, followed by Level II training, with potential special interest rotations during the last two years. Level III corresponds to full subspeciality training with consecutive subspecialization after this five-year training period. It is important to satisfy the needs and integrity of the radiology profession, to avoid fragmentation and take over by other specialities. Endorsement of the curriculum by the UEMS Council is critical to provide support to the defense of the profession and as a guaranty of training, to assure quality and safety in radiology practice. The European Diploma in Radiology (EDIR) is available to radiologists and radiology residents in their fifth year of training. To certify knowledge and competency in line with the ESR ETC for radiology, it represents a valuable additional qualification and a recognised certificate to standardize and facilitate the accreditation of radiologists across the EU borders.

Learning Objectives:

1. To learn about the different levels of curricula within radiology on a European level.
2. To understand the importance of endorsement of the curriculum by the UEMS Council (i.e. the importance to secure and defend the practice of radiology against hostile take-over by other specialties).
3. To know about the value of the European Diploma in Radiology (EDiR).

A-112 16:45

Recognition of qualifications (part I)

Z. Fras; *Ljubljana/SI*

"No abstract submitted."

Learning Objective:

1. To know about the EU Directive on Professional Qualifications Recognition.

A-113 16:55

Recognition of qualifications (part II)

E.J. Adam; *London/UK (drjaneadam@gmail.com)*

The ESR is actively engaged in EU affairs related to radiology, with an office in Brussels. Only by direct engagement can the profession's voice be heard. The EU Directive on Professional Qualifications aims to facilitate the free movement of some professionals, including doctors within the EU. The ESR has been active in consultations on this subject and, alongside the UEMS, broadly supports the aims of the directive. However, it has emphasised that quality should not be compromised, and that language issues and differences in radiological training across the EU should be acknowledged. Fortunately the European training curriculum developed by the ESR is a potential means of addressing the latter together with the EDiR examination. Both are supported by the UEMS, as tools to promote uniform standards. Collaboration between the ESR and UEMS has been very successful in the past, and this is another area where a unified approach and shared goals may prove fruitful.

Learning Objectives:

1. To know how ESR is involved in the political lobby at the EU using the EU Directive on Professional Qualifications Recognition as an example.
2. To understand the importance of cooperation between ESR and UEMS using the EU Directive on Electromagnetic fields as an example.

A-114 17:05

Continuing professional development (CPD) (part I)

M. Adriaensen; *Heerlen/NL (miraude@gmail.com)*

Continuing Professional Development (CPD) has been defined as the educative means of updating, developing and enhancing how doctors apply the knowledge, skills and attitudes required in their daily practice. In January 2000, the European Accreditation Council for Continuing Medical Education (EACCME®) was established by the European Union of Medical Specialists (UEMS) with the aim of encouraging high standards in the development, delivery and harmonisation of Continuing Medical Education (CME) by the establishment of an independent, dual, peer-reviewed system for the accreditation of international CME events and international recognition of CME credit points, i.e. European CME credits (ECMEC®s). The EACCME® also provides for accreditation of e-learning materials. The EACCME® is solely financed by the application fees paid by CPD-providers. Independent accreditation, based on cooperation of all medical specialities, is important to foster professional autonomy and self-regulation, and deliver high-quality CME with the ultimate goal to assure high-quality patient care.

Learning Objectives:

1. To learn about the European Accreditation Council for Continuing Medical Education (EACCME®).
2. To understand why an international independent, dual reviewing process is important.
3. To know about the existence of European CME Credit (ECMEC®).

A-115 17:15

Continuing professional development (CPD) (part II)

D. Negru; *Iasi/RO (draneg@gmail.com)*

In January 2016, the ACI was officially launched. It was established under the umbrella of the European Board of Radiology (EBR) to cooperate and collaborate with the accreditation council of the UEMS, the European Accreditation Council for Continuing Medical Education (EACCME). The structure of the ACI, whose committees are composed of active experts in radiology, members of the EBR and the UEMS Radiology Section, allows to maximise the synergies between both organisations. Continuing Professional Development (CPD) is considered a cornerstone of quality assurance in medical care and recognition by the EACCME® is a contributing factor as well as a necessary step towards European harmonisation of educational standards in radiology.

Learning Objectives:

1. To learn about the set-up and structure of the Accreditation Council in Imaging (ACI).
2. To understand the importance of cooperation with and recognition by the EACCME®.

17:25
Questions

16:00 - 17:30 **Room E1**

Breast

RC 402
Screening for breast cancer

A-116 16:00

Chairman's introduction

E.A. Morris; *New York, NY/US*

Breast cancer screening as currently practised is not a perfect test, nor is it ever likely to be. Improvements on current digital techniques are available; however, the question whether these techniques move the needle far enough in the direction of detection of biologically relevant invasive cancers with the minimization of call backs and biopsies. Furthermore, there is the question of size of cancer at detection - the average size of cancer detected is still over 1 cm which has not dramatically improved over decades. If we are to make a difference in breast cancer mortality we need a technique that can detect breast cancer when it is very small - likely well under a cm - before it has a chance to become heterogeneous and undergo clonal expansion. Resistance to treatment and development of subclones which may be different from the original tumour contribute to the mortality. There is a need to be able to differentiate those cancers requiring aggressive detection and treatment from those that do not.

Author Disclosure:

E.A. Morris: Advisory Board; Delphinus, Devicor. Board Member; Avon. Consultant; Grail. Research/Grant Support; Hologic.

A-117 16:05

A. Screening with mammography only

R.M. Pijnappel; *Utrecht/NL (r.m.pijnappel@umcutrecht.nl)*

Screening with mammography has proven to save lives. The reduction in mortality is substantial. In the Netherlands, woman who attend all biannual offered screening rounds from 50-75 years reduce their chance of dying from breast cancer before the age of 80 to 50%. The basis for this positive effect from screening with mammography is only training and auditing. The shift from analogue form to digital between 2005 and 2010 has improved these results and showed that more high-risk tumours were detected by mammography. The cost-effectiveness of screening with mammography only is acceptable. The drawbacks of screening with mammography, false positive and overdiagnosis will be discussed. So far no other modality has proven to save lives and no information is available regarding the aggressiveness of other modalities that detected breast cancers. The positive predictive value of ultrasound is substantially lower and quality control (operator dependent) is difficult. For these reasons, screening with mammography only still is the gold standard for population-based screening with an average risk.

Learning Objectives:

1. To learn about benefits and limitations of mammography screening.
2. To become familiar with common findings, recall rates and assessment outcomes.
3. To appreciate errors.

A-118 16:30

B. Screening with mammography and ultrasound

T.H. Helbich; *Vienna/AT (Thomas.Helbich@meduniwien.ac.at)*

The sensitivity and specificity of mammography are limited in highly fibroglandular breasts. Digital mammography provides increased sensitivity in young women and those with moderately dense breasts, and digital three-dimensional mammography (tomosynthesis) promises further improvement. For women with the densest breasts, however, radiography is unlikely to be the optimum solution. MRI, although not affected by breast density, is expensive and access is often limited. Ultrasonography is attractive for breast cancer screening because, likewise, it is not impaired by breast density, and it avoids the use of ionising radiation and the need for breast compression. Nevertheless, enthusiasm for the use of ultrasonography has been limited because its specificity has been much lower than that of mammography, but technical developments have given rise to sharper, more informative images. These improvements foster the use of ultrasound particular in those women with higher breast density. Different trials have been preformed and promising results have been reported. This talk will focus on benefits, harms, and cost-effectiveness of supplemental ultrasonography screening for women with dense breasts.

Learning Objectives:
1. To learn about the added value of US in screening and its indication.
2. To become familiar with the common level of evidence.
3. To appreciate its role in clinical practice.
Author Disclosure:
T.H. Helbich: Grant Recipient; EU Horizon 2020. Research/Grant Support; Siemens, Guerbet, Angiomed, Medicor.

A-119 16:55

C. Screening with tomosynthesis
U. Bick; *Berlin/DE (Ulrich.Bick@charite.de)*

By eliminating ambiguity from superposition of normal breast parenchymal structures, digital breast tomosynthesis (DBT) holds the potential to improve cancer detection rates while at the same time reducing call-backs related to false-positive findings. The magnitude of these two effects will depend on the clinical setting. In European population-based screening programs, where recall rates are kept low, DBT will primarily increase detection rates. On the other hand, in screening practices with high recall rates such as in North America, the main effect of DBT will be to lower recall rates by improving specificity. In screening, the advantages of DBT must be weighed against the potential disadvantages of DBT such as higher costs (higher equipment and image storage costs, longer reading times) and possible increases in radiation exposure, especially if DBT is used as an adjunct to 2D mammography. Synthetic 2D views reconstructed from the DBT dataset can be used to replace 2D mammography in screening; however, the impact of this especially on the detection of microcalcifications is still unclear. Despite the very promising data from the available first DBT screening trials, which all showed a significant increase in detection rates with DBT; further studies are needed before DBT can replace 2D mammography in population-based screening programs. The key question still unanswered up to now is whether the additional cancers found by DBT are in the majority clinically relevant and contribute to a reduction in advanced-stage interval cancers.
Learning Objectives:
1. To learn about the role of tomosynthesis in the screening setting.
2. To become familiar with the different protocols.
3. To appreciate potential advantages of tomosynthesis in screening.
Author Disclosure:
U. Bick: Patent Holder; Patent Royalties, Hologic, Inc. Research/Grant Support; Institutional Research Collaboration until August 2014, Siemens AG, Institutional research collaboration, GE Healthcare.

17:20
Panel discussion: What is the best modality approach to screen for breast cancer?

16:00 - 17:30 **Room E2**

Multidisciplinary Session

MS 4
Neuroimaging and mental health disorders

A-120 16:00

Chairman's introduction
T.A. Yousry; *London/UK (t.yousry@ucl.ac.uk)*

Over the last decade, neuroimaging has been central to research in mental illness elucidating disorders of the underlying rather complex network. However, neuroimaging has not only been relevant to research but also to clinical management of patient. This can be illustrated in two diseases: Obsessive compulsive disorder (OCD) and Tourette syndrome (TS). Neuroimaging was central to the process of identifying anatomic targets for surgical intervention. In this intervention - functional stereotactic neurosurgery - electrodes are placed in these targets, an intervention known as "deep brain stimulation". This intervention in turn is also reliant on imaging. This session will, therefore, clarify the important role of imaging in the understanding and treatment of mental health disorders.
Session Objectives:
1. To understand the concept of mental illness as illustrated by obsessive compulsive disorder (OCD) and Tourette-Syndrome (TS).
2. To show how neuroimaging is furthering our understanding of OCD and TS.
3. To understand the central role of neuroimaging in functional neurosurgery of OCD and TS.
Author Disclosure:
T.A. Yousry: Advisory Board; Biogen Idec; Genzyme, Ixico. Board Member; Neuroradiology. Grant Recipient; Medical Research Council, MS Society of Great Britain and Northern Ireland, Stroke Association, British Heart Foundation. Research/Grant Support; BRC. Speaker; Novartis.

A-121 16:05

Unpicking obsessive compulsive disorder (OCD) networks with neuroimaging
E. Joyce; *London/UK*

Obsessive compulsive disorder (OCD) has a life time prevalence world wide of 1-2% and is the 11th leading cause of non-fatal burden (WHO). OCD is characterised by anxiety provoking thoughts, images and impulses which trigger mental or motor rituals designed to neutralise the anxiety. This leads to temporary relief only and patients become trapped in a vicious circle of disabling thoughts and actions. Effective treatments are available but 10-20% remain resistant. Deep brain stimulation (DBS) has been shown to be effective in 50-60% of such cases who have extremely severe OCD. Understanding the neural basis of OCD is important in order to develop new treatments and better targets for DBS. This talk will review how our understanding of OCD has developed over the past 20 years following advances in neuroimaging. Early PET findings showed that patients with OCD have increased metabolism in fronto-striatal circuitry which is decreased following successful pharmacological treatment. This concept of OCD as a network disorder has been elaborated since then but has also been found to be more complex. For example, tractography studies have shown altered topography and connectivity between the orbitofrontal cortex and striatum; structural MRI has shown reduced volumes of not only prefrontal and cingulate cortex but also hippocampus and increased volumes of pallidum and thalamus. MRI spectroscopy has contributed to our understanding of the neurochemical basis of OCD with abnormalities of GABA and glutamate being implicated. In the light of these neuroimaging findings the psychological understanding of the behavioural characteristics of OCD has been modified which might pave the way for better interventions.
Learning Objectives:
1. To understand the concept of severe mental illness exemplified by OCD.
2. To demonstrate the impact of neuroimaging - structural and functional MRI and PET - to our understanding of OCD as a neural network disorder.
3. To show the central role of neuroimaging in enabling us to pinpoint the critical neural target for successful treatment with deep brain stimulation.
Author Disclosure:
E. Joyce: Speaker; Boston Scientific

A-122 16:25

Bridging movement and mind: neuroimaging in Tourette-Syndrome
T. Foltynie; *London/UK (t.foltynie@ucl.ac.uk)*

In this lecture I will describe the potential of deep brain stimulation as a treatment for severe, medication refractory Tourette syndrome. I will introduce the concept of patient-specific simulations of the DBS electrical field using neuroimaging. I will show how the clinical efficacy of DBS for Tourette syndrome can be related to simulated electrical field on a voxel by voxel basis.
Learning Objectives:
1. To understand the importance on neuroimaging in understanding Tourette-Syndrome as a neural network disorder.
2. To introduce the concept of DBS as a treatment for severe medication refractory Tourette-Syndrome and the role of neuroimaging of the DBS electrical field.
3. To show how the clinical efficacy of DBS for Tourette-Syndrome can be related to simulated electrical field on a voxel by voxel basis.
Author Disclosure:
T. Foltynie: Advisory Board; BIAL. Research/Grant Support; MJ Fox Foundation, European Union, Brain Research Trust, John Black Charitable Foundation.

A-123 16:45

Precision neurosurgical targeting in Tourette's and obsessive compulsive disorder (OCD): critical role of neuroimaging
L. Zrinzo; *London/UK (l.zrinzo@ucl.ac.uk)*

Functional neurosurgery involves precise surgical targeting of anatomic structures to modulate neurologic function. Preoperative stereotactic localization places several demands on image acquisition that go beyond those required for diagnostic imaging. MRI coils must accommodate the relevant stereotactic frame. Target structures are often small placing demands on image resolution. Specific MR sequences that provide high tissue contrast between the target structure and the surrounding tissues must be used while ensuring clinically practical acquisition times. Geometric distortion represents a significant obstacle to accurate spatial representation and can render MR images useless for the purpose of accurate anatomic targeting. Numerous anatomical targets have been proposed in the management of Tourette syndrome (e.g. globus pallidus, centromedian/parafascicular nucleus) and obsessive compulsive disorder (ventral capsule / ventral striatum, anterior cingulate gyrus, anteromedial subthalamic nucleus). A vital step to assessing the efficacy of each anatomical target is confirming the anatomical location of

the intervention, whether after placement of a stereotactic lesion or a deep brain stimulation lead. Many commercially available DBS leads are MR conditional and the gold standard in verification is obtaining a stereotactic MRI as part of the surgical procedure. It is imperative that appropriate safety precautions be followed when obtaining such images. Likewise, it is inappropriate that a radiology department places a blanket ban on MR imaging of DBS patients. MR physicists and neuroradiologists are an essential part of the multidisciplinary team that offers neurosurgical interventions in patients with mental health disorders, including Tourette syndrome and obsessive compulsive disorder.

Learning Objectives:

1. To understand the essential differences between diagnostic and stereotactic MR imaging.
2. To introduce the concept of image-guided and image-verified DBS surgery.
3. To provide an overview of the different anatomical targets used for DBS in Tourette syndrome and OCD surgery and describe their radiological correlates.

Author Disclosure:

L. Zrinzo: Advisory Board; Medtronic, Boston Scientific.

17:05

Multidisciplinary case presentation and discussion

16:00 - 17:30 **Room F1**

E³ - Rising Stars Programme: Basic Session

BS 4

Gynaecology and obstetrics

Moderator:
M. Bekiesinska-Figatowska; Warsaw/PL

A-124 16:00

Benign gynaecological pathologies

R.N. Lucas; *Lisbon/PT (ritalucas1@gmail.com)*

The internal reproductive organs in the female include the vagina, uterus, uterine tubes and ovaries. Ultrasound and MRI are the most useful imaging modalities for female reproductive organs evaluation. Leiomyomas, are the most common benign tumours of the uterus made up of smooth muscle cells fascicles. Histologically, different subtypes are distinguished, of which cellular, myxoid leiomyoma and lipoleiomyoma can have particular MRI features. Benign ovarian masses include functional cysts and benign ovarian tumours. Cystic mature teratomas and cystadenomas comprise the majority being followed by benign stromal tumours fibromas/fibrothecomas and Brenner tumours. Ultrasound is usually the first imaging modality to identify the ovarian lesion and MRI is used for further characterisation.

Learning Objectives:

1. To describe the normal anatomy of the female reproductive organs.
2. To describe the imaging features of uterine leiomyomas.
3. To learn the key features of benign ovarian tumours.

A-125 16:30

Gynaecological malignancies

A.G. Rockall; *London/UK (a.rockall@imperial.ac.uk)*

Gynaecologic malignancies are initially detected either clinically or on ultrasound examination. Cervix cancer, which is increasingly rare in Europe due to screening, is detected clinically and histologically. Staging of disease is usually undertaken with MRI; PET/CT may also be used in cases of advanced disease. Features suitable for fertility-preserving surgery will be illustrated. Endometrial cancer is often first suspected on ultrasound and the diagnosis is confirmed histologically by endometrial sampling. Staging may be performed with CT and/or MRI. The stages of disease will be illustrated. Ovarian cancer is usually first detected on ultrasound. Further staging of disease for treatment planning may include CT and MRI. The typical appearances of ovarian cancer will be demonstrated on the different modalities.

Learning Objectives:

1. To describe the imaging appearance of malignant tumours of myometrium.
2. To review and illustrate the imaging features of cervical cancer.
3. To describe the imaging features of malignant ovarian tumours.

A-126 17:00

Foetal imaging

M. Bekiesinska-Figatowska; *Warsaw/PL (m.figatowska@gmail.com)*

Ultrasonography (US) is a method of choice in foetal imaging. It is obligatory in many European countries at certain points of pregnancy and is also used whenever it is necessary to follow-up suspected pathology. It is usually performed by gynaecologists-obstetricians and not by radiologists. Magnetic resonance imaging (MRI) is the second line method, performed always after US, to confirm, correct or complete the sonographic findings. It is not dependent on foetal or placental position, maternal obesity, oligohydramnios and other factors that limit US. It offers an "all in one" evaluation of complex malformations, is more illustrative for surgeons and parents and is more and more widely used for decision making in the pre- and postnatal period as it provides additional useful information that helps in the management of the foetus and the newborn. MRI can be safely performed after 18-19 weeks of gestation and does not require sedation or other preparation. Single-shot T2-weighted sequence, balanced steady-state gradient echo sequence, T1-weighted images, echo-planar gradient-echo T2*-weighted sequence, susceptibility- and diffusion-weighted sequences are nowadays available in foetal MRI, allowing for detailed analysis and diagnosis of various abnormalities of the foetal brain and body. Each sequence performed serves as a pilot study for the next one, taking into consideration foetal motility. The knowledge of the normal appearance of the foetal organs and its changes with gestational age is obligatory to be able to differentiate normal and abnormal anatomy and to point out and name the pathology.

Learning Objectives:

1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To have a basic knowledge about the role of ultrasonography in foetal imaging.
3. To have a basic knowledge about foetal magnetic resonance imaging.

16:00 - 17:30 **Room F2**

Special Focus Session

SF 4a

Image-guided interventions in oncology: the pieces of the jigsaw

A-127 16:00

Chairman's introduction

J.I. Bilbao; *Pamplona/ES (jibilbao@unav.es)*

Establishing a program that includes continuous assessment of clinical outcomes ensures patient safety and increases the quality of the services. It is thus important to organise an accurate auditing system that will allow the identification and minimisation of risks and the maintenance of a low incidence of complications. Several safety practices can substantially reduce errors and medical complications and provide an optimal standard of care to patients. Imaging in oncology has dramatically evolved with the inclusion of functional information of the underlying process. A better understanding of which tumoural areas still remain active after therapy ensures the obtaining of accurate information that may improve the targeting of percutaneous biopsies or the direct guidance of selective therapies. If interventional radiologists are willing to be a robust pillar in the management of cancer patients they must be part of multidisciplinary teams, acquire skill in clinical responsibilities and obtain solid support, based in evidence, for the procedures they perform. For obtaining such conditions, interventional radiologists must have dedicated programs of training, must improve their social visibility and must conduct research and clinical trials.

Session Objectives:

1. To explain the importance of quality assurance in image-guided interventions in oncology and their effect on treatment outcomes.
2. To describe how developments in functional imaging are affecting clinical practice in oncology.
3. To summarise the current evidence regarding the treatment of cancer patients by interventional radiologists and explain the methods being employed to obtain the relevant data.

Author Disclosure:

J.I. Bilbao: Advisory Board; Boston Scientific, Cook Medical, Bayer. Speaker; Sirtex Medical Europe.

A-128 16:04

How molecular imaging and image fusion are shaping oncology

E. de Kerviler; *Paris/FR (eric.de-kerviler@sls.aphp.fr)*

Molecular and functional imaging has become an integral step in the evaluation of cancer patients. Most primary tumours are now biopsied under image-guidance to determine the best therapeutic strategy. However, the standard image-guided biopsy entails sampling a small portion of a tumour. Tumours are notoriously heterogeneous so that a small amount of tissue may not adequately represent the most aggressive component. Serial biopsies to account for variable expression of molecular targets throughout the tumour (tumour heterogeneity) are typically not practical. To optimize tissue sampling, molecular imaging can provide a more complete insight into living tumours. The ability of PET/CT to demonstrate malignancies, which are not visible on

anatomic images, increases the number of biopsy requests based on foci of tracer uptake. In addition, some neoplasms may demonstrate non-uniform tracer uptake and can be mostly necrotic or contain metabolically active tumour cells in only a small portion of the total mass. Whenever no PET tracers are available, SPECT/CT may be used as well for image guidance. Image fusion with MR can also be used to target biopsies toward areas with restricted diffusion. Lastly, dynamic contrast enhancement studies using MRI, CT or ultrasound nicely demonstrate foci of microvascular anomalies suitable for biopsy.

Learning Objectives:

1. To summarise the main developments in molecular imaging.
2. To highlight the importance of image fusion in the diagnosis and treatment of cancer.
3. To explain how functional imaging is changing oncological practice.

Author Disclosure:

E. de Kerviler: Consultant; Galil Medical.

A-129 16:23

Registries, trials and the evidence base

P.L. Pereira; *Heilbronn/DE (philippe.pereira@slk-kliniken.de)*

Medicine, in some instances more than other fields, undergoes a constant development process, making guidelines and standard operative procedures an important tool for the medical community. This is especially true in oncology, a discipline for which multidisciplinarity and combined therapies are essential for treatment success or better outcomes. Principles of clinical guidelines are based on current scientific knowledge with participants coming from different medical societies and on the consensus of medical experts, sometimes called good clinical practice. Furthermore, high-quality guidelines are necessary not only for a structured knowledge transfer, but they also find their place in the structures of the health system, being more and more a reference for discussions with reimbursement institutes and insurances. At least, evidence-based guidelines serve as a basis for creating and updating of disease management programs and to define quality indicators that will be used for the certification process of comprehensive cancer centres. If one refers to the number of papers, lectures and conferences focused on interventional radiology, we are forced to admit that the interventional oncology is taking a large place in interventional radiology. Over the last 30 years, interventional oncology has not only developed palliative monotherapies but could also obtain curative treatment for selected patients with renal, hepatic or pulmonal cancers.

Learning Objectives:

1. To explain the methods of gathering evidence in practical disciplines.
2. To outline the evidence base for image-guided interventions in oncology.
3. To outline the main current trials and registries in image-guided interventions in oncology.

A-130 16:42

Clinical practice: why it matters and how to do it

A. Adam; *London/UK (andy.adam@kcl.ac.uk)*

Interventional radiologists working in the field of cancer care have an excellent understanding of imaging and a diversity of interventional skills. However, they lack formal training in oncology and have a relatively poor understanding of chemotherapy and radiotherapy. Furthermore, their relative lack of sub-specialisation in interventional oncology is a disadvantage when communicating with other disciplines. It is very important to consider the patient and not the image. Talking to the patient, establishing his/her general state of physical and psychological health and their family and domestic circumstances is very important. In addition, the interventional oncologist should understand the disease and should be familiar with treatment alternatives other than those offered by interventional radiology. Sub-specialisation in interventional oncology is likely to increase and has substantial advantages because it provides a clear path for referrals and makes it easier for interventional oncologists to participate fully at multidisciplinary meetings. Participation at multidisciplinary meetings is very important because interaction with other disciplines improves decision-making and reduces the risk of error. Interventional oncologists should practise as clinicians at every stage in the patient pathway. Delegation of care to other disciplines can lead to inadequate consideration of the indications for and limitations of interventional radiological treatment, is wasteful of resources and is frustrating and unkind to patients. Practising as a clinician makes it easier for the interventional radiologist to prepare the patient appropriately, obtain true informed consent and ensure adequate follow-up.

Learning Objectives:

1. To explain the importance of clinical practice in image-guided interventions in oncology.
2. To describe how interventional radiologists can practice as clinicians rather than technicians.
3. To outline the curriculum being developed for image-guided interventions in oncology.

A-131 17:01

Quality assurance: an essential development

L.M. Kenny; *Brisbane/AU (lizkenny@bigpond.net.au)*

In acknowledgement of the overwhelming importance of standards of practice and their ultimate incorporation into a quality assurance programme, CIRSE has developed a set of practice standards for interventional oncology. The framework is based on the Australian and New Zealand Radiation Oncology Practice Standards and they follow the entire care pathway for patients undergoing interventional cancer procedures. They will support safe quality care for patients and will also act as a basis on which interventional oncologists can work with facilities to improve the infrastructure and processes required for their teams to practise effectively. There are 14 standards, broadly divided into three areas, and each follows a standard format: facility management (7 standards), treatment planning and delivery (3 standards), safety and quality management (4 standards). There is a consistent format for each standard, as follows: i. each standard refers to a corresponding goal or outcome, ii. criteria describe the key processes required to attain that goal, iii. a commentary provides information which outlines how a criterion applies in everyday practice and iv. the required evidence that documents the records that the facility should be able to provide to demonstrate compliance with the standards. These draft standards have been piloted in a number of interventional oncology units during the second half of 2016. Upon completion, CIRSE will incorporate the standards into a quality assurance and credentialing programme.

Learning Objectives:

1. To highlight the importance of quality assurance in image-guided interventions in oncology.
2. To explain how quality assurance affects clinical outcomes in cancer care.
3. To summarise the content and practical implications of the framework developed for quality assurance in image-guided interventions in oncology.

17:20

Panel discussion: What will be the future of image-guided interventions in oncology?

16:00 - 17:30 **Room D**

Bone trauma in the axial skeleton: patterns of injury and how I describe them

Moderator:

A. Barile; L'Aquila/IT

A-132 16:00

A. Thoracic and lumbar spine

V.N. Cassar-Pullicino; *Oswestry/UK (Victor.Pullicino@rjah.nhs.uk)*

Thoracolumbar spinal injuries occur in up to 4% of blunt trauma cases with an incidence of associated neurological deficit in up to 50%. The radiologist is pivotal in the evaluation of these patients. Plain film radiology, CT and MRI all play a role in the evaluation of the injury. They are often complementary as all imaging modalities have inherent strengths and weaknesses. The aim is to expedite prompt and accurate characterisation of the injured segment with the added task of excluding concomitant non-contiguous injury in the rest of the spine. The patterns of injury differ, reflecting underlying unique differences in the anatomy and biomechanics of each region, and this also varies with age and pre-morbid states such as the fused spine. The primary objective is for the radiologist to become familiar with the types of injury to ensure accurate description based on sound image interpretation. Although many classification systems have evolved with time they are primarily descriptors and not predictors of outcome. More recent classification systems include a prognostic theme. Although they are a clinical tool aiding in therapeutic decision making, the radiologist needs to have a basic understanding of the ones that are commonly used. With this in mind, the report should present the imaging data to the clinician.

Learning Objectives:

1. To become familiar with the types of injury seen in the thoracic and lumbar spine.
2. To learn how to describe the injuries in a manner useful to the clinician.

A-133 16:30

B. Pelvis

K. Verstraete; *Ghent/BE*

Bone injury to the pelvis may be caused by high-energy trauma, stress fractures, and avulsion fractures. Pelvic ring fractures are a common consequence of motor vehicle accidents or falls from heights. Major patterns of injury include lateral compression, anteroposterior compression, vertical shear injury, or complex injury due to a combination of these fracture forces. Anteroposterior radiographs are still included in the initial evaluation, but pelvic inlet and outlet views and lateral projection are replaced by CT, which allows multiplanar reformatted imaging for diagnosis, classification and surgical planning. CT angiography is essential to detect active bleeding from cancellous bone, injured vessels or soft tissues. The typical sites of pelvic stress fractures are the sacrum and pubic rami. Fatigue or overuse stress fractures occur in athletes due to repetitive microtrauma. Insufficiency fractures are caused by normal, physiologic stress on weakened bone, usually in elderly women with osteoporosis, corticotherapy or after pelvic irradiation. These stress fractures can be undetectable on radiography in initial stages, and have an aggressive lytic appearance in late stages when patient keeps on moving. CT demonstrates fracture lines or sclerosis, and on MR bone marrow oedema is an early sign of bone stress injury. Apophyseal avulsion fractures occur in young recreational or competitive athletes (sprinters, gymnasts, football, baseball players, etc.), usually teenagers. Radiography is the technique of first choice in acute avulsion injuries. Comparison with the contralateral side is important, and in selected cases, ultrasound, CT, MRI and bone scintigraphy may be needed.

Learning Objectives:

1. To become familiar with the types of injury seen in the pelvis.
2. To learn how to describe the injuries in a manner useful to the clinician.

A-134 17:00

C. Acetabulum

A. Kassarjian; *Majadahonda/ES (akassarjian@gmail.com)*

Acetabular trauma can present a challenge to radiologists given the complex nature of the anatomy of the acetabulum and the various configurations of fractures. The objectives of this lecture on acetabular trauma are: to become familiar with the types of injury seen in the acetabulum and to learn how to describe the injuries in a manner useful to the clinician.

Learning Objectives:

1. To become familiar with the types of injury seen in the acetabulum.
2. To learn how to describe the injuries in a manner useful to the clinician.

Professional Challenges Session

PC 4

Design and implementation of structured reporting

A-135 16:00

Chairman's introduction

W.H. Sommer; *Munich/DE (Wieland.sommer@med.uni-muenchen.de)*

The role of the radiologist will evolve during the next years and decades from the interpretation of imaging data by free-text to providing sets of quantitative and mineable data based on these images. In this context, structured reporting has become one of the most discussed topics. When talking about this topic, one should consider the different forms of structured reporting, ranging from the simple introduction of fixed subsection headers in a free-text report on the one hand to complex decision support algorithm and synoptic reporting on the other hand. The form of structured reporting determines the challenges of integration into the workflow as well as the possible goals which can be obtained by the implementation. The aim of this session is to give an overview on different forms of structured reporting and describe possible achievements of each of these forms, such as quality improvement, educational aspects, improvement of referring physicians' satisfaction and the possibility of data mining. The session presents several ongoing initiatives, such as the ESR/RSNA structured reporting initiative. There will be a special focus on the combination of structured reporting and natural language processing and how this can be implemented into clinical routine for quality management.

Session Objectives:

1. To get an overview on different initiatives for structured reporting.
2. To understand pros and cons of different forms of structured reporting, including template-based reporting, decision support and modular structured reporting.
3. To appreciate the wide range of possibilities for quality management which become possible with structured reporting.
4. To become familiar how different institutions integrate structured reporting in the clinical workflow.

Author Disclosure:

W.H. Sommer: Founder; Smart Reporting GmbH.

A-136 16:10

Beyond templates: modular multilingual structured reporting

M. Fatehi; *Tehran/IR (fatehi@irsr.org)*

Structured reporting is still following the traditional concept of putting the report together through the template library. So, the efforts and applications are based mostly on the template-driven concepts. But in practice, even using the templates the radiologists address a particular part of the text that may be called sub-templates or modules. These modules can be presented in detailed or brief format or even deleted from the final report. The ideal solution is an expandable flexible dynamic template builder where the modules are selected according to the need letting the user to tailor the length and order of the report to the problem of the patient. Currently available template libraries mostly provide templates for normal findings. But the missing component is the structure for description of abnormal findings. But a library of modules is required to let radiologists report their abnormal cases in a similar manner to achieve the best from the data storage and mining in radiological reports. Using structured reporting to store a report technically means to follow a tabular data structure which bears the potential to be codified rather than being stored as a character set. So, the codes may be presented in any pre-defined languages and one of the major advantages of structured reporting is the potential to be language independent. In this presentation, multiple models of structured reporting applications will be shown as examples of modular, language-independent, problem-specific approach.

Learning Objectives:

1. To get familiar with advantages of modular structured reporting to template-based approach.
2. To know challenges in language independent reporting in radiology.
3. To understand importance of availability of modules for structured description of abnormal findings.
4. To learn about already developed modular structured reporting tools and apps.
5. To understand features of a problem specific flexible structured reporting application to tailor the template to clinical condition of the patient.

A-137 16:30

Introducing quality management for radiology reports

C. Wald; *Boston, MA/US (christophwald@me.com)*

Modern radiology reporting quality assurance must ascertain that radiologists understand the hallmarks of a high-quality report and implement proper reporting. A value-added report is the most important and visible work product of our profession, increasingly expected by our patients and referring clinicians. Required specifications may include use of a standard document model, inclusion of required data elements, qualitative and quantitative image descriptors and the use of building blocks of standardized language. Considering the large number of reports routinely issued in a radiology department, systematic, scalable quality control tools are needed to efficiently assess and improve compliance of radiologists. Modern, natural language processing-based methods can check for errors (laterality, gender), check compliance with reporting requirements (Bi-Rads, LungRads, etc.), completeness of reporting, but also help evaluate more elusive concepts such as frequency of self-referral and use of ambiguous language. The lecture presents a novel reporting quality toolbox that can facilitate those assessments while also analysing report generation metrics. Result can be used for change management in the department. In the future, many of these quality assessments can be performed on the fly to allow the radiologist to make immediate adjustments prior to report issuance. Other approaches to increasing the value of reports, such as multimedia reporting and dashboard presentation of report content, are also presented.

Learning Objectives:
1. To learn about available options for basic quality control of radiology reporting.
2. To understand challenges of current prevailing practice for consumers of radiology reports and risk management.
3. To appreciate the importance of performing systematic report quality control and reporting compliance control.
4. To become familiar with tools for Q/C as well as structured data generation and presentation, including multimedia reports and dashboard presentation of report content.

A-138 16:50

Structured reporting: two decades of surveys and subcommittees, but what do we wish to achieve?

J.M.L. Bosmans; *Ghent/BE (janbosmans@telenet.be)*

Since the beginning of this century, a considerable number of surveys have shown that radiologists as well as referring physicians prefer structured reporting (SR) to reporting in free text, at least for complex imaging studies. Comparison of these studies, however, shows a wide variety in the definition of SR. Although the quantitative results of the surveys are very similar, it is possible that they reflect preferences on vastly different forms of reporting, the common factor being that findings should be presented in a predefined, orderly way, in the interest of clarity, coherence and comparability. Several authors have challenged this minimal interpretation. A limited number of studies have also revealed a preference for SR based on an underlying lexicon. Initiatives have been undertaken to create a coherent system of SR templates and a radiology-oriented coded lexicon, the most conspicuous being the ESR/RSNA structured reporting initiative. A new concept in the development of SR is the creation of common data elements (CDE), units of information used in a shared, predefined fashion, that can improve the ability to exchange information among information systems. While in surveys the preference for SR was mainly based on well-chosen, theoretical examples, a few real-life applications of SR have been greeted with enthusiasm by referring clinicians. Many obstacles, however, hinder its acceptance, e.g. the absence of SR-based radiology information systems, the slow introduction of the electronic health record in many countries and, particularly in Europe, the rich variety in languages other than English.

Learning Objectives:
1. To learn about the preferences of radiologists and referring physicians concerning text-oriented vs structured reporting.
2. To understand the definition of structured reporting, and the evolution in thinking about the objectives to attain.
3. To become familiar with initiatives to create a framework for structured reporting, including a SWOP analysis.

Modern imaging of major trauma

Moderators:
P.H. Hogg; Salford/UK
L. van den Hauwe; Antwerp/BE

A-139 16:00

A. Use of MSCT in disaster victim identification

J. Kroll; *Maastricht/NL (j.kroll@mumc.nl)*

Radiology, mainly as a tool for forensic odontology, has long been an essential discipline in the post-mortem identification of human remains. Because forensic radiology is a rapidly developing field due to the fast technical developments of CT scanners, the possible applications are increasing. A whole body CT scan contains a wealth of identification information that can be used in an identification process. This presentation will highlight the contribution of forensic radiology, and more specific a whole body CT scan, for a DVI-process, discussing its applications, equipment, advantages and positioning within a DVI-process. It will also discuss future developments, opportunities and challenges which future DVI-processes will face.

Learning Objectives:
1. To appreciate the role of forensic radiology in a disaster victim identification process.
2. To learn about the methods using forensic radiology in a disaster victim identification process.
3. To discuss added value of forensic radiology in a disaster victim identification process.

A-140 16:25

B. Conventional radiography in major trauma: role, technique modification and impact on interpretation

M. Hardy; *Bradford/UK (M.L.Hardy1@bradford.ac.uk)*

The role of imaging in major trauma is to inform life-saving medical intervention and assist in the prioritization of patient care pathways. The modality of choice to undertake this is CT. However, what happens when cross-sectional imaging is not available due to equipment malfunction, planned service or lack of availability locally? In these situations, image referrals may revert back to conventional radiographic imaging. But with so little opportunity to undertake these examinations in the modern trauma setting, the radiographic skills and decision-making necessary to produce diagnostic images may be limited. This talk revisits the acquisition of chest and pelvis radiographs following major trauma and, through a series of case studies, provides an overview of important diagnostic features and explores the impact that radiographic technique may have on these.

Learning Objectives:
1. To appreciate the limited role of conventional radiography in major trauma.
2. To learn key radiographic indicators and signs of major trauma.
3. To discuss the impact of technique modification on anatomical appearances and the accurate identification of trauma on conventional radiographs.

Author Disclosure:
M. Hardy: Author; Multiple Journals & textbooks. Grant Recipient; ISRRT Award, HEE Award, CCIP HEIF Award. Other; President UKRC, Associate Editor JMIRS Journal, Editorial Board Member Radiography Journal.

A-141 16:50

C. Applications of ultrasound in the evaluation of major trauma

T. Herlihy; *Dublin/IE (therese.herlihy@ucd.ie)*

Ultrasound is the most widely used and readily available imaging modality in the world. In recent years, ultrasound has moved from its classic use in the radiology department to playing a useful and sometimes vital role in the assessment and management of the trauma patient. Focused assessment with sonography for trauma (FAST), chest abdominal-focused assessment sonography for trauma (CA-FAST) and extended-FAST (E-FAST) are now widely performed in cases of both penetrating and non-penetrating trauma. Despite this, more research needs to be done to elicit the affect ultrasound has on patient prognosis and survival. As ultrasound is portable it can be used both in the hospital and ambulance setting. FAST is now an integral part of the training of emergency physicians; however, there is a lack of standardisation around education and clinical competencies and there are also variations in the use of FAST between centres. While ultrasound on trauma patients is primarily performed by physicians, some countries are now training and using paramedics to perform ultrasound in the field and in ambulances before the patient is moved/arrives at the hospital. Ultrasound is extremely operator dependent and so anyone using ultrasound to assess patients must be properly trained and understand the advantages and limitations of ultrasound scanning. As ultrasound machines become cheaper and more accessible ultrasound is being used more and more in the emergency setting.

Learning Objectives:
1. To appreciate the role ultrasound can play in assessing the trauma patient, both in the hospital and ambulance setting.
2. To learn about focused assessment with sonography for trauma (FAST) and what training is required to perform FAST scanning.
3. To discuss the expanding role of ultrasound in the accident and emergency room. Who does what and when and how does it impact on patient care?

17:15
Discussion and questions: Imaging of major trauma - what are the challenges?

EuroSafe Imaging Session

EU 1

Clinical diagnostic reference levels

Moderators:
G. Simeonov; Luxembourg/LU
G. Frija; Paris/FR

A-142 16:00

Introduction
G. Frija; *Paris/FR (guy.frija@egp.aphp.fr)*

Diagnostic reference levels (DRLs) are an important tool for optimisation. With the new Basic Safety Standards Directive (Council Directive 2013/59/Euratom) DRLs have been included in European legislation. The BSS Directive defines DRLs as "dose levels in medical radiodiagnostic or interventional radiology practices, or, in the case of radio-pharmaceuticals, levels of activity, for typical examinations for groups of standard-sized patients or standard phantoms for broadly defined types of equipment". A working group on clinical DRLs has been established under the umbrella of EuroSafe imaging, the European Society of Radiology's campaign to promote quality and safety in medical imaging. Clinical DRLs take into account the different clinical tasks of the same area, which do not require the same image quality. The working group aims at developing a first set of DRLs for clinical indications to transform the requirements of the BSS Directive into concrete action for users. This presentation will give an overview of the concept of DRLs and the standard-sized patient generally used to define DRLs, although most patients do not comply with the definition. In addition, the preliminary results of the "Is your Imaging EuroSafe?" surveys, which have collected data on CT DRLs for different indications, will be briefly presented.
Session Objectives:
1. To become familiar with the concept of local and clinical diagnostic reference levels.
2. To discuss the need for DRLs specific to body size, disease distribution and clinical indication.
3. To present the results of the first EuroSafe Imaging Stars survey.

A-143 16:15

Clinical diagnostic reference levels: from concept to impact in clinical practice
R.W.R. Loose; *Nürnberg/DE (Loose@klinikum-nuernberg.de)*

Today most diagnostic reference levels (DRL) are based on modalities and anatomical body regions to be examined (e.g. CTDIvol and DLP in CT, or DAP in radiography). In film-based radiography, the detector dose is given by the film-screen sensitivity and can be modified only within narrow limits. Introduction of digital radiography enabled substantial dose reduction with increased image noise for specific clinical questions (e.g. control of metal removal after surgery or measurement of scoliosis angles in children). CT as a digital modality with the highest collective medical dose contribution enabled dose modifications from the first beginning. Because of digital viewing conditions (window width) high-contrast objects in general require lower CT doses than low-contrast objects. A CT of the brain (window width ~80 HU) requires a typical CTDIvol of ~50 mGy which is significantly higher than a CT of the lung parenchyma (window width 1500-2000 HU) with a CTDIvol < 10 mGy. Typical clinical DRLs with reduced dose in CT are screening for lung nodules, sinusitis or ureteral stones. In addition, clinical DRLs have to include the number of required CT scan series. In fluoroscopy, setting up clinical DRLs is more complex, as in addition to image quality the complexity and duration of a procedure have a major impact. Setting up more clinical DRLs requires a classification of patient conditions where different dose levels for one anatomical region are reasonable. Such a process will increase the number of DRLs but probably reduce the overall dose to patients.
Learning Objectives:
1. To understand the different quality requirements to answer specific clinical imaging questions in CT exams of the same body region.
2. To learn about the steps needed for a transition to clinical DRLs.
3. To appreciate the practical impact of clinical reference levels.

A-144 16:30

ICRP perspective: from methodological region-related DRLs to DRLs based on clinical indications
E. Vaño; *Madrid/ES (eliseov@med.ucm.es)*

The International Commission on Radiological Protection (ICRP) has recently completed a report updating the recommendations on "Diagnostic Reference Levels - DRLs - in Medical Imaging". DRLs have been proven to be an effective tool that aids in optimisation of protection in the medical exposure of patients for diagnostic and interventional procedures. There are issues related to definitions of the terms used in previous guidance, determination of the values for DRLs, the appropriate interval for re-evaluating and updating these values, appropriate use of DRLs in clinical practice, methods for practical application of this tool, and application of the DRL concept to newer imaging technologies. The report has already been submitted to public consultation and it is expected to be published in 2017. According to ICRP recommendations, DRL quantities should be appropriate to the imaging modality being evaluated, should assess the amount of ionising radiation applied to perform a medical imaging task, and should be easily measured or determined. Data for determining DRL values are obtained from surveys or registries of the DRL quantities for procedures performed on appropriate samples of patients. The 75th percentile value of the distribution of median values of a DRL quantity at healthcare facilities throughout a country is used as the 'national DRL'. DRLs are not intended to be used for individual patients or as a trigger (alert or alarm) level for individual patients or individual examinations. The appropriate image quality or diagnostic information needed for the clinical task should be a priority when setting DRL values.
Learning Objectives:
1. To become familiar with ICRP's term of 'DRLs for a defined clinical task'.
2. To learn about methodological requirements for establishing DRLs.
3. To understand the potential uses and limitations of DRLs.

A-145 16:45

EuroSafe Imaging clinical DRLs: detailed results of the pilot survey and lessons learnt for the survey among the EuroSafe Imaging Stars
P. Vock; *Spiegel/CH*

While the reasons for using clinical DRLs have been demonstrated by the previous speakers of the session, there is still a lack of concrete indication-based DRLs. The ESR has performed a pilot survey to overcome this deficit, concentrating on CT examinations of a few frequent indications. The results of this survey will be analysed: no matter what indication, there was a wide spread of exposure levels for one clinical task. The most important sources of variation - the equipment and protocol used, patient body size, and locally different specifications of a general indication - will be discussed. Different image quality needs for frequent indications are illustrated. Based on the experience of the ESR pilot study and of other European DRL projects, the methodological approach to reducing variation has been defined and will be used for a survey among EuroSafe Imaging Stars. This project will not compete with the establishment of national DRLs: based on dose management software tools it will be a faster way to see the trends in DRL evolution over time in European centres dedicated to radiation protection whereas national DRLs, by the fact that they have to be representative for all providers and all equipment in use, will take longer time and more efforts to be established.
Learning Objectives:
1. To present results of the pilot survey.
2. To learn about the different exposure levels needed in important indications.
3. To appreciate complimentary uses of EuroSafe Imaging and national DRLs.

A-146 17:00

North American DRLs: a view from across the pond
R.L. Morin; *Jacksonville, FL/US (morin.richard@mayo.edu)*

The purpose of this work was to use the American College of Radiology Computed Tomography (CT) Dose Index Registry (DIR) to develop diagnostic reference levels (DRLs) and achievable doses (ADs) for the 10 most common adult CT examinations in the US as a function of patient size. These examinations are: head brain without contrast, cervical spine without contrast, neck with contrast, chest without contrast, chest with contrast, chest with pulmonary embolism protocol, chest abdomen pelvis with contrast, abdomen pelvis with contrast, abdomen pelvis without contrast, and abdomen pelvis nephrolithiasis protocol without contrast. For the head exams, lateral thickness dimension was used as an indicator of patient head size. For neck, c-spine, chest, abdomen and pelvis exams, effective diameter was used. Data from over 1.3 million examinations were used to determine median values (AD) as well as mean, 25th and 75th (DRL) percentiles of $CTDI_{vol}$, DLP and SSDE. The median CTDIvol did not vary significantly but DLP increased with lateral thickness for head exams. For neck and c-spine, the median CTDIvol and the 75th percentile did not vary significantly but the median DLP did with effective diameter. Similar trends were seen for the median CTDIvol and SSDE for

chest, abdomen and chest-abdomen-pelvis exams. Our data agree well with the data from other resources. This talk will enable facilities to compare their patient doses to size-specific national benchmarks and optimize their CT protocols resulting in lower dose at the appropriate image quality.
Learning Objectives:
1. To present the US approach to quantitative benchmarking in optimisation and the role of DRLs.
2. To understand how the ACR finds consensus about minimal image quality requirements in different clinical indications.
3. To share the ACR experience with DRLs.
Author Disclosure:
R.L. Morin: Board Member; RSNA Research and Education Board of Trustees. Employee; Mayo Clinic. Speaker; Over 100 meetings and confernces.

17:15
Panel and public discussion
1. To discuss advantages and limitations of clinical DRLs. 2. To appreciate the initial cooperation among EuroSafe Imaging Stars. 3. To discuss the future role of EuroSafe Imaging DRLs and national/European DRLs.

16:00 - 17:30 **Room M 2**

Special Focus Session

SF 4b
The female pelvis

A-147 16:00
Chairman's introduction
R.A. Kubik-Huch; *Baden/CH (rahel.kubik@ksb.ch)*

Gynaecologic emergencies are disorders typically characterised by acute pelvic pain related to the female genital organs, related or unrelated to pregnancy. In an acute clinical setting, gynaecologic conditions must be separated from gastrointestinal diseases. Diagnoses implicate potentially profound consequences for the patient. Imaging plays an increasing role in the emergency setting by 1) assisting clinicians to diagnose acute gynaecological pathology and 2) helping to guide surgical or medical treatment. Therefore, it is important to accurately interpret the imaging findings in the context of the clinical signs. Chronic pelvic pain is a common problem. It presents a major challenge because of its unclear aetiology and often poor response to therapy. The condition is best managed using a multidisciplinary approach. Common gynaecologic and non-gynaecological causes as well as the role of imaging will be discussed. The aim of this session is to illustrate frequently encountered gynaecologic pathologies responsible for acute and chronic pelvic pain to raise awareness among radiologists and to ensure adequate patient care.
Session Objectives:
1. To discuss the differential diagnosis of acute and chronic pelvic pain with a special emphasis on the female genital organs.
2. To learn how to optimise the imaging work-up for pelvic pain in the pregnant and non-pregnant patient.

A-148 16:05
Acute pelvic pain
R. Manfredi; *Verona/IT (riccardo.manfredi@univr.it)*

Acute pelvic pain is a common symptom necessitating emergent medical evaluation, to make a prompt diagnosis and perform ovary-sparing or life-saving surgery. Clinical evaluation and laboratory testing are essential when a gynaecologic condition is suspected to be the cause of acute pelvic pain. For the initial diagnostic imaging evaluation, ultrasonography (US) is the modality of choice; however, the role of computed tomography (CT) in the evaluation of abdominal and pelvic pain continues to expand. In recent years, magnetic resonance (MR) imaging has been increasingly employed to assess those patients, because of the lack of ionizing radiation beneficial in possibly pregnant patients. Given the many possible causes of pelvic pain, a structured approach to image interpretation is necessary to narrow the differential diagnosis. First, the distinction between pregnant and non-pregnant patients, as determined by beta human chorionic gonadotropin (β-hCG) levels in correlation with menstrual history, is crucial. This clinical information portends the physiologic changes that may be expected and allows accurate image interpretation. Among ovarian causes of acute pelvic pain are follicular cysts, cystic corpus luteum, haemorrhagic ovarian cysts, endometriomas, teratomas and cystadenomas. Any mass ovarian lesion predisposes the ovary to torsion on its vascular pedicle, although torsion also occurs in the absence of an ovarian mass in pre-puberal girls. Among non-ovarian causes of acute pelvic pain are para-ovarian cysts, hydrosalpinx, peritoneal inclusion cysts, ectopic pregnancy and pelvic inflammatory disease. Among uterine causes, fibroids are the most common tumours of the uterus causing pelvic pain in as many as 30% of cases.
Learning Objectives:
1. To learn about the underlying aetiologies of acute pelvic pain.
2. To recognise various emergencies of the female pelvis and to take appropriate action.
3. To learn how to optimise MRI of the female pelvis in patients with acute pelvic pain.

A-149 16:30
Chronic pelvic pain
R. Forstner; *Salzburg/AT (r.forstner@salk.at)*

Chronic pelvic pain refers to pain of at least 6 months duration. It is a major issue in health care due to its often debilitating nature and its estimated prevalence of up to 18%. It is also a common cause of both diagnostic and curative surgeries. The spectrum of aetiologies is broad and comprises gynaecologic and non-gynaecologic conditions. The latter include gastrointestinal, urological, musculoskeletal, neurological and psychological disorders. MRI is most useful to differentiate between the gynaecological causes of chronic pelvic pain including endometriosis, adenomyosis and uterine leiomyomas. Clinical history and meticulous analysis of the character of pain may help to identify deep endometriosis, which is the most common cause of chronic pain in the reproductive age. A structured analysis of the MRI findings will assist in assessing also subtle findings of endometriosis, e.g. of the bowel or along the uterosacral ligaments. Unlike sonography, MRI allows also differentiation of adenomyosis and uterine leiomyomas. Although a controversial topic, pelvic congestion syndrome may be treated by interventional radiology. Due to its multifactorial character, patients with chronic pain often will require interdisciplinary management, with radiology rendering crucial information.
Learning Objectives:
1. To learn about prevalence and aetiologies of chronic pelvic pain.
2. To become familiar with gynaecologic causes of chronic pelvic pain.
3. To become familiar with common non-gynaecological causes of chronic pelvic pain.
4. To understand the role of imaging in the interdisciplinary management.

A-150 16:55
Pain in pregnant women
M. Weston; *Leeds/UK (michael.weston2@nhs.net)*

The pregnant woman may suffer pain related to her pregnancy or the pain may be co-incidental, related to other systems outside of the gravid uterus. Ultrasound is the starting point for imaging in the pregnant woman and has a recognised role in ectopic pregnancy, fibroid degeneration, adnexal torsion and appendicitis. There are sometimes when ultrasound is not enough and MR is required. This may be so in renal colic, uterine dehiscence and placental abruption. A radiologist should use the test that is most likely to answer the question in their hands. So, to use appendicitis as an example, it maybe that the best chance of an accurate diagnosis will be with CT, if the radiologist has not used MR in this scenario before. CT is often the imaging test of choice in significant trauma or suspected pulmonary embolus. The merits of each imaging modality and typical appearances will be discussed.
Learning Objectives:
1. To learn about causes of pain specific to pregnancy, such as ectopic pregnancy, placental abruption, fibroid degeneration and uterine dehiscence.
2. To learn about causes of pain in other organs that may present during pregnancy, such as appendicitis, renal colic and ovarian torsion.
3. To understand how pregnancy alters the way imaging is undertaken.
4. To appreciate the relative risk to the mother and foetus of imaging irradiation and misdiagnosis.
5. To become familiar with the increasing role that MR can play.

Molecular Imaging

RC 406

Molecular imaging: what can we quantify?

Moderator:
O. Clément; Paris/FR

A-151 16:00

A. Advanced MRI techniques
M. Smits; *Rotterdam/NL (marion.smits@erasmusmc.nl)*

Functional MR imaging (fMRI) and diffusion tensor imaging (DTI) are used extensively in the research arena to study an infinite number of questions regarding the brain's function and structure under normal conditions, as well as with neurological and psychiatric disease. The clinical use of these techniques, however, is by comparison fairly limited. The current main indication is the presurgical assessment of the relationship between the brain tissue to be resected and functionally eloquent brain tissue. In the context of brain tumour surgery, the aim is maximum tumour resection, while at the same time avoiding functional deficit. With tumour localisation in or near presumed eloquent brain areas, such as the motor or language areas, additional fMRI and DTI may be advantageous to guide the neurosurgical approach, shorten surgery duration and obtain prognostic information prior to surgery. fMRI is used to localise eloquent cortex, which is particularly useful when normal anatomy is obscured by tumour mass effect or in cases of cortical plasticity. With DTI the anatomy and involvement of white matter tracts may be evaluated. Inadvertent transection of white matter tracts during surgery leads to severe neurological deficit. DTI-tractography offers attractive visualisation of the major white matter tracts such as the corticospinal tract and the arcuate fasciculus, and offers valuable preoperative information on their relationships with the brain tumour to be resected. As well as providing such anatomical information, colour-coded eigenvector maps obtained with DTI can be used to categorise involvement of the white matter tracts by brain tumour.

Learning Objectives:
1. To learn about functional MRI (fMRI, DCE-MRI), diffusion tensor imaging (DTI) and diffusion-weighted imaging (DWI).
2. To understand the application of these techniques in the study of the healthy and diseased.
3. To learn about quantification using MR.

A-152 16:30

B. Advanced PET imaging techniques
T. Beyer; *Vienna/AT (thomas.beyer@meduniwien.ac.at)*

PET is a non-invasive imaging technique that provides reproducible and fully quantitative information on preselected metabolic/signalling pathways. PET is highly sensitive, thus, requiring only small amounts of biomarkers to be used for visualization and quantification purposes. Today, clinical PET imaging systems are offered almost exclusively in combination with CT and MR systems. Advantages of these imaging combinations are manifold and include, mainly for PET/CT, a marked reduction in total acquisition time, and improved spatio-temporal alignment of the complementary image information. Advancing PET-imaging technology into combined PET-based imaging technology included methodological input and technical innovation. We will highlight the most important advances of PET instrumentation that help increase volume sensitivity, improve spatial resolution and overall image quality. PET imaging in the context of combined PET/MRI was made possible only through the introduction of completely revised PET detectors that can operate in high-strength magnetic fields. Overall, increased volume sensitivity helps reduce the amount of radiotracer injected into patients or shorten the emission scan time, in combination with increased signal-to-noise in the emission images it helps increase sensitivity and reader accuracy of PET images. Lastly, advances in image reconstruction have brought the level of PET, and the appearance of the PET images, closer to the common understanding of radiologically useful images. Following this presentation, the audience will 1. learn about the benefits and challenges of quantification in PET, 2. understand the fundamentals of PET physics relevant to PET/MR imaging and 3. appreciate the advantages of PET/MR and its complementary role in diagnostic oncology.

Learning Objectives:
1. To understand the fundamentals of PET physics relevant to MR/PET imaging.
2. To appreciate the advantages of MR/PET and its complementary role in diagnostic oncology.
3. To learn about the benefits and challenges of quantification in PET.

Author Disclosure:
T. Beyer: Research/Grant Support; Siemens Healthcare. Other; Manging Director cmi-experts GmbH.

A-153 17:00

C. Clinical applications of quantitative hybrid imaging in oncology
L. Umutlu; *Essen/DE (Lale.Umutlu@uk-essen.de)*

Over the past 15 years, hybrid imaging, in terms of PET/CT, has become an essential part of clinical oncologic imaging. It has been well demonstrated to provide fast, high-quality, quantifiable imaging for numerous application fields, including whole-body staging and restaging in cancer patients, therapy monitoring and for radiation therapy planning. The combined assessment of morphological and metabolic features of tumours has not only been shown to add valuable non-invasive information concerning tumours, but also improve the diagnostic competence to higher levels than sole morphological cross-sectional imaging. The successful introduction of simultaneous PET/MRI into clinical imaging, in terms of the interchange of the CT component for anatomical correlation to MRI, has leveraged hybrid imaging onto utterly new and emerging platforms of tumour assessment. The application of multi-parametric PET/MRI imaging, comprising high-resolution morphological imaging as well as functional parameters such as diffusion-weighted imaging, perfusion parametrics and tumour metabolism, facilitates an improved understanding of tumour biology as well as prognostic factors. Furthermore, it enables improved therapy monitoring to better differentiate between potential responders and non-responders to chemo- and/or radiation therapy.

Learning Objectives:
1. To become familiar with the role of hybrid imaging in clinical oncology.
2. To learn about quantification in oncology: its benefits and limitations.
3. To understand hybrid imaging applications in relationship to disease presentations.

16:00 - 17:30 **Room M 4**

E³ - ECR Academies: Tips and Tricks in Liver, Bile Ducts and Pancreas Imaging

E³ 418

Bile ducts imaging: not so simple

A-154 16:00

Chairman's introduction
S.A. Jackson; *Plymouth/UK (simon.jackson1@nhs.net)*

Despite rapid technological advances, which have resulted in significant improvements when imaging the biliary tree, the accurate assessment and diagnosis of bile duct pathology still offers challenges for the clinical radiologist. Multi-modality imaging techniques remain central to optimal multi-disciplinary patient management with this interactive ECR academy covering the presentation and imaging appearances of both benign and malignant biliary diseases. In particular, lectures will focus on the imaging features of cholangiocarcinoma and the underlying differential diagnosis of patients presenting with chronic cholangitis. Tips and tricks for accurate diagnosis and the importance of clear diagnostic algorithms will also be emphasised using a range of challenging illustrative clinical cases.

A-155 16:05

A. Cholangiocarcinoma
S. Kim; *Seoul/KP (sykim.radiology@gmail.com)*

Cholangiocarcinoma (CCA) is a malignant epithelial neoplasm with biliary differentiation, which arises from any portion of the biliary system including epithelium and peribiliary gland. Although it shows the highest incidence in Asia, the incidence appears to be increasing recently in western countries. Of late, the concepts of CCA has been progressed regarding precancerous lesions of CCA, biliary disease with a pancreatic counterpart, and the relationship of CCA with cancer stem cells. Based on its anatomic location, CCA is classified as intrahepatic (iCCA), perihilar (pCCA), and distal (dCCA) CCA. CCA exhibits three growth patterns: mass-forming (MF), periductal infiltrating (IF), and intraductal growing (IG). The list of radiologic differential diagnosis is varied according to its gross morphology. For MF CCA, tumours with abundant fibrosis such as metastasis, sclerosing HCC, combined HCC-CC are important mimickers. PI CCA looks similar to sclerosing cholangitis. IG CCA has various morphology depending on tumour location and mucin production. Patients with CCA are usually treated with surgery. Because of its various morphology, infiltrative nature and underlying diseases, it can be a challenge to diagnose and stage CCA accurately. Although contrast-enhanced CT and MRI play an important role to assess resectability, a multidisciplinary approach is needed to accomplish best results.

Learning Objectives:
1. To become familiar with the different presentations of cholangiocarcinoma (including hilar and peripheral) tumours.
2. To learn about the role of imaging in staging the lesion and its limitations.
3. To understand the principle of surgical and non-surgical treatment.

A-156 16:33

B. Chronic cholangitis

M. Ronot; *Clichy/FR (maxime.ronot@bjn.aphp.fr)*

Chronic cholangitis are a group of diseases resulting in a chronic inflammation of the bile ducts, with variable causes and consequences. They can be roughly divided into two main groups: sclerosing cholangitis (SC) and secondary cholangitis. The first group includes primary and IgG4-related SC. They correspond to the biliary lesion of chronic extrahepatic/systemic diseases, respectively, inflammatory bowel diseases and IgG4-related disease. Secondary cholangitis is associated with specific identified causes: biliary ischaemia, trauma, chronic infections, iatrogeny, etc. The diagnosis of chronic cholangitis is difficult and relies on four pillars: laboratory tests, associated diseases and medical history, pathology, and of course imaging. The latter plays a central role. Magnetic resonance imaging including MR cholangiography is now considered as the best imaging technique. On imaging, the affected segments demonstrate irregular stenosis, focal, or diffuse circumferential thickening of the wall with contrast enhancement. Ultrasound can be useful to detect small biliary lesions and stones. It remains difficult to distinguish IgG4-SC from primary SC or bile duct malignancy based on imaging features alone. Careful analysis of cholangiograms can be helpful. Nevertheless, biopsy should be used in all patients with a suspicion of malignancy.

Learning Objectives:
1. To understand the appropriate technique for the non-invasive evaluation of bile ducts.
2. To become familiar with the main causes for chronic cholangitis, including primary sclerosing, autoimmune and ischaemic cholangitis.

A-157 17:01

C. Tough clinical cases

E.M. Merkle; *Basle/CH (emerkle@uhbs.ch)*

In this interactive session, various clinical cases that focused on the biliary system will be presented. Case presentations will include a wide range of pathologic entities, both benign and malignant. Images will be shown from various modalities including but not limited to percutaneous ultrasound, computed tomography, magnetic resonance imaging including magnetic resonance cholangiography and positron emission tomography. Case presentations are intended to represent typical clinical scenarios; as such information regarding the patient's history and physical exam will be shown first, followed by laboratory data. Subsequently, the audience will be asked to recommend the most appropriate imaging modality and to participate in solving these cases!

Learning Objectives:
1. To be able to define the most likely diagnosis facing an unknown case.
2. To understand the diagnostic strategy.

Author Disclosure:
E.M. Merkle: Advisory Board; Siemens Healthineers. Equipment Support Recipient; Siemens Healthineers. Research/Grant Support; Bayer, Bracco, Guerbet. Speaker; Siemens Healthineers.

16:00 - 17:30 **Room M 5**

E³ - ECR Master Class (Cardiac)

E³ 426

Assessment and lifelong follow-up of congenital heart disease

A-158 16:00

Chairman's introduction

L. Saba; *Cagliari/IT (lucasaba@tiscali.it)*

Congenital heart disease (CHD) identifies several cardiac and vasculature prenatal defects and CHD is the most common birth defect: in 2013, they were present in 34.3 million people globally. Many congenital heart defects can be diagnosed prenatally by foetal echocardiography when the woman is 18-24 weeks pregnant and thanks to the evolution of interventional and surgical treatment, the survival of newborns with CHD has improved dramatically over the past half century. A number of classification systems exist for CHD and to correctly identify these pathologies, it is mandatory a knowledge of the anatomy and pathophysiology because the broad spectrum of diseases ranges from small septal defects and minor valvar obstructions to complex single ventricle malformations. Sometimes CHD improves without treatment whereas other defects are so small that they do not require any treatment. However, most of the time CHD is serious and requires surgery and/or medications. A vital component to the multidisciplinary management of newborn with the CHD is adequate imaging of the heart and circulation. The development of those complementary non-invasive techniques has made decrease the need for invasive catheterization. CT, MRI and TTE have potentialities and pitfalls but allow obtaining a tailored imaging, fundamental to offer the best chances to CHD subjects. Although MRI is generally more flexible and appropriate for congenital imaging, it is not entirely free of limitations whereas CT is likely to become an increasingly important imaging technique for the CHD population, in part because of greater access to CT than MRI.

Session Objectives:
1. To enhance knowledge of anatomy and physiology of common congenital cardiac conditions as well as the surgical/interventional procedures used to treat them.
2. To discuss the appropriate use and performance/interpretation of non-invasive tests examining patients with CHD.

A-159 16:10

A. A primer: what do the most important anomalies look like?

O. Rompel; *Erlangen/DE (oliver.rompel@uk-erlangen.de)*

Congenital heart disease (CHD) has an incidence of 6-8 per 1,000 live births. CHD is a term for a variety of cardiac and vasculature prenatal defects. The broad spectrum of diseases ranges from small septal defects and minor valvar obstructions to complex single ventricle malformations. The concept of developmental “errors” helps us to explain, define and classify these inborn diseases. A common pathophysiological classification of CHD is based on the clinical consequence of structural defects on the physiology of blood circulation: CHD with increased pulmonary blood flow can be differentiated from CHD with decreased pulmonary flow, CHD with obstruction to blood progression and no septal defects and CHD so severe as to be incompatible with postnatal blood circulation. For diagnostic management of patients with CHD, knowledge of the underlying pathophysiology is essential. This is also true for the effects of catheter-based intervention or surgical repair on anatomical and haemodynamic changes. Physicians must be familiar with the complex terminology used in CHD to effectively communicate findings. Due to further development of interventional and surgical treatment concepts, the life expectancy of newborns with CHD has improved dramatically over the past decades. For instance, more and more patients with ventricular hypoplasia can nowadays be treated successfully, either by biventricular repair or refined functionally single ventricle palliation. Thus, an increasing number of adults with CHD can now be followed up in tertiary cardiac care centres.

Learning Objectives:
1. To get an overview on the spectrum of congenital heart disease (CHD), from the foetus and newborn through adults with congenital heart disease.
2. To explain the pathophysiology, manifestations, diagnosis and management of cyanotic, acyanotic and obstructive congenital cardiac anomalies.
3. To discuss the implications of cardiac anomalies on complexity and urgency of treatment indications.

A-160 16:30

B. CT for assessment and follow-up

J.-N. Dacher; *Rouen/FR (Jean-Nicolas.Dacher@chu-rouen.fr)*

The number of grown-ups requiring lifelong follow-up for congenital heart disease is increasing continuously due to the improvement of surgical and medical treatments. In this context, trans-thoracic echocardiography (TTE), MRI and CT appear complementary and help decrease the use of invasive angiography. Today, using the most recent CT equipment, it is possible to obtain high-resolution images of the heart and great vessels with minimal radiation and contrast medium doses. Prospective gating, low x-ray power and current intensity protocols, iterative reconstruction, limited field of views and number of scans all contribute to limit the radiation dose to a strict minimum. The advantages of CT match the MRI (and TTE) limitations, so that we believe that radiologists involved in one of both techniques should also practice the other one. The target organs of CT are small moving vessels such as coronary arteries (origin and course). The 2D and 3D CT depiction of pulmonary arteries, pulmonary veins and thoracic aorta is excellent. CT is very efficient in showing stented vessels or conduits. Finally, its capability to evaluate the lung (infection, pleural fluid, arterial venous malformation) and thoracic cage is unique. CT remains limited in cardiac functional information (ejection fraction, regurgitations and stenosis) that would require multiphase acquisition, e.g. retrospective gating involving significant dose. A series of illustrative examples will be shown.

Learning Objectives:

1. To learn how to decide which imaging modality is the most appropriate for which indication in CHD patients, and to recognise their advantages and limitations.
2. To integrate the most up-to-date CT imaging techniques for CHD patient management, including dose reduction strategies.
3. To be able to perform a complex CT protocol in CHD, and how to systematically read and evaluate CT imaging in CHD patients.

Author Disclosure:

J. Dacher: Equipment Support Recipient; GE HealthCare. Investigator; Shire. Speaker; GE, Siemens, Guerbet, Bayer.

A-161 16:50

C. MR imaging for assessment and follow-up

N. Schicchi; *Ancona/IT (schicchi.n@alice.it)*

The number of patients with congenital heart disease (CHD) is rapidly increasing in the adult population, mainly due to the improved long-term survival. Serial follow-up with cardiac magnetic resonance imaging (CMR) is very appealing due to its non-invasive nature. CMR exam is able to provide specific information about cardiac function, haemodynamics, anatomy and tissue characterization unlikely achievable by other diagnostic techniques. CMR in CHD plays a role both in early diagnosis and in post-operative follow-up. Black-blood T1-weighted sequences are used to acquire morphological information. Cine steady-state free precession sequences are mainly used to provide data about cardiac function and kinesis. Haemodynamic assessment is routinely performed using phase contrast sequences, which provide reliable information concerning vessel flow pattern, cardiac output and intracardiac shunts. Magnetic resonance angiography (MRA) and 3D coronary MRA of the whole thorax can provide detailed morphological information regarding great vessels and proximal coronary arteries. Presence of late gadolinium enhancement suggesting myocardial macroscopic fibrosis seems to play a prognostic and diagnostic role even in this field.

Learning Objectives:

1. To learn how to decide which imaging modality is the most appropriate for which indication in CHD patients, and to recognise their advantages and limitations.
2. To learn about the role of MRI in the diagnosis and planning of therapy of CHD in both paediatric patients and adults, in comparison and correlation to echocardiography.
3. To be able to perform a complex MRI protocol in CHD, and how to systematically read and evaluate MR imaging in CHD patients.

17:10

Panel discussion: How to best assess congenital anomalies?

Thursday, March 2

08:30 - 10:00 **Room A**

E³ - ECR Academies: Interactive Teaching Sessions for Young (and not so Young) Radiologists

E³ 521

Integrating diagnostic tools in breast imaging

A-162 08:30

A. Multimodality breast imaging

K. Kinkel; *Chêne-Bougeries/CH (karen.kinkel@grangettes.ch)*

The different tasks of breast imaging concern screening, characterization and staging breast cancer as well as diagnosing patients with symptomatic breasts. This lecture gives an overview of the respective place and complementarity of imaging modalities for a variety of clinical situations taking into account evidence-based medical recommendation and recent advances in breast imaging. Case-based teaching covers choice of imaging modalities for breast pain, breast mass, nipple discharge, positive screening mammography, multiple breast imaging abnormalities, complex lesion characterization and known breast cancer staging. The information provided by imaging requires adequate ranking and organization into a final report with a final risk of malignity translated into a BIRADs category. Multi-modality imaging of the breast takes advantage of the strength of each imaging modality to allow an optimal diagnostic procedure. Examples of a variety of breast problems are documented using state-of-the-art imaging techniques and reporting.

Learning Objectives:

1. To choose the adequate imaging modality according to the clinical question taking into account the performance and the cost of ultrasound, mammography and MRI.
2. To combine information provided by different imaging modalities into a final report with special focus on mammography/tomosynthesis and ultrasound.
3. To update your BI-RADS knowledge.

A-163 09:15

B. Multiparametric breast MRI

J. Camps Herrero; *Valencia/ES (juliacamps@gmail.com)*

Breast MRI's main sequence is dynamic contrast-enhanced T1-weighted 3D (DCE-MRI), but there are other MRI techniques that can add very useful information due to the fact that they convey different functional information based on varying approaches to the biological hallmarks governing breast cancer. Angiogenesis is the basis for DCE-MRI, as the newly formed blood vessels show endothelial gaps that allow for the passage of gadolinium-based contrast media thus making it possible for tumours to enhance earlier than normal tissue. Diffusion-weighted imaging reflects the thermally induced movement of water molecules in the tissues and through the ADC or apparent diffusion coefficient is able to improve specificity of DCE-MRI in the characterisation of breast lesions, as well as response evaluation to neoadjuvant chemotherapy treatment. DWI and its 3D counterpart, diffusion tensor imaging or DTI, are breakthrough techniques in breast MRI characterisation, response evaluation and also in breast cancer screening. Spectroscopy MRI assesses elevated membrane metabolism through analysis of altered phospholipid metabolites; this technique remains, however, subject to cutting-edge research.

Learning Objectives:

1. To learn about the different technical and clinical aspects of the MRI sequences that are used currently in breast imaging.
2. To know how to unify the information thereof provided in everyday clinical practice.

Author Disclosure:

J. Camps Herrero: Advisory Board; Bayer.

08:30 - 10:00 **Room B**

E³ - ECR Master Class (Abdominal Viscera)

E³ 526a

The obesity epidemic: what is radiology's role?

A-164 08:30

Chairman's introduction

E.M. Merkle; *Basle/CH (emerkle@uhbs.ch)*

In the chairman's introduction, the history of the obesity epidemic in the western world will be briefly described followed by outlining the evolution of the various invasive treatment options. These main surgical procedures may cause specific complications with radiology playing a key role in the detection and management of these.

Session Objectives:

1. To learn about the obesity epidemic and the relevance of fat disorders for the Western world.
2. To understand the methodical and diagnostic challenges when imaging obese patients including postoperative conditions after bariatric surgery.
3. To appreciate the role of radiology in abdominal fat quantification.

Author Disclosure:

E.M. Merkle: Advisory Board; Siemens Healthineers. Equipment Support Recipient; Siemens Healthineers. Research/Grant Support; Bayer, Bracco, Guerbet.

A-165 08:36

A. The metabolic syndrome: what the radiologist needs to understand

H.J. Lamb; *Leiden/NL (h.j.lamb@lumc.nl)*

Recently, the concept of the 'metabolic syndrome' was introduced, which is a constellation of risk factors of metabolic origin that are accompanied by increased risk for cardiovascular disease and type 2 diabetes. The two major underlying risk factors for the metabolic syndrome are obesity and insulin resistance. Metabolic imaging and total body fat distribution may be used to determine if obese subjects are an increased risk for developing type 2 diabetes. In this situation, more intensive lifestyle intervention can be advised and monitored. MR techniques offer unique possibilities for monitoring effects of new dietary strategies. Whole body imaging may also allow one to study interaction between different organs. For example, initial results show that high liver triglyceride content in type 2 diabetes is associated with decreased myocardial perfusion, glucose uptake and high-energy phosphate metabolism, in conjunction with impaired whole body insulin sensitivity. Multi-organ imaging in a single patient opens interesting possibilities to study interaction between key organs involved in the metabolic syndrome, such as liver, pancreas, kidney and heart, in relation to vascular morphology and function. In summary, metabolic MR imaging and total body fat distribution may be used in the future for risk assessment and personalised medicine in patients with the metabolic syndrome. Furthermore, multi-organ MR imaging is promising for evaluation of interaction between different organs in the metabolic syndrome.

Learning Objectives:

1. To learn about the causes and consequences of the metabolic syndrome.
2. To become familiar with the abdominal manifestations of the metabolic syndrome.
3. To understand the role of radiology in surveillance of the population at risk.

A-166 08:57

B. Imaging the obese patient presenting as an emergency: challenges and solutions

M. Rengo; *Latina/IT (marco.rengo@gmail.com)*

Laparoscopic sleeve gastrectomy, Roux-en-Y gastric bypass and laparoscopic gastric banding are the dominant bariatric procedures. All these techniques may be associated with short- or long-term complications which can become an emergency. We will discuss the appearance of common and uncommon complications associated with the bariatric procedures on MDCT and fluoroscopy. We will discuss the technical features of imaging modalities and the indications according to the clinical setting.

Learning Objectives:

1. To understand the most common abdominal causes leading to an emergency presentation.
2. To become familiar with the specific technical difficulties and challenges that obese patients present for the imaging department in an emergency situation.
3. To learn about tips and tricks in order to optimally image the obese patient in this situation.

A-167 09:18

C. Evidence and recommendations for quantification of hepatic and visceral fat

C.B. Sirlin; *San Diego, CA/US (csirlin@ucsd.edu)*

Obesity is associated with the accumulation of excess fat in solid organs such as liver and in adipose tissues such as visceral adipose tissue. Quantification of hepatic and visceral fat accumulation are increasingly important for research and it is anticipated that they will become important for clinical care in the years to come. This lecture reviews confounder-corrected chemical shift-encoded MRI methods to quantify the proton density fat fraction (PDFF) as a marker of hepatic fat accumulation as well as semi-automated MRI-based segmentation methods to quantify the volume of visceral abdominal tissue.

Learning Objectives:

1. To understand the current evidence for the role of imaging in the quantification of hepatic and visceral fat.
2. To become familiar with the various techniques and recommendations used for fat quantification.
3. To learn about future directions for accurate fat quantification.

Author Disclosure:

C.B. Sirlin: Advisory Board; Bracco, Virtual Scopics, Pfizer, Tobira, Guerbet. Investigator; Alexion, AstraZeneca, Bioclinica, BMS, Fibrogen, Galmed, Genentech, Genzyme, Gilead, Icon, Intercept, Isis, Janssen, NuSirt, Perspectum, Pfizer, Profil, Sanofi, Shire, Synageva, Tobira, Takeda. Research/Grant Support; GE, Siemens, Guerbet.

A-168 09:39

D. Bariatric surgery: normal postoperative imaging appearances and spectrum of complications

A. Blachar; *Tel Aviv/IL (ablachar@gmail.com)*

Recently, there has been a tremendous increase in the utilization of laparoscopic surgery to control morbid obesity that is very common and increasing in incidence in Western nations. Bariatric restrictive procedures include reduction of the gastric capacity causing an early sensation of fullness after ingestion of small quantities of food. In bariatric combination procedures, a part of the digestive tract is bypassed, thus causing decreased absorption of nutrients and calories. In this lecture, we discuss the most common laparoscopic bariatric procedures: Roux-en-Y gastric bypass, gastric sleeve surgery, both combination procedures and adjustable silastic ring gastric banding, a restrictive procedure. Imaging plays an important role in the evaluation and management of patients before and after bariatric surgery. Imaging findings relating to these bariatric procedures will be discussed, focusing on the role of fluoroscopy and CT in evaluation of the normal post-operative anatomy and gastrointestinal complications.

Learning Objectives:

1. To become familiar with the common bariatric surgical procedures.
2. To learn about the normal postoperative anatomy and imaging appearances.
3. To understand the role of imaging for the assessment of both, early and late postoperative complications.

08:30 - 10:00 **Room C**

State of the Art Symposium

SA 5

Lung cancer screening: past, present, future

A-169 08:30

Chairman's introduction

L. Bonomo; *Rome/IT (lorenzo.bonomo@unicatt.it)*

This state-of-the-art symposium (SA) aims to inform the audience about the real state of the art of the lung cancer screening. The session includes three lecturers each of whom will focus in some specific aspects of the lung cancer screening. The design, conduct, results and limitations of the largest randomised trial, the NLST, will be discussed by the first lecturer. The results and the latest insights from European trials will be presented by the second lecturer. The opportunities for future screening research will be discussed by the third lecturer. The panel discussion will focus on how to implement lung cancer screening in Europe.

Session Objective:

1. To learn about the results of European and international lung cancer screening and to appreciate opportunities for future screening research.

A-170 08:35

What did we know: NLST and previous trials

S. Diederich; *Düsseldorf/DE (stefan.diederich@vkkd-kliniken.de)*

Radiologic examinations have been used since the 1960s to identify asymptomatic lung cancers in at-risk populations. Chest radiography alone or in combination with sputum cytology was used in several randomized trials and was able to detect more cases of lung and more early cancer stages in the study groups compared to the control groups with no chest radiography. However, no study was able to demonstrate mortality reduction from chest radiography screening. In the 1990s, unenhanced low radiation dose computed tomography was used in feasibility studies to screen for asymptomatic lung cancer in risk populations, mainly active or ex-smokers. Several non-randomized trials were able to demonstrate that low-dose CT had a much improved sensitivity for asymptomatic lung cancers compared to chest radiography with an acceptable rate of invasive procedures for false-positive findings, although the rate of false-positive findings was high.The first randomized controlled trial of low-dose CT versus chest radiography screening in active or (maximum 15 years) ex-smoker aged 55 -74 years with a minimum of 30 pack years of cigarette smoking in the US (National Lung Screening Trial: NLST) to publish results on mortality reduction showed a 20% reduction of mortality from lung cancer.

Learning Objectives:

1. To understand the design, conduct, results and limitations of the randomised NLST trial.
2. To learn about the results of previous trials in terms of mortality reduction.
3. To understand the results of feasibility studies in terms of prevalence and incidence of screening detected lung cancer.

A-171 09:00

What do we know: latest insights from European trials, modelling studies and current screening programmes

M. Prokop; *Nijmegen/NL*

"no abstract submitted"

Learning Objectives:

1. To learn how to select participants for maximum yield of screening.
2. To understand how to optimise reading and nodule management.
3. To learn how to improve patient outcome by quality control of screening and treatment.

A-172 09:25

What don't we know: opportunities for future research

A. Devaraj; *London/UK*

Opportunities for future research for lung cancer screening with CT will be guided by the need to answer specific questions related to implementation. Many of these questions are relevant to radiology. How frequently should participants be screened? How can nodule follow-up or biopsy be minimised without impacting on cancer diagnosis and patient outcomes? How can the reading process be optimized? Since many lung cancer screening trials are already completed or nearing completion, the methods by which these areas could be addressed and their challenges will be discussed.

Learning Objectives:

1. To understand the limitations of existing screening protocols.
2. To learn about opportunities for optimisation of future screening protocols.
3. To appreciate questions, not answered by current trials, for future screening research.

Author Disclosure:

A. Devaraj: Advisory Board; GrailBio.

EIBIR Session

EIBIR 1

VPH-DARE@IT: Novel biomarkers and platforms for earlier dementia diagnosis

A-173 08:30

Introduction

Z.A. Taylor; *Sheffield/UK (z.a.taylor@sheffield.ac.uk)*

Dementia, in all its forms, is recognised as one of the key healthcare problems facing Western societies, especially as populations age, and concomitant economic and societal costs of the condition expand. Enabling more objective, earlier, predictive and individualised diagnosis and prognosis of dementias will support health systems worldwide to cope with this burden. The VPH-DARE@IT integrated project aims at precisely this. To this end, it pursues, first, a unique programme of biomarker discovery founded on a combination of patient-specific mechanistic and phenomenological models of disease. Second, it supports development of two new IT infrastructures aimed at clinical research and clinical decision support, respectively, which facilitate the complete pipeline from biomarker discovery and validation, to clinical deployment and evaluation. In this session, we will present latest developments in these areas.

Session Objective:

1. To learn about the VPH-DARE@IT project and the use of its results.

A-174 08:40

Patient care platform

M. van Gils; *Tampere/FI (Mark.vanGils@vtt.fi)*

Diagnosing complex diseases, such as dementia, is a challenging task. Clinicians need to combine in their minds a multitude of data from different sources, to consider a high number of different possible reasons behind clinical symptoms, to take into account the background information based on the precision medicine concepts, and finally to apply existing economic constraints. This complexity easily leads to suboptimal decision making, even with profound clinical expertise available. Clinical decision support systems (CDSS) based on the principles of data-driven medicine hold potential for making the process more quantitative and objective. In VPH-DARE@IT, the Patient Care Platform (PCP) implements a CDSS integrating heterogeneous biomarkers from medical images, neuropsychological tests and other measurements, and helping to form a holistic view of the patient's status based on the principles of data-driven medicine. The PCP uses a data-driven approach where large databases of previously diagnosed patients are used for building models of several dementing diseases, including Alzheimer's disease (AD), frontotemporal dementia (FTD), vascular dementia (VaD) and dementia with Lewy bodies (LBD). When a new patient arrives at a clinic, studies and tests are done, after which all available patient data are contrasted to the disease models, revealing the most likely reasons for dementia. The software architecture enables the CDSS to access heterogeneous patient data from several data sources. Furthermore, it communicates with the VPH-DARE@IT Clinical Research Platform to allow incorporation of novel biomarkers into the decision making.

Learning Objectives:

1. To learn about dementia patient's needs.
2. To understand the VPH-DARE@IT patient care platform.

A-175 09:00

Clinical research platform

S. Varma; *Sheffield/UK (susheel.varma@sheffield.ac.uk)*

This presentation will inform the audience about the VPH-DARE@IT project that will deliver the first patient-specific predictive models for early differential diagnosis of dementias and their evolution using an integrative and validated multi-scale modelling platform for biomedical research and clinical decision support, underpinned by a set of unique databases and modelling paradigms. This platform will tackle the early and differential diagnosis of dementias using a combination of mechanistic and phenomenological models of the ageing brain, taking into account the environmental context.The objectives of the project are: deliver a systematic, multi-factorial and multi-scale modelling approach to understanding dementia, explore the lifestyle and environmental factors that predispose individuals to the development of dementia, deliver more objective and accurate differential diagnoses than those currently available in Europe, shorten the current average time-lapse between the onset of cognitive and memory deficits and its specific clinical diagnosis. We will present the VPH-DARE@IT clinical research platform that has integrated existing datasets, tools and workflows focused on dementia research, providing a single framework where new generation workflows will be created focusing on multi-scale patient-specific treatment for dementia. By means of this platform, novel modelling strategies will be developed and disseminated to unravel the brain ageing processes and progression of dementia through high-throughput analysis of clinical, biological and environmental data.

Learning Objectives:

1. To learn about the setup of a research platform.
2. To understand the data in the VPH-DARE@IT clinical research platform.

A-176 09:20

Mechanistic model-based biomarkers

Y. Ventikos; *London/UK (y.ventikos@ucl.ac.uk)*

Chronic cerebral hypoperfusion has been identified as a possible initiator of neurodegenerative processes leading to dementia. Lifestyle and environmental factors (LEFs), such as smoking, have an effect on the vascular system physiology. Pathophysiological changes in this system are, therefore, going to have an effect on the functioning of the brain. We propose to relate LEFs that act via the cardiovascular system and that have been shown to associate with AD. These LEFs are garnered from the preliminary data of a cross-sectional case-control study (Lido study). This multi-modal dataset is used to drive a patient-specific circulation model that provides predictions of CBF. The additional mechanistic components include a poroelasticity model used to acquire 4D maps of perfusion, clearance and ICP, in addition to a high-throughput imaging pipeline capable of providing anisotropic tissue permeability to capture the patterns of interstitial flow in addition to the parenchymal tissue and cerebroventricular representations required by the poroelasticity model. Preliminary simulation results indicate that predisposition to cognitive loss may be linked to modifiable risk factors, such as those witnessed relating to ICP, perfusion and clearance. Based on the preliminary data obtained from the Lido study, the CBF parameters that were found to be associated with MCI status were: reduced total CBF, reduced total perfusion (in women), increased APP (in very old subjects) and increased PI. The multiscale model of brain fluid transport developed in VPH-DARE@IT will be used to account for the long-term response to hypothetical LEF patterns and timings.

Learning Objectives:

1. To learn about mechanistic model-based biomarkers for dementia.
2. To understand the biomarkers used in the VPH-DARE@IT project.

A-177 09:40

Phenomenological model-based biomarkers

S. Klein; *Rotterdam/NL (s.klein@erasmusmc.nl)*

Both normal ageing and neurodegenerative disorders such as Alzheimer's disease cause morphological changes (i.e. atrophy) in the brain, which can be visualised using magnetic resonance imaging (MRI). However, it is often difficult to distinguish normal ageing from neurodegenerative disorders by visual inspection of these images. In the VPH-DARE@IT project, we have developed a novel method for distinguishing between normal and abnormal brain morphology, based on a quantitative phenomenological modelling approach. A comprehensive spatiotemporal model of normal brain morphology is derived, in a data-driven and hypothesis-free fashion, from MRI brain data collected in a large-scale population study (the Rotterdam scan study). Based on this model, percentile curves are constructed that characterise the distribution of brain morphology in the general population as a function of age. These percentile curves serve as reference charts to which patient data can be compared. Experiments using data of the Alzheimer's disease neuroimaging initiative (ADNI) show that the model generalises across study populations, and that it could be used to quantify a patient's brain health.

Learning Objectives:

1. To learn about phenomenological model-based biomarkers for dementia.
2. To understand the biomarkers used in the VPH-DARE@IT project.

08:30 - 9:30 **Room Z**

ESR Working Group on Ultrasound

WG 3

Minimising the risk of cross infection: how to keep patients safe in ultrasound

A-178 08:30

Chairman's introduction

M. Claudon; *Vandoeuvre-les-Nancy/FR (m.claudon@chu-nancy.fr)*

Ultrasound (US) is considered one of the safest imaging modalities. However, a survey undertaken by the US working group of the European Society of Radiology (ESR) to know about potential risk of cross-infection showed large diversity in protocols and practice throughout European countries. This leads to present detailed results and discuss how to establish currently applied infection control measures in US and highlight the importance of good medical practice in this area.

Session Objectives:

1. To understand how the issue of infection transmission risks in ultrasound was raised and what the US WG has done to investigate and address concerns.
2. To gain an overview of current infection control practice in Europe.
3. To become familiar with best practice recommendations to prevent cross transmission of infection in ultrasound.
4. To understand different viewpoints of practitioners, patients as well as the industry.

Author Disclosure:

M. Claudon: Speaker; Philips Ultrasound.

A-179 08:35

Risk of cross transmission of infection in ultrasound: current European practice (ESR survey results) and best practice recommendations prepared by the ESR US WG

C. Nyhsen; *Sunderland/UK (nyhsenc@doctors.org.uk)*

Ultrasound is generally considered one of the safest diagnostic modalities available. Causing significant harm to imaged patients by performing ultrasound is not anticipated by professionals or patients. However, risks of infection transmission through ultrasound have been highlighted increasingly in the last years and patient groups are becoming more concerned. Current European infection prevention standards in ultrasound were evaluated by a survey of the ESR ultrasound working group which has just been published, showing a very wide range of practice. Survey results highlight the need to raise awareness of the risk of infection transmission through ultrasound probes/gel and the need for stricter guidance to safeguard patients. The ultrasound working group, in close collaboration with expert microbiologists, have, therefore, worked on a consensus statement on best practice, which will also be presented in this talk.

Learning Objectives:

1. To gain an overview of the current infection control practice in Europe by presenting the main results of the ESR US WG survey undertaken.
2. To become familiar with the issued US WG recommendations for best practice, which are aimed to minimise the risk of cross infection.

A-180 08:50

Comments from the ESR Patient Advisory Group regarding infection control practice in Europe

J. Birch; *Poole/UK (judy_b@dsl.pipex.com)*

This presentation will assess patient knowledge and concerns relating to hygiene in ultrasound procedures. Current practice in several countries regarding the level of disinfection and various methods of ultrasound probe decontamination in particular will be discussed. I will also refer to anecdotal information regarding personal experience of ultrasound examinations and hygiene procedures.

Learning Objective:

1. To understand the patient's perspective regarding cross contamination risks in ultrasound.

A-181 09:00

Comments from industry representation

N. Denjoy; *Brussels/BE*

"No abstract submitted."

Learning Objective:

1. To understand the industry's perspective.

09:10

Panel discussion: How can safer practice be achieved?

08:30 - 10:00 **Room O**

Paediatric

RC 512

Paediatric musculoskeletal imaging

Moderator:
A.C. Offiah; Sheffield/UK

A-182 08:30

A. The occurrence of bone marrow oedema, joint fluid, ganglion cysts and erosion like features in the normal paediatric wrist

D. Avenarius; *Tromsø/NO (Derk.Avenarius@unn.no)*

Normal variations in the amount of joint fluid, ganglion cysts, bone marrow oedema, and bony depressions that resemble erosions are frequent in the wrists of children. The results of a follow-up of a healthy cohort aged 6-17 will be presented. The cohort was examined twice with MR of the wrist, and the second time also with a cartilage sequence for better visualization of the bony depressions. Knowledge of these normal variations is important because they can resemble disease.

Learning Objectives:

1. To discuss MRI protocols for the paediatric wrist.
2. To give an overview of normal development and variations in MR anatomy and signal patterns.
3. To provide an understanding of features indicative of pathology.

A-183 09:00

B. MRI of the temporomandibular joints: findings that can mimic arthritis

T. von Kalle; *Stuttgart/DE (t.vonkalle@klinikum-stuttgart.de)*

Arthritis of the temporomandibular joint (TMJ) is common in children and adolescents with juvenile idiopathic arthritis (JIA). Early treatment is warranted to prevent severe growth disturbances and joint deformities. As TMJ arthritis is often clinically silent, MRI with contrast-enhancement has been considered to be the most reliable method to assess signs of inflammation. To reliably guide therapeutic decisions and monitor outcomes it would be of utmost importance to clearly define the MR characteristics of a normal TMJ as a basis for the assessment of minor pathologies. However, similar to other small joints in children, we are just beginning to understand its developmental, physiological and anatomical characteristics as well as its reaction to inflammatory diseases and their treatment. Recent studies on normal TMJ in children have revealed age-dependent changes in shape and angulation of the mandibular condyle as well as typical time-intensity curves of contrast-enhancement in the soft joint tissue and the condyle. To date, the differentiation between normal synovial findings and mild signs of synovitis remains challenging. This lecture presents typical MR images of normal and inflamed TMJs in children and adolescents, including age-dependent anatomical variations. It discusses the available data on possible cutoffs between normality and pathology, the impact of the temporal dynamics of contrast enhancement, and presents findings that can mimic arthritis. It summarizes the minimum requirements of image quality and spatial resolution, the best image orientation, as well as the advantages of fat suppression and subtraction analysis in contrast-enhanced imaging.

Learning Objectives:

1. To discuss MRI protocols for imaging of the temporomandibular joints (TMJ).
2. To give an overview of MR imaging finding in arthritis of the TMJ.
3. To highlight the major differential diagnoses of TMJ arthritis and its MR imaging characteristics.

A-184 09:30

C. Skeletal trauma in children

I. Barber; *Esplugues de Llobregat/ES (ibarber@hsjdbcn.org)*

Paediatric fracture patterns, mechanisms of Injury and complications are different to those in adults. Differences are related to the dynamic state of a growing skeleton and its decreased mechanical strength. Imaging skeletal trauma is based on orthogonal radiographs but we will also discuss the role of other imaging techniques such as US, CT and MR imaging. Differential diagnosis with normal developmental variant and tumours, and recognition of an underlying metabolic syndrome are also important in children. Finally, complications of paediatric fractures will also be reviewed including growth arrest, malunion, nonunion, synostosis and avascular necrosis. We will try to give a rationale for diagnostic imaging based on the clinical and surgical demand.

Learning Objectives:

1. To become familiar with the types of injuries seen in children.
2. To understand the basic mechanisms.
3. To learn about the diagnostic imaging approach.

08:30 - 10:00 **Room N**

Cardiac

RC 503

Imaging of cardiac valves: new trends

Moderator:
H. Alkadhi; Zurich/CH

A-185 08:30

A. Echocardiography remains the reference technique

F. Knebel; *Berlin/DE (fabian.knebel@charite.de)*

Echocardiography is the most widely used technology to assess the valves. The talk will focus on the current guidelines and standards on the assessment of valvular heart disease by echocardiography. The transthoracic and transoesophageal techniques will be presented. Furthermore, there will be critical discussion of the role of other imaging technologies (MRI and CT) in this field.

Learning Objectives:

1. To learn about state-of-the-art echo techniques to evaluate cardiac valves.
2. To provide a practical approach to assessing valve pathology based on echocardiography.
3. To become familiar with the role of echo in the diagnosis, clinical management and prognosis.

A-186 09:00

B. MRI is the best comprehensive approach

M. Francone; *Rome/IT (marco.francone@uniroma1.it)*

Valvular heart disease has a direct impact on cardiac morphology and haemodynamics requiring comprehensive morphological and functional imaging for its assessment, which includes the evaluation of anatomy (leaflets, chordae tendineae and papillary muscles) and quantification of trans-valvular flow (i.e. degree of stenosis and regurgitation). Cardiac magnetic resonance (CMR) represents an ideal, non-invasive diagnostic tool on this regard, which has emerged as an alternative or complementary modality to echocardiography providing insight into the pathophysiology of the disease including the consequences of a valvular lesion, from the effects of ventricular volume or pressure overload to alterations in systolic function. A further unique strength of the exam is its ability to characterise myocardial tissue changes, which has further expanded with the recent implementation of T1/T2 mapping techniques providing potentially relevant information regarding the amount and distribution of replacement fibrosis in valvular pathology. CMR is also indicated to follow-up post-operative patients and as a reference tool for planning before TAVI procedures with some relevant advantages towards MDCT. Present lecture will overview principles of CMR technique and recommended acquisition protocol with particular emphasis on phase-contrast pulse sequences analysing its respective strength and weaknesses. Pathophysiology with common and less common imaging findings in left- and right-sided valve disease will also be presented and discussed.

Learning Objectives:

1. To learn about the role of MRI in diagnosis and evaluation of valvular disease.
2. To become familiar with state-of-the-art MRI techniques to evaluate valvular disease.
3. To learn about typical imaging findings in MRI with impact on clinical management.

Author Disclosure:
M. Francone: Speaker; Bracco Medical Imaging Invited Speaker.

A-187 09:30

C. Does CT have a role in diagnosing valvular disease?

G. Feuchtner; *Innsbruck/AT (Gudrun.Feuchtner@i-med.ac.at)*

Imaging of cardiac valves by computed tomography is an emerging topic. Technical development has created new horizons in the clinical triage of patients and changed old-fashioned paradigms. Therefore, the aim of of this course is to learn "how-to" evaluate cardiac valves and prosthesis by cardiac computed tomography, including the entire spectrum of valvular disease and prosthesis malfunction. Clinical implementations based on current scientific evidence and AHA /ESC guidelines will be discussed. Multimodality imaging will be highlighted.

Learning Objectives:

1. To learn about state-of-the-art CT techniques to evaluate cardiac valves at low dose.
2. To review CT appearance of the most common conditions causing valvular disease.
3. To become familiar with the role of CT in the diagnosis and clinical management.

08:30 - 10:00 **Studio 2017**

New Horizons Session

NH 5

Hyperpolarised MRI: imaging tissue metabolism in real time

A-188 08:30

Chairman's introduction

J.M. Gomori; *Jerusalem/IL (moshe.gomori@mail.huji.ac.il)*

Conventional MRI can access only 10-4-10-5 of the potential nuclear magnetic polarisation. Hyperpolarisation can achieve greater than 10% polarisation, i.e. more than 10,000 increase in polarisation and MRI signal of atoms such as 13C, 15N, 3He and 129Xe. This hyperpolarisation is achieved by transfer of polarisation from: polarised laser light, polarised supercooled electrons or polarised parahydrogen. Its short in-vivo T1 is usually much less than a minute. Since the hyperpolarisation is achieved outside the body, it must be quickly injected or inhaled and rapidly imaged with sequences adapted to optimal utilisation of the non-renewable nuclear magnetisation. Despite the hyperpolarisation, the signal is still relatively low, and large, usually non-physiologic, doses are required for imaging. In SNR it cannot compete with PET which has picomolar sensitivity. However, PET is not spectroscopic, i.e. it is not sensitive to the chemical bonds of the reporter atom. PET also has a much lower temporal resolution and does not have available the rich family of MRI sequences that can probe diffusion, motion, etc. Therefore, the promise and uniqueness of hyperpolarised MRI is in metabolic and physiologic quantitation and imaging. In our New Horizon session, some of the leading experts in the field will present the current status and research on applications of hyperpolarised MRI. We will finish off with a panel discussion and speculation on the future of hyperpolarised MRI.

Session Objectives:

1. To understand the basic principles of hyperpolarisation (how is it achieved, how long does it last, and how does it compare to PET).
2. To present clinical and preclinical applications of hyperpolarisation.
3. To explore potential future applications of hyperpolarisation.

A-189 08:35

Hyperpolarised MRI in oncology

F.A. Gallagher; *Cambridge/UK (fag1000@cam.ac.uk)*

There is increasing evidence to support a role for metabolism in tumour development, for example, deregulation of cellular energetics is now considered to be one of the key hallmarks of cancer. Changes in tumour metabolism over time are now known to be early biomarkers of successful response to chemotherapy and radiotherapy. There are a number of imaging methods that have been used to probe cancer metabolism: the most widely

available is 18F-fluorodeoxyglucose (FDG), an analogue of glucose, used in PET. Hyperpolarised carbon-13 MRI (13C-MRI) is an emerging molecular imaging technique for studying cellular metabolism, particularly in the field of oncology. This method allows non-invasive measurements of tissue metabolism in real time. To date, the most promising probe used in conjunction with hyperpolarised MRI has been 13C-labelled pyruvate: pyruvate is metabolised into lactate in normal tissue in the absence of oxygen, but in tumours this occurs very rapidly even in the presence of oxygen. Results from many animal models have shown that there is a reduction in the metabolism of pyruvate following successful treatment with chemotherapy. Tumour lactate labelling has also been shown to correlate with the grade of some tumour types. There are now a small number of sites performing human hyperpolarised carbon-13 MRI imaging. This talk will discuss the progress that has been made in this field within the area of oncology and potential clinical applications.

Learning Objectives:

1. To explore the role of metabolism in cancer development.
2. To understand how these changes in metabolism can be exploited using hyperpolarised 13C-pyruvate.
3. To review the current evidence for hyperpolarised carbon-13 imaging in oncology.
4. To understand potential clinical applications for hyperpolarised carbon-13 imaging.
5. To consider the role of new hyperpolarised molecules in oncology.

F.A. Gallagher: Grant Recipient; GSK, GE Healthcare.

A-190 08:52

Hyperpolarised MRI in cardiology

A. Comment; *Lausanne/CH (arnaud.comment@epfl.ch)*

The tremendous polarization enhancement afforded by dissolution dynamic nuclear polarization (DNP) can be taken advantage of to perform molecular and metabolic imaging. Following the injection of molecules that are hyperpolarized via dissolution DNP, real-time measurements of their biodistribution and metabolic conversion can be recorded. This technology, therefore, provides a unique and invaluable tool for probing cellular metabolism *in vivo* in a noninvasive manner. It gives the opportunity to follow and evaluate disease progression and treatment response without requiring *ex vivo* destructive tissue assays. Five sites across the globe are currently performing human studies using hyperpolarized ^{13}C-pyruvate and several other institutions are on the brink of being ready to inject their first patients. One of the most promising fields of application of this technology is cardiology. Cardiac dysfunction is often associated with a shift in substrate preference for ATP production and hyperpolarized ^{13}C magnetic resonance has the unique ability to detect real-time metabolic changes *in vivo* due to its high sensitivity and specificity. Several proposed methods for assessing metabolic flux through different enzymatic pathways will be presented. It will be shown how hyperpolarized ^{13}C magnetic resonance enables mechanistic studies of the changing myocardial energetics often associated with disease.

Learning Objectives:

1. To become familiar with the principles of hyperpolarised MRI.
2. To understand the key parameters required to integrate a hyperpolariser into a MRI facility.
3. To learn about the cardiac metabolic pathways that can be probed by hyperpolarised MR.

Author Disclosure:

A. Comment: Employee; General Electric Healthcare. Research/Grant Support; ERC Consolidator grant ASSIMILES.

A-191 09:09

Hyperpolarised MRI in respirology

J. Vogel-Claussen; *Hannover/DE (vogel-claussen.jens@mh-hannover.de)*

In the last decade, functional imaging of the lungs using hyperpolarized noble gases has entered the clinical stage. Both helium (3He) and xenon (129Xe) gas have been thoroughly investigated for their ability to assess both the global and regional patterns of lung ventilation. With advances in polarizer technology and the current transition towards the widely available 129Xe gas, this method is ready for translation to the clinic. Also advantages and disadvantages of hyperpolarized gas functional lung imaging are highlighted and compared to MRI techniques for regional ventilation quantification without the need for hyperpolarization such as 19F MRI and Fourier decomposition ventilation MRI.

Learning Objectives:

1. To learn about the promises and challenges to build a hyperpolarised gas enhanced lung imaging programme.
2. To compare hyperpolarised gas enhanced lung MRI with emerging multinuclear functional lung MRI techniques without the need for hyperpolarised gas.

Author Disclosure:

J. Vogel-Claussen: Advisory Board; Boehringer Ingelheim, Novartis,. Research/Grant Support; Siemens. Speaker; Bayer, Siemens.

A-192 09:26

Available and potential hyperpolarised molecular targets

R. Katz-Brull; *Jerusalem/IL (rkb@hadassah.org.il)*

The dissolution-dynamic nuclear polarization technology had revolutionized the way small molecules can be imaged and their chemical evolution monitored, in physiologically relevant doses, by magnetic resonance imaging and spectroscopy. In this presentation, we will review several molecules that have proven useful as such molecular imaging probes. The specific stable isotopes with which these molecules were labelled will be reviewed (13C, 15N, 2H). The basis for these labelling strategies will be explained, predominantly the effects on MR visibility and T1. Naturally abundant nuclei such as protons and yttrium that are useful for hyperpolarized MRI will also be introduced. The main biochemical pathways that can be followed with hyperpolarized MRI and spectroscopy of these molecular imaging probes will be reviewed in the context of the potential emerging applications for hyperpolarized MRI and spectroscopy.

Learning Objectives:

1. To get an overview of the many targets available for hyperpolarised molecular targets.
2. To understand the basic chemical properties of hyperpolarised MRI molecular imaging probes.
3. To understand the role of stable-isotopes in hyperpolarised MRI.
4. To understand the biochemical processes that can be imaged with hyperpolarised MRI.

09:43

Panel discussion: Is hyperpolarisation worth all the hype?

08:30 - 10:00 **Room L 8**

ESR Research Committee Session

A few examples of European structures for imaging research

A-193 08:30

Chairman's introduction

O. Clément; *Paris/FR*

Session Objectives:

1. To explain the different research activities of ESR.
2. To learn how to set up a research project with EIBIR.
3. To learn how to organise research in an imaging department.
4. To learn how to use imaging biomarkers in clinical studies.

A-194 08:40

How EIBIR can help to prepare and manage a H2020 project

G.P. Krestin; *Rotterdam/NL*

With decreasing national R&D budgets and a substantial increase of the European budget for research, the new framework program Horizon 2020 became an attractive source for funding for many researchers in Europe. However, the competition is fierce and success rates around 3% are discouraging many scientists to engage into a complicated, time-consuming application process with unsecure outcomes. The European Institute for Biomedical Imaging Research (EIBIR) has developed a track record of successful services for imaging scientists engaging into the adventure of submitting a grant application within the Horizon 2020 funding scheme. The European Institute for Biomedical Imaging Research is a non-profit limited liability company that was founded in 2006 by the European Society of Radiology (ESR), dedicated to the coordination of research. EIBIR aims to deliver services to scientists involved in biomedical imaging research by fostering multidisciplinary collaboration. The platform supports research networking activities and plays a key role in spreading good practice, promoting common initiatives and interoperability in the field of biomedical imaging research. The mission of EIBIR is to coordinate research in, and innovation of, biomedical imaging technologies within Europe and support the dissemination of knowledge with the ultimate goal of improving prevention, detection, diagnosis and treatment of disease. EIBIR offers expert advice,

project management and coordination, and dissemination and exploitation services for research projects and clinical studies. This allows researchers to save time and focus on the scientific aspects and ensure the best possible outcome. EIBIR can support both the preparation and the execution of projects.

Learning Objectives:

1. To explain the mission of EIBIR and its organisational structure.
2. To learn about the activities of EIBIR and its Joint Initiatives.
3. To learn about the services offered by EIBIR related to project application and management.

A-195 08:55

Imaging biobanks and big data

E. Neri; *Pisa/IT (emanuele.neri@med.unipi.it)*

Biobanks are collections, repositories and distribution centres of all types of human biological samples. In 2014 the European Society of Radiology established an Imaging Biobanks Working Group of the Research Committee, aimed at defining the concept and scope, exploring the existence, and providing guidelines for the implementation of imaging biobanks. The WG defined imaging biobanks as "organised databases of medical images, and associated imaging biomarkers (radiology and beyond), shared among multiple researchers, linked to other biorepositories" and suggested that biobanks (which focus only on the collection of genotype data) should simultaneously come with a system to collect related clinical or phenotype data. Imaging biobanks may be developed to collect data from the general population. The aim of population-based biobanks is to identify risk factors in the development of disease, to develop prediction models for the stratification of individual risk or to identify markers for early detection of disease. Imaging biobanks may be developed to collect data from a specific disease cohort, such as neurodegenerative disorders, or oncologic diseases in order to understand the genetic nature of cancer or assess the efficacy of drugs and to identify features that may predict treatment response as early on in disease as possible.

Learning Objectives:

1. To understand the concept of imaging biobanks.
2. To learn about the different types of biobanks and imaging biobanks.
3. To have an overview of the existing network of biobanks in Europe and the collaboration between BBMRI and ESR.

A-196 09:10

Role of EIBALL and EORTC to promote imaging biomarkers in clinical studies

N.M. deSouza; *Sutton/UK (nandita.desouza@icr.ac.uk)*

The European Imaging Biomarkers Allowance (a subcommittee of the ESR) works to identify and validate new imaging biomarkers prior to their introduction into clinical trials. In partnership with the EORTC Imaging Group, it is possible to standardise acquisitions for implementation in a multicentre setting and arrange a QA and QC process together with central reading. Both EIBALL and EORTC interact with North America's QIBA in the development of standardised test objects, procedures and protocols for their use in trial set-up and monitoring. The EIBALL-EORTC partnership ensures that imaging biomarkers can be embedded into clinical trials of multiple cancer types through the EORTC's disease oriented groups.

Learning Objectives:

1. To learn the requirements for biomarker standardisation.
2. To understand the requirements for qualitative and quantitative biomarker assessments.
3. To learn how to address biomarker variability.

A-197 09:25

How to organise an imaging research unit within a clinical department: the Force Imaging French project

L.S. Fournier; *Paris/FR*

Radiology and nuclear medicine imaging provide independent and complementary information from clinical examination and biological explorations, such as drug development and validation. In these cases, imaging is not the object of the research but a tool to measure outcomes, therefore its quality must be assured to guarantee the quality of the overall research data. This clinical research occurs on imaging platforms in public or private structures, most of which are part of clinical departments organised to deal with clinical care. There are several challenges to integrate a research among a clinical workflow. First, the volume of imaging dedicated to clinical research is steadily increasing, as imaging is recognised as giving useful biomarkers of disease and drug efficacy. Second, the quality assurance and quality control required are also becoming more stringent. However, there has not been a proportional investment in departments in terms of material and personnel resources. Faced with this, we formed a working group named FORCE Imaging dedicated to make recommendations for the organisation of imaging research units in clinical departments, including image standardisation, quality control, archiving and processing. The issue of financing was also addressed, proposing a unified national grid for overcosts intended for supporting dedicated imaging CRAs.

Learning Objectives:

1. To learn about the French national initiative to organise imaging research units in clinical departments.
2. To understand the challenges of managing research patients among a clinical routine workflow.
3. To learn about solutions to allow an economically viable organisation for clinical research in imaging departments.

09:40

Panel discussion: Imaging biomarkers as a roadmap for promoting imaging research in Europe

08:30 - 10:00 **Room E1**

Breast

RC 502

The high-risk lesions enigma

Moderator:
F. Kilburn-Toppin; Cambridge/UK

A-198 08:30

A. Lesions with an elevated risk for breast cancer

G. Forrai; *Budapest/HU (forrai.gabor@t-online.hu)*

The histological, clinical presentation, together with the mammography and US appearance of the high-risk lesions would be demonstrated. They have very different probability figures of developing cancer, this would be detailed for each type of lesion. The concept and the global problem of the management of these lesions will be explained, together with the conflict of over/under-diagnosis/treatment.

Learning Objectives:

1. To learn about different types of high-risk lesions.
2. To become familiar with the risk of developing a cancer.
3. To appreciate the different imaging modalities for diagnosis.

A-199 09:00

B. Value of breast MRI: rate of underestimation and impact on treatment decision

R.M. Mann; *Nijmegen/NL (r.mann@rad.umcn.nl)*

The evaluation of high-risk lesions on biopsy with MRI is commonly performed. One of the major ideas is to ascertain that there is not more disease present than seen with other techniques. As many high-risk lesions are in fact accidental findings on needle biopsy the absence of enhancement within the breast reduces the likelihood of more extensive disease. Nevertheless, the underestimation rate with MRI is dependent on the type of high-risk lesion initially found and is still substantial for lesions like atypical ductal hyperplasia and lobular neoplasia. Moreover, several high-risk lesions may in fact enhance strongly in breast MRI, but are not upgraded at subsequent pathological assessment. In this lecture, MRI features of common and less common high-risk lesions will be discussed. In general, MRI cannot preclude the need for extensive tissue sampling, but it may be used for guiding of the biopsy and may obviate complete surgical excision.

Learning Objectives:

1. To learn about the evidence based on MRI in evaluating high-risk lesions.
2. To become familiar with different imaging appearances of high-risk lesions.
3. To appreciate the added value for diagnosis and treatment decision.

C. Could surgery be avoided?

S.J. Vinnicombe; *Dundee/UK (s.vinnicombe@dundee.ac.uk)*

Within the UK National Health Service Breast Screening Programme (NHSBSP), a median of 7% of screen detected lesions subjected to needle core biopsy are categorised as B3, of uncertain malignant potential. These lesions are either heterogeneous (such that, though the area sampled by needle core is benign, this may not be representative) or they may be associated with malignancy (in-situ or invasive) - or both. They comprise a group of pathological entities with or without epithelial atypia, which have a variable rate of upgrade to malignancy on surgical excision biopsy, which until recently has been the diagnostic procedure of choice. With increasing

concerns about overdiagnosis (and subsequent overtreatment) in breast screening programmes and widespread availability of large bore vacuum-assisted biopsy (VAB) or excision (VAE), it is timely to consider alternative minimally invasive modes of treatment for these lesions. Various techniques are available, from large bore vacuum-assisted devices where the lesion is removed in a piecemeal fashion, through to devices which remove the lesion in its entirety with a single pass. These approaches to management of B3 lesions are cost-effective and well tolerated, but oncological safety must be the key consideration. In this respect, the literature is challenging to synthesise, since there is wide variability in the rates of surgical excision in differing series and it seems likely that B3 lesions that are surgically excised differ from those treated non-operatively, introducing a source of bias. Nonetheless, many countries are adopting minimally invasive approaches and some consensus has been achieved.

Learning Objectives:

1. To learn about the different non-invasive modalities to excise high-risk lesions.
2. To become familiar with the risk of avoiding surgery.
3. To appreciate the standard protocols in different countries.

Special Focus Session

SF 5a

Stroke, beyond the usual suspects

A-201 08:30

Chairman's introduction

O. Jansen; *Kiel/DE (olav.jansen@uksh.de)*

Stroke is the third leading cause for death and the most often reason for invalidation in modern societies. With the introduction of endovascular thrombectomy, medicine has found a sufficient answer for the most vesting cause of severe strokes; however, acute occlusion of larger brain supplying vessels is responsible for only 10-15% of all acute strokes. Besides microvascular disease and acute haemorrhage, there are more rare causes for acute stroke symptoms which have to be kept in mind in the imaging workup of acute stroke patients. This special focus session will take care for three of these more rare but nevertheless important diseases which can result in acute stroke symptoms.

Session Objectives:

1. To learn that stroke can be a more complex disease than only acute arterial vessel occlusion.
2. To understand the possibilities of advance imaging.
3. To appreciate different diagnostic approaches.

A-202 08:35

Understanding watershed infarcts

P. Mordasini; *Berne/CH*

"no abstract submitted"

Learning Objectives:

1. To understand the pathophysiology of cerebral circulation.
2. To review the difference between “internal” and “external” watershed infarcts.
3. To demonstrate how to diagnose watershed infarcts.

A-203 09:00

Reversible cerebral vasoconstriction syndrome

J. Linn; *Munich/DE*

"no abstract submitted"

Learning Objectives:

1. To understand the pathophysiology and clinical presentation of RVCS.
2. To review imaging findings on CT and MR.
3. To show how the diagnosis can be confirmed on angiography.

A-204 09:25

Thrombosis of cerebral veins and dural sinuses

V. Costalat; *Montpellier/FR*

"no abstract submitted"

Learning Objectives:

1. To review the radiologic anatomy of the intracranial venous system (vascular territories, imaging techniques).
2. To diagnose deep vein and dural sinus thrombosis.
3. To understand cortical vein occlusions.

09:50

Panel discussion: Rational imaging in patients with acute stroke symptoms

Head and Neck

Moderator:

S.S. Özbek; Izmir/TR

A-205 08:30

Sinuses

R. Maroldi; *Brescia/IT (roberto.maroldi@unibs.it)*

Paranasal sinuses are air-filled cavities developed within the bones of the face and skull from invaginations of the nasal cavity. They are composed of four paired sinuses: maxillary and ethmoid (present at birth), frontal and sphenoid (develop during infancy). A mucous blanket covers their ciliated epithelium. The mucus is moved by cilia towards the ostium, from which it eventually drains into the nasal cavity along narrow passages, which may be longer (frontal recess, ethmoid infundibulum) or shorter (superior meatus, spheno-ethmoidal recess). Conditions impairing the drainage may lead to the accumulation of mucus inside the sinuses. The most frequent condition is acute sinusitis (AS), usually due to viral infection, which causes inflammation (and thickening) of the nasal mucosa, consequently blocking the drainage passages. The diagnosis is clinical. Imaging is required only when symptoms suggest bacterial superinfection with possible involvement of the orbit or intracranial structures (veins, meninges). Chronic rhinosinusitis (CRS) is an inflammatory process involving the nose and paranasal sinuses, persisting for 12 weeks or longer. Though frequently a continuation of an unresolved AS, CRS may be noninfectious, related to allergy or other conditions. CRS may manifest as one of three major clinical syndromes: CRS without nasal polyps, CRS with nasal polyps, or allergic fungal rhinosinusitis. CT is indicated to identify the causes of impaired mucus drainage, to map the changes of the mucosa and bone, to precisely delineate the unique individual anatomy of sinuses, which may increase the risk in case of endonasal surgery or hamper the mucus drainage.

Learning Objectives:

1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe common imaging manifestations of inflammatory diseases.
3. To review tumour and tumour-like lesions.

A-206 08:52

Thyroid and parathyroid

A. Levai; *Budapest/HU (andrealevai@freemail.hu)*

The main objectives of this lecture are to review the normal imaging findings and to emphasize the main radiological features in different modalities in benign and malignant thyroid and parathyroid conditions. Normal anatomy and main radiological features of the thyroid and parathyroid gland are covered briefly including description of developmental abnormalities, followed by demonstration of inflammatory diseases and main benign and malignant lesions of the thyroid. Imaging characteristics of Grave’s thyrotoxicosis and common subtypes of thyroiditis will be detailed. Thyroid malignancy - predominantly papillary carcinoma as the most frequent type of thyroid cancer - will be characterized comprehensively. High-resolution ultrasonography is commonly used in the detection of thyroid and parathyroid abnormalities; however, it is frequently unhelpful in distinguishing between benign and malignant lesions. In case of undetermined nodules, diagnosis can be obtained by ultrasound-guided biopsy. Ultrasound can be sufficient in early staging of thyroid cancer; however, CT and MRI is required in more advanced cancer stages to determine extra-thyroid extension and metastatic spread. Imaging of the parathyroid glands revolves around the detection of parathyroid adenomas and hyperplastic parathyroid glands in the setting of hyperparathyroidism. Imaging is also key to determine pre-operative localization of ectopic

parathyroid glands. Scintigraphy and ultrasound are usually the first-line imaging modalities; CT and MRI can be helpful to reveal supernumerary glands, unusual localizations of ectopic parathyroid, as well as persistent/recurrent disease after surgery.

Learning Objectives:

1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe common imaging manifestations of inflammatory diseases.
3. To identify and describe the imaging appearance of malignant pathologies.

A-207 09:15

Salivary glands

S.J. Golding; *Oxford/UK (stephen.golding@nds.ox.ac.uk)*

This presentation offers a clinically orientated approach to imaging salivary gland disease in which the alignment between findings and further management is defined. Salivary imaging has been changed dramatically by the development of cross-sectional imaging. Ultrasound, CT and MRI have consigned radiographs and sialograms to a subsidiary role. Scintigraphy offers the best measure of global salivary gland function but currently is not widely used in practice. Today investigation is closely related to the underlying pathology of salivary disorders and to providing reliable guide to surgical or medical treatment. Masses are well detected by cross-sectional imaging, which provides accurate guidance on appropriate approaches for surgical management. Differential diagnosis cannot always be achieved but this is rarely a clinical problem because biopsy or resection is usually indicated. Sialography remains a reliable method of showing calculi and ductal changes in sialadenitis but cross-sectional techniques, especially ultrasound and MRI, have advantages in inflammatory disease and complete sensitivity in detecting ductal disease may not be necessary in practice because patients may be treated symptomatically. A strong case can be made for using MRI as sole investigation as this has been shown to be sensitive to both surgical and medical conditions. On this basis, the radiologist may be well placed to offer a primary referral service with triage, directing clinical management of patients or further referral on the basis of findings on MRI. Salivary interventional techniques have more recently extended the role of the radiologist.

Learning Objectives:

1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe common imaging manifestations of inflammatory diseases.
3. To identify and describe the imaging appearance of malignant pathologies.

A-208 09:37

Lymph nodes

S.S. Özbek; *Izmir/TR (sureyya.ozbek@ege.edu.tr)*

In case of a visible or palpated neck mass, lymph node enlargement is routinely included in the differential diagnosis list. Medical imaging can be effectively used to distinguish other causes of cervical swelling, as well as normal lymph nodes from abnormal ones. Characteristically, normal lymph nodes have well-defined borders, reniform shape and central fatty hilum contiguous with adjacent cervical fat tissue. Although commonly used as a criterion, nodal size is not reliable in characterizing abnormal lymph nodes. Apart from enlargement, imaging parameters including internal structure, vascularity pattern, degree of enhancement and perinodal tissue changes shed light on the aetiology of any lymphadenopathy, which may be reactive hyperplasia, infection, inflammation or neoplastic infiltration. In children, and in most of the adult cases with a low risk of malignancy, ultrasound is the first choice of imaging modality owing to its radiation-free nature, and due to practical reasons. However, when further characterization of nodal abnormality or evaluation of sonographically inaccessible anatomic locations is required, use of other cross-sectional techniques such as CT and MRI is mandatory. These modalities provide not only more detailed information including anatomic localization, size, number, internal structure and enhancement characteristics of lymph nodes, but also important data about perinodal soft tissue and other associated pathologic processes in the region. Although the choice of imaging modalities to be used in the evaluation of cervical lymph nodes changes according to the means, experience and preferences of institutions, the role of medical imaging remains pivotal and decisive in this common indication.

Learning Objectives:

1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe the imaging features of infectious and inflammatory disorders.
3. To describe the imaging appearance of neoplastic disorders.

08:30 - 10:00 **Room F2**

Oncologic Imaging

RC 516

A multidisciplinary approach to prostate cancer: can we make a difference?

A-209 08:30

Chairman's introduction

B. Hamm; *Berlin/DE (bernd.hamm@charite.de)*

The session deals with the multidisciplinary approach to prostate cancer. First, we will learn about the diagnostic challenges in prostate cancer from the urologist's point of view. This includes an outline of current treatment options and the role of imaging in therapeutic decision-making. Next, the radiologist's point of view will be presented, providing an outline of how to perform and interpret multiparametric MRI and how to use the PIRADS classification system. A radiation oncologist will then outline the rationale for focal treatment of prostate cancer including strategies as to how these treatments can be guided by multiparametric MRI. The session will conclude with a discussion among the speakers and the audience.

Session Objectives:

1. To understand the pathophysiological properties of prostate cancer and its impact on diffusion-weighted imaging and dynamic contrast-enhanced MRI.
2. To understand the necessity of functional MRI (compared with mere morphological MRI) in the assessment of prostate cancer.
3. To learn about PiRADS classification system.
4. To learn about the role of MRI in selecting patient-tailored therapy.
5. To learn about the option of active surveillance vs immediate treatment.

Author Disclosure:

A-210 08:35

A. The urologist: evidence-based clinical decision making

N. Mottet; *St. Etienne/FR (nicolas.mottet@chu-st-etienne.fr)*

Prostate cancer is the third cause of cancer death in men. While systematic screening is not promoted, an individual early diagnosis is standard of care. Based on risk factors (such as family history), PSA and DRE, pathology obtained after sonography-guided biopsies is the only diagnostic possibility. If indicated a normal mpMRI should not rule out the biopsy decision. Although a systematic mpMRI before a first biopsy is not yet recommended, it is standard of care before rebiopsying. This increases the biopsy reliability using a combination of 12 systematic plus targeted scores. The treatment policy is based on individual life expectancy, patient's wishes and staging. The classical risk categories (known as d'Amico's classification) are more and more challenged by information from image results. Apart from biopsy results (number of positive scores, Gleason score) and DRE, the local staging (T stage) is based on MRI. Its sensitivity is mild (intraprostatic localisation, microscopic extracapsular extension). But its specificity is acceptable and the MRI is a must in intermediate-/high-risk situations. It is also mandatory before considering active surveillance. N staging is poorly done, even with the PET. As for M staging, PSMA might represent the future, but remain experimental in 2017. For M staging, bone scan should be replaced by a whole body MRI. However, for mCRPC progression characterisation, bone and CT scan remain standard, as no consensus definition of progression with MRI exists yet.

Learning Objectives:

1. To understand how a diagnosis is established by PSA evaluation and biopsy.
2. To learn about different treatment options: surgery, radiotherapy, local ablative and hormonal treatment; as well as active surveillance.
3. To learn how imaging impacts treatment selection.
4. To understand what the urologist needs to know from the radiologist.

A-211 08:58

B. The radiologist: evidence-based use of multiparametric MRI

H.-P. Schlemmer; *Heidelberg/DE (h.schlemmer@dkfz.de)*

Prostate cancer diagnosis is challenged by significant variability in cancer multifocality and biologic heterogeneity. Risk stratification is urgently required for individualized patient management, particularly as active surveillance and various focal therapy options are nowadays emerging. Several clinical studies have demonstrated that multiparametric MR imaging (mpMR) is advantageous for detection and localisation of significant cancer, for biopsy guidance as well as for local staging. Transrectal or transperineal TRUS/MR image fusion biopsy

methods with targeted +/- random biopsies have been proven beneficial for improved diagnosis and risk assessment, particularly also in case of negative (cancer free) results. In active surveillance the combination of morphologic and functional MR data represent important objective and reproducible biomarkers for monitoring individual temporal changes of cancer size and aggressiveness. Standardization and quality assurance of mpMR is challenging, however, particularly concerning DWI, which has been proven most important for detection and characterisation of peripheral zone cancers. Standardised high-quality mpMR including standardized reporting according to PI-RADS has been proven to be important for individualised decision making. Standardisation is of clinical relevance concerning improved image acquisition, interpretation, documentation and communication. This lecture will provide detailed knowledge about evidence-based "state-of-the-art" mpMRI according to PI-RADS. It will specify how mpMRI can improve the complex management of prostate cancer patients.

Learning Objectives:

1. To learn how to perform and interpret multiparametric MRI.
2. To become familiar with the PiRADS classification system.
3. To become familiar with the role of imaging for patient stratification and treatment planning.

A-212 09:21

C. The radiation oncologist

D. Georg; *Vienna/AT (dietmar.georg@meduniwien.ac.at)*

Various treatment techniques are successfully used for treating prostate cancer (PCa) with irradiation. In conventional radiation therapy, the tumour volume is irradiated with a homogeneous dose and clinical practice is to carry out treatment planning based on a computed tomography (CT). A morphological MRI is often used in addition. However, technology developments and achievements made in radiation oncology during the last decade enable to focus the high-dose irradiation very precisely on the tumour, while sparing of the surrounding normal tissue. Improved precision of treatment planning and delivery warrant equally precise tumour definition; moreover, new treatment concepts are stimulated by the advancements in medical imaging to visualize and quantify biological, physiological and pathological processes. During the last years, positron emission tomography (PET), perfusion computed tomography (CT) and especially multiparametric magnetic resonance imaging (mp-MRI) have been continuously explored for lesion characterization, improved target definition and response assessment for radiotherapy of PCa. Elucidating tumour biology and identifying subvolumes of more aggressive behaviour, which are often radiotherapy resistant, are feasible with mp-MRI. The concept of inhomogeneous tumour irradiation according to its biological behaviour, called dose painting, is motivated by selective dose escalation based on biological tumour characteristics. This approach may lead not only to higher local control but also to better sparing of normal surrounding tissue. With the clinical implementation of dose painting, improvements in the therapeutic outcome can be expected. Due to the existing technical challenges, extensive collaboration between radiation oncologists, radiologists, medical physicists and radiation biologists is needed.

Learning Objectives:

1. To learn the rationale and scientific basis for focal therapies for prostate cancer.
2. To learn how focal therapies are performed in prostate cancer.
3. To learn through personal experience and from literature how multiparametric MRI can guide focal therapies of the prostate.

09:44

Panel discussion: Prostate cancer: evidence-based multidisciplinary approach to imaging and treatment

08:30 - 10:00 **Room D**

Musculoskeletal

RC 510

Musculoskeletal ultrasound in the management of sports injuries

Moderator:
C. Cyteval; Montpellier/FR

A-213 08:30

A. Ultrasound of foot and ankle injuries: technique and diagnosis

C. Martinoli; *Genoa/IT (carlo.martinoli@libero.it)*

In sports injuries, the role of ultrasound (US) has become increasingly important in the assessment of tendons, joints, ligaments and other soft tissue injuries about the foot and ankle. With many structures to be examined, the US examination should be focused on clinical findings in an attempt to save time and increase the efficacy of the study. In eversion trauma, the status of the anterior tibiotalar, anterior tibiofibular and calcaneofibular ligaments can be assessed with effective results by means of static and dynamic scans. Some midtarsal ligaments (e.g. dorsal calcaneocuboid, superior talonavicular, bifurcate) can be also evaluated. In inversion injuries, US can detect abnormalities affecting the individual bundles of the medial ligamentous complex (i.e. tibiotalar, tibiocalcanear, tibiospring and tibionavicular). US can diagnose peroneal tendon instability based on tendon displacement relative to the malleolar groove and recognize retinacular/periosteal tears. Dynamic scanning can help to detect cases of intermittent subluxation. Longitudinal splits of the peroneus brevis is well recognized with this technique. Occult fractures (i.e. lateral talar process) and ankle neuropathies (i.e. superficial, deep peroneal) may be detected occasionally in sports injuries. At hindfoot level, US can provide diagnosis and percutaneous treatment of Achilles tendinopathy and plantar fascia injuries.

Learning Objectives:

1. To become familiar with ultrasound findings seen in ankle instability.
2. To learn about the ultrasound patterns of tendon abnormalities.

A-214 09:00

B. Ultrasound of the hip and knee: what is it good for and what are its limitations?

E. Rowbotham; *Leeds/UK (emmarowbotham@doctors.org.uk)*

The high-resolution nature of ultrasound coupled with its dynamic capabilities make this an ideal modality for assessing the soft tissues about the hip and knee joints. Assessment of the tendons for tendinopathy, tears or rupture is a common indication alongside evaluation of the collateral ligaments at the knee and snapping hip syndromes at the hip. In the athletic population, muscle tears are extremely common; ultrasound may be used to demonstrate both the site and extent of a muscle tear in the majority of situations. However, ultrasound is less sensitive than MRI to low-grade tears where there is little in the way of muscle fibre disruption or where the injury is imaged very early following the event. Ultrasound is particularly useful when image-guided intervention around either the hip joint or knee joint is performed to ensure accurate placement or injectate or aspiration of haematoma. However, it is also important to recognise the limitations of this technique and where either plain film, MRI or CT may be needed either in addition or instead of ultrasound. These indications include assessment of cartilage, bone marrow oedema, intra articular bodies, low grade muscle injuries and assessment of the meniscus at the knee and the labrum at the hip.

Learning Objectives:

1. To become familiar with examination technique and typical findings of ultrasound of the hip and knee.
2. To understand the limitations of ultrasound of the hip and knee.

A-215 09:30

C. Ultrasound-guided intervention in the athlete: indications and techniques

H. Guerini; *Paris/FR (henri.guerini@gmail.com)*

Diagnostic and interventional ultrasound is a rapidly evolving field in sports medicine. The use of ultrasound has increased exponentially during the past decade. Ultrasound-guided procedure is performed for joint and tendon sheath injections with PRP or steroïd drugs. We will discuss of the the indications, technical considerations about interventional ultrasound in sports medicine.

Learning Objectives:

1. To become familiar with the indications for ultrasound-guided interventions in the athlete.
2. To learn about the different injection techniques.

08:30 - 10:00 **Room G**

Special Focus Session

SF 5b

Diffusion-weighted imaging (DWI): from physics to practice

A-216 08:30

Chairman's introduction

N. Papanikolaou; *Lisbon/PT (npapan@npapan.com)*

Diffusion-weighted MR imaging (DWI), based on the thermally driven random motion of water molecules (otherwise called Brownian motion) has been increasingly applied in the evaluation of a wide variety of oncological diseases not only in the brain but in the body during recent years. Promising results for improved detection and treatment evaluation, in terms of prediction and early response assessment, have been reported. DWI is probing water mobility propelled by thermal energy, and since water molecules are interacting with cellular membranes or other structures, DWI has the potential to provide us with information regarding the cellular architecture in a non-invasive manner. The apparent diffusion coefficient (ADC) is a property of tissue that reflects local water mobility. In the presence of pathology, ADC, has been correlated with important histologic properties, including the tumour proliferation index, tumour grade, the presence of necrosis, and tumour cell apoptosis. The model that is used to calculate the ADC value is based on a mono-exponential function that generally works well. However, in the presence of increased vascularity, there is a second component that is called microperfusion and needs to be taken into consideration. In that case, the use of a bi-exponential function where ADC is decomposed into D and D*, the true diffusion coefficient and the microperfusion coefficient is providing more accurate modelling of diffusion signals. In the presence of increased tissue heterogeneity, a non-Gaussian diffusion model should be considered to take into account the interactions between water molecules and local tissue architecture components.

Session Objectives:

1. To review the basic theoretical and technical aspects behind DWI.
2. To discuss the clinical yield of DWI in the brain and body.
3. To compare DWI with other modalities like PET/CT for whole-body applications.

A-217 08:35

The physics behind the images: diffusion in oncology

T. Scheenen; *Nijmegen/NL (tom.scheenen@radboudumc.nl)*

Next to T1- and T2-weighted MR imaging, diffusion-weighted imaging plays an increasing role in the detection and characterization of cancer in a variety of soft tissues. DWI probes the random displacement of water molecules by applying a pair of pulsed magnetic field gradients with a certain amplitude, duration and spacing (the labelling time), summarized in the so-called b-value. From DWI of at least two b-values, the apparent diffusion coefficient image (ADC) can be calculated. Within DWI labelling times, in the order of tens of milliseconds, the random displacements are usually restricted by the presence of cells, cell organelles and extracellular structure elements. Differences herein will cause differences in the mean displacements of water in the DWI labelling time, which results in contrast in the ADC image. Cancer tissue often exhibits high cellular densities, restricting water motion, lowering the ADC values compared to nearby healthy or non-cancer tissue. In this talk, the concepts of DWI, the origin of its contrast and examples of clinical applications will be shown.

Learning Objectives:

1. To understand the basics of measuring diffusion with MRI.
2. To understand the concept of b-value, and its shortcomings.
3. To explain contrast mechanism of DWI.
4. To review established and potential clinical applications of DWI in oncology.

A-218 08:58

Diffusion in the brain

A. Radbruch; *Heidelberg/DE*

"no abstract submitted"

Learning Objectives:

1. To differentiate pseudoprogression from pseudoresponse in glioma patients with DWI.
2. To analyse the contribution of DWI in glioma radiomics.
3. To define the role of DWI in ischaemic stroke.

A-219 09:21

Whole-body diffusion

A.R. Padhani; *London/UK (anwar.padhani@talk21.com)*

The disease detection and response assessment performance of WB-MRI is enhanced by adding DWI sequences, which also help to overcome some of the limitations of morphologic sequences. When evaluating test performance, it should be noted that there are intrinsic verification biases particularly prevalent on lesion-level analyses because it is simply not possible to obtain histopathology for every lesion detected. The potential exists that WB-MRI are suitable for wide deployment in disease detection settings, given their test performance, potential wide availability, and multiorgan evaluation capabilities. Sufficient data now indicate that WB-MRI has better accuracy for detecting bone metastases than bone scans to confidently recommend use for bone metastasis detection. Preclinical and small-scale clinical studies indicate that ADC changes can be useful for assessing therapy response but there are few systematic studies. To date, however, there are few data on the benefits of treatment modifications based on the earlier detection of treatment failure or primary resistance or on the negative quality of life effects of continued treatments with ineffective drugs. Nevertheless, a recent EORTC position paper concluded that MRI offers a good “one size fits all” solution for patients who do not have substantial non-bone disease to assess therapy effectiveness. The MET-RADS-P imaging recommendations have recently been developed to address that need for standardisation of acquisition, interpretation and reporting of WB-MRI.

Learning Objectives:

1. To provide a rationale for the use of DWI to supplement morphologic assessments in whole-body MRI examination.
2. To show how measurements are acquired in the body and to distinguish between tumour detection and response assessment protocols.
3. To provide interpretation guidelines for disease detection and response assessments including how to recognise false positive and negative cases.
4. To provide the scientific evidence comparing WB-MRI with PET/CT, bone and CT scans for disease detection including areas of potential synergy.

Radiographers

RC 514

CT imaging: the role of the radiographer and technological developments

Moderator:

C. Beardmore; London/UK

R. Siemund; Lund/SE

A-220 08:30

A. The role of the radiographer in interventional CT procedures

J. Santos; *Coimbra/PT (joanasantos@estescoimbra.pt)*

Computed tomography (CT) is a valuable medical tool to plan and guide interventional or therapeutic procedures. The interventional procedures can be performed based in 2 dimensions images (2D), image reconstructions (3D) or using CT fluoroscopy. These procedures allow continuous monitoring of needle course to the lesion. CT interventional typical diagnostic procedures are biopsies, which can be done as aspiration or fine-needle biopsies, punch biopsies, or drill biopsies. The goal is to acquire material for a microbiological analysis, to classify tumours before treatment or search for remaining living tumour cells after treatment. Various therapeutic procedures were drainages, tumour/ablation therapy, neurolysis, anesthesia injection and skeletal interventions can also be performed by CT. Several authors described CT fluoroscopy as successful method for percutaneous interventional procedures in the chest, spine, abdomen, and pelvis, however it is particularly more useful for deep structures, liver and lungs. Despise this applications CT fluoroscopy is the high radiation exposure procedure and radiation protection safety measures must apply. However the use of fluoroscopy CT is controversial and interventional procedures are regularly performed based on 2D images. Sterile conditions are required in all the interventions, the scanner room and the CT scanner needs to be carefully cleaned and disinfected, especially the CT table and the gantry. Planning the procedure is recommended in order to protect the staff and decrease the risk of patient’s over exposure and procedures complications. CT interventional procedures require teamwork and

radiographers must be aware and involved in all the phases promoting the safety.

Learning Objectives:

1. To appreciate the clinical role of the most common CT interventional procedures.
2. To understand the role of the radiographer in CT interventional procedures.
3. To be aware of procedure optimisation in order to promote patient and staff safety.

A-221 08:55

B. Optimising CT doses

F. Zarb; *Msida/MT (francis.zarb@um.edu.mt)*

Computed tomography (CT) is well documented as a main contributor to the radiation dose in medical imaging and constitutes the largest provider of radiation exposure to the population from medical imaging examinations. Once justified, CT examinations should be optimised to provide images from which a diagnosis can be obtained using the lowest radiation dose. The purpose of this presentation is to 1) outline the importance of the role of the radiographer throughout the optimisation process which should include all the links of the imaging chain, i.e. x-ray production, x-ray detection, image processing, image display and image interpretation; 2) learn about available methods in evaluating image quality during CT optimisation (the resultant image being the final link in the imaging chain) and 3) discuss the impact of CT optimisation on patient dose and image quality, i.e. limiting radiation exposure to the patient without compromising diagnostic efficacy.

Learning Objectives:

1. To appreciate the role of the radiographer in CT optimisation.
2. To learn about different ways of evaluating image quality resulting from CT dose optimisation strategies.
3. To discuss the impact of CT dose optimisation on patient radiation dose and image quality.

A-222 09:20

C. State-of-the-art CT technology

S.D. Mørup; *Odense/DK (sdmo@ucl.dk)*

In recent years, the manufacturers of computed tomography (CT) have developed several new applications that continue to make it possible to improve the image quality and reduce the radiation dose to the patient in CT. Radiographers must understand and appreciate these new applications and be able to use them wisely to achieve a dose reduction without compromising the image quality. There is no single method that works perfectly for all diagnostic challenges in CT and, therefore, the radiographer should be aware of the advantages and disadvantages when applying different new methods for dose reduction or for improving the image quality. This presentation discusses present challenges related to the new developments in CT, some of the developments are the organ effective modulation, which is a technique that delivers safer exams for patients by limiting the dose to radiosensitive organs like the breast or lens. Other applications are the automatic kV selection and improved software that can reduce metal artefacts without the use of dual energy or increasing the radiation dose.

Learning Objectives:

1. To appreciate new development in hardware and software with regards to image quality and radiation dose in CT.
2. To learn about the disadvantages of the new technologies in regards to the image quality and radiation dose.
3. To discuss how the radiographer can combine these new technologies with regard to image quality and radiation dose.

09:45

A. New beads and new drugs: new indications

S.N. Goldberg; *Jerusalem/IL (sgoldber@bidmc.harvard.edu)*

Primary liver cancer is the second most common cause of cancer-related deaths worldwide. As most patients present with intermediate to advanced stage disease, non-amendable to curative therapies (i.e. ablation, resection or liver transplant), catheter-based intra-arterial therapies have meanwhile become officially incorporated into treatment guidelines. The most commonly used modality, transarterial chemoembolization or TACE, uses the preferentially arterial blood supply of liver tumours (both primary and metastatic) to deliver a highly concentrated cocktail of embolic material and chemotherapeutic agents directly to the target lesion while preserving healthy liver tissue with is preferentially supplied by the portal vein. This talk will discuss the rationale for TACE in a variety of clinical scenarios and provide an overview of the most recently available data on different drug-eluting particles and drug delivery platforms. Furthermore, most recent evidence and clinical trial data for the combination of TACE with systemically applicable anti-angiogenic agents will be discussed. Finally, novel intra-procedural imaging technologies for improved targeting as well as assessment of treatment response will be summarized.

Learning Objectives:

1. To explain new technological improvement with regards beads.
2. To discuss about new drugs potentially used for chemoembolisation.
3. To review experimental literature as well as preliminary experience on the use of new devices and drugs for liver chemoembolisation.

Author Disclosure:

S.N. Goldberg: Consultant; Angiodynamics, Cosman Instruments. Research/Grant Support; Angiodynamics.

A-224 09:00

B. Prostate arterial embolisation

H. Rio Tinto; *Lisbon/PT (hugo.tinto@gmail.com)*

Benign prostatic hyperplasia (BPH) has a prevalence of more than 50% in men over 60 years. It is associated with lower urinary tract symptoms (LUTS). The indication treatment depends on disease staging. Medical therapy is usually the first-line treatment. TURP is the gold standard surgical treatment for BPH. There are several minimally invasive treatments that offer safety and efficacy and are valid options without the burden and risk of operative morbidity. Prostatic arterial embolisation (PAE) for BPH has been shown as a safe and effective procedure after failure of medical therapy. Unilateral femoral approach is routinely used; a catheter is advanced to the anterior division of the internal iliac artery. First angiograms with specific angulations are performed to identify the prostatic arteries. Deep knowledge of the pelvic arterial anatomy is essential since there are several variations. Selective access is performed with a micro-catheter. The embolisation material of choice is spherical particles. Controlled embolisation is crucial to avoid non-target embolisation until near stasis is achieved. It is a minimally invasive treatment that can be performed as an outpatient procedure. Short and mid-term studies in BPH have shown that PAE also improves LUTS related to BPH. Potential major complications are associated with non-target embolisation but in experienced hands the rate is extremely low. The most frequent minor complications are perineal pain, haematuria, haematospermia, transient urinary retention and others associated with femoral access.

Learning Objectives:

1. To learn about anatomic variations of prostatic vasculature and technical difficulties of embolisation.
2. To understand clinical indications - who is a good candidate for embolisation?
3. To review the results and possible advantage for minimally invasive treatment.

A-225 09:30

C. Haemorrhoid embolisation

T. Jargiello; *Lublin/PL (tojarg@interia.pl)*

Haemorrhoidal disease is the most common proctologic pathology with the prevalence of up to 35%. Anorectal discomfort, pain and of course bleeding are typical symptoms. Evaluating pathophysiology of this disease it was stated that haemorrhoids are not varicose veins but they are the normal tissue - a sort of physiological network of small arterioles and venous spaces. This part of rectum is called the corpus cavernosum recti and its role is not to bring oxygen but to create the cushion with functional role as the anal closure. This pathophysiologic mechanism together with theory of high arterial flow causing haemorrhoids gave basic thinking of possible arterial embolization of superior rectal arteries in the endovascular treatment of the disease. Minimally invasive embolization seems to be less harmful for the patient and similarly effective when compared with alternative surgical therapies like: open haemorrhoidectomy, Longo technique or Doppler-guided haemorrhoid artery ligation. The technique of haemorrhoid embolization is not very sophisticated - it is routine microcoil placement into both superior rectal arteries, usually at the level of superior edge of pubic arch. Some operators use also embolic particles. The potential benefit of endovascular treatment is the absence of direct anorectal trauma but we still do not know which arteries should be embolised (possible anastomoses) and how to choose the ideal patient?

Learning Objectives:

1. To understand vascular anatomy of the rectum and arterial physiology of haemorrhoids.
2. To review other treatment options.
3. To learn about haemorrhoid embolisation technique.

08:30 - 10:00 **Room M 2**

ESR Audit and Standards Session

How (Euro)safe is your department?

Moderator:
B.E. Kelly; Belfast/IE

A-226 08:30

Audit and raising the standard: the role of audit in 2017

M.F.J. Ryan; *Cork/IE*

Clinical Audit is considered to be a tool designed to improve the quality of patient care experiences and outcomes though the formal review of systems, pathways and outcomes of care against defined standards and the implementation of change on the basis of the results. There is wide variation in the understanding and implementation of clinical audits in Europe.

Learning Objectives:

1. To understand the definition and function of audit.
2. To learn about the distinction between audit and research.
3. To appreciate the importance of reaudit.

A-227 08:50

Auditing the auditors: safe health care professionals in safe departments

P. Soffia; *Santiago/CL (psoffia@alemana.cl)*

For radiologists to change the way they are perceived they will have to establish their value, not just as report generators, but as guardians of patient safety through efficient management with justification of every study and optimization of radiation exposure. Appraisal and revalidation of radiologists is mandatory for today standards. In most developed countries, there are official mechanisms for certification and re-certification of radiologists, but every department should have its own appraisal system for evaluating staff on a regular basis. This evaluation should consider not only both knowledge and technical skills but also soft skills, such as communication, ethics and professionalism. Professionalism is a key issue for most doctor and radiologists are not an exception. Disruptive behaviour of radiologists is not an uncommon problem in large imaging departments having a significant medical, economic and emotional consequences. Thus, every medical organization has to establish essential aspects to deal with disruptive behaviour. An organized and standarized approach is recommended and must be documented. Most authors recommend including a zero tolerance policy. Considering that reporting errors is a key indicator of quality, discrepancy meetings are an excellent way to improve practice learning from errors. These meeting should take place periodically and should not be punitive. Finally, communications within the radiology department are crucial, specially in organ-based practices with little interaction between staff radiologists from different subspecialities. An effective way to improve communication is a schedule of weekly meetings of quality and safety with participation of radiologists from different sections within the department.

Learning Objectives:

1. To learn about appraisal and revalidation.
2. To learn about managing the failing doctor.
3. To understand discrepancy meetings, root cause analysis and no blame culture.
4. To hear examples of effective communication within and between radiology departments.

A-228 09:10

Audit: what a regulator needs to know

S. Ebdon-Jackson; *Didcot/UK (steve.ebdon-jackson@phe.gov.uk)*

Within the European Union, legislation and regulations relating to the hazards of ionising radiation in medical exposures are addressed in Euratom Directives 97/43 and 2013/59. These directives both require that clinical audits are carried out in accordance with national procedures and national regulations should reflect this. The directives deliberately avoid detail, recognising that clinical audit has wide application across medicine and not just in radiation specialities. Member states may wish to transpose this requirement in different ways, but all European regulators will wish to see that implementation of the directives is meaningful. There is widespread acceptance that the processes of inspection by regulators and professionally led clinical audit should and will differ. Nevertheless, regulators will wish to see how clinical audit can help to demonstrate appropriate implementation of the key principles of justification and optimisation as well as other legal requirements.

Learning Objectives:

1. To learn about National Standards and local guidelines.
2. To understand systems to ensure patient safety.
3. To learn about minimising ionizing radiation exposure to staff and patients.

A-229 09:30

Audit and the patient journey

E. Briers; *Brussels/BE (erikbriers@telenet.be)*

The radiology department is part of medical professionals involved in the care of patients. The patient is referred to the department by his clinician who may have explained the purpose of the visit but maybe not what to expect once in the department. We can state that once the patient crosses the threshold of the department, the department is in charge of the patient, as well for optimal results (outcome) as for a smooth journey through the department. The quality of the journey is influenced by the quality of communication. Modern patients want to know what will happen, meaning before it happens. This requires that this information is available in different forms (print, internet kiosk, etc.) and addressing different levels of literacy. It is clear that the retired university professor of philosophy will need another brochure (if any) compared to the cleaner, and both are entitled to be well informed. Understanding what will happen gives the patient a safe feeling, his first issue may not be the radiation that will be applied but perhaps where the next toilet is, or if the contrast will cause discomfort. Most of communication is “patient” listening to patients to learn what their concerns are so that this smooth journey can be assured. Discussing examination results is no easy task, in serious pathologies the multi-professional approach (example a tumour board) is the preferred route to bring together the information from the many experts, and to only have one line of communication to the patient.

Learning Objectives:

1. To learn about communicating with the patient before, during and after their examination.
2. To appreciate the patient-centred department.
3. To appreciate well thought-through, timely and accurate discussion of examination results.

Interventional Radiology

RC 509

Introduction to percutaneous interventional procedures: a practical guide

A-230 08:30

Chairman's introduction

R. Iezzi; *Rome/IT (roberto.iezzi.md@gmail.com)*

Percutaneous imaging-guided interventions are making an increasing contribution to the treatment of patients with many non-vascular conditions. Minimally invasive techniques enable effective treatment that is followed by rapid recovery, with a low complication rate. However, the effectiveness of such methods of treatment is enhanced by an accurate preprocedural planning, an adequate selection of image guidance technique, as well as an optimal intra/periprocedural sedation. In detail, analgesia and sedation before, during, and after interventional procedures allow a safe, comfortable, and technically successful procedure to be performed. This session will explore different imaging-guided methods to define advantages, disadvantages, as well as tips and tricks for successful percutaneous intervention.

Session Objectives:

1. To appreciate the importance of pre-procedure planning and selection of image guidance technique.
2. To learn about intra-procedure patient analgesia and adjunctive techniques for access to sites for intervention.
3. To discuss tips and tricks for successful percutaneous intervention.

A-231 08:35

A. How to safely perform US-guided procedures

D. Akinci; *Ankara/TR (akincid@hotmail.com)*

Ultrasound (US) guidance is a frequent modality of choice in percutaneous biopsy, drainage and ablation procedures, because it enables continuous real-time visualization, is radiation free, has a lower cost and is better for angled access. In most of the abdominal organ biopsies (e.g. liver, kidney, pancreas and spleen) and drainage of fluid collections, local ablation of liver tumours, drainage of pleural collections, biopsy of peripheral pleural-based thoracic lesions, US guidance is utilized. Endocavitary approaches can be used safely in pelvic biopsy and drainage procedures with transvaginal or transrectal US guidance. Fusion techniques combine US images with CT or MRI images, enabling targeted US-guided biopsy for lesions that are difficult to see on US.

Learning Objectives:

1. To learn about patient positioning for US-guided percutaneous and endocavitary approaches to sites in the body.
2. To learn about real time guidance advantages of US-guided intervention.
3. To explain image fusion techniques for US-guided intervention.

A-232 08:58

B. How to safely perform CT-guided procedures

R. García Marcos; *Valencia/ES (raulgamar@hotmail.com)*

Percutaneous computed tomography (CT) guided is a minimally invasive approach for interventional procedures. Although is a procedure with few complications precise planning and knowledge of the indications, technique and material. CT-guided interventions may be divided into diagnostic (biopsies) and therapeutic interventions (drainages, thermal ablation, vertebroplasty, etc.). The main problems of access to lesions depend on the situation due to poor imagery, mobility and distance. Therefore, we are obliged to know and identify the structures along the established route. Different techniques of CT exist. Multidetector CT is commonly used for guiding percutaneous biopsy and catheter drainage of fluid collections. CT fluoroscopy has the potential to improve the efficacy of CT-guided interventions and to reduce the procedure time. C-arm cone-beam CT (CBCT) is a real-time needle guidance technique that can be used to visualise the needle trajectory from skin to target lesions. The aim of this study is to present the types and advantages of the CT-guided interventions, the patient positioning and adjunctive techniques for access to sites for intervention.

Learning Objectives:

1. To learn about patient positioning for CT-guided percutaneous approaches to sites in the body.
2. To learn the types of CT guidance and advantages of CT-guided intervention.
3. To learn about adjunctive techniques for access to sites for intervention.

A-233 09:21

C. Post-procedure follow-up and complication management

M. Seidensticker; *Magdeburg/DE (max.seidensticker@med.ovgu.de)*

Biopsy procedures bare - although commonly at a low rate - potentially life-threatening risks. To know about potential complications and proper patient monitoring is the key to identify the complications and to react accordingly. The lecture will give information about common and uncommon complications after biopsy procedures and help will be given to identify the patient at risk and how to avoid/reduce specific complications. Further on, management of complications will be addressed. Of note, not all complications are avoidable, but proper patient management helps to reduce associated morbidity and mortality.

Learning Objectives:

1. To appreciate the potential for complications in common biopsy procedures.
2. To learn about management of post-procedure complications.
3. To discuss the role of quality improvement.

New challenges of pancreatitis

A-234 08:30

Chairman's introduction

M.A. Bali; *Sutton/UK (mantoniettabali@icr.ac.uk)*

The 1992 Atlanta Classification aimed to promote uniformity in terminology to facilitate communication among clinicians. The 2012 revision provides a more comprehensive classification of AP and peripancreatic collections and gives new information about the aetiology, pathophysiology, severity and radiologic findings. The role of imaging is: 1. to confirm the diagnosis (non-conclusive clinical/laboratory findings); 2. to detect the cause; 3. to stage the severity; 4. to detect the complications; 5. to guide the treatment. Autoimmune pancreatitis is a distinct form of pancreatitis presenting with obstructive jaundice, periductal lymphoplasmacytic infiltrate (IgG4-positive cells) and fibrosis at histology and response to corticosteroids. Type I (IgG4-related lymphoplasmacytic sclerosing pancreatitis, pancreatic manifestation of IgG4-related diseases demonstrates diffuse pancreatic enlargement ("sausage-shaped" in 30-50%), delayed enhancement at the venous phase, highly specific low-attenuating rim (30-40% of cases), long main pancreatic duct stricture without marked upstream dilatation. Other organs can be involved (bile ducts, kidneys, retroperitoneum). It responds to corticosteroids but 20-60% of the cases will relapse. Type II (idiopathic duct-centric pancreatitis) is less common with pancreatic-limited disease and no extra-pancreatic involvement . The imaging findings are similar to type I. Disease relapse after corticosteroids is rare. Pancreatic cystic lesions (PCL) represent a significant clinical entity. According to WHO, PCL include epithelial and non-epithelial neoplasm classified as benign, potentially malignant and malignant. The diagnosis includes patient clinical data, imaging findings and cystic-fluid analysis. Several imaging findings allow differential diagnosis and may be suggestive of malignancy. However, cystic lesions smaller than 3 cm may lack specific morphologic features.

A-235 08:35

A. Understanding the Atlanta 2012 classification of acute pancreatitis

W. Schima; *Vienna/AT (wolfgang.schima@khgh.at)*

According to the Revised Atlanta Classification of 2012, acute pancreatitis is categorized as interstitial oedematous or necrotizing pancreatitis. In interstitial oedematous pancreatitis, acute peripancreatic fluid collections may occur early (< 4 weeks from). In the late phase, these either resolve or evolve into pseudocysts, which are hypodense at CT and hyperintense on T2w MRI. Treatment of pseudocysts is indicated in symptomatic patients or if complications (gastric outlet obstruction, cholestasis or haemorrhage) develop. Necrotizing pancreatitis may present with combined pancreatic and peripancreatic or pancreatic necrosis or peripancreatic necrosis alone. Acute necrotic collections may evolve into walled-off necrosis (WON) in the late stage (≥ 4 weeks). A WON containing digested fat and parenchyma must not be confused with a pseudocyst. They are similar on CT, but US/MRI reveal the

predominantly solid nature of WON. Secondary infection of necrotizing pancreatitis results in high mortality. Diagnosis of infection is difficult based on imaging. Gas within a collection is not sensitive, but specific. If feasible, CT-guided abscess drainage is recommended. Necrotic collections with debris require a more aggressive approach. In general, MDCT for diagnosis of pancreatitis should be performed no less than 2-3 days from clinical onset, because development of necrosis may take some time. In case of suspected biliary pancreatitis, early MRCP guides further treatment (ERCP and stone removal). The Revised Atlanta Classification system introduces a uniform terminology for imaging features of pancreatitis. Contrast-enhanced CT is the primary tool of diagnostic imaging and image-guided therapy. MRCP characterizes fluid collections and delineates the duct system.

Learning Objectives:

1. To be aware of the new terminology for the evaluation of acute pancreatitis.
2. To learn about how to report imaging findings.
3. To understand the relationship between imaging findings and prognosis.

A-236 09:03

B. Autoimmune pancreatitis and its relatives

G. Morana; *Treviso/IT (gmorana@ulss.tv.it)*

Autoimmune pancreatitis (AIP) is a immune disorder affecting the pancreas, with or without a pancreatic mass, characterized by a dramatic clinical response to steroids. Symptoms are similar to that of pancreatic cancer: fluctuating obstructive jaundice, vague abdominal pain, weight loss, steatorrhoea and diabetes due to decline in exocrine function. AIP is subdivided into: Type 1: is the pancreatic manifestation of an IgG4-related systemic disease and is characterized by elevated IgG4 serum levels, infiltration of IgG4-positive plasma cells and extrapancreatic lesions. Type 2: usually has none or very few IgG4-positive plasma cells, no serum IgG4 elevation and appears to be a pancreas-specific disorder without extrapancreatic involvement. There are three patterns of autoimmune pancreatitis: diffuse disease is the most common type, with a “sausage-like” diffuse pancreatic enlargement with sharp margins and loss of the lobular contours; focal disease is less common and manifests as a focal mass, mimicking a pancreatic malignancy. Focal disease tends to be relatively well demarcated and, when present, upstream dilation of the main pancreatic duct is typically milder than what is observed in patients with pancreatic carcinoma. Multifocal involvement can also be evident. Established imaging criteria allow a confident diagnosis. Differential diagnosis with pancreatic carcinoma is of utmost importance to establish the optimal therapeutic strategy and to avoid unnecessary laparotomy or pancreatic resection in AIP patients. Non-invasive imaging plays also an important role in OOI in case of Type I AIP, therapy monitoring, in follow-up and in early identification of disease recurrence.

Learning Objectives:

1. To understand the various forms of autoimmune pancreatitis, especially cases that are associated with extra pancreatic disease.
2. To learn about the usual and unusual appearance of autoimmune pancreatitis.
3. To understand the principles of the follow-up.

Author Disclosure:

G. Morana: Speaker; BRACCO IMAGING SpA.

A-237 09:31

C. Tough clinical cases of cystic pancreatic lesions

M. Karcaaltincaba; *Ankara/TR (musturayk@yahoo.com)*

Cystic lesions are the most common lesion in pancreas, particularly in the elderly. Crucial points in reporting of a cystic lesion will be reviewed, which are size, location, septal enhancement, mural nodule and pancreatic duct dilatation. In the absence of worrisome features, cysts can be safely followed up. Weaknesses and strengths of radiologic modalities will be emphasized. The most common cystic lesions of pancreas are serous cystadenoma, intraductal papillary mucinous tumour, mucinous cystadenoma and pancreatitis-related cysts. Typical and atypical forms of these entities and distinction from malignant lesions will be discussed during the lecture. Finally, difficult cystic pancreatic lesions will be reviewed and imaging findings for correct diagnosis and management will be presented.

Learning Objectives:

1. To understand how to report a cystic pancreatic lesion, including recommendation for imaging strategy.
2. To become familiar with the most common cystic neoplasms of the pancreas.
3. To learn how to differentiate neoplasms and inflammatory cystic lesions of the pancreas.

Author Disclosure:

The ABCs of hybrid imaging

Moderators:
A. Drzezga; Cologne/DE
K. Riklund; Umea/SE

A-238 08:30

A. What you need to know about PET-physics

J. Axelsson; *Umea/SE (jan.e.axelsson@vll.se)*

This lecture covers PET physics without equations, to give a basic understanding of how radioactive decay of anti-matter, positrons, lead to acquisition of positional information of radioactively labelled molecules. In a further step, quantitative tomographic image reconstruction is described. In this step, attenuation correction and the benefits and problems arising from CT-based attenuation correction is described.

Learning Objectives:

1. To understand the basics of physics in PET imaging.
2. To learn about the different approaches of PET attenuation correction.
3. To learn about potential artefacts in hybrid imaging.

A-239 09:00

B. How MR physics influence image quality in hybrid imaging

C. Catana; *Boston, MA/US (ccatana@nmr.mgh.harvard.edu)*

The introduction of combined PET/MR scanners allows the PET emission data to be corrected for photon attenuation effects using the anatomical MR images. This approach has both advantages and limitations. On the one hand, MR eliminates the radiation exposure associated with CT scans. On the other hand, assumptions regarding the composition of the body based on the available morphological information have to be made since the MR signal does not reflect electron densities. MR physics influences PET in several ways, potentially leading to artefacts and bias that could affect qualitative and quantitative PET studies. The purpose of this presentation is to present such artefacts, describe their origin and impact on PET attenuation correction and discuss strategies to overcome them. Artefacts related to bone and lung tissue misclassification, B0 field inhomogeneity, aliasing/wrap-around, positron-range effects, metallic implants, MR contrast agents, MR hardware, image quality phantoms and subject motion will be discussed.

Learning Objectives:

1. To learn about MR for attenuation and motion correction.
2. To learn about MR artefacts influencing PET-quality.
3. To understand the complexity of physics in MR/PET.

Author Disclosure:

E³ - ECR Academies: Interactive Teaching Sessions for Young (and not so Young) Radiologists

E³ 621
Emergency radiology II

A-242 10:30
A. Abdominal vascular emergencies
A. Palkó; *Szeged/HU (palkoand@gmail.com)*

The goal of this problem-oriented, case-based presentation is to involve the audience in an interactive communication aimed at clarifying and clearly understanding the role and clinical significance of imaging and image-guided intervention in the diagnosis and treatment of abdominal vascular emergencies. We will discuss and solve typical but also unusual cases to introduce the proper diagnostic algorithm providing the fastest possible treatment to the patient in these most frequently very severe, potentially lethal conditions; in which time elapsing between onset of symptoms and correct diagnosis is critical from the point of view of successful therapy and chance of survival.

Learning Objectives:
1. To understand the different types of abdominal vascular emergencies.
2. To learn about imaging findings and treatment options.

Author Disclosure:
A. Palkó: Advisory Board; Affidea.

A-243 11:15
B. Chest trauma
J. Biederer; *Heidelberg/DE (juergen.biederer@med.uni-heidelberg.de)*

Chest trauma involves the respiratory system and the main cardiovascular structures of the body. The respiratory system is the functional unit of lung parenchyma, pleura, airways, vasculature, mediastinum, chest wall and diaphragm. Any trauma to single or multiple of these structures directly or indirectly impairs the genuine task of this complex system, which is to guarantee gas exchange by ventilation and perfusion. The spectrum of traumatic mechanisms to the respiratory system covers blunt and perforating trauma, barotrauma and aspiration of foreign bodies or gases and fluids, or any combination of these. The typical scenarios for blunt trauma of the chest are motor vehicle accidents or deep falls with deceleration leading to lung contusion/laceration and aortic or cardiac injury. Perforating trauma is typically related to stabbing or gunshot. Depending on the intensity of trauma and the structures involved, chest trauma is an immediately life-threatening condition. For ER imaging (whole body CT or “classical” x-ray/ultrasound), this requires fast imaging and an efficient concept for data management, reading and reporting. In severely injured patients, the first look of the radiologist should be for ABC: airway/breathing/circulation. The key diagnostic signs are abnormal lung opacity (aspiration, bleeding, atelectasis, pleural fluid accumulation, chest wall haematoma), pneumothorax/pneumomediastinum (alveolar rupture, tracheobronchial rupture or esophageal injury) or widened mediastinum (aortic/arterial injury, venous injury or fracture of sternum/spine). Fractures of the spine, sternum, clavicle, or scapula are indicative of extreme forces and a high probability of life-threatening injury, such as aortic rupture or cardiac contusion.

Learning Objectives:
1. To understand the imaging technique.
2. To become familiar with the differential diagnosis.

10:30 - 12:00 **Room X**

EuroSafe Imaging Session

EU 2
Focus on appropriate image quality: what we have to know

Moderators:
W. Stiller; Heidelberg/DE
J. Damilakis; Iraklion/GR

A-244 10:30
EuroSafe Imaging on "appropriate image quality": Introduction
S.T. Schindera; *Aarau/CH (sschindera@aol.com)*

To define the appropriate image quality in diagnostic imaging (e.g. CT) is a very challenging task, as many factors, such as the diagnostic task, patient size and technical parameters, can impact the image quality. The goal of the radiologist is to achieve the best diagnosis without harming the patient, which means that the image quality has to be set at a level, where the clinical question can be answered at the lowest achievable dose. Various subjective and objective measurements for image quality have been introduced in the past, which unfortunately have all limitations. To date, a robust, meaningful and easy-to-use measurement for image quality in CT is still missing.

Learning Objectives:
1. To become familiar with the goals and methods of the work on appropriate image quality.
2. To learn about preliminary results and future work for ensuring appropriate image quality in daily imaging routine.

A-245 10:40
Metrics and methods for quantitative image quality determination: a physicist's perspective
C. Hoeschen; *Magdeburg/DE (christoph.hoeschen@ovgu.de)*

The physicist would like to measure image quality as objective as possible to be able to a) compare systems, b) assure constant quality, c) have direct access to procedure optimisation outcomes. The measured image quality should in addition be directly related to the diagnostic quality. The latter is sometimes not a trivial condition. First of all, the talk will present the mathematical basics for Fourier-based (modulation transfer function - MTF, noise power spectrum - NPS, detective quantum efficiency - DQE) as well as task-based image quality metrics (as signal-to-noise ratio - SNR or contrast-to-noise ration - CNR and others) on an easy to understand basis. Possible interlinks will be presented. Afterwards, various options to measure these image quality parameters will be discussed e.g. grating or edge method for projectional image MTF determination, wire or ball characterisation for 3D MTF and noise analysis with Fourier methods or eigenvector and-eigenvalue determination for task based measures. All these will be shown on easy to understand examples from own measurements. Afterwards, a discussion about advantages and potential limitations will follow. Here, the focus will be on aspects of measurement time, generality appropriateness in terms of fulfilment of mathematical conditions, predictivity of diagnostic outcomes. This will be separately investigated for Fourier-based and task based image quality descriptors using examples. The final comments will show the importance of accurate determination of radiation exposure for tasks of quantitative image quality investigations. Again, this will be shown for example on measurements of CNR for mammography image quality evaluation.

Learning Objectives:
1. To learn about mathematical metrics used for the quantitative description of image quality.
2. To become familiar with the methods employed for measuring image quality quantitatively.
3. To understand advantages and limitations of quantitative image quality assessment.

A-246 11:00
Balancing diagnostic image quality and radiation exposure in clinical routine: a radiologist's perspective
H. Geijer; *Örebro/SE (hakan.geijer@regionorebrolan.se)*

The balance between image quality and radiation exposure is not easy to optimise. The goal should be to choose an image quality that is good enough for the diagnostic task at hand, at a radiation exposure that is as low as reasonably achievable according to the ALARA concept. One way to do this is to adjust equipment settings such as tube current (mA) or tube potential (kV). Iterative reconstruction might give the opportunity to reduce the dose settings in CT. Sometimes a change of modality can reduce the radiation exposure.

This was often seen when moving from storage phosphor radiography to flat-panel detectors. Another approach is to improve the diagnostic potential of a method without necessarily reducing the dose. This can sometimes be achieved by moving from radiography to low-dose CT. In the lecture, the efficacy of diagnostic imaging will also be mentioned. Many studies of diagnostic methods stop at measuring the physical characteristics of the image or the sensitivity and specificity of the method, while the really important test of a method is if it benefits the patients, for example, by reducing the mortality or morbidity for those who undergo the test.

Learning Objectives:

1. To learn about the image features mainly determining diagnostic image quality in clinical routine.
2. To become familiar with the factors influencing image quality in clinical practice.
3. To raise awareness of the interrelation between image quality and radiation exposure.

A-247 11:20

Image quality assessment via model observers: connecting objective and subjective perspectives

F.R. Verdun; *Lausanne/CH (Francis.Verdun@chuv.ch)*

The course will focus on the description and implementation of mathematical model observers for objective image quality assessment in CT. The limitations of the standard methods when dealing with iterative reconstruction will be first presented. Then the concept of model observers will be introduced with some background theory in psychophysics. The concept of ideal and anthropomorphic model observers will be discussed together with their strengths and weaknesses. Then practical examples will be given to show how model observers could be used in the framework of the patient dose optimisation. Finally some work in progress will be presented.

Learning Objectives:

1. To become familiar with the concept of model observers for objectively assessing image quality for clinically relevant tasks.
2. To learn about how objective measurements of physical parameters characterising image quality in CT connect to clinically task-based assessment of image quality.
3. To understand the potential and limitations of automated image quality assessment by means of model observers.

A-248 11:40

Implementing a review process on image quality: experiences from a EuroSafe Imaging Star

F. Deferme; *Edegem/BE (filip.deferme@uza.be)*

Implementing a review process on image quality is the logical next step in documenting justified use of ionising radiation. At Antwerp University Hospital, we are implementing a review process on image quality in 3 different areas. The first step is to implement daily quality control (QC) of all x-ray equipment, using a phantom or copper filter. Depending on the outcome, ”thumbs up” or “thumbs down” dashboard view is provided for management (modality-related QC). The second step involves registration of patient age, weight and gender. For every patient group and for every procedure, the radiographer performing the study is profiled for fluoroscopy time, number of retakes and dose per study. This generates an anonymized dashboard overview of all the radiographers within the department. Individual performances are compared to the “Dose Reference Levels” (DRL), with Belgian and European outcomes in a management dashboard (dose-related QC). The third step entails assessment of image quality by identifying: correct use of lead letters for laterality, positioning, radiation exposure, image noise, and absence of artefacts (removal of jewellery, clothing, etc.). This step is done by the radiologist during reporting (image-related QC). The outcomes of all 3 steps are converted into “Key Performance Indicators” (KPI) for modality, workflow and patient safety. KPI can be used for process improvement and education. In conclusion, it is essential to implement this review process in a fully automated software environment, in conjunction with a dose management and registration system.

Learning Objectives:

1. To learn about the criteria employed for assessing image quality of radiologic examinations.
2. To become familiar with the structure and course of the review process and its routine implementation.
3. To learn about the results of the image quality review process, the intervention levels identified, and the actions taken.

Oncologic therapies

Moderator:
O. Akhan; Ankara/TR

A-249 10:30

Kidney

O. Akhan; *Ankara/TR (oakhan@hacettepe.edu.tr)*

RCC is the most common malignant renal tumour accounting for an estimated 2% to 3% of all malignancies in the United States. Although the incidence of renal tumours has reached to a plateau in the developed countries in recent years it is still increasing in developing countries. As the incidence of the incidentally detected renal masses is increased in the last decade, the management of RCC has greatly changed from radical nephrectomy to nephron-sparing treatment options such as partial nephrectomy or local ablative therapies with RFA, microwave or cryoablation. Although guideline of American Urological Association suggests partial nephrectomy as a standard treatment option for the T1 renal masses, local ablative approach with RFA, microwave or cryoablation are getting to be more applied for the treatment. Relative contraindications for the ablative procedures include proximity to the central collecting system, bowel and adrenal glands. These limitations are overcome by the fluid injection along the margin of the targeted lesion by displacing these anatomical structures. The main indications for renal artery embolization (RAE) include preoperative embolization before nephrectomy, treatment of angiomyolipoma, an adjunctive treatment for RCC ablation and for palliation of advanced-stage RCC. RAE is also indicated to reduce blood loss before resection of metastatic RCC.

Learning Objectives:

1. To have a basic knowledge about indications and limitations of interventional radiology procedures in renal malignancies.
2. To have a basic knowledge about embolisation of renal tumours.
3. To become familiar with ablation of renal tumours.

A-250 10:52

Lungs

M. Bezzi; *Rome/IT (mario.bezzi@uniroma1.it)*

Percutaneous needle biopsy has been a mainstay of oncologic diagnosis for more than three decades, since the advent of CT and ultrasound, and has become the standard of care in the diagnosis of most lung tumours and often in lung inflammation. The technique is also beneficial in the staging of patients with cancer, particularly when another treatment method may be more appropriate than surgical resection. Advantages of percutaneous biopsy over surgical excisional biopsy include time and cost savings and reduction in morbidity. Aim of this presentation is to discuss the practical aspects of lung biopsy, needle selection and guidance techniques and to show how to approach difficult lesions and avoid complications. About 70% of patients with lung cancer are not surgical candidates, either due to advanced disease or comorbidities. Thermal ablation is a minimally invasive treatment that is commonly used in this group of patients, with promising results. Currently, the most widely used ablation techniques in the treatment of lung malignancies are radiofrequency ablation (RFA), microwave ablation, and cryoablation. This presentation reviews the application of thermal ablation in the thorax, including patient selection, basics of procedure technique, imaging follow-up, and treatment results.

Learning Objectives:

1. To have a basic knowledge about indications and limitations of interventional radiology procedures in lung malignancies.
2. To have a basic knowledge about image-guided biopsy.
3. To become familiar with ablation of lung cancer.

A-251 11:15

Bones

A. Gangi; *Strasbourg/FR*

"No abstract submitted."

Learning Objectives:

1. To have a basic knowledge about indications and limitations of interventional radiology procedures in bone malignancies.
2. To understand the basic concepts of embolisation of bone tumours.
3. To have a basic knowledge about bone tumours ablation.

A-252 11:37

Liver

J.I. Bilbao; *Pamplona/ES (jibilbao@unav.es)*

The liver has a dual vascular supply with seventy-five percent of the blood coming from the portal vein and the rest from the hepatic artery. Small (<1mm) tumours are initially nourished by portal branches; however, when they start growing they deliver pro-angiogenic agents which may create an arterial network that ensures its vascularisation. Thus, liver tumours are almost exclusively vascularised by the hepatic artery and can be safely treated by an endovascular approach. The angiographic appearance of a liver tumour depends on the amount of the arterio-capillary network and hypervascular tumours are easily detected and more adequate for receiving endovascular treatments. One therapeutic possibility is to occlude the vascular network and close the afferent vessels ("embolisation") provoking ischaemia that will lead to necrosis. However, since the tumour sends continuously pro-angiogenic signals, if there is a decrease in the blood supply the ischaemic effect will trigger an increase in angiogenesis. For abolishing such effect it is possible to add chemotherapeutic agents ("chemoembolisation"), together with the occluding particles, with the aim of obtaining a more complete antineoplastic effect. A different approach consists in the use of small particles just as carriers, with no occluding effect, that will place an anticancer agent intratumourly. When the agent is a radioisotope the procedure is called "radioembolisation", a form of brachytherapy. Using a percutaneous access, some tumours (<3cm) can be punctured with probes through which energy (heat-radiofrequency/microwaves or cold-cryotherapy) is delivered which will lead to tumoural necrosis ("ablation").

Learning Objectives:

1. To understand the basic concepts of chemoembolisation in liver malignancies.
2. To understand the basic concepts of radioembolisation in liver malignancies.
3. To have a basic knowledge about liver tumours ablation.

Pancreatic tumours

A-253 10:30

Chairman's introduction

J. Votrubová; *Prague/CZ (votrubovajana@seznam.cz)*

Pancreatic tumours represent a major challenge to radiologists in their recognition and characterisation. Appropriate radiological examination has become increasingly important for appropriate treatment and survival. A variety of imaging studies, including CT, endoscopic ultrasound (EUS), MR and positron emission tomography with 18F-fluorodeoxyglucose (FDG PET) have important roles to play in the diagnosis, initial staging and follow-up of pancreatic tumours. Primary epithelial neoplasms of the pancreas arise either from the endocrine islet cells or from the exocrine parenchymal tissue. The most often pancreatic malignancy represents pancreatic ductal adenocarcinoma, accounting for 75 to 92% of all pancreatic neoplasms. The extent of surgery may depend on tumour size, location, extrapancreatic extension, vascular involvement , lymph nodes involvement and metastases. The primary goals of imaging include accurate diagnosis and staging and, in patients with locally advanced and/or metastatic disease avoidance of inappropriate radical surgery. Among endocrine pancreatic tumours, insulinoma and gastrinoma often cause symptoms of hormone excess despite their inconspicuous size, but they can be successfully removed with improved pre- and intraoperative localization. Other tumours -glucagonoma, VIPoma and non-functioning endocrine pancreatic tumours - are often large or metastasizing, but generally require surgical debulking to alleviate hormonal symptoms and have favourable survival. In some patients, neuroendocrine pancreatic tumours occur as a part of multiple neuroendocrine neoplasia (MEN 1) syndrome. We herein discuss the currently available imaging modalities and their applications in tumour detection and staging as well as in choice of therapy, imaging follow-up and prediction of response, with emphasis on the recent knowledge.

A-254 10:35

A. Staging adenocarcinoma

N. Kartalis; *Stockholm/SE (nikolaos.kartalis@me.com)*

Pancreatic cancer is a disease with very dismal prognosis. The 5-year survival is around 5% and has been stable over the last decades. The only potential curative treatment is surgical resection combined with adjuvant and/or neoadjuvant medical therapy. However, at diagnosis less than 20% of patients have a resectable tumour, while the rest have tumours that are locally advanced and/or have distant metastases. To improve survival, there is a need to increase the number of patients that undergo surgery. However, for the surgical removal to be meaningful, the goal is to achieve complete macroscopic and microscopic removal of tumour (R0-resection). For the identification of patients who will benefit from surgery, the so-called "resectability status" was developed. It is based on the presence and extent of tumour contact with the major peripancreatic vessels such as portomesenteric axis (PV/SMV), hepatic artery, celiac artery and superior mesenteric artery. Depending on the degree of the circumferential tumour-vessel contact, the tumours are classified into one of the three categories: resectable, borderline resectable and unresectable. The criteria of the various existing classification systems will be discussed and their differences outlined. Furthermore, the role of CT, MRI and PET-CT in the evaluation of these patients will be analysed and, finally, important aspects of the post-operative imaging follow-up will be presented.

Learning Objectives:

1. To understand the rationale behind local staging of pancreatic adenocarcinoma.
2. To learn about the respective role of CT, MRI and PET-CT.
3. To become familiar with the principle of postoperative follow-up.

A-255 11:03

B. Neuroendocrine tumours

R. Manfredi; *Verona/IT (riccardo.manfredi@univr.it)*

Neuroendocrine tumours account for 1.2%-1.5% of all gastrointestinal neoplasms, with an incidence of 1.6-2.0 new cases per 100,000 persons per year. The majority of neuroendocrine tumours occur sporadically, that is, they are non-familial. However, they sometimes occur as part of complex familial endocrine cancer syndromes such as type 1 multiple endocrine neoplasia (MEN 1) and neurofibromatosis type 1. Immunohistochemical staining has played an important role in the diagnosis of neuroendocrine tumours. The neuroendocrine cells of the diffuse neuroendocrine system are characterized by the expression of certain marker protein, such as chromogranin, synaptophysin and neuron-specific enolase (NSE). Clinically, neuroendocrine tumours of the pancreas are classified into functioning and non-functioning tumours, according to the symptoms. Non-functioning, hormonally silent, neuroendocrine tumours (NF-NET) represent 68-80% of all NETs, and are diagnosed because of the mass effect exerted by the tumour. Abdominal pain is the most frequent presenting symptom (35-78%), followed by weight loss (20-35%), anorexia and nausea (45%), palpable mass (7-40%) and jaundice (17-50%). According to the 2010 WHO classification, neuroendocrine neoplasms are classified according to the percentage of Ki67, a protein index of cell replication, on the pathologic specimen. There are three categories: G1, Ki-67 index ≤2%; G2, Ki-67 index between 3% and 20%; G3, with Ki-67 index >20%. At diagnostic imaging, neuroendocrine neoplasms are hypervascular compared to adjacent pancreas in 74% of the cases. Hyper- or isovascularity represents the most suggestive features of neuroendocrine neoplasms that are helpful in the differential diagnosis with adenocarcinoma.

Learning Objectives:

1. To understand the basics of histological classification of neuroendocrine tumours.
2. To learn about the natural history of these tumours.
3. To become familiar with the usual appearance and imaging specificities of neuroendocrine tumours.

A-256 11:31

C. Tough clinical cases

T.C. Lauenstein; *Essen/DE (thomas.lauenstein@evk-duesseldorf.de)*

The ability to non-invasively diagnose and characterise pancreatic tumours has vast therapeutic implications. However, there are several aspects that may impede a reliable characterisation of a pancreatic lesion. While some pancreatic tumours exhibit typical imaging findings, there is often an overlap of imaging findings between different lesions, e.g. pseudotumours due to chronic pancreatitis and adenocarcinoma of the pancreas. We often face the same dilemma as far as cystic pancreatic lesions are concerned since some cystic tumours have a potential for malignant transformation including IPMN or mucinous cystadenomas. Furthermore, there is a large variety of diagnostic tools available for the assessment of pancreatic disease, including ultrasonography, endosonography, CT, MRI and PET. It is important to

understand strengths and weaknesses of these diagnostic modalities particularly in equivocal cases of pancreatic lesions. Eventually, biopsy samples are often needed either to establish a diagnosis or to allow for a more profound histopathological analysis of tumour tissue. Several challenging cases of pancreatic tumours will be presented in this lecture. Differential diagnoses will be discussed and a diagnostic algorithm for each case will be proposed.

Learning Objectives:
1. To be able to define diagnostic probabilities when facing an unknown case of solid mass in the pancreas.
2. To understand the role of multimodality approach, including endosonography and biopsy.

Joint Course of ESR and RSNA (Radiological Society of North America): Hybrid Imaging

MC 628
Hybrid imaging in the female

Moderators:
A. Drzezga; Cologne/DE
K. Riklund; Umea/SE

A-257 10:30
A. Pelvic tumours
F. Dehdashti; *St. Louis, MO/US (dehdashtif@mir.wustl.edu)*

This presentation summarizes the literature in PET/CT and PET/MRI in the evaluation of the three most common gynaecologic malignancies: cervical, endometrial and ovarian cancers. The advantages and challenges of each hybrid modality will be briefly discussed. In addition to clinically used 2-[^{18}F]fluoro-2-deoxy-D-glucose (FDG), novel tracers such as ^{18}F-fluorooestradiol (FES), an oestrogen-receptor imaging tracer, 3´-deoxy-3´-[^{18}F]fluorothymidine (FLT), a proliferative tracer and ^{18}F-fluoroazomycinarabinoside (FAZA), a hypoxic tracer that are currently used for research purposes in these malignancies will be briefly discussed.

Learning Objectives:
1. To learn about different tracers.
2. To understand how to interpret hybrid imaging examinations of the pelvis.
3. To learn about the role of hybrid imaging in staging, treatment evaluation and follow-up.

A-258 11:00
B. Breast cancer
O. Ratib; *Geneva/CH*

Hybrid imaging has gained important role in staging and treatment monitoring as well as in detection of recurrence of breast cancers. From SPECT-CT applications of bone metastases, to whole-body staging with PET-CT to the newer applications of hybrid PET-MR that allow to benefit from that added value of functional imaging and tissue characterization of MRI combined with metabolic and imaging biomarkers of PET. In this refresher course, we will review the current state of recommended applications of hybrid imaging in breast cancers. The basic applications of FDG - PET in staging of regional lymph nodes and distance metastases as well as its added value in monitoring the responses to neoadjuvent chemotherapy. Beyond these well-established applications a review of upcoming new tracers and their potential advantages will also be addressed. Finally a detailed evaluation of hybrid PET-MRI applications in management of breast cancers will be presented highlighting the added value of complementary information gathered from these two modalities.

Learning Objectives:
1. To learn about pathophysiology and relation to different tracers.
2. To understand how to interpret hybrid imaging examinations of the breast.
3. To learn about the role of hybrid imaging in staging, treatment evaluation and follow-up.

A-259 11:30
C. Interactive case discussion (part 1)
F. Dehdashti; *St. Louis, MO/US (dehdashtif@mir.wustl.edu)*

Imaging is critical for staging, determining prognosis and treatment strategy, and in predicting prognosis in gynaecological malignancies. In this case presentation session, common clinical applications of PET/CT and PET/MRI in the evaluation of the most common gynaecologic malignancies will be presented. In addition, the advantages and disadvantages of each hybrid modality will be illustrated and discussed.

Learning Objectives:
1. To understand how to interpret hybrid imaging in female pelvic tumours.
2. To understand how to interpret hybrid imaging in breast cancer.
3. To learn how to avoid common pitfalls.

A-260 11:45
C. Interactive case discussion (part 2)
O. Ratib; *Geneva/CH*

Learning Objectives:
1. To understand how to interpret hybrid imaging in female pelvic tumours.
2. To understand how to interpret hybrid imaging in breast cancer.
3. To learn how to avoid common pitfalls.

A-261 12:15
Dissatisfaction, burnout and inequality: three major challenges in radiology
M. Castillo; *Chapel Hill, NC/US (Mauricio_castillo@med.unc.edu)*

Are you working more? Is your salary higher? Are you hiring more, or less women in your practice? Recent statistics show that radiologist's salaries are decreasing and that only one half of us feel fairly compensated and would become radiologists again given the opportunity. This has led to radiologists leaving our profession to work for the industry at record numbers. With less radiologists, we work more. Studies show that radiology residents have a high burnout rate and that nearly 20% of them feel clinically depressed. These rates are even higher for radiologists in practice in whom depression rates reach 40% and suicidal ideation reaches 7%. Perfectionism, self-critical, inflexible and idealism are personality traits that contribute to burnout. At my school, the University of North Carolina, the School of Medicine has now adopted "improving the life of the provider" as one of its main aims in an attempt to prevent burnout. Dissatisfaction and burnout have resulted in an all-time low number of applications to radiology residencies and fellowships, especially from women who find the speciality incompatible with their lifestyle and family responsibilities. Only 16% of all radiologists are female, in academia Radiology departments have one of the lowest percentages of women, and overall women make 25% less salary than males. Thus, we must work to improve our life-work balance, our purpose-values balance, our professional-personal health, and end salary and academic inequalities for women.

12:30 - 13:30 **Room C**

E³ - The Beauty of Basic Knowledge: Chest Imaging

E³ 25B
How to avoid misdiagnosis on the chest x-ray

Moderator:
N. Howarth; Chêne-Bougeries/CH

A-262 12:30
A. Neoplastic lesions
J. Vlahos; *London/UK*

"no abstract submitted"

Learning Objectives:
1. To review the reasons for misdiagnosis on the chest x-ray.
2. To learn how to focus on blind areas.
3. To know the consequences of a misdiagnosis.

A-263 13:00

B. Non-neoplastic lesions

A.R. Larici; *Rome/IT (annarita.larici@unicatt.it)*

Although the clinical value of chest x-ray remains undiminished, errors in interpreting chest x-ray is still one of the most frequent issue in clinical practice, also in the context of benign lesions. This presentation will cover the predefined learning objectives using side-by-side plain film and CT imaging to help understand how to systematically review chest x-ray and improve radiologist's performance and accuracy in interpreting images. Observer error is one of the most important cause of misdiagnosis when looking at the chest x-ray, and includes scanning error, recognition error, decision-making error and satisfaction of search. Technical considerations, such as image quality and patient positioning and movement, are also factors that can contribute to the likelihood of missing lung lesions. Lesion characteristics also play a critical role and include lesion size, conspicuity and location. Imaging features of the common chest diseases, including those of the diaphragm, pleura and chest wall, as well as diseases of the mediastinum, pulmonary hilum and vascular system, will be reviewed on a case-based approach. The possible consequences of misdiagnosing a benign lesion at chest x-ray will be shown by discussing some explicative clinical cases. The skills required for an accurate interpretation of imaging of the mediastinum, pleura and chest wall will be explored and provided.

Learning Objectives:

1. To review the reasons for misdiagnosis on the chest x-ray.
2. To learn how to interpret the chest x-ray more accurately.
3. To know the consequences of a misdiagnosis.

12:30 - 13:30 **Room D**

E³ - The Beauty of Basic Knowledge: A Survival Guide to Musculoskeletal Imaging

E³ 24B

Chronic trauma: spectrum of bone response

Moderator:
V.N. Cassar-Pullicino; Oswestry/UK

A-264 12:30

Chronic trauma: spectrum of bone response

A.H. Karantanas; *Iraklion/GR (akarantanas@gmail.com)*

The bones are able to develop adaptive mechanisms which are sensitive to their mechanical environment. Thus, bone is constantly remodelled, throughout life, by the coordinated action of bone-resorbing osteoclasts and bone-forming osteoblasts. This remodelling process serves to prevent and heal fatigue-related micro-injuries due to overloading. The balance between the amount of bone resorption and formation determines whether the process of bone remodelling leads to a net loss or gain of bone mass. Chronic trauma may be applied on normal or weakened bone and on mature or immature skeleton. The imaging findings of the resulting painful syndromes cover a wide spectrum. Chronic overload ranges from stress reaction to stress fracture. The former is occult and the latter rarely obvious on radiographs. Fatigue injuries result from stress on normal bone and insufficiency injuries from stress on abnormal bone. Both pathomechanisms may coexist in certain groups of adults. In the immature skeleton, repetitive injury may cause in addition osteochondritis dissecans, osteochondral lesions, physiolysis and chronic apophysitis. Abnormal loading matched with various parameters may result in periprosthetic fractures. Bisphosphonates may induce suppression on the bone turnover, particularly in jaw and proximal femur, resulting in osteonecrosis and insufficiency fractures. Plain films remain the first imaging modality for exploring a pain response in chronic trauma. However, very often, plain films are normal. MRI is able not only to show even subtle findings, responsible for the clinical syndrome, but also to grade the lesions and match with known risk factors to guide the treatment.

Learning Objectives:

1. To become familiar with the pathomechanisms that can affect the axial and peripheral skeleton in chronic trauma.
2. To understand the radiological manifestation of these pathological mechanisms.
3. To appreciate how to best use imaging modalities in diagnosing occult and overt injury and monitoring the response to Treatment.

MR imaging in sports medicine II

A-265 14:00

A. Sports injuries of the ankle

P. Robinson; *Leeds/UK (philip.robinson10@nhs.net)*

Acute ankle injuries are among the commonest problems encountered at all levels of sporting activity and thus even rare chronic sequelae are still a significant problem. Radiologists play an important role in imaging and treatment of athletes with acute and chronic injuries as clinical assessment is often difficult and non-specific. This presentation will illustrate ankle anatomy and the most significant sports-related acute and chronic injury processes and demonstrate the use of MR imaging and ultrasound in the diagnosis and management of these conditions, where appropriate image-guided therapy will also be discussed. Acute sports injury processes will include osseous, osteochondral and ligament injury. Chronic overuse injuries to the tendons, osteochondral unit and soft tissue impingement syndromes will be illustrated.

Learning Objectives:

1. To learn the anatomy of the ankle.
2. To learn the evaluation of common ankle injuries.

A-266 14:45

B. Shoulder injury

M. Zanetti; *Zurich/CH (marco.zanetti@hirslanden.ch)*

Standard radiographs, MR imaging, CT and ultrasound provides clinically useful information in detecting and characterizing injuries of the rotator cuff, cartilage, labrum and bone. The appropriate use of these modalities in common and uncommon shoulder injuries will be demonstrated in an interactive session. Tips and tricks will be given with the special focus on the normal anatomy, variants and potential pitfalls.

Learning Objectives:

1. To review the anatomy of the shoulder in three dimensions.
2. To learn the evaluation of common shoulder injuries.

14:00 - 15:30 **Studio 2017**

Joint Session of the ESR and ERS

ESR/ERS

Novel strategies in idiopathic interstitial pneumonia

Moderators:
K.M. Antoniou; Iraklion/GR
C.M. Schaefer-Prokop; Amersfoort/NL

A-267 14:00

Updated clinical practice guidelines for classification

A.U. Wells; *London/UK (RBHILD@rbht.nhs.uk)*

Updated clinical practice guidelines for classification. The 2011 ATS/ERS/JRS/ALAT guidelines for the diagnosis of idiopathic pulmonary fibrosis (IPF) serve to identify a large sub-group of IPF patients in whom a confident diagnosis can be made with, based upon a) typical HRCT findings of usual interstitial pneumonia (UIP) or b) UIP at surgical biopsy when HRCT appearances are atypical. However, guideline criteria fail to diagnose at least 50% of IPF patients, due to concerns about mortality associated with diagnostic surgical biopsy. Developments related to classification and the diagnostic tools by which disease is classified include: 1) in the 2013 ATS/ERS updated classification of the idiopathic interstitial pneumonia, a category of "unclassifiable disease" is formalised and a disease behaviour classification is proposed as a guide to treatment goals and their achievement. This category includes a large sub-group of IPF patients not diagnosed using current criteria. 2) The development of cryobiopsy should allow increased use of histologic data in the formulation of an IPF diagnosis with particular reference to older patients with greater pulmonary function impairment. 3) A current ERS task force has proposed an algorithm allowing the formulation of a working diagnosis of IPF in multidisciplinary discussion in cases not meeting guideline criteria.

Learning Objectives:
1. To appreciate the rationale for the roles of pathology, radiology, and pneumology.
2. To understand strengths and weaknesses of pathology.
3. To become familiar with novel developments in histopathology.
Author Disclosure:
A.U. Wells: Advisory Board; Roche/Intermune, Boehringer Ingeleim, Bayer. Consultant; Roche/Intermune, Gilead, Boehringer Ingelheim, Bayer. Speaker; Roche/Intermune, Chiesi, Boehringer Ingelheim, Bayer.

A-268 14:22

CT patterns for classification
N. Sverzellati; *Parma/IT*

In 2013, the consensus statement on idiopathic interstitial pneumonias (IIPs) was updated, with the aim of adding further precision to the diagnosis/management of the IIPs. Radiologists are central to the evaluation of patients with IIPs. Radiologists should first distinguish fibrosing from non-fibrosing entities. The main computed tomography (CT) differential of fibrosing lung disease is between the usual interstitial pneumonia (UIP) pattern and other fibrotic patterns such as non-specific interstitial pneumonia (NSIP). When definite UIP pattern is not fulfilled, the differential between UIP and NSIP should rely on CT characteristics of reticular opacities and clinical features, notably age. An important addition is a disease behaviour classification, which provides a framework for management of cases that are unclassifiable or where a histologic diagnosis cannot be obtained.
Learning Objectives:
1. To consolidate knowledge about the anatomical and pathological correlates.
2. To learn about the criteria for usual interstitial pneumonia (UIP).
3. To learn about the criteria for non-specific interstitial pneumonia (NSIP).
Author Disclosure:
N. Sverzellati: Speaker; Dr. Sverzellati reports personal fees from Roche and Boehringer Ingelheim.

A-269 14:45

Updated clinical practice guidelines for treatment
V. Poletti; *Forli/IT (venerino.poletti@gmail.com)*

IPF is a disorder with a sort of unpredictable behaviour with, broadly speaking, rapid progressions and slow progressions. Biomarkers such as specific autoantibodies, morphologic features might be valid indicators of the incoming lung function decline. The use of less invasive procedures such as transbronchial cryobiopsy may strengthen the clinical-radiologic correlation and allow identification of new imaging markers of the disorder that could have diagnostic and prognostic impact (presence of upper lobe subpleural thickening-elastotic fibrosis, nodular calcifications, peripheral bronchiolar proliferation, etc.). Also genomic studies on lung samples or even culture of cells obtained by this method could increment the "personalized diagnostic and therapeutic" approach. So far, however, specific antifibrotic drugs are identified as efficacious in reducing the functional decline in IPF subject and in reducing the mortality risk. Clinicians' task is to clearly define patients with a high probability diagnosis of IPF (not only according to rigid guidelines but also taking into account the clinical profile/clinical behaviour, data provided by biomarkers, CT scan and morphology) to adjust the therapy for the single patient. Learning points: clinical diagnosis of IPF, treatment of patients with a high probability diagnosis of IPF, identification of new effective endpoints to design clinical trials and identification of new efficacious drugs.
Learning Objectives:
1. To learn about the clinical course and prognosis.
2. To consolidate knowledge about the standard therapy.
3. To become familiar with novel therapies.
Author Disclosure:
V. Poletti: Advisory Board; oche, Boehringer Ing. Speaker; oche, Boerhinger Ing, Chiesi.

A-270 15:07

CT and MRI for monitoring therapy response and inflammatory activity
J.A. Verschakelen; *Leuven/BE (johny.verschakelen@uz.kuleuven.ac.be)*

Being an integral tool in the multidisciplinary team approach of idiopathic interstitial pneumonias (IIPs), CT helps to make the diagnosis and may predict prognosis and survival. However, since it is clear now that less typical CT patterns may also be predictive of pulmonary fibrosis and especially since the recent successful introduction of antifibrotic therapy, there is a growing need for a more accurate prognostic evaluation and for an accurate assessment of longitudinal behaviour and response to treatment. While monitoring prognosis and therapy response is predominantly based on clinical data (pulmonary function tests), many methods to quantify disease with CT (and few with MRI) ranging from visual estimates to the use of sophisticated software were developed and used although mostly in study circumstances. In this presentation, the need for prognostic and therapy response imaging and the potentials and pitfalls of (semi)quantitative imaging biomarkers will be discussed. Using imaging biomarkers is challenging since both qualitative and (semi)quantitative measurement results reflect the effect of different processes like inflammation, fibrosis and lung destruction that interact with each other, vary in time and may be different in different parts of the lung. In addition, some of these processes are not well understood. Especially, estimating the amount of inflammation may be difficult, although novel techniques to image inflammation have been proposed. A short review of these techniques will be given.
Learning Objectives:
1. To consolidate knowledge about the rationale for therapy response imaging.
2. To learn about quantitative imaging biomarkers.
3. To become familiar with novel options of imaging inflammation.

14:00 - 15:30 **Room M 3**

ESOR Session

How to gain and maintain quality education in radiology

Moderators:
N. Gourtsoyiannis; Athens/GR
P.M. Parizel; Antwerp/BE

A-271 14:00

Introduction
P.M. Parizel; *Antwerp/BE*

A-272 14:05

N. Gourtsoyiannis; *Athens/GR (gournick@gmail.com)*

A-273 14:15

How to improve education in radiology
S.J. Golding; *Oxford/UK (stephen.golding@nds.ox.ac.uk)*

Most radiologists require teaching skills: there is always someone to teach, whatever the professional setting. Academic radiologists have undergraduate and postgraduate students but all radiologists may teach clinicians, technicians and nurses. These skills begin with understanding both the needs and the viewpoint of the particular student and ensuring that teaching exchange is bilateral and interactive. An ability to understand and set an appropriate learning environment is essential, as is a broad knowledge of the methods of teaching delivery which may be employed. In addition to traditional methods, these include computer-based methods, e-learning approaches and use of social media: radiology lends itself well to such methods. An understanding of the mental process which takes place in learning and the role of student assessment in driving this should be acquired by all teachers. The effective teacher of radiology will possess the widest armamentarium of approaches to teaching and will be able to adapt these to the needs and circumstances of the individual student. They will also proactively practice self-improvement by obtaining regular feedback from their students and colleagues and by attending courses and studying the educational literature. Ideally, radiologists will always be represented on the bodies which set students' curricula and define their learning outcomes.

A-274 14:30

Feeling confident? Evaluating competencies
O. Kolokythas; *Seattle, WA/US (orpheus@uw.edu)*

Development of competency and professionalism of medical trainees is fostered by regular self-reflection and assessment. While promoted and recommended by national and local educational authorities, the implementation of a robust evaluation process in clinical routine might be challenged by many factors including lack of formal assessment tools, time constraints, absence of incentives, subjective decision making and non-separation of performance related and professional issues. Two basic forms of assessments are being distinguished: A) verbal feedback, which is based on informal communication, is instant, spontaneous, personal and specific, is given by one peer and is related to one situation; B) written evaluation, which is based on a standardized structured approach, is scheduled to occur regularly, done by more than one peer, assessing competency and professionalism over a period of time. Requirements to a robust assessment process include standardization, consistency, objectivity, specificity, relevance, validity, impact, practicability, timeliness, efficiency, availability, comparability, confidentiality, transparency and stability of systems. Since a purely number-based approach on competency and professionalism is of poor prognostic value, individual comments are a precious asset to the assessment process and allow for documentation of more specific nuances without jeopardizing overall efficiency

of the process for all. Demands on trainees and peers to successfully participate in a standardized evaluation process include the willingness to promote the quality of education, the commitment to regularly participate in the process, readiness for realistic self-reflection of trainees and commitment of peers to openly address deficiencies of trainees using a fair and non-subjective approach.

A-275 14:45

Lifelong learning: stay sharp in the field of radiology
B. Ertl-Wagner; *Munich/DE (Birgit.Ertl-Wagner@med.uni-muenchen.de)*

The performance and reporting of radiological procedures and of image-guided interventions is a complex clinical act, which only appropriately trained physicians should embark on. The European Training Curriculum for Radiology recommends a five-year training period in radiology, consisting of Level I training for the first three years followed by two years of a more flexible Level II training scheme with potential special interest rotations during the last two years. Its content is based on knowledge, skills, competences and attitudes. The European Diploma in Radiology (EDiR) can be undertaken after a five-year training period in radiology. In addition to the Level I and II curricula of the ETC, the level III curriculum provides the content basis for subspecialisation. To stay sharp in the field of radiology, it is of utmost importance to remain on a path of lifelong learning. Important tools include not only lectures and workshops at conferences but also online resources.

A-276 15:00

Find your mentor and stick together
C.A. Minoiu; *Bucharest/RO (costin.minoiu@gmail.com)*

Mentorship is widely accepted as an important component of development in most medical specialities; however, radiology residents, in many training centres in Europe, lack mentoring. The present talk highlights the importance of a reciprocal collaboration between junior and senior professionals with the primary goal being the nurturing of the junior professional's future pathway, mentoring relationships being critical for the professional development and career advancement. The role of the mentor should be focused both on professional and personal development of the mentees based on their needs and according to a well-defined specific teaching agenda. For a successful mentoring relationship, potential barriers should be understood, and specific pathways for improved implementation of mentor programmes should be defined to allow a good matching system between compatible mentors and mentees. Although the importance of mentorship in facilitating both professional and academic research careers has been largely described, little is understood about early career research mentorship for residents. Successful mentoring programs have been associated with increased involvement in research, enhanced career satisfaction, and pursuit for academic careers. Such programs can help at an individual level as well as at an institutional one, widening networking and cross-disciplinary research and clinical collaborations.

E³ - ECR Academies: Spinal Imaging

E³ 719
Spine: osseous lesions

A-277 14:00

Chairman's introduction
F. Kainberger; *Vienna/AT*

Osseous lesions of the vertebra, mainly manifesting as signal alterations of the bone marrow, are challenging because of the sometimes only subtle differences among these entities. Indications drive the proper work-up especially in these situations: Spondylarthropathies may be suspected clinically with a sensitivity of more than 70 percent. Skeletal metastasis, plasmocytoma and primary bone tumours are in many cases part of a step-wise oncologic workup. Bone marrow hyperplasia can be better differentiated from hematopoetic diseases better when knowing the life-style parameters. The red-flags concept has only in part been proven helpful and may be replaced by more sophisticated questionnaires. The investigation with projection radiography and MRI should include in many of these cases the whole-spine. In rheumatic and infectious inflammatory diseases the sacrum and the sacroiliac joints must be included. The interpretation of focal spinal lesions relies on the differentiation of osteolytic or sclerotic bone lesions. Pitfalls may be avoided by exactly differentiating the localisation within the vertebra and the patterns of bone marrow edema. Tricky lesions are atypical hemangioma, metastasis with a mixed pattern, lytic-expansile fibrous dysplasia and SAPHO. Diffuse spinal abnormalities mainly manifest as osteoporotic on projection radiographs or bone marrow changes with MRI. Diffuse haematopoetic marrow hyperplasia may be due to chronic anaemia, infection, chemotherapy, adiposity in females, heavy smoking and long-distance running. In conclusion, the diagnostic workup of osseous spinal lesions, mainly the indications for imaging, has changed and is continuously changing.
Session Objectives:
1. To establish a structured indication basing on clearly pre-defined questions.
2. To understand the distinct patterns of osseous spine lesions on projection radiographs and MRI.

A-278 14:05

A. Primary bone tumours
J.L. Bloem; *Leiden/NL (j.l.bloem@lumc.nl)*

Metastases and myeloma are much more frequent than primary tumours of the spine. Only mature haemangiomas and enostosis are frequent asymptomatic incidental findings in the spine. In patients younger than 30 years, primary osseous tumours do occur with an incidence of <5% of primary osseous tumours, and may present with pain, associated scoliosis, or neurological symptoms. Most of these, with the exception of Ewing sarcoma (and its metastases) and osteosarcoma are benign and include osteoid osteoma, osteoblastoma, ABC, Langerhans cell histiocytosis, giant cell tumour, and vascular haemangiomas. These aforementioned tumours constitute 80% of all primary osseous tumours in the spine. In patients >30 years, some of these benign conditions are also seen (giant cell tumour), but malignant tumours (chordoma, lymphoma) are becoming more frequent. Benign lesions that are increasingly diagnosed and have specific features are hibernoma and benign notochord tumour. Normally primary osseous tumours of the spine can be differentiated using radiologic criteria from metastases and infection. Radiological features used in diagnosis that will be discussed include location in the spine (sacrum: chordoma, GCT. Location in posterior elements: osteid osteoma, osteoblastoma, osteochondroma), MR signal intensity (low SI in GCT), presence of marked reactive changes (osteoid osteoma, osteoblastoma, Langerhans cell histiocytosis, chondroblastoma), CT density, morphology, way of extending into nearby anatomical structures.
Learning Objectives:
1. To learn how to use MR parameters to suggest a specific diagnosis.
2. To learn how to use radiographic and clinical parameters to suggest a specific diagnosis.
3. To identify the new types of spinal tumours and their radiological features.

A-279 14:33

B. Early diagnosis of spondyloarthropathies
J.A. Narvaez; *Barcelona/ES (jose_a_narvaez@hotmail.com)*

The use of magnetic resonance imaging (MRI) has changed the understanding of SpA. The ability of MRI to directly detect typical inflammatory changes makes possible to establish the diagnosis early in the disease, when radiographs are normal (non-radiographic axial SpA). Detection of inflammatory changes (bone oedema) on MRI of the sacroiliac joints has been included as a major criterion in the Assesment of Spondyloarthritis International Society (ASAS) classification criteria for axial SpA. Although not included in these ASAS criteria, MRI of the spine is an useful tool in the diagnosis, because spinal involvement may occur prior to or even without sacroiliitis. The lesion type most characteristic for SpA on spinal MRI is bone oedema at one or more of the four corners of vertebral bodies (called anterior/posterior spondylitis). Bone oedema in the lateral body and posterior arch of the spine (costovertebral arthritis, spinal ligaments enthesitis) is highly specific, but their use for diagnostic purposes was limited by low sensitivity. Fatty deposition at the vertebral corners is typical for axial SpA, but lacks specificity, because may also be seen as a consequence of degenerative disc disease. MRI of the spine may also be used to: a) assess and monitor disease activity, b) predict outcome/severity, since MRI vertebral corner inflammatory or fatty lesions are associated to the development of new radiographic syndesmophytes, and c) predict treatment effect, because extensive bone oedema on MRI, particularly in the spine in patients with AS, is a good predictor to clinical response to anti-TNF-alpha treatment in axial SpA.
Learning Objectives:
1. To identify the MR features in the axial skeleton of early spondyloarthropathies.
2. To differentiate systemic inflammatory changes from other entities.
3. To learn the importance of imaging in patients managing and outcome.

A-280 15:01

C. Diffuse bone marrow disorders: myeloma and metastases

A. Baur-Melnyk; *Munich/DE (Andrea.Baur@med.uni-muenchen.de)*

Multiple myeloma represents a malignant bone marrow neoplasia in which a monoclonal strain of atypical plasma cells proliferate. Due to various therapeutical options and due to the large variance in survival, the sensitive detection of myeloma involvement of the skeleton is mandatory to enable for an accurate staging. In MRI, 5 different infiltration patterns can be found. The most sensitive imaging method for multiple myeloma is MRI. Whole body MRI is superior to conventional skeletal survey and whole body MDCT. On the other hand, MDCT is the method of choice for displaying osteolysis and determining the fracture risk. Durie and Salmon staging system created in 1975 is the most widely used clinical staging system. It combines laboratory and imaging data (x-rays). In 2003, the Durie and Salmon PLUS staging system has been released, which includes whole body MRI and or PET-CT data. Bone metastases are the most common secondary bone tumours of the spine. CT can clearly demonstrate tumour matrix and the extent of osseous destructions. The radiologist should give a fracture risk assessment. MRI is the most sensitive method for metastasis detection by showing directly bone marrow involvement. Different pseudotumours and bone marrow lesions and variations can mimic metastases. Sometimes malignant collapse of a vertebra is the first sign of a malignancy. It is of clinical importance to differentiate it from an acute benign osteoporotic vertebral collapse. Morphologic as well as special sequences, such as DWI, can help in finding the correct diagnosis.

Learning Objectives:

1. To discuss the advantages and disadvantages of MR, CT, and PET/CT in diagnosis.
2. To identify MR features in multiple myeloma and metastasis.
3. To know the imaging role in treatment planning and monitoring therapy of metastases and myeloma.

14:00 - 15:30 **Room M 5**

Joint Course of ESR and RSNA (Radiological Society of North America): Hybrid Imaging

MC 728

Hybrid imaging of the brain

Moderators:
A. Drzezga; Cologne/DE
K. Riklund; Umea/SE

A-281 14:00

A. Neurodegenerative disorders

H. Barthel; *Leipzig/DE (Henryk.Barthel@medizin.uni-leipzig.de)*

Integrated PET/MRI systematically offers a complementary combination of two modalities which has often proven itself superior to the single modality approach in the diagnostic workup of neurodegenerative diseases. Emerging brain PET tracers, like amyloid or tau tracers, technical advances in multi-parametric brain MRI and obvious workflow advantages may enable brain PET/MRI to significantly improve diagnostics of dementia disorders and Parkinsonian syndromes. Moreover, simultaneous PET/MRI is well suited to study complex brain function in which fast fluctuations of brain signals (e.g. related to task processing or in response to pharmacological interventions) need to be monitored on multiple levels. Further, brain PET/MRI is considered the ideal tool for anti-neurodegenerative drug testing.

Learning Objectives:

1. To learn about pathophysiology in neurodegenerative disorders.
2. To learn about different tracers and how to interpret the findings.
3. To understand the role of hybrid imaging in neurodegenerative disorders.

Author Disclosure:
H. Barthel: Consultant; Piramal Imaging. Speaker; Siemens Healthcare, Piramal Imaging.

A-282 14:30

B. Brain tumours

J. McConathy; *St. Louis, MO/US (jmcconathy@uabmc.edu)*

Neuroimaging with positron emission tomography (PET) and magnetic resonance imaging (MRI) plays a critical role in the diagnosis, treatment planning, and post-treatment evaluation of patients with primary and metastatic brain tumours. This presentation will discuss the use of molecular neuroimaging in conjunction with MRI for neuro-oncology. The use of [F-18]FDG and radiolabeled amino acids will be reviewed, and the potential applications of PET/MRI for brain tumour imaging will be presented.

Learning Objectives:

1. To get an overview of brain tumours and tracers used.
2. To learn how to interpret the examinations.
3. To understand the role of hybrid imaging of brain tumours.

Author Disclosure:
J. McConathy: Advisory Board; Blue Earth Diagnostics. Consultant; Siemens Healthcare, GE Healthcare.

A-283 15:00

C. Interactive case discussion (part 1)

H. Barthel; *Leipzig/DE (Henryk.Barthel@medizin.uni-leipzig.de)*

Integrated PET/MRI systematically offers a complementary combination of two modalities which has often proven itself superior to the single modality approach in the diagnostic workup of neurodegenerative diseases. In this presentation, interesting case examples of neurodegenerative disorders will be discussed. It will be demonstrated how combined PET/MRI simplifies and improves early and differential diagnosis.

Learning Objectives:

1. To learn about evaluation of hybrid imaging in neurodegenerative disorders.
2. To learn about evaluation of hybrid imaging of brain tumours.

Author Disclosure:
H. Barthel: Consultant; Piramal Imaging. Speaker; Siemens Healthcare, Piramal Imaging.

A-284 15:15

C. Interactive case discussion (part 2)

J. McConathy; *St. Louis, MO/US (jmcconathy@uabmc.edu)*

Learning Objectives:

1. To learn about evaluation of hybrid imaging in neurodegenerative disorders.
2. To learn about evaluation of hybrid imaging of brain tumours.

Author Disclosure:
J. McConathy: Advisory Board; Blue Earth Diagnostics. Consultant; Siemens Healthcare, GE Healthcare.

16:00 - 17:30 **Room A**

E³ - ECR Academies: Interactive Teaching Sessions for Young (and not so Young) Radiologists

E³ 821

Paediatric radiology for the general radiologist

A-285 16:00

A. Fractures in children

K.J. Johnson; *Birmingham/UK (karl.johnson@bch.nhs.uk)*

Traumatic injury and fracturing is one of the commonest reasons why children present to hospital and undergo radiological investigation. The anatomy and physiology of the growing skeleton is different to that of adults and as a consequence, some of the fractures and injuries are unique to children. This presentation will demonstrate the various types of incomplete fracture which occur within the more plastic skeleton of the child. It will detail the different types of Salter-Harris fractures which can occur across the unfused growth plate. The differences in relative strength of bone and ligamental attachments which are seen in children and the consequences of the different types of injuries which can occur will be illustrated. The importance of recognising normal variants of growth from pathological change will also be highlighted. The importance of understanding the child's development and mobility and how this correlates with the injury patterns seen in normal childhood will be discussed along with an understanding of the injury patterns and fracture types which occur from inflicted physical injury.

Learning Objectives:

1. To become familiar with different traumatic fracture types.
2. To identify possible criteria for child abuse.

A-286 16:45

B. MRI-typical paediatric applications in musculoskeletal imaging

A.M.J.B. Smets; *Amsterdam/NL (a.m.smets@amc.uva.nl)*

Musculoskeletal MRI plays an important role in the diagnosis of developmental, metabolic, infectious, inflammatory, traumatic and oncologic diseases in children and adolescents. Before skeletal maturity, imaging characteristics are influenced by the transformation of cartilage to bone and the conversion of red to yellow bone marrow. These features are to be taken into account both for the choice of sequences and parameters as for image interpretation. The

processes of growth also affect the mechanisms of trauma and infection and the types of conditions that can be encountered in childhood and adolescence. Indications for paediatric musculoskeletal MRI and MRI findings in paediatric musculoskeletal disorders will be discussed.

Learning Objectives:

1. To learn indications of paediatric MRI.
2. To become familiar with MR imaging findings in children.

16:00 - 17:30 **Room B**

Special Focus Session

SF 8

The postoperative abdomen: lost in translation?

A-287 16:00

Chairman's introduction: Presentation of a challenging case

Y. Menu; *Paris/FR (yves.menu@sat.aphp.fr)*

Previous surgery is always a major difficulty when reporting on abdominal imaging. Some surgery is quite obvious, like hepatectomy or colectomy, some may be less apparent like by-pass, complex bowel surgery or even atypical liver resection. Knowledge of the exact surgical procedure is critical for the radiologist. This is even more true when looking for complications as some are quite specific. Differentiating fistulae, abscesses and bowel loops can be really challenging. Defining criteria for bowel obstruction is tricky. This session intends to clarify the most common clinical situations, allowing the radiologist to fully understand the specific situations and to enhance the dialogue with the surgeon.

Session Objectives:

1. To learn about the most common complications following abdominal surgery, either immediate or delayed.
2. To become familiar with the most common surgical procedures and to understand the mechanism of complications.
3. To be able to detect these complications with imaging methods, and to understand the principle of management, including conservative, interventional and/or surgical treatments.

A-288 16:05

Inflammatory complications (peritonitis, abscess)

Z. Tarján; *Budapest/HU (ztarjan@gmail.com)*

Postoperative complications can be general or specific to particular operations. Infections may occur in the operative site or organ, like wound infection, biliary infection or UTI and the peritoneum may be contaminated during or after surgery. Anastomotic leaks, traumatic organ injuries like lacerations and haematomas may develop to form abscesses. Abscesses can be categorised as intraperitoneal retro/subperitoneal or visceral. Pathways of infection are related to well-defined anatomical structures but may extend to contiguous structures and erode boundaries. In the early postoperative period, fever may be caused by tissue necrosis at the operation site. In a few days later sepsis, wound infection and abscess formation may start. Around 5 days after surgery anastomosis breakdown, fistula formation, wound infection and distant site infections may occur. Pelvic collections usually form in the first week, while subphrenic collections tend to form later. Inflammatory damage of vessels in the operation field often results in late postoperative bleeding. CT is the most widely used modality to detect postoperative conditions. Exams should be tailored to be able to demonstrate the altered anatomy, signs of peritonitis, possible source of leakage and collections. Imaging features of inflammatory complications and checklist of critical findings related to different abdominal and pelvic operations will be shown. The team of clinicians, surgeons and radiologists should always discuss treatment options and minimal invasive techniques are preferred; therefore, radiological intervention plays a major role. CT, US, EUS and image fusion (technical or cognitive) may help to guide the intervention.

Learning Objectives:

1. To learn about the incidence of immediate postoperative inflammatory complications and their outcome.
2. To understand the surgical procedures that are most commonly exposed to inflammatory complications.
3. To be able to detect inflammation and abscesses and to identify direct and indirect signs of leakage.
4. To understand the discussion about treatment, conservative, surgical or interventional.

A-289 16:23

Vascular complications (bleeding, thrombosis, ischaemia)

R. Nolz; *Vienna/AT (richard.nolz@meduniwien.ac.at)*

Immediate vascular complications after abdominal surgery require early detection and treatment. Their incidence depends on different factors, including patient characteristics, complexity of surgery and surgeon's learning curve. Transplantations are the surgical procedure most frequently affected by vascular complications in up to 20%. Imaging has a fundamental role in the postoperative period to screen for complications and to monitor the recovery process. Multidetector contrast material-enhanced computed tomography (MDCT) is the gold standard to detect immediate vascular complications. Delayed application of MDCT is leading to a higher patients mortality and morbidity. Accurate interpretation of postoperative findings requires that radiologists have sound knowledge and understanding of surgical procedures and related surgical anatomy. Most postoperative vascular complications provide a fertile ground for interventional radiology (IR), which can circumvent a major surgery on most occasions. The minimally invasive nature and lower morbidity associated with IR procedures make them preferable to similar surgical procedures.

Learning Objectives:

1. To learn about the incidence of immediate postoperative vascular complications and their outcome.
2. To understand the surgical procedures that are most commonly exposed to vascular complications.
3. To be able to manage the diagnostic strategy using appropriate imaging modalities.
4. To understand the role of intervention.

A-290 16:41

Postoperative obstruction

A. Palkó; *Szeged/HU (palkoand@gmail.com)*

Post-operative complications, including gastrointestinal obstruction may be responsible for increasing morbidity and mortality. Recognition of early signs and identification of cause, location and type of immediate and late postoperative obstruction is a difficult task that may not be accurately accomplished by clinical examination. Imaging plays a paramount role in properly detecting and characterising such conditions, allowing for a timely and adequate treatment. Detection, diagnosis and differential diagnosis may be challenging because of the atypical postoperative anatomy and the effect of the underlying disease. Understanding their influence on imaging appearance is critical for correct diagnosis. Plain abdominal x-ray examination may be of little use in the immediate postoperative cases because of the commonly present paralytic ileus obscuring any characteristic signs and also not sufficiently accurate in most late postoperative cases. Barium examinations are usually not performed in acute abdominal conditions. Ultrasound does not play a significant role in the exploration of gastrointestinal pathology. Computed tomography with or without endoluminal contrast is the proper diagnostic modality to establish the definitive diagnosis; however, being familiar with typical signs of postoperative conditions (inflammation, infection, adhesion, dysfunction, volvulus, herniation, etc.) resulting in mechanical obstruction is mandatory to make an accurate and timely diagnosis.

Learning Objectives:

1. To learn about the incidence of immediate and long-term intestinal obstruction after surgery and/or radiotherapy.
2. To understand the mechanism of obstruction related to previous surgery, including adhesion, volvulus, internal hernia and recurrence/complication of initial disease.
3. To be able to detect obstruction, characterise the mechanism and evaluate the severity.
4. To feed the discussion of conservative vs surgical treatment.

Author Disclosure:

A. Palkó: Advisory Board; Affidea.

A-291 16:59

Complications of weight-loss surgery

M. Rengo; *Latina/IT (marco.rengo@gmail.com)*

Obesity is a disease that has reached epidemic proportions around the world. During the past 20 years bariatric surgery has become an increasingly popular form of treatment for morbid obesity. The most common bariatric procedures performed include laparoscopic Roux-en-Y gastric bypass, laparoscopic adjustable gastric banding and laparoscopic sleeve gastrectomy. Fluoroscopic upper gastrointestinal examinations and abdominal computed tomography (CT) are the major imaging tests used to evaluate patients after these various forms of bariatric surgery. We will illustarate the common bariatric surgical procedures, the imaging procedures accordingly to become familiar with the normal post-operative anatomy and to appreciate the role of imaging in the

assessment of suspected immediate and long-term postoperative complications.
Learning Objectives:
1. To learn about the main surgical techniques of bariatric surgery and to understand the mechanism of the most common immediate and delayed complications.
2. To be able to identify the normal post-surgical appearance on imaging methods.
3. To detect the main complications associated with bariatric surgery on imaging methods.

17:14
Panel discussion: Where might we go wrong and how can we avoid it?

16:00 - 17:30 **Room C**

Chest

RC 804
CT - patterns in chest radiology: back to basics and beyond

A-292 16:00
Chairman's introduction
H. Prosch; *Vienna/AT (helmut.prosch@meduniwien.ac.at)*

The diagnosis of diffuse parenchymal lung diseases (DPLD) is one of the most challenging tasks in radiology. As DPLD include more than 200 diseases, the diagnosis frequently requires an extensive workup in which HRCT plays a central role. HRCT is not only essential in the detection of DPLD, but even more important in providing a brief differential diagnosis. Some DPLD, like Langerhans cell histiocytosis or lymphangioleiomyomatosis, can even be diagnosed confidently with HRCT alone. Given the large number of DPLD, the HRCT diagnosis of DPLD requires a systematic approach, and should be based on an analysis of the CT patterns, which can be classified into four categories: increased lung densities, decreased lung densities, a linear pattern and a nodular pattern. A prerequisite for the analysis of the CT pattern is a knowledge of the anatomy of the lung, with a fundamental understanding of the architecture of the secondary pulmonary lobule in particular. The secondary pulmonary lobule is the smallest anatomical unit of the lung, bordered by connective tissue septa. An analysis of HRCT images should aim to narrow the differential diagnosis by attributing CT patterns to the components of the secondary pulmonary lobule: the interlobular septa, the centrilobular structures, or the lobular parenchyma. Such a structured approach can provide a narrow list of differential diagnoses and thereby guide additional steps to diagnose the underlying disease.
Session Objectives:
1. To emphasise the importance of anatomy in reading CT.
2. To appreciate the necessity of defining patterns to improve CT diagnoses.
Author Disclosure:
H. Prosch: Advisory Board; Boehringer Ingelheim, Roche. Speaker; Boehringer Ingelheim, Roche.

A-293 16:05
A. Secondary pulmonary lobule anatomy: essential to tackle with the nodular pattern
T. Frauenfelder; *Zurich/CH (thomas.frauenfelder@usz.ch)*

The goal of this lecture is to provide information about the anatomy of the lung and to provide a structured approach to nodular pattern. High-resolution CT gives detailed morphologic information about lung structures. This allows distinguishing findings by their typical predominance in certain anatomical compartments. The anatomy of secondary lobule, therefore, plays a key role. Based on the distribution of nodular lesions in relation to the bronchial, vascular and lymphatic structure of the secondary lobule the number of possible pathologies can be narrowed down. For example, centrilobular predominance of nodules is a frequent sign of bronchiolitis. Perilymphatic predominance in the periphery of the lobules is associated with sarcoidosis or lymphangitic spread of cancer. Random distribution of nodules is interpreted as a sign of haematogenic spread of disease. Therefore, a subtle interpretation can contribute substantially to clinical decision making. Nevertheless, these signs may not always replace biopsy and histologic workup. During this lecture, a stepwise algorithm for differentiating nodular pattern will be provided that allows a pragmatic approach for a successful reading of HRCT.
Learning Objectives:
1. To become confident in recognising the anatomical compartments of the lung.
2. To describe typical nodular imaging patterns of lung disease using appropriate terminology.

A-294 16:28
B. Linear and reticular pattern
F. Molinari; *Lille/FR (francescomolinari.dr@gmail.com)*

The reticular pattern is one of the imaging findings that may suggest the presence of a diffuse parenchymal lung disease at HRCT. Reticulations are typically formed by a collection of innumerable small linear opacities that by summation produce an appearance resembling a "net". Lines may vary from smooth to nodular and irregular. The resulting "net" may alter the normal HRCT appearance of the lung and become suspected for an underling lung disease. Chest radiologists typically use a structured approach to interpret this finding and eventually to propose a diagnosis. The radiologic approach consists in identifying the dominant types of lines, in establishing what portion of the lung interstitium is predominantly involved, and in correctly classifying the type of reticulation (namely inter-lobular, peri-lobular, intra-lobular). When all the radiologic features are correctly interpreted, the radiologist can differentiate reticulations that represent an acute disease from those that indicate a chronic inflammatory or fibrotic change in the lung. In addition, by integrating clinical and laboratory data, it is possible to significantly narrow the final differential diagnosis.
Learning Objectives:
1. To recognise and interpret typical reticular imaging patterns.
2. To differentiate acute and chronic diseases which cause septal patterns.

A-295 16:51
C. Ground glass opacities (GGO) and consolidation
J. Vogel-Claussen; *Hannover/DE*

Ground glass opacity (GGO) is a nonspecific finding on computed tomography (CT) scans of the chest that indicates a partial filling of air spaces in the lungs by exudate or transudate, as well as interstitial thickening or partial collapse of lung alveoli. The term derives from the similarity in appearance of the small objects to small chips of glass that are a by-product of glass grinding. The differential diagnosis of the many causes of GGO includes pulmonary oedema, infections (including cytomegalovirus and Pneumocystis jirovecii pneumonia), various noninfectious interstitial lung diseases (such as hypersensitivity pneumonitis, Hamman-Rich syndrome), diffuse alveolar haemorrhage, and cryptogenic organising pneumonia. Thus, clinical correlation and disease dynamics are important to narrow down the differential diagnosis. The aim of this refresher course is to distinguish ground glass opacities from consolidations on chest CT and give practical instructions for daily clinical routine.
Learning Objectives:
1. To appreciate the different conditions which cause GGO pattern and consolidation.
2. To learn how to interpret GGO and consolidation in different clinical settings.

Panel discussion: Is it always easy to detect a pattern? Tips for success

16:00 - 17:30 **Room X**

Joint Session of the ESR and EORTC

Imaging biomarker and education for multicentre clinical oncological trials

Moderators
N.M. deSouza; Sutton/UK
Y. Liu; Brussels/BE

A-296 16:00

Imaging as primary endpoint in clinical trials: perspective of the EORTC
Y. Liu; *Brussels/BE (yan.liu@eortc.be)*

Imaging biomarkers have evolved in clinical trials, thanks to improvements in conventional imaging and innovation in advanced imaging techniques. Imaging biomarkers play key roles as outcome measures in trials, and are also used for patient selection, stratification, and safety monitoring tools (measure harm or lack of harm related to treatment). Despite the obvious values of imaging, the integration of imaging biomarkers into trials faces various challenges, such as the complexity of imaging techniques, lack of standardization across multivendor platforms, and paucity of optimized trial design and operational support. Those pitfalls become more apparent, especially in centers with little experience in clinical trials that involve imaging. A risk management approach will be introduced in the presentation, to manage trials with imaging endpoints. It could be a useful tool for prioritization, and avoid undue cost and eventually decreases trial attrition rate. An initial risk assessment plan should be performed before study initiation, which might be achieved with a multidisciplinary team, including imaging experts, clinicians, and study project managers. The risk plan should also be reviewed and updated throughout the trial, to ensure that actions have been or will be taken. This session will set the scene for discussion with imaging experts, to improve the implementation and utilization of imaging biomarkers within clinical trials.
Learning Objectives:
1. To become familiar with the importance of imaging biomarker in oncologic trials.
2. To learn about the role of the Imaging group of the EORTC.
3. To appreciate how standardisation and quality assessment enhances the role of imaging in oncologic trials.

A-297 16:22

Imaging biomarker for clinical trials in brain tumours
M. Smits; *Rotterdam/NL (marion.smits@erasmusmc.nl)*

Gliomas are the most common primary brain tumours and constitute a group of tumours with heterogeneous clinical behaviour, with many therapeutic agents under investigation for their effectiveness. The assessment of treatment effect is, however, not without difficulty. It is on the one hand hampered by therapy-related changes which can be indistinguishable from tumour progression, such as pseudoprogression or radiation necrosis, and on the other hand by a phenomenon called pseudoresponse, occurring in the context of anti-angiogenic treatment, in which contrast enhancement diminishes unrelated to an actual anti-tumoural effect. New, preferably quantitative, markers of response are desperately needed to assess treatment response as accurately and early as possible within the context of a clinical trial. Furthermore, recent insights indicate that the clinical heterogeneity of glioma behaviour can - at least in part - be attributed to the tumour genotype. In the context of clinical trials, it is adamant that patients are correctly stratified according to their tumour genotype, which at this point in time can only be determined from tumour tissue acquired through biopsy/surgery. To avoid such invasive procedures, as well as to obtain a full overview of the tumour and its heterogeneity, and to be able to follow changes over time, imaging can play an important role using a radiogenomic approach. In this presentation, I will discuss the current and potential imaging markers of glioma biological behaviour and response to treatment, and the challenges for implementation in clinical, multicentre trials.
Learning Objectives:
1. To consolidate knowledge about state-of-the-art quantitative MRI.
2. To learn about standardisation and validation.
3. To appreciate the value of quantitative MRI in tumour grading and therapy response.

A-298 16:45

The importance of collaboration between the European Initiative on Biomarkers Alliance (EIBALL) and EORTC
S. Trattnig; *Vienna/AT (siegfried.trattnig@meduniwien.ac.at)*

EORTC performs many clinical multicentre trials per year, has 150,000 patients in its database, with 50,000 in the follow-up stage, and comprises 2000 collaborators. Organizationally, EORTC is subdivided into 18 disease-oriented groups with their own respective steering committees in which multicentre trials are planned and performed. The imaging group (comprising radiologists, nuclear medical physicians, physicists and imaging scientists) is part of the "Translational Research and Imaging Department" within EORTC, and is responsible for imaging protocols in multicentre trials, in collaboration with the disease-specific groups and their steering committees in EORTC. The role of EIBALL is to strengthen the collaboration with the imaging group of EORTC with the integration of more radiologists into the imaging group. There is also a need to integrate more imaging people, particularly radiologists, into the disease-oriented groups and their respective steering committees of EORTC where multicentre studies are developed and to which imaging protocols can be implemented. This will allow clinical validation of different imaging biomarkers in multicentre trials. Imaging protocols, including quantitative imaging biomarkers, should be proposed and distributed to the members of EIBALL, and an expert consensus should be achieved, which then should be integrated within the EORTC multicentre studies. Imaging protocols that are acceptable for a number of sites should be established and a program of quality assurance/quality control should be implemented prior to imaging in multicentre trials. In planned multicentre projects, potential sites should be recruited based on a site qualification process for clinical validation of imaging biomarkers.
Learning Objectives:
1. To become familiar with recent developments of collaboration between EIBALL and EORTC.
2. To learn about the increasing role of radiologists in oncologic trials.
3. To appreciate the importance of imaging biomarker in multicentre trials.

A-299 17:07

Training possibilities for radiologists involved in clinical multicentre trials
L.S. Fournier; *Paris/FR*

Learning Objectives:
1. To become familiar with education of radiologists for oncologic trials.
2. To learn about the advantages of education for implementation and evaluation of clinical trials.
3. To appreciate the value of educational courses on clinical multicentre trials for radiologists.

Simulation training in ultrasound

Moderators:
M. Bachmann Nielsen; Copenhagen/DK
V. Cantisani; Rome/IT

A-300 16:00

How to evaluate simulation training
L. Konge; *Copenhagen/DK (lars.konge@regionh.dk)*

Naturally, we treat our patients according to the best available evidence and the same principle should be applied to the way we train our future colleagues. High-quality research in medical education using assessment tools with solid evidence of validity is needed to create the most efficient training programs. Learner satisfaction or self-assessed competence is not a valid measure of learning outcome. Evidence shows that simulation-based training is cheaper and more effective than traditional apprenticeship training in the early part of the learning curve. Specific examples of this will be presented at the lecture.
Learning Objectives:
1. To learn the theories behind training assessment in medical education.
2. To understand why some study designs are valid and others are not.
3. To learn about simulation studies in radiology and other medical specialties (e.g., OB/GYN).

A-301 16:15

Different ultrasound simulators for different purposes

A. Kabaalioglu; *Antalya/TR (adnank@akdeniz.edu.tr)*

Simulation training is increasingly becoming an essential part of many educational activities. Simulation methods have long been used for training the military personnel, pilots, astronauts and engineers. Medical use of simulation training is not only limited to basic teaching of "blood draw" or other interventions that are helpful for the patient safety. Complex interactive simulator mannequins have been developed for helping medical students to learn how to act in several clinical scenarios. Moreover, this environment is regarded as a better standardised evaluation or assessment system. Ultrasound simulators have been introduced for training the medical personnel before having "troubled times" during real life scanning. The patients may complain of the time spent on their body, especially when they have a serious illness and/or severe pain and anxiety. Besides these factors, safety concerns regarding tissue heating with long exposures to sound waves, especially prolonged Doppler use in pregnancy, inhibit the trainer and the trainee to spend sufficient time on a patient. Ultrasound simulators have been successfully developed for use in abdominal, obstetrics/gynaecological and cardiac exams. Interventional models for abdominal and breast biopsies and vascular access are also available for training the residents or fellows. In this part of the session, several ultrasound simulators used for medical training will be presented with advantages and disadvantages. Their potential for future applications will be discussed.

Learning Objectives:

1. To learn about different types of simulators on the market.
2. To learn about which are suitable for beginners or advanced levels, for OB/GYN or abdominal, and which can be used for training interventional ultrasound.
3. To learn about advantages and disadvantages of different types of ultrasound simulators.

A-302 16:30

US simulation training in student education

R. Badea; *Cluj-Napoca/RO (rbadea2012@gmail.com)*

Ultrasound is a operator-dependent procedure. Source of errors that should be avoided are: multimodal picture, real-time data, artefacts, large number of transducers, diversity and lack of standardisation of machines. Because of these, ultrasonography is apparently unfriendly and medical students are reluctant in practising it. Main purpose of implementation of ultrasonography in education of students should be "sonovisualisation" of some areas to improve and accelerate the clinical diagnosis. Simulators are educational instruments that replace the human body. A combination between a model and a ultrasound machine like computer can replace the ultrasound examination. Some devices explain images by comparing ultrasound and anatomical/imaging slices, other devices explain images focusing on small anatomical area to facilitate "point of care" diagnosis. Advantages are: good real-time picture; friendly utilisation. Disadvantages are: insufficient connection to the student curriculum; insufficient versatility; low possibility of simulation of clinical syndromes or signs (e.g. compressibility, pain, etc). Outcomes depend on the year of study and educational objectives. In a linear curriculum, ultrasonography should make the student to understand anatomy and physiology including pathological phenomenon (blood flow; vascular stenosis/obstruction; shape/function of heart; anatomical relation between organs; pathological processes like inflammation, angiogenesis, tumoural detection/characterisation; evaluation of fluids). Next step should be integration of ultrasonography into the clinical judgement as geste part of the physical examination of the patient. Final step should be integration of ultrasound evaluation in a emergency situation and ultrasound guidance of some simple invasive procedures.

Learning Objectives:

1. To learn about the basis for training in medical students in US.
2. To learn about reported outcomes from ultrasound simulation training of medical students.
3. To learn about possible ways of its implementation.

A-303 16:45

Experience with ultrasound simulators in training radiologists

M.L. Østergaard; *Copenhagen/DK (mia.louise.ostergaard@gmail.com)*

The traditional apprenticeship training is being challenged by multiple factors such as time restraints, supervisor shortage, patient's safety and sub-specialised clinical setups. Simulation-based training may be the answer to a lot of these challenges and could secure adequate training time and skill level. In combination with the prevailing approach of competency-based education it could provide a setup for evidence-based education. In this session, I will give a recap of what we know about simulation-based training in ultrasound, present a simulation-based test with solid validity evidence and offer a perspective on what simulation-based assessment might bring to ultrasound education.

Learning Objectives:

1. To learn about the present literature on simulation training in abdominal ultrasound.
2. To understand the level of evidence for the effect of ultrasound simulation training.
3. To learn about the experience from starting simulation training as part of the curriculum in Denmark.

Professional Challenges Session

PC 8

How to make best use of cardiac imaging in a radiology department

A-304 16:00

Chairman's introduction

G.I. Kirova-Nedialkova; *Sofia/BG (gal.kirova@gmail.com)*

Over the past two decades, almost all aspects of imaging diagnostic have undergone fundamental change. In the light of the advances in technology, the health care environment and the transit to the patient-oriented medicine, the need of a reform of the organization and practice is unambiguous. As the equipment becomes increasingly sophisticated, the ability of the general radiologist to keep up with the advancing technology will be even further outperformed. The main goal of the session will be to stress the audience's attention to the new tendencies in the development of noninvasive cardiac radiology and how to narrow the gap between the needs of the society and the ability of the profession to respond. The relationship between the science and practice, the applicability and cost effectiveness of new guidelines and the challenges in implementation working training programmes in a real situation will be discussed. The panel discussion will focus on the integration of cardiac imaging in the routine radiology workload and the role of the radiologist into the multidisciplinary team, addressing the medical decision-making.

Session Objectives:

1. To focus on the needs for and challenges in organising a non-invasive cardiac imaging programme.
2. To learn about the main factors driving cost-effectiveness in the setting of cardiac imaging.
3. To understand the process of credentialing and accreditation in the practice of cardiac imaging.
4. To understand the radiologists' role as a team player.

A-305 16:06

Starting a cardiac imaging programme

G.A. Krombach; *Giessen/DE (gabriele.krombach@uniklinikum-giessen.de)*

To successfully initiate an imaging programme serving the needs of an interdisciplinary team consisting of cardiologists, paediatric cardiologists, vascular surgeons and cardiac surgeons requires dedicated knowledge regarding the typical spectrum of questions raised by these referring colleges as well as of the current guidelines. The radiologist needs to choose the appropriate modality and to apply the best suited imaging protocol. Reading the images implies the description of all cardiac pathologies, quantifying cardiac function, describing extra cardiac pathologies, summarizing all findings to a final diagnosis and writing a comprehensive report. A specific training program certified by the respective National radiological society or by the European society of radiology itself that consists of courses and practical training provides the necessary knowledge and ensures high quality of cardiac imaging. A team of technicians must be trained as well to accurately carry out

imaging protocols. To finally gain the best value from imaging, consistent ways of communication with the referring physicians have to be established. In addition to the written report, regular multidisciplinary conferences might be best suited for radiological departments in larger hospitals, while a timely structured written report combined with regular personal communication with the referring physicians might be best suited for radiological practices. With a structured approach, starting a cardiac imaging programme will be successful. It gains quality for patients and referring physicians by providing the exact diagnosis, allowing to choose the best suited therapy and monitoring the response to the treatment.

Learning Objectives:

1. To understand the challenges for starting a cardiac imaging programme.
2. To learn about requirements for starting a cardiac imaging programme.
3. To learn about the steps necessary for starting a successful cardiac imaging programme.

A-306 16:28

Cost-effectiveness of cardiac imaging

M.G.M. Hunink; *Rotterdam/NL (m.hunink@erasmusmc.nl)*

Coronary artery disease (CAD) is one of the leading causes of mortality and morbidity. This presentation reviews the evidence on comparative cost-effectiveness of imaging strategies for patients presenting with stable chest pain symptoms suggestive for CAD. The literature was systematically reviewed for formal economic evaluations or decision analyses written in English. The identified studies compared very different testing strategies using very different methods and provided mostly short-term results. Strategies of no-testing and stress ECG were underrepresented. Nonetheless, the findings suggest that for patients with a low to intermediate prior probability of having obstructive CAD, CT coronary angiography (CTCA) is cost-effective as an initial diagnostic imaging test in comparison with catheter angiography or other non-invasive diagnostic tests. If functional testing is required, stress echocardiography or SPECT are suggested to be cost-effective initial strategies in patients with intermediate prior probability of CAD. Other functional testing strategies such as stress ECG and PET scanning have not been studied as extensively. Catheterisation angiography is cost-effective in patients at a high prior probability of having obstructive CAD whom may benefit from revascularisation.

Learning Objectives:

1. To understand the issues related to cost-effectiveness calculations.
2. To learn how cost-effectiveness in cardiac imaging can be influenced by different parameters.
3. To learn about the thresholds for cost-effectiveness in cardiac imaging.

Author Disclosure:

A-307 16:50

Training cardiac imaging in the radiology department

F. Pugliese; *London/UK (f.pugliese@qmul.ac.uk)*

Due to advances in imaging technology and improved infrastructure availability, advanced cardiac and cardiovascular imaging applications (cardiac magnetic resonance, cardiac computed tomography) have become appealing diagnostic tools in increasing numbers of patients with a range of cardiac conditions. While a growing body of literature and recently issued clinical guidelines stress the role of cardiac imaging in contemporary clinical cardiology, to date the availability of trained staff performing and reading cardiac imaging appears patchy, geographically variable and insufficient.

Learning Objectives:

1. To understand the challenges of training cardiac imaging.
2. To learn about the ideal training conditions for cardiac imaging.
3. To learn about how to implement cardiac imaging training programmes.

17:12

Panel discussion: Are we ready to integrate cardiac imaging in routine radiology workload?

16:00 - 17:30 **Room N**

Head and Neck

RC 808

Pitfalls in interpretation of head and neck disease

Moderator:
S. Robinson; Vienna/AT

A-308 16:00

A. Anatomical variants without clinical consequence

F.A. Pameijer; *Utrecht/NL (f.a.pameijer@umcutrecht.nl)*

Variant: "Something that is slightly different". Imaging methods can provide an extraordinary amount of useful data to specialists treating head and neck (cancer) patients. It is crucial that these data are used to full advantage of individual patients. The most important factor in this process is mutual cooperation between the physicians in charge of patient care and the diagnostic imaging specialist. Anatomical variants in the head and neck are frequently encountered and may result in interpretation problems for the radiologist. Usually, anatomical variants are without clinical consequence. However, normal variants may simulate diseases not recognized, normal variants may lead to unnecessary interventions. The presentation aims to familiarize general radiologists, who have an interest in head and neck imaging, with common anatomical variants encountered on head and neck CT and MR studies. Many examples from daily practice will be discussed.

Learning Objectives:

1. To gain insight into the great variability of head and neck anatomy.
2. To be able to recognise pseudo lesions.

A-309 16:30

B. Anatomical variants posing surgical risks

D. Farina; *Brescia/IT (nappaje@yahoo.it)*

Several anatomic variants may pose a threat during surgery. A large part is found in the sinonasal region basically due to the widespread use of endoscopy which, inherently, provides the operator with narrow accesses and limited exposition of submucosal anatomic structures. Onodi cell is probably the most feared anatomic threat, because if not correctly indicated by the radiologist and identified by the surgeon, it generates a high risk of disastrous intracranial penetration. Similarly, bone dehiscence of the lamina papyracea of the ethmoid increases the risk of iatrogenic damage, mainly of intrinsic ocular muscles. The inferior alveolar nerve is at high risk of surgical damage during molar teeth extraction, particularly when the curved apex of roots embrace the inferior wall of the nerve canal. In the neck, the main threats are related to anomalous course of major vessels: not infrequently the common or internal carotid artery display a medialized course reaching the lateral aspect of the pharyngeal wall or even protruding in the retropharyngeal space towards the midline. Simultaneous medial deviation of the arteries on both sides is referred to as kissing (common or internal) carotids. The risk in these eveniences are mainly related to the possible effects of a deep biopsy performed by an unaware surgeon. At the cervicomediastinal junction, vascular rings may embrace the trachea or the esophagus and, consequently, pose a threat during intubation or tracheostomy.

Learning Objectives:

1. To learn about structures at risk during functional endoscopic sinus surgery (FESS).
2. To become familiar with vascular variants in the head and neck.
3. To appreciate surgical anatomical landmarks in the head and neck.

A-310 17:00

C. Distinct head and neck disease or systemic disease?

M.G. Mack; *Munich/DE (m.mack@radiologie-muenchen.de)*

Head and neck manifestations of systemic disease is characterized by a multitude of maladies that have manifestations in the head and neck. This lecture relates commonly encountered head and neck symptoms and signs to an array of diseases and disorders that should be considered in the differential diagnosis. During this lecture, systemic disorders with head and neck manifestation (e.g. Sjögren's syndrome, Adamantiades-Behcets disease, granulomatous disease like Wegener's granulomatosis), infectious disease (e.g. tuberculosis fungal rhinosinusitis and HIV-related disease), malignant disease (e.g. lymphoma, myeloproliferative disorders and leukaemia, malignant melanoma, histiocytosis, sickle cell anaemia and rhabdomyosarcoma) or other systemic disorders (e.g. Paget's disease of bone and fibrous dysplasia) will be presented.

Learning Objectives:

1. To recognise head and neck manifestations of systemic disease.
2. To categorise lesions into different pathologic entities.

Imaging of the prostate

Moderator:
P. Puech; Lille/FR

A-311 16:00

A. MRI staging of prostate cancer

G.M. Villeirs; *Ghent/BE*

Staging involves the correct assessment of the local tumour situation (T), involvement of lymph nodes (N) and of distant metastases (M). According to the European Association of Urology (EAU) Guidelines, assessment of lymph nodes is only useful in patients with a PSA >10, Gleason score >7, >cT2b. Imaging can be performed using the well-known size criteria (round node >8mm, short axis of oval node >10mm) on CT or MRI, but this approach clearly lacks both sensitivity and specificity. Diffusion-weighted MRI incorporating morphologic features, MR-lymphangiography using ultra-small particles of iron oxide (USPIO), and nuclear medicine techniques such as choline- and PSMA-PET/CT offer higher sensitivity and specificity, but cannot (yet) replace the current gold standard (pelvic lymphadenectomy). The search for distant metastases (T) primarily involves skeletal assessment in patients at increased risk (PSA >20, Gleason >8, cT3-cT4). The current gold standard is the bone scan, but whole body MRI and new PET tracers seem to be on track to replace the bone scan as gold standard. In the absence of N+ or M+ disease, MRI can be used to assess the local status (T). High-resolution T2-weighted images are used to assess potential extracapsular extension or seminal vesicle invasion. Although this is a recommended approach according to the EAU guidelines, the accuracy of such T-staging is currently still quite variable. However, standardization of scanning techniques for staging and standardization of diagnostic criteria may solve this problem.

Learning Objectives:

1. To understand the current role of prostate MRI.
2. To learn how to optimise imaging and reporting.
3. To illustrate the staging approach.

A-312 16:30

B. Pitfalls in MRI of the prostate

V. Panebianco; *Rome/IT (valeria.panebianco@uniroma1.it)*

Currently, high-quality multi-parametric magnetic resonance imaging (mpMRI) represents a promising modality for the diagnosis, characterisation and treatment planning of prostate cancer. However, some physiological changes in the peripheral and central zone may simulate prostate cancer. Consequently, mp-MRI often leads to interpreting doubts and misdiagnosis due to the many interpretative pitfalls that a tissue, whether healthy or treated, may cause. The detection of prostate cancer on mpMRI can be confounded by false-positive or false-negative findings. These “false-positive/negative” findings may occur in each stage of the disease history, from the primary diagnosis and staging, to post-treatment stage and their recognition is critical for proper treatment and management. Knowledge of these known pitfalls and their interpretation can help radiologist to avoid misdiagnosis and consequently a wrong treatment. PI-RADS score often is decisive for definitive diagnosis and in particular PIRADS vers. 2 even more based on “dominant sequence” for each portion of the gland. In the lecture, a wide spectrum of prostate mp-MRI pitfalls that may occur in clinical practice will be presented, with radiological and pathological correlation. In addition, some difficult cases focusing on the presence of cancer in pitfalls will be discussed. In summary, the purpose of this course is to provide a practical guide to the radiologist for imaging interpretation in prostate cancer, with a focus on how to discriminate pathological tissue from the most common pitfalls that may be encountered during daily clinical practice with the aid of PI-RADS v. 2.

Learning Objectives:

1. To illustrate the classification of the most common pitfalls on mpMRI of the prostate.
2. To discuss the role of PI-RADS version 2 in interpreting pitfalls in prostate MRI.
3. To learn how to avoid pitfalls.

A-313 17:00

C. Imaging of PSA recurrence

H.-P. Schlemmer; *Heidelberg/DE (h.schlemmer@dkfz.de)*

Although radical prostatectomy and radiotherapy are first-line treatment options for patients with organ-confined prostate cancer, subsequent biochemical recurrence develop in ca. 40% of the cases. Early detection and precise localisation of local recurrence and/or systemic cancer spreading is essential for optimised treatment. Early detection of local cancer recurrent after radical prostatectomy is particularly challenging, as salvage radiotherapy with curative intention is achievable only in case of low tumour load and accordingly low PSA serum levels. Conventional TRUS has limited sensitivity and specificity for detection of local recurrence. Multiparametric MRI (mpMRI) has been shown to be superior for detection of local recurrence, although early detection of small cancer foci is also significantly limited. mpMRI is, furthermore, significantly limited concerning early detection of lymph node and/or bone marrow metastases, which is on the other hand essential for prognostic stratification and individualised therapy. In case of PSA recurrence after therapy highest sensitivity for cancer detection is achieved by PET, although the accuracy strongly depends on the radiotracer. In clinical routine, C-11 or F-18 choline and Ga-68 or F-18 PSMA PET/CT is used most notably. PET/MR imaging provides additional advantaged by combining the highest sensitivity of PET with best anatomical referencing and functional tissue characterisation by mpMR. This lecture will provide an overview about the currently available imaging methods for detection of recurrence in case of PSA recurrence. Their clinical relevance will be discussed against the background of the potential therapy options.

Learning Objectives:

1. To understand the clinical need and indications for advanced imaging in patients with PSA recurrence.
2. To learn about the potentials of multiparametric MR for the detection of locoregional recurrence.
3. To become familiar with the clinical impact of PET/CT and PET/MRI using different radiotracers.

EuroSafe Imaging Session

EU 3

European Alliance for Medical Radiation Protection Research (EURAMED)

Moderator:
G. Frija; Paris/FR

A-314 16:00

Introduction of EURAMED

C. Hoeschen; *Magdeburg/DE (christoph.hoeschen@ovgu.de)*

EURAMED is currently a Joint Initiative of EIBIR. It has been launched in September as a platform at the Radiation Protection Week 2016. EURAMED is a platform which is intended to be a counterpart and partner of the existing platforms MELODI, ALLIANCE, NERIS and EURADOS representing radiation protection research in Europe. The last four mentioned platforms kind of determined the research topics in radiation protection research funding in Europe in the last few years due to their existing Strategic Research Agendas (SRAs). MELODI and EURADOS did sign memoranda of understanding with the five associations representing use of ionizing radiation in medical application (EANM - European Association of Nuclear Medicine; EFOMP - European Federation of Organisations for Medical Physics; EFRS - European Federation of Radiographer Societies; ESR and ESTRO - European SocieTy

for Radiotherapy and Oncology) reviewing the impact of use of ionising radiation in medicine. The associations initiated with the help of the EU Project OPERRA the development of a "medical strategic research agenda". This SRA is available for the public using the EIBIR webside. The importance of medical radiation protection research got more prominent and the associations therefore decided to set up a platform. This platform was already able to foster the preparation of a proposal for a EURATOM call and to determine a subtopic for the second CONCERT call. The platform plans to do biannual actualisations of the SRA and to foster medical radiation protection research by helping with European calls and develop a corresponding researcher database. Further developments are planned.

Learning Objectives:

1. To be introduced to EURAMED.
2. To become familiar with how EURAMED has been developed.
3. To learn what its objectives are.
4. To understand how EURAMED could benefit the ESR.

A-315 16:18

Cardiovascular effects of radiotherapy in breast cancer patients: potential mechanisms

W. Dörr; *Vienna/AT (wolfgang.doerr@meduniwien.ac.at)*

Most of the clinical endpoints of radiation effects in the heart are clearly promoted by factors like pre-existing vascular disease, such as atherosclerosis, and hence must be considered multifactorial. Radiation effects are observed in the peri- and myocardium, cardiac valves, coronary arteries and the microvasculature, as well as in the conduction system. In the pericardium, early inflammatory reactions are uncommon even at high doses of ionizing radiation. Late pericardial changes are usually asymptomatic, but can develop into chronic and/or constrictive pericarditis. The dominant late change is pericardial fibrosis. Myocardial changes follow three phases: acute (within 6 h after exposure) inflammation, a clinically silent latent phase where myocardial capillary endothelial cell damage results in capillary obstruction and thrombi formation, and then local ischaemia and consequent myocardial cell death and fibrosis. The cardiac valves are also subject to fibrotic transformation, with unclear radiopathological mechanisms - independent of microvascular changes, as the valves are avascular - potentially related to direct radiation-induced differentiation of fibroblasts into collagen-producing fibrocytes. Both types of cardiovascular morbidity, i.e. coronary artery disease (mainly left anterior descending and right coronary arteries) through the acceleration of age-related atherosclerosis and a decrease in capillary density causing chronic ischaemia and focal myocardial degeneration, are relevant for radiation effects in the heart. The radiation exposure of the surrounding tissues (particularly the lung, but also the liver) seems to impact on the clinical manifestation.

Learning Objectives:

1. To become familiar with which CV effects we see in breast cancer treated patients.
2. To learn how these effects could be optimised in terms of endpoint specificity.

A-316 16:36

Circulating biomarkers reflecting dose exposure

R. Tamarat; *Fontenay-aux-Roses/FR (radia.tamarat@irsn.fr)*

Microparticles (MPs) are extracellular membrane vesicles with potent biological activities. Circulating levels of MPs have been associated with outcome of several cardiovascular and inflammatory diseases. We conducted a large prospective study to determine whether the number and/or the type of circulating MPs could be used as potential biomarkers of rectorragic grade and severe complications in patients with prostate adenocarcinoma overexposed to radiation. We also assessed their biological activity with regard to their pro-coagulant and pro-inflammatory potential. Blood samples were obtained from a cohort of 217 patients overexposed to irradiation during their radiotherapy. Flow cytometry analysis of platelet-free plasmas indicated that circulating levels of Annexin V+ MPs were increased by 3-fold in grade 3/4 patients compared to grade 0, 1 and 2 patients according to the rectorragic grade. Platelet-derived MPs constituted the major MPs sub-population while the endothelial cell and monocyte-derived MPs were increased in grade 3/4 patients compared to the other grades. Clotting assays revealed a trend towards decreased pro-coagulant activity of MPs in grade 3/4 patients compared to other groups. MPs from grade 3/4 patients affected the endothelium activation in a P-selectin manner. High levels of circulating MPs derived from platelets, endothelial cells and monocytes correlate with grade 3/4 chronic radiation enteritis patients. MPs could be considered as a biomarker and may be valuable for the prognostic of radiation therapy complications.

Learning Objectives:

1. To learn about the extracellular vesicles (EV) as circulating biomarkers.
2. To understand how to evaluate the different EV and their origins.
3. To learn how to use EV as biomarkers in a prostate adenocarcinoma cohort.

A-317 16:54

General physical principles used for optimisation

G. Paulo; *Coimbra/PT (graciano@estescoimbra.pt)*

For an optimisation strategy to be effective, all health professionals involved in the use of x-ray equipment need to have knowledge and access to the results of performance tests and patient dose surveys. In addition, there should be a continuing programme of assessment to track any changes in equipment performance. Links between the radiographer, the medical physicist and the radiologist to provide a greater opportunity for optimisation are essential. The main objective of optimisation of radiological procedures is to adjust imaging parameters and implement measures in such a way that the required image is obtained with the lowest possible radiation dose and maximised benefit, considering patient characteristics and clinical indication. To achieve this goal, good practice in radiographic technique is needed and, therefore, special attention must be given, simultaneously, to several aspects of the procedure, such as (a) patient positioning and immobilisation, (b) accurate field size and correct x-ray beam limitation, (c) the use of protective shielding, when appropriate and (d) optimisation of radiographic exposure factors. Using a correct beam limitation is crucial to avoid unnecessary radiation dose outside the area of interest, and prejudice the image contrast and resolution by increasing the scattered radiation. Applied research in radiology is the necessary tool to analyse the problems and find the solutions on how to best optimize the medical imaging procedure. Translating the research results into clinical practice will contribute to improve the quality of care delivered to our patients.

Learning Objectives:

1. To learn how optimisation should take place.
2. To understand that image quality and dose depends on the class of patients.
3. To learn how to transfer this optimisation into clinical practice.

A-318 17:12

Dose distribution in interventional radiology

H. Schlattl; *Munich/DE (helmut.schlattl@helmholtz-muenchen.de)*

The small field sizes applied during radiological interventions lead to significant dose gradients in organs close to the region of interest. Thus, mean organ doses might be misleading when estimating the actual radiation risk of the patient. With the largest skin entrance doses observed for coronary angiographic interventions, these are examined in more detail. Local dose conversion coefficients are computed using Monte Carlo simulations by employing human models which represent the average Caucasian adult man and woman as defined by the International Commission on Radiological Protection. In the 21 investigated projections, the mean organ dose conversion coefficients vary from a few 0.01 to 2 mGy/(Gy cm²), depending on the projections. Especially in portions of the lungs and the active bone marrow, the conversion coefficients can locally amount up to 10 mGy/(Gy cm²), i.e., half the average conversion coefficient of the skin at the field entrance. The dependence of the patient dose on the projection has been estimated too. Highest patient doses are observed for left anterior oblique views with strong caudal or cranial orientation, while for the remaining image-intensifier positions no significant dose differences could be identified.

Learning Objectives:

1. To learn how to determine dose distributions by simulations.
2. To understand reasons for dose differences in organs for interventions.
3. To understand optimisation of dose distributions in interventional radiology, e.g. to avoid deterministic effects.

16:00 - 17:30 **Room E1**

Radio-pathological correlation: more important than you thought

A-319 16:00
Chairmen's introduction
F.J. Gilbert; *Cambridge/UK (fjg28@cam.ac.uk)*
M.R. Parizel; *Antwerp/BE (maxim.parizel@gmail.com)*

In breast imaging, correlation of the pathology results with imaging findings is essential to properly carry out triple assessment of clinical examination, imaging and core biopsy. This approach has a very high sensitivity and if correctly implemented will result in very few cancers being missed. Multidisciplinary team meetings ensure that women's biopsy findings are reviewed to ensure that the correct area has been targeted and that the pathological findings are appropriate for the clinical and imaging diagnosis.
Author Disclosure:
F.J. Gilbert: Research/Grant Support; Hologic, GE Healthcare.

A-320 16:05
A. Pretreatment planning
C.K. Kuhl; *Aachen/DE*

"no abstract submitted"
Learning Objectives:
1. To know the role of the imaging methods for preoperative staging.
2. To understand the need for imaging-guided needle sampling and localisation for a tailored surgery.
3. To appreciate the need for changing surgical guidelines for treating breast cancer.

A-321 16:28
B. Intraoperative specimen evaluation
J. Camps Herrero; *Valencia/ES (juliacamps@gmail.com)*

After a thorough integrated radiological diagnosis in breast cancer staging, the following phase is as important as the rest to achieve a thorough and exact map of the cancer's extent and minimize the risk of positive margins. Preoperative planning together with the surgeon is essential, especially in those instances which are complex and have higher possibilities of yielding positive margins if the surgical decision is to preserve the breast: extensive DCIS, extensive multifocal disease, cancers with extensive intraductal component (EIC) and rare instances of multicentric cancers in which the surgeon chooses to preserve the breast. After the patient is marked with one of the many available options (hook-wire, radioactive seeds, SNOLL, ROLL), the next step is to evaluate the specimen obtained during surgery. The most common technique is the radiography of the specimen, although ultrasound has also been used in nodular lesions and lately, tomosynthesis is also being used. The most important issues in peroperative evaluation of specimens are: to know well the orientation protocol used by the surgeon, to know with detail the patients' staging results and to be fast conveying the information on margins to the surgeon.
Learning Objectives:
1. To learn about different imaging techniques for preoperative marking and intraoperative specimen evaluation.
2. To become familiar with methods for specimen orientation and handling.
3. To understand the need for immediate reporting/reaction from radiological department to surgical room.
Author Disclosure:
J. Camps Herrero: Advisory Board; Bayer.

A-322 16:51
C. The breast radiologist sitting down with the pathologist
T. Tot; *Falun/SE (tibor.tot@ltdalarna.se)*

Most breast carcinomas exhibit complex subgross morphology already in the in situ phase. If the cancer is located in the terminal ductal-lobular units, it may manifest as unifocal or multifocal disease and may be associated with clustered calcifications. Cancer in situ that develops predominantly in larger ducts is most often diffuse, extensive, high grade, and may be associated with linear branching (casting type) calcifications or may cause architectural distortion. The invasive component of the tumour usually manifests as circular/oval or stellate density, and rarely as architectural distortion only. One third of invasive cases are unifocal, with a single invasive focus and in situ component within and/or in the vicinity of this focus. Another third of the cases are characterized by the presence of a single invasive focus, but associated with a diffuse or multifocal in situ component. The final third of the cases exhibit a multifocal invasive component. Almost half of these cases are extensive in which the individual foci occupy a tissue volume of greater than 4 cm in the largest dimension. Multimodality breast radiology is able to asses this complexity of subgross morphology with high and ever increasing accuracy. Small samples of the specimen with invasive cancer used in conventional pathology may be fully sufficient for typing and grading the tumour and for molecular and genetic analysis, but a special technique using non-fragmented contiguous tissue slices including the cut surface of the entire specimen (large-format histology) is required for detailed and systematic radiological-pathological correlation.
Learning Objectives:
1. To understand the importance of using imaging to guide the pathologist in complex lesions.
2. To know the different ways of correlating radiology and pathology.
3. To learn how to enhance this cooperation in order to achieve the best results in terms of tumour extension and tumour margins.

17:14
Panel discussion: How to enhance the interaction between radiologists and pathologists?

Toxic brain disorders
Moderator:
P. Due-Tønnessen; Oslo/NO

A-323 16:00
A. Alcohol-related changes in the brain
M. Knauth; *Göttingen/DE*

Alcoholism is a major problem (not only, but also) in the western industrial societies, including Europe, of course. Therefore, every radiologist has to be familiar with the MRI detectable changes that can occur in the brain in acute, chronic or acute on chronic alcohol intoxication. This does not only include alterations of the brain structure that are directly caused by ethanol, but also those that are more correctly attributable to the circumstances of chronic alcohol addiction, i.e. malnutrition. Also, the lecture will deal with the reversibility potential of some of these brain changes when alcohol abstinence can finally be achieved. The main focus will be the ethanol-induced brain changes, but we will glance at "neighbouring" alcohols as well.
Learning Objectives:
1. To document how imaging can help to make the diagnosis of acute alcohol poisoning and chronic alcoholic encephalopathy.
2. To discuss Wernicke encephalopathy.
3. To present the imaging findings in methanol and ethylene glycol poisoning.

A-325 17:00
B. Recreational drugs and occupational hazards
L. van den Hauwe; *Antwerp/BE (lucvdhauwe@mac.com)*

Drug abuse is a substantial problem in society and is associated with significant morbidity and mortality. It is an epidemic that crosses racial, socioeconomic, and age barriers. According to the 2016 Global Drug Survey, besides alcohol, tobacco and caffeine products the top 10 drugs used across the world are: cannabis, MDMA, cocaine, amphetamines, LSD, magic mushrooms, prescribed & non-prescribed opioid medication, nitrous oxide, ketamine and poppers. Various drugs may cause central nervous system (CNS) complications and include neurovascular complications, toxic leukoencephalopathy, atrophy, infection, changes in the corpus callosum, etc. The lecture will focus on acute neurovascular complications: the most frequent drug-related emergencies. They include ischaemic stroke, subarachnoid and intracerebral haemorrhage. Multiple drugs are associated with neurovascular complications, but cocaine is the hallmark drug. Mechanisms of action contributing to these ischaemic strokes include direct vasospasm, enhanced platelet aggregation, cardioembolic sources, accelerated atherosclerosis, and cerebral vasculitis. Subarachnoid haemorrhage may be found as a result of aneurysm rupture; up to 50% of patients have aneurysms and arteriovenous malformations. Also toxic leukoencephalopathies have been described. A specific pattern has been ascribed to the inhalation of heroin vapour when the drug is heated on tinfoil, a practice known as "chasing the dragon". A more nonspecific leukoencephalopathy is seen in chronic inhalant abuse of industrial solvents, e.g. toluene. Such lesions can be explained by the high affinity of

these lipophilic volatile agents for myelin. Imaging changes as a result of occupational exposure to other chemical substances such as lead, mercury, and cyanide will be discussed.

Learning Objectives:

1. To present an overview of recreational drugs and how they influence the brain.
2. To illustrate the effect of drugs on imaging studies (amphetamines, ecstasy, cocaine, heroin, methadone, …).
3. To understand how occupationally used toxic substances can influence the brain (including toluene, cyanide, organophosphates, lead and mercury poisoning, …).

Author Disclosure:

L. van den Hauwe: Consultant; icometrix, Leuven/BE.

A-324 16:30

C. Treatment-induced effects on the brain parenchyma

T. Lim; *Singapore/SG (tchoyoson_lim@nni.com.sg)*

Radiation and chemotherapy are the most common causes of iatrogenic CNS damage. The consequences of brain irradiation can be early (within weeks) early delayed (1-4 months) or late delayed (years after therapy). MRI features of contrast-enhancing mass surrounded by oedema and mass effect are not specific, and surgical brain biopsy is often needed for definitive diagnosis. Magnetic resonance spectroscopy and perfusion-weighted imaging showing increased choline/creatine ratio and increased relative cerebral blood volume in recurrent high-grade neoplasia, and increased tumour metabolism detected using fluorodeoxyglucose positron emission tomography and thallium 201 single photon emitted computed tomography may be helpful to distinguish recurrent neoplasm from radiation necrosis. Intrathecal chemotherapy drugs (especially methotrexate) can cause bilaterally symmetrical leucoencephalopathy, especially in patients receiving concurrent radiotherapy. Other examples of iatrogenic effects include posterior reversible encephalopathy syndrome (PRES, vasogenic oedema in the posterior part of the brain particularly the subcortical white matter). Causes include cyclosporin and cancer chemotherapy. Patients with systemic lupus erythematosus may develop post progressive multifocal leucoencephalopathy associated with intensive immunosuppressive therapy. Finally, transient diffusion-weighted imaging hyperintensity of the splenium of the corpus callosum has been reported, associated with antiepileptics and capecitabine. Radiologists should be familiar with the patterns of neuroimaging abnormality associated with treatment-induced effects, especially radiotherapy and chemotherapy in cancer treatment.

Learning Objectives:

1. To show the imaging findings after radiation therapy in the acute, early and late delayed stages.
2. To present an overview of long-term sequelae after radiation therapy.
3. To discuss treatment induced leukoencephalopathy after chemotherapy (especially methotrexate).

16:00 - 17:30 **Room F1**

ESR/ESOR 1

Radiologic anatomy: abdomen

Moderator:
S. Gourtsoyianni; London/UK

A-326 16:00

Liver

G. Brancatelli; *Palermo/IT (gbranca@yahoo.com)*

The liver is the largest organ in the human body. The penetration and branching of the hepatic artery, portal vein and hepatic veins allow to divide the organ into the eight traditional segments of the Couinaud scheme. Knowledge of vascular and segmental anatomy is important to correctly locate the site of disease and to perform increasingly demanding and challenging liver resection and transplantation. Anatomy of the liver can be altered by congenital variants, diseases causing hepatic dysmorphy and after surgery.

Learning Objectives:

1. To locate and identify, using cross sectional medical imaging, superficial and internal structures of common liver anatomy.
2. To learn and understand how the vasculature define the eight Couinaud segments.
3. To explain how common pathological conditions affect the structure of the liver.

Author Disclosure:

G. Brancatelli: Author; Springer; Elsevier. Speaker; Bayer. Other; funding for travel to educational meetings from Bayer Healthcare and Bracco..

A-327 16:30

Biliary tree

O. Benjaminov; *Petach Tikva/IL (obenjaminov@gmail.com)*

"no abstract submitted"

Learning Objectives:

1. To discuss current imaging techniques for evaluation of normal biliary anatomy.
2. To learn and understand possible anatomical variants that may occur.
3. To explain how common pathological conditions affect the bile ducts.

A-328 17:00

Pancreas

M. Dioguardi Burgio; *Clichy/FR (marco_dioguardi@hotmail.it)*

The pancreas is a retroperitoneal gland, which is anatomically divided into 4 portions: head, neck, body and tail. Main anatomical relationships of the head are duodenal loop, the porta hepatis, and the superior mesenteric vessels. Body and tail anatomical relationship includes left kidney and adrenal gland, posterior gastric wall and lesser sac, splenic hilum, celiac region and duodenojejunal junction. Main pancreatic duct (Wirsung) drains into the major papilla most of the pancreatic secretions. A common biliopancreatic tract may be present. An accessory duct (Santorini) is usually present draining the anterior part of the pancreatic head in the minor papilla. Pancreatic gland is the result of the fusion of two buds. During the seventh gestational week the ventral bud rotates around the duodenum and it locates inferiorly and posteriorly to the dorsal bud. The fusion of the two buds leads to anastomosis of the ductal systems. Anomalies of this fusion process are at the base of the wide spectrum of anatomical variants which pancreatic parenchyma and ductal system may present. Those variants include pancreas divisum, ansa pancreatica, annular pancreas, ectopic pancreas, pancreatic hypoplasia or agenesis. Pathological involvement of the pancreas may be focal or diffuse. Radiological appearance of the gland is modified depending on aetiology and chronology of pancreatic involvement. Moreover, ductal system and peripancreatic tissue/organ changes are often associated. Knowledge of basic CT and MR modifications induced by common pancreatic pathologies is necessary to reach a proper diagnosis and to orientate patient's follow-up and therapeutic strategy.

Learning Objectives:

1. To review and illustrate the imaging features of normal pancreatic anatomy.
2. To review the possible congenital variants and anomalies of the pancreas and pancreatic duct.
3. To explain how common pathological conditions affect the pancreas.

16:00 - 17:30 **Room F2**

Oncologic Imaging

RC 816

Evaluating lymph node involvement: an impossible task?

A-329 16:00

Chairman's introduction

P. Lalitha; *Hyderabad/IN*

Session Objectives:

1. To understand diagnostic imaging difficulties in the evaluation of nodal involvement.
2. To understand the complementary information obtained with CT, MRI and PET.
3. To learn about advanced imaging techniques (CT - dual-energy; MRI - DWI, and PET) for evaluating nodal involvement.
4. To recognise pitfalls in evaluating nodal involvement using CT, MRI and PET.

A-330 16:05

A. The current criteria for nodal involvement MRI/CT

D. Tse; *Hong Kong/HK (donald.tse@gmail.com)*

Lymph nodes are often the first site of metastasis in many of the common cancers. Presence or absence of regional lymph node metastasis is a critical component of the UICC/AJCC TNM classification, now in its 8th edition. Nodal(N) staging has therapeutic significance in a number of cancers in determining operable vs inoperable disease, and use of neo-adjuvant or adjuvant therapy. For most malignancies, CT and MRI (and ultrasound) remain the main imaging modalities for nodal staging. Differentiation of metastatic lymph nodes from normal or benign reactive nodes relies on various

parameters afforded by CT/MRI; size is most widely used, and the only parameter used for nodal classification in the RECIST v1.1 criteria. In RECIST, 10mm is used as cutoff for non-pathological nodes, though in the chest and abdomen location-specific threshold sizes have been described. However, using size criteria alone has limited diagnostic accuracy when compared with the reference standard of histology; in rectal cancer, there is significant overlap in the sizes of benign and malignant nodes. Thus, various other imaging parameters, including attenuation, signal, homogeneity, border regularity, location, number, clustering and contrast enhancement, are also used for nodal classification in routine clinical practice. While each feature individually offers relatively poor diagnostic accuracy, with possible pitfalls such as necrotic nodes in infection, combinations of multiple imaging parameters can lead to improved sensitivity and specificity for diagnosing malignant nodes. Techniques including computer-aided algorithms have been explored to provide more quantitative nodal assessment. Nevertheless, nodal staging on CT and MRI remains a challenge.

Learning Objectives:

1. To understand the role of local nodal staging and its importance for management and prognosis.
2. To become familiar with the current imaging criteria for assessment of nodal metastases.
3. To understand the diagnostic performance of cross-sectional imaging.

A-331 16:28

B. Advanced MRI techniques: what do they contribute?

H.C. Thoeny; *Berne/CH (harriet.thoeny@insel.ch)*

Up-to-date lymph node staging is based on size and shape criteria only; however, micrometastases can also be present in normal-sized lymph nodes and nodes can be enlarged due to inflammatory changes. New contrast agents in MRI such as ultrasmall particles of iron oxide (USPIO) have substantially improved the diagnostic accuracy of lymph node staging. Unfortunately, USPIO are not commercially available on the market. DW-MRI is a noninvasive method that provides tissue microstructural information, and several studies mainly in the pelvis have shown promising results for lymph node detection and differentiation between benign and malignant nodes. These studies reported sensitivities of 79-100% and specificities of 74-93% using the underlying ADC-value; lower ADCs were reported in malignant nodes as compared to benign ones. On the other hand, it has been shown that there is a considerable overlap between ADC values of benign and malignant nodes. A recent prospective study in 120 patients with bladder and prostate cancer and normal-sized pelvic LNs on conventional cross-sectional imaging compared DW-MRI to histopathology based on extended pelvic lymph node dissection. It has been shown that the combination of DW-MRI findings and meticulous analysis of morphological findings allowed to detect malignant lymph nodes even in normal-sized nodes. The combination of USPIO with DW-MRI might further facilitate and improve lymph node staging in the future, provided that USPIOs will become available for clinical use. Initial promising results on the use of ferumoxytol in this context have already been publishes recently.

Learning Objectives:

1. To understand the principle of DWI of nodes.
2. To learn about the appearances of malignant nodes on diffusion-weighted MRI.
3. To become familiar with node-specific enhanced MRI.

Author Disclosure:

H.C. Thoeny: Advisory Board; Guerbet.

A-332 16:51

C. PET and other nuclear medicine techniques

T. Barwick; *London/UK (tara.barwick@imperial.nhs.uk)*

PET/CT imaging using 18-fluoro-deoxyglucose (FDG), a glucose analogue, has an established role in oncology for the staging and response assessment of a variety of tumours. For the assessment of nodal involvement visual analysis and semi-quantitative SUV analysis are utilised. However, there are no reliable absolute SUV cutoffs to differentiate between benign and malignant lymph nodes. It is very important to be familiar with the typical patterns of spread of the specific cancer being assessed as this also influences the likelihood of disease involvement. Glucose metabolism is not specific for malignancy and false positives can occur with inflammation, infection and other processes such as a sarcoid-like reaction to malignancy. Further pitfalls are that some well-differentiated malignancies have only low-level glucose metabolism and the limited spatial resolution of PET means involvement of small nodes may be missed or the level of metabolic activity may be underestimated in small nodes. New radiotracers which target more specific pathways such as C-11/ F-18 fluorocholine which target cell membrane metabolism and Ga-68 prostate-specific membrane antigen (PMSA) which targets a cell surface protein are gaining increasing use in prostate cancer imaging and the Ga-68 Dota-peptide tracers for somatostatin receptor imaging of neuroendocrine tumours.

Learning Objectives:

1. To learn the typical appearance on nodal metastatic disease on FDG.
2. To recognise the pitfalls for interpretation.
3. To become familiar with new radiotracers, including choline and PSMA PET, for the demonstration of nodal disease.

16:00 - 17:30 **Room D**

Musculoskeletal

RC 810

Inflammatory arthritis: beyond the radiograph

A-333 16:00

Chairman's introduction

M. Reijnierse; *Leiden/NL (m.reijnierse@lumc.nl)*

Radiographs have been the cornerstone of rheumatology for a long time. Hand and foot radiographs are scored in rheumatoid arthritis patients to assess baseline bone destruction and are used in follow-up. In spondyloarthritis, pelvic radiographs are used to detect sacroiliitis. Radiographs and scoring methods are based on the identification of structural changes secondary to disease. Since new effective medication has become available, the focus in rheumatology has shifted towards early disease detection to treat early and prevent damage. Ultrasound and MRI might play a role in this since they detect active inflammation. With the use of colour Doppler in ultrasound, hypervascularisation can be appreciated and (teno)synovitis diagnosed. MRI has the additional value of the detection of bone marrow oedema and shows subclinical inflammation. The exact position of these imaging techniques in rheumatology is still under debate; however, they are increasingly used in research and daily practice. This refresher course aims to give an update on the diagnosis of inflammatory arthritis beyond the radiograph.

Session Objectives:

1. To gain insight into the merits of various imaging modalities in the daily practice of radiology of rheumatology.
2. To appreciate the crucial radiological contribution we need to provide in order to support optimal clinical decision making.

Author Disclosure:

M. Reijnierse: Grant Recipient; Dutch Arthritis Foundation.

A-334 16:05

A. Rheumatoid arthritis: what does MRI show and how do I do it?

I. Sudoł-Szopińska; *Warsaw/PL (sudolszopinska@gmail.com)*

Magnetic resonance imaging is being increasingly used both in RA research and in clinical practice due to its capacity to provide insight into pathogenesis of RA, the ability to identify the key pathologic features of this entity at presentation, to follow up patients' treatment results, and to establish remission. This presentation will cover two issues: 1. MRI techniques used in the assessment of rheumatoid arthritis, including sequences and protocols most frequently applied in imaging of various peripheral joints and the spine; 2. MRI findings in rheumatoid arthritis within synovial joints, tendons' sheaths, subchondral bone marrow, articular and extraarticular fat tissue. This part will make us aware that next to the synovium, which is a well-known source of inflammatory cells and a site for aggressive pannus formation, the same process may occur within the subchondral bone marrow or adipose tissue. In addition, the following issues will be addressed: 1. the importance of MRI in subclinical and early diagnosis of RA. 2. Monitoring the disease activity and progression, including the clinical relevance of synovitis and BME in terms of their role as an erosion precursor. 3. Assessing remission/residual synovitis, tenosynovitis, osteitis. 4. Identification of disease complications, especially within the spine.

Learning Objectives:

1. To become familiar with MRI techniques used in the assessment of rheumatoid arthritis.
2. To learn about the MRI findings in rheumatoid arthritis and their significance.

A-335 16:28

B. The axial skeleton in spondyloarthritis: conventional radiograph to MRI

R. Campbell; *Liverpool/UK (Rob.Campbell@rlbuht.nhs.uk)*

Inflammatory spondyloarthropathy (SpA) includes ankylosing spondylitis, psoriatic and reactive arthritis, enteropathic SpA, juvenile SpA and undifferentiated SpA. The assessment of spondyloarthritis (ASAS) International Society criteria for diagnosis of SpA includes MRI for disease staging. Imaging should include the sacro-iliac (SI) joints, and the dorsal and lumbar spine, utilising a combination of T1W and STIR or T2W fat-saturated sequences. In the SI joints, bone marrow oedema and sclerosis are present in areas of sub-chondral inflammation. Identification of bone erosion helps differentiate inflammatory disease from stress related or degenerative change. In the spine, inflammatory corner lesions of the vertebral bodies are one of the earliest signs of SpA, with bone marrow oedema on MRI. They may become sclerotic (previously termed Romanus lesions on radiographs), or fatty replacement may occur in inactive lesions. Inflammatory lesions also involve the facet joints, spinous processes, and costovertebral joints. Other features include disco-vertebral erosion, and syndesmophyte formation. Syndesmophytes may progress to profuse spinal ossification, with ankylosis across the intervertebral disc. Ankylosis of the facet joints, intervertebral ligaments and costovertebral joints also occurs in advanced disease. The proliferative bone formation in psoriasis and reactive arthritis tends to show more asymmetry than ankylosing spondylitis and enteropathic SpA, with more pronounced bony excrescences and paravertebral ossification. The radiologic patterns of inflammatory SpA must be differentiated from the bone formation associated with spondylosis deformans and DISH. Disco-vertebral erosion may mimic Modic changes associated with disc degeneration, cartilaginous Schmorl nodes an even infective discitis.

Learning Objectives:

1. To become familiar with imaging findings seen in the axial skeleton in spondyloarthritis.
2. To understand features on imaging which distinguish spondyloarthritis from other spinal diseases.

A-336 16:51

C. Ultrasound in inflammatory arthritis: what does it show and what does it mean?

A. Klauser; *Innsbruck/AT*

Ultrasound (US) is an established imaging modality for early detection, characterisation and follow-up of various forms of inflammatory arthritis, performed by radiologists and rheumatologists as well. It allows for the detection and characterisation of changes like synovial thickening, synovial proliferation, destructive pannus, effusion, erosions and enthesitis. Using PDUS a further assessment of synovitis and erosions can be obtained by classifying them in active versus nonactive, what has implication for the therapeutic management. Beside intraarticular inflammatory changes also periarticular and extraarticular inflammation in terms of tenosynovitis and enthesitis can be sensitively detected, not always easy to differentiate from articular inflammation by clinical investigation. However, as every imaging modality when assessing arthritis, the initial analysis has to start from the "joint-organ" concept, by dividing the imaging findings in synovial disease, cartilage disease or enthesis disease. This allows not only for basic differential diagnosis but is fundamental especially in more challenging cases, which will be also discussed in this lecture.

Learning Objectives:

1. To become familiar with US techniques used in the assessment of inflammatory arthritis.
2. To learn about the US findings in inflammatory arthritis and their significance.

17:14

Panel discussion: How practical is it for radiologists to support ultrasound and MRI for clinical rheumatology? Is it something the rheumatologists should undertake themselves?

16:00 - 17:30 **Room G**

State of the Art Symposium

SA 8

Forensic and post-mortem imaging

A-337 16:00

Chairman's introduction

P.A.M. Hofman; *Maastricht/NL (paul.hofman@mumc.nl)*

Radiology has always played a role in forensic and death investigations but only after the introduction of high-resolution cross-sectional imaging techniques both forensic and clinical postmortem radiology are evolving into a new subspeciality. There are two application fields: court procedures or law enforcement and the clinical use as a quality assurance or teaching tool. In all these cases, imaging can be an independent examination and the combination with an external examination, an autopsy and toxicological examination will provide more comprehensive information on the cause and manner of death and disease processes. The questions in a forensic setting will differ from a clinical setting but in both applications the level of expertise of the interpreter will determine the quality of the examination. It is, therefore, essential that radiologists are involved in these procedures. As in all new applications of imaging techniques it is important to establish a scientific basis, which positions forensic and postmortem radiology as a reliable method. The last decade many studies have been publishes but there are still many issues that need to be addressed. This includes pathologies that are difficult visualize. Another important question that needs to be answered during a forensic examination deals with injury patterns, and injury mechanisms and most research has been focused on individual injury rather than on injury patterns. Also the timing of injury and the time of death are important forensic issues that are still challenging for imaging. Therefore, more and larger studies are needed to establish a scientific basis.

Session Objectives:

1. To update delegates on the role of radiologists in post-mortem and forensic radiology.
2. To update delegates on the radiology in death investigations.
3. To discuss the role of various imaging modalities.
4. To highlight areas where further research is required.

A-338 16:07

Introduction to post-mortem radiology

T. Ruder; *Zurich/CH (Thomas.Ruder@irm.uzh.ch)*

Over the last 20 years, forensic radiology underwent tremendous growth and today, pre-autopsy post-mortem CT or MR are standard practice in many countries worldwide. Imaging is used for personal identification, documentation of injury, as evidence in court and for research and teaching in forensic sciences. The aim of this lecture is to provide an introduction to the field of forensic radiology and entice radiologists to get involved in this growing sub-speciality area. The lecture includes a discussion about the role and the potential of radiologic imaging in forensic medicine; a description of imaging modalities used in post-mortem imaging such as CT, CTA and MR; an outline of minimum standards for image acquisition in post-mortem forensic radiology; a review of current applications of cross-sectional imaging in forensic death investigations, including forensic identification, documentation of injury, disease and death; a note on legal aspects and peculiarities of reading, reporting and presenting findings in forensic radiology.

Learning Objectives:

1. To understand the potential role of post-mortem imaging and forensic imaging.
2. To discuss the different imaging techniques and protocols for post-mortem imaging.
3. To learn about the typical imaging findings and pitfalls.
4. To discuss relevant legal issues related to forensic radiology.

A-339 16:24

Post-mortem imaging: a pathologist's perspective

D. Ranson; *Melbourne/AU (david.ranson@vifm.org)*

PMCT is completely integrated with Coroners' death investigation procedures in Melbourne and this has been associated with a halving of the autopsy rate over the past 15 years. In Australia, the reliance on PMCT as a death investigation tool is becoming firmly established. The historical background to this change in death investigations and the medical, social and legal advantages that have accrued will be explored. We believe that considering autopsies to be the main medical tool (or the 'gold standard') of medico-legal death investigation is an outdated approach today. Unfortunately, legislation is often focused on these traditional approaches and this has influenced some of

the case law that has emerged following family objections to autopsy. These views have also driven the academic and community debate that seeks to address the question as to whether PMCT can replace autopsy. We believe this approach is fundamentally flawed and it should be replaced by a consideration of how PMCT can provide part of the evidence base that helps identify what are procedures are appropriate in a particular death investigation. This paper outlines the benefits that arise when you analyse the medico-legal death investigation process and re-engineer it so that PMCT, autopsy, 24-hour toxicology, 24-hour DNA, fast electronic access to medical records, scene photography/video and early external examinations are seen as equally valuable tools in the death investigation. The way in which these various modalities are chosen by the legal investigator (coroner) in partnership with forensic pathologists in Melbourne will be explored.

Learning Objectives:

1. To understand the potential role of post-mortem imaging in relation to pathology.
2. To become familiar with relevant questions in a death investigation.
3. To discuss the contribution of imaging to a death investigation.

A-340 16:41

Paediatric forensic post-mortem radiology

R.R. van Rijn; *Amsterdam/NL (r.r.vanrijn@amc.uva.nl)*

Postmortem radiology is mostly focussed on imaging of foetuses and neonates. However, in recent years it has found its way into the field of forensic medicine. The advantage of post-mortem imaging is the fact that imaging can be reviewed indefinitely and images can easily be shared between experts. Using post-processing techniques imaging findings can be used as illustrations for laymen in forensic reports. This lecture will present legal cases and the advantage and limitations of post-mortem imaging.

Learning Objectives:

1. To learn about the role of imaging in child abuse.
2. To discuss the different imaging techniques and protocols in paediatric forensic radiology.
3. To discuss relevant legal issues related to paediatric forensic radiology.

Author Disclosure:

R.R. van Rijn: Author; Several books, bookchapters and publications.

A-341 16:58

Post-mortem CT and MRI: imaging techniques

A. Persson; *Linköping/SE (anders.persson@cmiv.liu.se)*

Postmortem imaging has been used for more than a century as a complement to medico-legal autopsies. The technique has also emerged as a possible alternative to compensate for the continuous decline in the number of clinical autopsies. The diagnostic accuracy of postmortem imaging for various types of findings are depending of the imaging acquisition technique that has been used. Only recently quantitative post-mortem magnetic resonance imaging (PMMRI) technique has been introduced. A particular quantitative MRI sequence feasible for simultaneous quantification of T1 and T2 relaxation times as well as proton density (PD) can be used to quantify and characterize post-mortem tissue. This technique has the potential to reduce the temperature dependents in PMMRI examinations. Another promising imaging technique is postmortem dual-energy computed tomography (PMDECT). This technique enables to some extent quantification and determination of soft tissues and other foreign materials in the body. These new quantification techniques lay the foundation for new advanced visualization techniques and the use of big data, machine learning tools and radiomics in future forensic radiology.

Learning Objectives:

1. To learn about quantitative MRI and temperature independent imaging.
2. To learn about DECT in post-mortem imaging.
3. To learn about advanced visualisation techniques in post-mortem and forensic radiology.
4. To understand areas where further research is needed.

A-342 16:00

A. E-learning and blended learning approaches to continuing professional development (CPD): is this the way forward?

E. Metsälä; *Helsinki/FI (eija.metsala@metropolia.fi)*

There are various ways of understanding blended learning. Most common definitions refer to the so-called media blend, activity blend, space blend or time blend. In 2015, it was performed an integrative review dealing with blended learning outcomes in health care staff education. Search engines EBSCO Host, Science Direct and Pro Quest comprising several databases were used to search studies being published during the years 2005-2015. Measures used comparing blended learning and traditional learning are competency, skills and knowledge; student satisfaction; effectiveness of learning; the capacity of BL in relating theory and practice; the 'blended' nature of the blended learning modules; cost-effectiveness. The selected studies reported that blended learning was either superior or equal to conventional class room teaching. Blended learning outcomes are little or not at all dependent on the learning content or the topic being taught. It seems to be a suitable teaching method for various types of content in health care education. Blended learning should be implemented into health care education in a controlled way, with the support of organizational leadership, by offering the educational staff strong support in curriculum construction, pedagogics, and user-friendly technology.

Learning Objectives:

1. To discuss about the concepts used related to e-learning and blended learning.
2. To learn about the measures used and outcomes received comparing blended learning and traditional learning.
3. To appreciate the possibilities of e-learning and blended learning in health care staff CPD.

A-343 16:25

B. The assessment of clinical knowledge, skills and competences for pre- and post- registration radiographers

L. Robinson; *Salford/UK (l.robinson@salford.ac.uk)*

Participants will be provided with an overview of the principles and good practices for the assessment of clinical competence, exploring the difference between skills and knowledge for practice. Examples from the UK context will be provided, looking at both pre- and post-registration. Post-registration will also be broadened out to consider extended skill roles versus advanced practice. In small groups, participants will then be facilitated to consider the barriers and potential solutions to measuring clinical competence, which exist within their own context. Each participant will leave with their own action plan for further work which may also include a list of potential collaborative partners and sources of reference.

Learning Objectives:

1. To appreciate the complexities involved in designing pre- and post-graduate assessments.
2. To learn about the differences between assessing and extended role skills and post-graduate cognition.
3. To discuss the differences between advanced practice and extended roles for radiographers.

A-344 16:50

C. Clinical placements: the challenges ahead

L.A. Rainford; *Dublin/IE (louise.rainford@ucd.ie)*

In medical imaging, the application and frequency of specific imaging modalities are ever-changing. The scope of imaging across all sub-specialities is expanding, however, clinical practice is partly determined by the availability of advancing technologies, reliant on social economic factors; therefore, training needs will not change in a standardised manner across European jurisdictions. Radiography education needs to keep abreast of these changes and modify curricula and training schemes to meet the needs of the clinical environment. Radiography role development is also progressing at different rates across Europe and requires consideration with respect to guideline

documents focused on professional education. With a growing list of subjects considered as graduate radiography requirements, the depth to which subjects are taught is challenging. In many jurisdictions, the presence/evolution of national regulatory agencies for allied healthcare professions drive the clinical training needs for radiographers; however, the mobility of the radiography workforce across Europe requires consideration. Clinical training enhancement requires equality of training opportunity and high standards of teaching across radiography programmes, which is evidenced. To ensure safe practice the supervisory staff should be adequately trained and all patient safety issues need to be fully addressed and form an integral part of competency verification. A further challenge to clinical training is the commencement of graduate entry pathways; training programmes must fulfil the needs of two socially different student cohorts. Additionally, the methods of recording clinical placement experience and assessment is moving from traditional written logs to ePortfolios which presents notable challenges. The presentation will address these issues.

Learning Objectives:

1. To appreciate the challenges of clinical practice placement enhancement for radiography students.
2. To review methods of addressing the challenges ahead.
3. To discuss how to best address safe clinical practice for radiography students.

Carotid artery disease: so what's new?

Moderator:
T. Jargiello; Lublin/PL

A-345 16:00

A. The diagnostic assessment of carotid arteries: do we still need US?
R. Iezzi; *Rome/IT (roberto.iezzi.md@gmail.com)*

Stroke is the third leading cause of death in industrialized nations, behind heart disease and cancer, and a leading cause of long-term disability. The current indication for intervention in patients with carotid artery stenosis is based primarily on the degree of stenosis and symptoms. Carotid ultrasonography, CTA and MRA can provide the information needed to guide the choice of medical, endovascular, or surgical treatment. As each imaging modality has strengths and weaknesses, choosing among the available vascular imaging modalities, deciding when to combine multiple modalities, and judicious application of angiography are challenging aspects of evaluation in patients with carotid artery disease. These features will be discussed and highlighted in the presentation to obtain a suggested diagnostic algorithm for diagnosis and follow-up of patients with carotid artery disease. The final section of the presentation will be dedicated on the discussion about plaque instability that in recent studies seems to be crucial in the aetiology of acute cerebral ischaemic events in patients with carotid disease. Some authors advocate the possibility that patients may soon be selected for intervention based more on plaque vulnerability than on the degree of stenosis or symptoms. The challenge could be to identify patients at high risk who have lesions that are vulnerable to thrombosis, so-called "vulnerable-plaques", before the event occurs. Moreover, to tailor and improve treatment strategies, appropriate diagnostic methods must be chosen that are able to determine the patient-specific risk of experiencing a cardiovascular event, the so-called "vulnerable-patient".

Learning Objectives:

1. To understand the role of US, CT, MR and DSA in diagnostic assessment.
2. To learn the optimal imaging algorithm for diagnosis and follow-up.
3. To appreciate the role of plaque characterisation in routine practice.

A-346 16:30

B. Carotid stenting vs endarterectomy: is the jury back yet?
K.D. Mathias; *Hamburg/DE*

In symptomatic patients with carotid artery stenosis invasive treatment with removal of the stenosis is international standard based on the data of numerous trials. Less clear is the choice of the treatment modality. Carotid endarterectomy (CEA) and carotid stenting (CAS) have recently shown similar early and late outcomes. The anatomy of the aortic arch and supra-aortic arteries as well as the characteristcs of the lesion are important information for the choice of the method. Carotid stenting is preferred in patients with the so called "hostile neck". Carotid endarterectomy is the better option in dense circular calcifications of the carotid stenosis and in elongated carotid arteries with kinks and loops. The preference for one or the other treatment modality concerns about 10 to 15% of the patients. In more than 80% of the patients both methods can be applied with similar results. Actual technical progress of endovascular devices makes carotid stenting safer than in the past. But sufficient volume of interventions (>100 CAS/year) is necessary to reach good results. In asymptomatic patients best medical treatment has shown that the annual stroke risk can be reduced to 1% or even less. Therefore, the selection criteria for invasive treatment are different. Invasive treatment requires a rate of morbidity and mortality of less than 3% and a life expectancy of the patient of at least 5 years to gain a benefit for the patient. The degree of stenosis should exceed 70%. Additional other vascular pathologies like multiple vessel disease, incomplete circle of Willis, isolated middle cerebral artery etc. increase the stroke risk and should be treated invasively. The international and european guidelines support this process. CAS should be performed when the complication rate of the intervention is in the range of 1 to 2% and clearly below 3%. In acute carotid occlusion endovascular treatment is the method of choice as long as a good penumbra is shwon by perfusion CT or MRI. In carotid T-occlusions thrombectomy should be performed as fast as possible. In bifurcational carotid occlusion thrombectomy is combined with CAS. After stenting of the underlying stenosis the thrombus is retrieved. Carotid stenting has some additional advantages in comparison to carotid endarterectomy. In patients with contra-lateral carotid artery occlusion the stroke risk of CEA is increased (NASCET 14.7%, SPACE 13%), but not of CAS. Endovascular treatment can also manage additional lesions in the same session such as ostial stenosis of the common carotid artery or stenosis of the distal internal carotid artery close to the skull base or intracranially.

Learning Objectives:

1. To understand the evidence supporting surgery and endovascular therapy.
2. To understand why the trials have been slow to bring clarity to optimal therapy.
3. To learn how best to triage patients for surgery or endovascular therapy.

A-347 17:00

C. Carotid interventions in the setting of acute stroke
S. Sencer; *Istanbul/TR (serrasencer@gmail.com)*

Leaning objectives in this lecture are to understand the indications and contraindications to carotid stenting, appreciate how MR/CT can aid patient selection for carotid stenting and learn about carotid stenting in the setting of acute thrombosis/dissection. Carotid stenting is a well-established method of revascularization in patients with carotid stenosis. Indications for carotid stenting are based upon the symptomatic status of the patient, degree of stenosis and possibly other factors (patient features such as co-morbidities, life expectancy, age, sex). In pre-treatment evaluation, Doppler ultrasound, CTA and MRA can be used to investigate the degree of stenosis and plaque character. Catheter angiography is usually reserved for cases where there is a discrepancy between noninvasive vascular imaging techniques. Cerebral MRI with diffusion-weighted imaging is used for assessing ischemic lesions (symptomatic and silent) in the territory of intended treatment as well as other findings. In patients with acute CVA, non-contrast head CT and advanced imaging techniques such as CT perfusion and perfusion MR studies can also be utilized for selecting the suitable treatment strategy. In the setting of acute stroke treatment, carotid angioplasty and/or stenting can be performed as an adjunct to thrombectomy/thrombolysis or as the primary choice of therapy depending on the angiographical findings. Dissection of the carotid artery may also present as an acute clinical picture and can also be treated with carotid stenting.

Learning Objectives:

1. To understand the indications and contraindications to carotid stenting.
2. To appreciate how MR/CT can aid patient selection for carotid stenting.
3. To learn about carotid stenting in the setting of acute thrombosis/dissection.

16:00 - 17:30 **Room M 2**

Computer Applications

RC 805
Daily use of mobile devices in radiology

A-348 16:00
Chairman's introduction
O. Ratib; *Geneva/CH*

Session Objectives:
1. To give an overview of tools available on mobile devices for education and exam reporting.
2. To underline the impact of mobile devices in routine clinical activity.
3. To learn about the legislative backbone and potential drawbacks of mobile technology.

A-349 16:05
A. What did mobile devices change in radiology education?
E. Kotter; *Freiburg/DE*

Mobile devices and fast networks are ubiquitous today. E-learning has been used in radiology for more than 30 years. The lecture will give an introduction to and an overview of e-learning systems for radiology with emphasis on e-learning on mobile devices. Advantages and limitations of mobile e-learning will be discussed. An outlook to future development of e-learning will be given.
Learning Objectives:
1. To give an overview of tools available for e-learning.
2. To explore the potential impact of e-learning in the daily radiological practice.
3. To explore future developments and limits of e-learning.
Author Disclosure:
E. Kotter: Consultant; Thieme Verlag - eRef.

A-350 16:28
B. Is it appropriate to read a study on a smartphone or a tablet?
E. Neri; *Pisa/IT*

The presentation will address the technological limitations and security concerns that arise for radiologists looking to go mobile. With regard to the technological aspect, while it is acceptable to occasionally read images on a smartphone or tablet for a second expert opinion or learning purposes, they should not be used in daily practice for primary diagnosis. Even then, only devices with a screen size of 9 inches or more, with a high-resolution display, are appropriate for medical imaging. Moreover, new high resolution retina displays with increased size (as the IPAD Pro) are bringing mobile devices closer to a standard medical monitor. Security concerns are now better clarified by the recent general data protection directive of the EU. It clearly addresses the need to protect patient's data with respect to privacy, and also highlights the importance of an informed consent to the use of data for any purpose, even in regard to the portability of such confidential information. Even if mobile devices make the reading, the portability and the exchange of patient's data easier, their use must be strongly regulated at a national level and across countries.
Learning Objectives:
1. To give an overview of available DICOM viewers and software for reporting imaging studies.
2. To discuss technical requirements of mobile devices for use in imaging interpretation.
3. To provide insight on future developments of imaging viewing technology.

A-351 16:51
C. Security and ethical issues of mobile device technology
E.R. Ranschaert; *Mol/BE (ranschaert@telenet.be)*

In clinical practice medical specialists use mobile devices to quickly exchange medical images and patient information with other health care professionals. Frequently they want to ask a colleague for advice regarding a diagnosis or treatment, sometimes even in an acute setting. Often popular messaging services such as WhatsApp are being used for this purpose. Transmission of patient data by public social media and messaging services, however, does have several limitations from an ethical point of view, which are mostly related to the security and privacy of patients. Some critical questions need to be answered: is this unsafe and/or illegal, and if yes, why? Are there any regulations and/or guidelines available? Are there any secure and legal alternatives? In this refresher course these issues will be discussed in more detail.
Learning Objectives:
1. To provide an overview of technical solutions for patients' image and data mobility.
2. To provide a risk assessment analysis (data loss, privacy, etc.) of mobile technology.
3. To give an overview of European legislation in relation to patient image and data mobility.
Author Disclosure:

Interventional Radiology

RC 809
Imaging and endovascular treatment of pulmonary embolism

A-352 16:00
Chairman's introduction
G. O'Sullivan; *Galway/IE (gerard.osullivan2@hse.ie)*

Venous thrombo-embolism (VTE) is an enormous healthcare issue. This session focuses on state of the art, cutting edge, and yet absolutely practical imaging of pulmonary embolus (PE), which is a bigger killer in Western Europe than AIDS, breast cancer, road traffic accidents, and prostate cancer all COMBINED. All radiologists need to know how to diagnose and interpret this important condition. Following diagnosis, interventional radiologists have the ability to treat PE by aggressive catheter-based therapy and the latter 2/3 of this session will focus on the evidence to support this and the "how to" application of same.
Session Objectives:
1. To appreciate the value of imaging in therapy planning and follow-up.
2. To learn about patient selection and evidence in catheter directed therapies for PE.
3. To learn about recent and ongoing trials in the endovascular treatment of PE.
Author Disclosure:
G. O'Sullivan: Advisory Board; iemens Healthcare. Author; New Horizons in Venous Disease. Speaker; Cook Medical, Straub, Bard, BSCI, Marvao Medical.

A-353 16:05
A. Imaging algorithm for pulmonary embolism
B. Ghaye; *Brussels/BE (benoit.ghaye@uclouvain.be)*

The diagnosis of pulmonary embolism (PE) is difficult since the clinical signs and symptoms are non-specific. Unstable patients usually undergo thrombolysis following demonstration of right ventricle (RV) dysfunction at echocardiography. Diagnostic algorithm strategies in stable patients have been developed to limit the number of patients requiring an imaging test. The first step includes the assessment of clinical probability of PE and D-dimers testing. Patients with either a high clinical probability or a positive D-dimers test should undergo further imaging test. Incompliance to such diagnostic algorithms has been demonstrated to increase the rate of PE recurrence and the rate of false-positive CT pulmonary angiographies. In patients not at high-risk of mortality (i.e. without clinical findings as cardiogenic shock or persistent arterial hypotension), signs of RV dysfunction (at echocardiography or CT pulmonary angiography) are used together with clinical prognostic scores, such as the PESI, and cardiac biomarkers dosage to discriminate patients with *intermediate* or *low* risk. This is usually performed by measuring the ratio between the diameters of RV and the left ventricle (RV/LV). More recent and potentially more powerful predictor CT findings have been reported, including among others RV/LV surface and volume ratios, severity of "perfusion" defect and cardiac function parameters as calculated from ECG-gated acquisition. Evidence concerning the follow-up of unselected patients after treatment is limited in the literature. Short-term follow-up after systemic thrombolysis or endovascular treatment has been performed using various techniques, including RV/LV dimensions, pulmonary arterial obstruction scores or pulmonary perfusion comparison.
Learning Objectives:
1. To learn how clinical findings influence the selection of the imaging strategy in PE.
2. To learn about the follow-up after treatment.
3. To learn how imaging may predict the outcome of the patient.

A-354 16:28

B. What is new in the recently published guidelines for pulmonary embolism treatment?

R. Uberoi; *Oxford/UK (Raman.Uberoi@ouh.nhs.uk)*

PE is a major cause of mortality, morbidity, and hospitalization in Europe. 317 000 deaths related to VTE were reported in six countries of the European Union (with a total population of 454.4 million) in 2004. 34% present with sudden fatal PE and 59% postmortem. Only 7% who died early were correctly diagnosed with PE before death. Following diagnosis, patients should undergo risk stratification using a scoring system such as the pulmonary embolism severity index and patients stratified into high-, intermediate- and low-risk groups based on the clinical status of the patient, i.e. shock , hypotension, signs of RV dysfunction and cardiac biomarkers. Patients with scores of PESI of III-IV will have a 30-day mortality of 24.5%. High-risk and intermediate-high-risk patients should undergo consideration for rapid primary pharmacologic treatment, or surgery and where available interventional treatment to rapidly clear thrombus. Acute right ventricular dysfunction critical determinant of outcome and persistent arterial hypotension and cardiogenic shock carries a high risk of early death. Primary reperfusion treatment, particularly systemic thrombolysis is currently the treatment of choice. This can result in early reduction of pulmonary resistance and improvement in RV function. The maximum benefit is in the first few days, ideally within 48 hours with 90% of patients showing improvement, with no benefit at one week. Low-risk patients, i.e. PESI scores I-II or sPESI 0 should be considered for early discharge and outpatient treatment with anticoagulation.

Learning Objectives:

1. To learn about the recently published guidelines for PE treatment in stable patients.
2. To learn about the recently published guidelines for PE treatment in unstable patients.
3. To learn about recent therapeutic algorithms in PE treatment.

Author Disclosure:

R. Uberoi: Grant Recipient; Bolton medical.

A-355 16:51

C. Updates on the endovascular treatment of massive and submassive pulmonary embolism

S.C. Spiliopoulos; *Athens/GR (12461)*

Minimal invasive percutaneous endovascular treatment of massive and submassive pulmonary embolism (PE) offer the benefit of low-risk, more aggressive management than systemic anticoagulation and have been correlated with reduced morbidity and mortality rates. Traditional endovascular methods include thrombus dissolution using standard pigtail catheters or balloons, presenting reasonable technical success rates of approximately 86%. Local low-dose catheter-directed thrombolysis combined with thrombectomy (e.g. pharmacomechanical thrombolysis) seems to improve outcomes, without increasing the risk of bleeding. The rationale of recent and ongoing trials is based on the fact that systemic thrombolysis, although more effective than anticoagulation alone, increases 5-fold the risk of major bleeding and 10-fold that of haemorrhagic stroke, while is contraindicated in many patients mainly due to recent surgery or intracranial haemorrhage. On the other hand, the majority of evidence for catheter-based interventions is based on few single-centre case series and prospective trials. Over the past few years, a number of prospective, multi-centre, randomized trials and large registries investigated novel pharmacological and pharmacomechanical thrombectomy techniques, such as ultrasound accelerated thrombolysis, providing high level of evidence regarding the safety and efficacy of endovascular treatment options in acute PE. However, studies comparing various endovascular modalities versus systemic fibrinolysis are missing, while additional large-scale, well-designed randomized trials are required to improve the level of evidence of currently available interventional radiology techniques. In this lecture, outcomes of available and ongoing clinical data will be presented and future perspectives will be discussed.

Learning Objectives:

1. To learn about the rationale of recent and ongoing trials.
2. To learn about the level of evidence for interventional radiology techniques in PE treatment.
3. To learn about clinical results and possible further developments.

17:14

Panel discussion: Appropriate diagnosis and risk stratification in the management of acute massive and acute submassive pulmonary embolism

16:00 - 17:30 **Room M 4**

E³ - ECR Academies: Spinal Imaging

E³ 819

Spinal trauma

A-356 16:00

Chairman's introduction

L. Manfrè; *Catania/IT (lmanfre@me.com)*

A-357 16:05

A. Looking for fractures

E.J. Ulbrich; *Zurich/CH (erika.ulbrich@usz.ch)*

In trauma patients, the spine is often involved with the thoracolumbar spine as the most common portion, especially T11-L2. The necessity of a radiography after trauma may be weighed with the help of the national emergency x-radiography use study (NEXUS) criteria and the Canadian C-spine rule (CCR). According to the clinical NEXUS criteria, the probability of absence of a fracture is 99.6% in patients with no posterior midline cervical-spine tenderness, no evidence of intoxication, a normal level of alertness, no focal neurologic deficit and no painful distracting injuries. The CCR defines clinical criteria for a low-risk patient for C-spine fractures after blunt trauma with a 100% sensitivity. Comparing the CCR with the NEXUS criteria, CCR performed somehow better. If imaging is indicated by clinical criteria (NEXUS, CCR) the American College of Radiology (ACR) Appropriateness Criteria list the precise indications of imaging modalities (x-ray, CT, MRI, myelography, angiography). Concerning thoracolumbar spinal fractures, the Magerl classification (exclusively applicable for assessment of CT findings) is used which is based on the three-column concept by Denis and the McAfee classification. The Magerl AO concept differentiates between compression (type A), distraction (type B) and rotation (type C). The thoracolumbar injury classification and severity (TLICS) scale is a guideline for management of treatment regarding thoracolumbar injuries. Based on the three major categories (injury morphology, posterior ligamentous complex integrity and patient neurology) patient scores determine a management plan for surgeons depending on the presence of injuries and co-morbidities.

Learning Objectives:

1. To understand the different standard clinical criteria for spine imaging (Canadian C-spine rule, Nexus criteria).
2. To understand the essential traumatic spinal mechanisms.
3. To become familiar with the different classification systems, from Denis to TLICS.

A-358 16:33

B. Looking for spinal cord and soft tissue injuries

F. Bonneville; *Toulouse/FR (bonneville.f@chu-toulouse.fr)*

In spinal trauma, MRI is the modality of choice for evaluation of ligamentous and other soft tissue structures, disc, spinal cord and vessels. Complete spinal ligamentous tears appear as interruption of those structures normally appearing as low signal intensity bands. It is best depicted on T2-weighted and STIR images. Spinal instability is defined by the involvement of two of the three vertical parallel columns biomechanically forming the vertebral column. Acute disk herniation can also occur and may worsen the symptoms. Neurological deficits may be due to cord compression by epidural or subdural haematoma, or intrinsic spinal cord injury. Axial gradient echo T2-WI is mandatory to identify such haemorrhagic lesions, especially within the cord, because haemorrhagic contusions and haematomyelia are correlated to worse outcome. They appear hypointense while cord oedema returns T2 hyperintensity. Spinal cord trauma usually demonstrates a mixture of both oedema and haemorrhage. In cervical spinal trauma, vascular injuries should be sought as asymptomatic injuries can subsequently lead to cerebral and cerebellar infarctions. Vertebral arteries are more commonly involved than carotid arteries. Main cervical traumas at risk for vascular injuries include C1-C3 fractures, fracture extending into a foramen transversarium, cervical spine luxation and expanding neck haematoma. Most of the vascular injuries can be seen as irregularity or loss of normal flow void on T2WI, and should be confirmed by adequate and dedicated vascular imaging.

Learning Objectives:

1. To understand which soft tissue structures are relevant for spinal stability.
2. To learn how to detect subtle soft tissue injuries.
3. To become familiar with the different traumatic cord injuries.

A-359 17:01

C. Looking for spinal injuries in children
P.C. Maly Sundgren; *Lund/SE (Pia.Sundgren@med.lu.se)*

Spinal injuries are generally less common in the paediatric population compared to adults with cervical spine injuries being most frequent spine injury of all spine injuries occurring in up to 40-60% of all injuries in children. The specific biomechanics of the paediatric cervical spine leads to a different distribution of injuries and distinct radiological features and represent a distinct clinical entity compared to those seen in adults. Young children have a propensity for injuries to the CCJ, upper cervical injuries (i.e. cranial base to C2) whereas older children are prone to lower cervical injuries similar to those seen in adults. In this lecture, typical injuries in the paediatric population will be presented including normal variants that can be misleading in the diagnosis of fractures.

Learning Objectives:
1. To understand that children are prone to different types and locations of injuries when compared to adults.
2. To become familiar with normal anatomy and anatomic variants that may mimic fractures in children.
3. To learn how to select the appropriate imaging modality in the individual patient.

A. Prostate cancer: novel tracers
S.P. Rowe; *Baltimore, MD/US*

"No abstract submitted."

Learning Objectives:
1. To learn about novel tracer and their biochemical properties.
2. To understand the differences of information given by the use of different tracers.
3. To understand how to interpret examinations with different tracers.

A-360 16:30

B. Prostate cancer: PET, MR or both?
M. Eiber; *Los Angeles, CA/US*

Currently national and international guidelines for imaging procedures for high-risk and advanced prostate cancer (PCa) include abdomino-pelvic cross sectional imaging, multiparametric prostate MRI, bone scintigraphy and in the case of therapy monitoring of mCRPC whole-body cross-sectional imaging mainly by means of computed tomography. Positron emission tomography (PET) has became increasingly important in the work-up of prostate cancer. In the past, the use was mainly limited to radiolabeled choline-derivatives which showed considerable limitations and did not always meet the diagnostic needs. Recently, a 68 Gallium-labelled ligand of the prostate-specific membrane antigen (68Ga-PSMA) has been introduced in PET-imaging of PCa with first promising results. Due to relatively exclusive expression of PSMA in prostatic tissue as well as increased expression in PCa 68Ga-PSMA was reported to exhibit a favourable lesion to background ratio compared to presently used choline- or fluorodeoxyglucose-based PET examinations. Together with the novel development of combined PET/MR, the combination of excellent morphological detail, multiparametric functional information and molecular PET data might lead to a significant improvement in detection and staging of PCa and thus may help to optimise oncological treatment. The talk encompasses: 1. The molecular basis of prostate cancer imaging targeting the prostate-specific membrane antigen (PSMA), review of the various PSMA-tracers. 2. The diagnostic performance and potential role of PSMA PET/CT and PET/MR for high-risk primary and advanced prostate cancer. 3. Comparison of the use of PSMA PET-imaging with conventional imaging as included in the guidelines.

Learning Objectives:
1. To learn about pathophysiology in prostate cancer.
2. To understand how to interpret hybrid imaging of prostate cancer.
3. To learn about the role of hybrid imaging in staging, treatment evaluation and follow-up.

A-362/A-363 17:00

C. Interactive case discussion (part 1)
M. Eiber; *Los Angeles, CA/US*
S.P. Rowe; *Baltimore, MD/US*

The third part of this session will contain interactive cases based on the previous teaching points.

Learning Objectives:
1. To learn how to interpret hybrid imaging of prostate cancer.
2. To understand the pathophysiology in relation to imaging.

A. RECIST 1.1 training
A. Graser; *Munich/DE (a.graser@radiologie-muenchen.de)*

RECIST 1.1 has been developed as an improvement of RECIST 1.0 to allow for reproducible and exact measurement of overall tumour load in patients with metastatic disease that are being treated as part of clinical trials. Furthermore, it can be used to guide decision-making in everyday clinical practice. This lecture will explain basic RECIST rules, teach about types of lesions (target versus non-target), and measurement strategies. Furthermore, clinical cases will be used to train correct use of the system. Recent additions to RECIST, e.g. Choi criteria, will also be covered. Finally, limitations of RECIST in clinical practice will be discussed.

Learning Objectives:
1. To understand the principle of the RECIST system.
2. To become familiar with the daily oncological work-up.

A-365 09:15
B. Gastrointestinal-abdominal masses
A. Ba-Ssalamah; *Vienna/AT (ahmed.ba-ssalamah@meduniwien.ac.at)*

The spectrum of abdominal masses is broad, as is the differential diagnosis. Cross-sectional imaging modalities, in particular computed tomography (CT) and magnetic resonance imaging (MRI), are routinely used to evaluate the size, morphology, location and relationship of the lesion to adjacent organs. It is essential to understand how to tailor the exam to the clinical indication, i.e. which modality is best, and which contrast agent to use for MRI. The role of PET-CT and PET-MRI, with various radiotracers, that can give us further insight into the metabolic properties of these masses, will be discussed. Furthermore, we will explain the enhancement pattern and tracer behaviour of the mass which may help us to narrow the differential diagnosis. Demonstrating the content of the lesion, such as fat, fluid, solid components or calcifications, is an important imaging clue, too. Malignant entities, including peritoneal carcinomatosis and pseudomyxoma peritonei, as well as lymphoma and GIST, will be demonstrated. We will include some uncommon entities that may present with and without symptoms, such as epiploic appendagitis, omental infarction and mesenteric panniculitis. Finally, we will illustrate exophytic masses originating from abdominal organs, such as the liver, pancreas and bile ducts, causing diagnostic challenges.

Learning Objectives:
1. To learn the characteristic features of some common and atypical abdominal masses.
2. To identify the key imaging findings that assist surgeons or oncologists treating specific abdominal masses.

08:30 - 10:00 **Room B**

GI Tract

RC 901
CT colonography today

A-366 08:30
Chairman's introduction
M. Hellström; *Gothenburg/SE*

A-367 08:35
A. How I perform it
P. Lefere; *Roeselare/BE (radiologie@skynet.be)*

According to the ESGE/ESGAR guidelines and the second ESGAR CTC consensus on CT colonography (CTC), correct technique of performing CT colonography is essential to obtain good results of polyp/tumour detection. CTC technique is related to an adequate preparation of the colon, optimal distension of the colon and the correct use of scanning protocols adapted to the specific requirements of CTC. 1. Bowel preparation and faecal tagging: a) principles of state-of-the-art preparation: diet, laxatives, faecal tagging, b) application according to the clinical presentation of the patient, c) full cathartic preparation vs reduced cathartic preparation: when, advantages/disadvantages, the future? and d) pitfalls related to preparation. 2. Colon distension: a) principles of state-of-the-art colonic distension, b) practical application of optimal colonic distension, c) possible issues/complications and how to prevent and d) pitfalls related to colonic distension. 3. Scanning protocols: a) acquisition of CTC in clinical practice, adapted to the different clinical presentations/indications, b) dose considerations: how to reduce dose in CTC and c) pitfalls related to acquisition.

Learning Objectives:
1. To learn about modern approaches to bowel preparation and faecal/fluid tagging.
2. To become familiar with colon distention, including prevention of possible complications.
3. To learn about different scanning protocols and their use according to patient status and clinical needs.

A-368 08:58
B. How I interpret it
T. Mang; *Vienna/AT (thomas.mang@meduniwien.ac.at)*

The evaluation of CT colonography (CTC) studies is based on detection, interpretation, and documentation of colonic findings. It is performed on a computer workstation equipped with dedicated CTC software by a primary 2D or a primary 3D approach. In either case, the alternative viewing technique must be available for rapid correlation and characterization of any suspicious findings. Primary 2D evaluation is based on “lumen tracking” by interactively scrolling through the axial slices and multiplanar reformatted images, focusing only on the air-distended colonic lumen from one end to the other one. Primary 2D evaluation provides information about the attenuation of findings during the search process. It is time-efficient. Primary 3D evaluation is based on 3D virtual endoscopy in an antegrade and retrograde fashion. It increases both, the conspicuity, especially of small and medium-sized polyps, and the duration of visualization. The use of advanced 3D displays like virtual dissection or unfolding techniques may reduce the interpretation time for primary 3D evaluation at the expense of increased image distortion. Colonic findings can be systematically characterized by their morphology, attenuation characteristics and mobility. Knowledge of the CTC imaging features of common colonic lesions and artefacts is necessary for characterization of findings and differentiation of genuine colonic lesions from pseudo-lesions. Computer-assisted detection (CAD) algorithms, used in CTC, can automatically detect polypoid findings. Specifically, if used as a second reader, CAD was found to reduce the number of perceptual errors by pointing out possible abnormalities that might otherwise be missed.

Learning Objectives:
1. To become familiar with different image presentations: 2D, 3D, enhanced views.
2. To appreciate the strengths and limitations of primary 2D and primary 3D reading.
3. To learn about the use of Computed Assisted Diagnosis (CAD) software.

A-369 09:21

C. Screening with CTC

D. Regge; *Turin/IT (daniele.regge@ircc.it)*

Colorectal cancer screening reduces cancer-specific mortality significantly and is cost-effective, or even cost-saving, with respect to not performing a screening test. In some European countries, tests with different lesion yield and costs (i.e. faecal occult blood test, sigmoidoscopy and colonoscopy) have been chosen for population screening programs. CT colonography has been approved by the American Cancer Society in 2008 as a test to detect polyps and colorectal cancer and has since then been adopted on an individual basis. Recently CT colonography has also been endorsed by US preventive services task force as a screening test paving the way to reimbursement by medicare and private insurers. In Europe, CT colonography has been explored in a screening context mainly in randomized controlled trials where CT colonography lesion yield and subject participation into running screening programs have been compared to that of other tests. These data are now available as those related to costs of the CT colonography arm. The lecture will focus on the evidence cumulated in the last decade on the use of CT colonography as a screening test, to review current guidelines and present possible scenarios for its future adoption in colorectal cancer screening.

Learning Objectives:

1. To understand basic principles of population and opportunistic screening.
2. To become familiar with data on accuracy of CTC in screening populations.
3. To learn about current guidelines on the use of CTC in screening.

Low-dose and no-dose chest imaging: opportunities and limitations

Moderator:
D. Tack; Baudour/BE

A-370 08:30

A. CT

C. de Margerie-Mellon; *Paris/FR (constancedemm@gmail.com)*

Radiation dose in CT scan must be as low as reasonably achievable. High natural contrast of lung parenchyma makes it particularly suitable for radiation dose reduction. Various technical parameters have to be optimized, especially tube current, tube potential, and reconstruction algorithm, to obtain the better trade-off between radiation dose level and image quality. Iterative reconstruction algorithms take currently a dominant role in radiation reduction by lowering image noise induced by reduced-dose examinations. On the other hand, reduced-dose CT protocols should be adapted to the clinical situation. Their relevancy have been largely investigated for solid nodules detection on non-enhanced CT and for pulmonary emboli diagnosis on CT pulmonary angiography. Other potential applications include infectious pneumonia and pleural abnormalities detection (especially in asbestos-exposed workers) and neoplasia follow-up. However, radiation dose reduction is still limited for obese patients and in case of interstitial pneumonia.

Learning Objectives:

1. To learn about techniques for decreasing the radiation dose.
2. To know in which clinical situations low-dose CT should be performed.

A-371 09:00

B. MRI

J. Dinkel; *Munich/DE*

Although many studies have advocated a valuable role for thoracic MRI, it has currently limited clinical utilization with the exception of cardiovascular imaging. However, new technical developments and MRI sequences have continuously improved the quality and broadened the clinical indications for thoracic MRI. Furthermore, due to its high soft tissue contrast and the lack of radiation exposure, MRI allows for repeated measurements of the lung structures and, therefore, appears to be appropriate for functional investigation of lung. The purpose of this presentation is to review the currently available MR techniques useful in thoracic imaging and to provide an overview of present and emerging clinical applications of thoracic MRI.

Learning Objectives:

1. To learn about the current lung MR protocols.
2. To know in which clinical situations lung MRI is a helpful adjunct to diagnosis.

A-372 09:30

C. US

F. Gleeson; *Oxford/UK (fgleeson@mac.com)*

Ultrasound has historically been used to determine the presence of pleural fluid prior to a decision on chest drain insertion. More recently it has been used to characterise pleural effusions, and is now being investigated as a potential tool to identify cardiac failure and pulmonary oedema. It is now also used to identify pneumothorax in patients in place of or more often as an adjunct to the CXR. Recent publications have also highlighted the ability to identify the intercostal vessels using colour Doppler to avoid potential laceration during biopsy or drain insertion.

Learning Objectives:

1. To learn when, how and why to perform a US study of the chest.
2. To become familiar with the strengths and limitations of the technique.

08:30 - 10:00 **Room X**

Joint Session of the ESR and ESTRO

Radiomics and imaging databases for precision radiation oncology

A-373 08:30

Chairmen's introduction (part 1)

K. Riklund; *Umea/SE (katrine.riklund@umu.se)*

In this session, biomarkers in imaging will be discussed as used in treatment planning, prognosis and prediction. Furthermore, we will learn about the potential of using big data analysis in imaging in radiation treatment. When using quantitative imaging biomarkers, it is also important to be aware of potential shortnesses of the methods and you will also hear about this in the joint session between ESR and ESTRO.

Session Objectives:

1. To discuss how radiomics will change the clinical practice both in radiology and oncology.
2. To understand the impact of quantitative imaging data uncertainties in the prognosis and predictive models.
3. To discuss the potential and challenges of large multicentre imaging datasets.

A-374 08:31

Chairmen's introduction (part 2)

V. Valentini; *Rome/IT (vvalentini.it@gmail.com)*

Radiomics is gaining an always greater attention in our scientific communities. Images are always less pictures and more mines of information that can be used by clinicians as decision-making tools, from prognosis assessment to therapy choice and outcome prediction. New paradigms, new uncertainty measurements, new statistical and mathematical tools are required to take advantage of radiomics potentialities and to become familiar with these approaches is unavoidable. Facing the entity of the challenge, an interdisciplinary approach is mandatory with all the imaging-based medical specialities hinged on imaging knowledge and images sharing in big data biobanks and DICOM repositories.

Session Objectives:

1. To discuss how radiomics will change the clinical practice both in radiology and oncology.
2. To understand the impact of quantitative imaging data uncertainties in the prognosis and predictive models.
3. To discuss the potential and challenges of large multicentre imaging datasets.

A-375 08:33

Radiomics in radiology, what are the parameters of interest for different imaging modalities?

H. Ahlström; *Uppsala/SE (HAKAN.AHLSTROM@AKADEMISKA.SE)*

CT, MRI, PET, PET-CT and PET-MRI datasets contain huge amounts of spatially detailed morphological, functional and metabolic information. Today, when analysed, these detailed datasets are typically heavily reduced to a few

measurements of a priori specified measurements of interest (e.g. volumes, areas, diameters, average/maximum tracer concentrations, etc.) and/or visually - and, therefore, inevitably subjectively - assessed by a human operator. As a result, normality/non-normality can only be assessed on these measurements and not on the entire data collected, and statistical interaction with non-imaging parameters can also be assessed only on these a priori specified measurements. To utilise the full potential of these image datasets, new analysis tools included in the concept radiomics, which allow objective or quantitative assessment of all imaging data (including, e.g. previously discarded information about texture), are needed. Radiomics can be divided into distinct processes: (a) image acquisition and reconstruction, (b) image segmentation and rendering, (c) feature extraction and feature qualification and (d) databases and data sharing with non-imaging data (e.g. different "omics" and clinical data) for (e) informatics analyses. Statistical knowledge of the normal range of radiomics features are needed for the analyses. These analyses are anticipated to bring out new associations and understandings that traditional approaches could not achieve. Radiomics features can, together with non-imaging data, be included in models that have shown to provide valuable diagnostic, prognostic or predictive information for oncological diseases. This information aims at improving individual patients' outcomes by a better treatment selection.

Learning Objectives:

1. To learn how radiomics can be measured with imaging methods.
2. To discuss how radiomics can be integrated in "omics" analysis.
3. To explore the potential of radiomics analysis in cancer care.

A-376 08:53

Radiomics in radiotherapy: how is it used to personalise treatment and to predict toxicity and/or tumour control

C. Gani; *Tübingen/DE (cihan.gani@gmail.com)*

Radiomics is defined as the automated or semi-automated extraction of a large number of features from imaging datasets resulting an individual "imaging phenotype". These features and the imaging phenotype can then be correlated with a variety of other parameters: from genetic phenotypes to oncological outcome data. Radiomics as a non-invasive procedure is of particular interest for the radiation oncologist in times of precision radiation oncology: The radiomics phenotype might help to identify patients at high risk for treatment failure and, therefore, candidates for more aggressive treatment. Furthermore, radiomics can also be a helpful tool to predict the risk for radiation-induced toxicities and guide the dose distribution within normal tissues. This lecture will give an overview about the existing data on radiomics in the field of radiation oncology.

Learning Objectives:

1. To understand how radiomics can be used to identify patients at high risk for failure after radiotherapy.
2. To discuss how radiomics can be integrated into radiotherapy treatment planning.
3. To explore the potential of radiomics to predict acute and long-term toxicity after radiotherapy.

A-377 09:13

Uncertainties in imaging: how they should be reported and propagated in prediction models using radiomics

L.P. Muren; *Aarhus/DK*

"no abstract submitted"

Learning Objectives:

1. To understand how to incorporate radiomics into RT response models.
2. To discuss how uncertainties should be estimated and reported.
3. To explore the effect of image uncertainties in RT response models.

A-378 09:33

Imaging banks: challenges and opportunities

A. Van der Lugt; *Rotterdam/NL (a.vanderlugt@erasmusmc.nl)*

An imaging biobank can be defined as an organised database of medical images and associated imaging biomarkers (radiology and beyond) shared among multiple researchers, and linked to other biorepositories. An imaging biobank is designed for scientific use. Image data are systematically analysed visually, manual, or (semi)-automated with the main aim to extract imaging biomarkers than can be related to patient characteristics such as medical history, genomic data, and outcome or disease characteristics such as genomic data, biomaterials or response to treatment. The data storage is structured in a way that the database can be queried and retrieved based on available metadata. To exploit the available information interactions with other databases are a perquisite. General requirements with respect to the data collection are, therefore, a database facilitating storage of image data and metadata, storage of derived image-based measurements, and storage of associated non-imaging data, taking into account the need to deal with longitudinal data, and to cope with multiple file formats. Finally, automated retrieval is needed for image analysis pipelines that extract image features for radiomics signatures or for hypothesis-free deep learning algorithms.

Learning Objectives:

1. To understand what is an imaging biobank.
2. To discuss how an imaging biobank can be integrated in cancer care.
3. To explore the intraoperability of clinical imaging biobank and other data repositories.

Joint Session of the ESR Working Group on Ultrasound with EFSUMB

Handheld devices: a game changer?

A-379/A-380 08:30

Chairmen's introduction

P.S. Sidhu; *London/UK (paulsidhu@btinternet.com)*
M. Claudon; *Vandoeuvre-les-Nancy/FR (m.claudon@chu-nancy.fr)*

Middle and high-quality portable ultrasound machines are now widely available in the market. There is a large range in commercial offer, with various levels of performances but most of these units allow for grayscale and Doppler mode. The basic concept is to meet patients at the point-of-care, in the hospital and in the outpatient clinic and take benefit form a fast, early imaging examination. Alternative interest has been proposed for education of medical and non-medical students.

Session Objectives:

1. To learn about which handheld devices are available and the price range in rent or buy setups.
2. To learn about the requirements for image quality and image storage.
3. To learn about the training requirements for medical personnel and how to potentially bring US into the medical school.

Author Disclosure:

P.S. Sidhu: Speaker; Bracco, Siemens, Philips, Samsung, GE Healthcare, Hitachi.**M. Claudon:** Speaker; Philips Ultrasound.

A-381 08:45

Reviewing the market

M. Bachmann Nielsen; *Copenhagen/DK (mbn@dadlnet.dk)*

Most ultrasound (US) manufacturers offer handheld or portable devices in addition to their more traditional larger mid- and high-end machines. The price of handheld devices is generally lower, but they may lack features like elastography, contrast agent imaging and biopsy guidance. An advantage of handheld US devices is that due to their small size they fit into the pockets of a physician's lab coat. The smallest handheld devices are composed of a transducer with a USB connection to a tablet or a smartphone. Many of the large companies we know from radiology now also offer handheld devices, e.g., GE Healthcare, Philips. Some comes with a screen; some connects to the user's own smartphone. Philips sell their Lumify system only as a rental product for a low monthly fee and only in the USA. In addition, a large market exists on the internet for cheap wireless or USB transducers and for portable devices on web-based marketplaces like Alibaba. Another addition to the market is a cloud-based telehealth service by some seen as another business case to distribute ultrasound to users with little experience in diagnostic ultrasound.

Learning Objectives:

1. To learn about which handheld US devices are available on the market.
2. To learn about different pricing levels of the US equipment based on rent or buy models.

A-382 09:00

Who can use the equipment and reimbursement

R.F. Havre; *Bergen/NO (roald.flesland.havre@helse-bergen.no)*

Ultrasound scanners have become portable and cheaper, while the image quality has improved. Several clinicians have discovered the usefulness of the portable ultrasound (US) scanners and they are increasingly used in general practice, by hospital departments and even in ambulances. The users of ultrasound should be health care professionals including medical doctors, sonographers and in some countries US midwifes. It is important that users of US equipment have adequate training to perform US examinations in their clinical practice. The responsibility for this should be the departments in which

the examinations take place and be defined by training curriculums for the medical specialities. US training can also be included in medical school. Basic or more advanced US courses arranged by national and international US societies. Not all portable devices have interfaces for easy and safe storage of images. This is an important issue as images serve as documentation. It is important that safe storage is provided preferably to the PACS systems of the department in charge of medical treatment. The solutions for image storing may be an important for selection of models. The reimbursement for ultrasound scanning is depending on the group of health care personnel who perform the examination and not by the type of equipment used. Medical doctors in general practice in Norway have reimbursement for specific US examinations. When point of care US is performed in hospitals as a part of a clinical examination of in-patients, it is generally not reimbursed specifically.

Learning Objectives:

1. To learn about the possible requirements for image quality and storage for handheld devices.
2. To learn about the requirements for training and profession for using the equipment.
3. To learn about different reimbursement requirements and practices in selected European countries.

A-383 09:15

Appropriate training

H. Prosch; *Vienna/AT (helmut.prosch@meduniwien.ac.at)*

Ultrasound (US) is an indispensable diagnostic tool, not only in radiology, but also in almost all clinical specialities. In addition to its use for thorough, systematic examinations, US is used more and more in point-of-care examinations where single, specific clinical questions are addressed (i.e. the search for pleural effusions or ascites, pneumothorax, hydronephrosis). With the use of ultrasound contrast media, the diagnostic value of US increases even further. As with all imaging modalities, specific training is required to gain the required skills. Consequently, the radiologic training curricula of most European countries, as well as the European training curriculum for radiology of the European Society of Radiology, demand that residents must learn US skills. In addition to a profound theoretical knowledge about the technical aspects of ultrasound, anatomy, and pathology, US requires substantial hands-on training to reach sufficient expertise. A comprehensive hands-on training necessitates a case-by-case teaching protocol in which the attending physician supervises the examination. Simulation-based training has proven to be an effective means to further improve US training, particularly to achieve mastery in ultrasound-guided biopsies. Only a structured training curriculum that combines all these different aspects of US training can make it possible for US to fulfil its role as the stand-alone diagnostic tool and the problem solving tool it can and should be.

Learning Objectives:

1. To get an overview on the current status of ultrasound training in radiology.
2. To appreciate the pivotal role of ultrasound in the understanding of basic anatomy and pathology.
3. To become familiar with the importance of one to one teaching in ultrasound.

A-384 09:30

Ultrasound to train students

V. Cantisani; *Rome/IT (vito.cantisani@uniroma1.it)*

Ultrasound is an effective method used throughout the world for clinical workup of patients with a wide range of diseases, particularly as first-line imaging modality. Technological advancements have made the equipment accessible and affordable up to hand-held ultrasound devices. Therefore, education and subsequently preparation and updating of US knowledge is crucial. EFSUMB (European Federation of Societies for Ultrasound in Medicine and Biology) and others have published an atlas on anatomy and examination technique of handheld devices. Medical student education is traditionally based on “classical” training methods such as presentations, courses and workshops. However, new technologies and web-based sources of information have opened novel educational applications in medical practice. The European Federation of Societies for Ultrasound in Medicine and Biology (EFSUMB) recommends that ultrasound should be used systematically as an easily accessible and instructive educational tool in the curriculum of modern medical schools. Medical students should acquire theoretical knowledge of the modality and hands-on training should be implemented and adhere to evidence-based principles. EFSUMB policy statements on medical student education in ultrasound, update of the actual status on US Medical Education worldwide and the activities already decided will be discussed.

Learning Objectives:

1. To provide current status of education in ultrasound of medical student.
2. To provide EFSUMB proposal and strategy in student education.

Understanding paediatric neuroradiology

Moderator:
A. Rossi; Genoa/IT

A-385 08:30

A. Imaging of the premature brain

N. Khandelwal; *Chandigarh/IN (khandelwaln@hotmail.com)*

Dramatic reduction in mortality rates of premature infants in recent times due to better perinatal care has not really translated to exceptional neurodevelopmental outcomes in these patients. Neuroimaging has taken a front stage in evaluation, diagnosis and prognostication of premature neonates. Ultrasound (US) forms the backbone of current neuroimaging practice in small babies. Magnetic resonance imaging (MRI) has matured recently as an excellent modality to better identify and classify intracranial structures. The premature brain is significantly different in terms of volume, structure, maturity (myelination pattern) and disease appearance as compared to childhood brain. Myelination progresses in the following order in human brain - caudal to cranial, centre to periphery and posterior to anterior. Identification of brain maturity by means of myelination pattern helps us in identifying and classifying white matter disorders. The distinctly variable patterns of involvement of susceptible structures, namely the deep grey nuclei and white matter in hypoxic-ischaemic brain injury in premature and mature brains is worth understanding as helps in evaluating and prognosticating such patients. MRI helps in comprehensive brain evaluation while US is a good, handy, radiation-free tool for follow-up.

Learning Objectives:

1. To discuss the roles of US, (CT) and MRI in preterm imaging.
2. To give an overview of the different imaging findings in the preterm brain related to age.
3. To discuss the prognostic role preterm brain imaging.

A-386 09:00

B. Abusive head trauma: the role of CT and MRI

C. Adamsbaum; *Le Kremlin-Bicêtre/FR (c.adamsbaum@bct.aphp.fr)*

Abusive head trauma (AHT) is a leading cause of morbidity and mortality in infants. The presence of a diffuse subdural haematoma (SDH) with no evidence of accident is a key diagnostic clue. The haematoma is due to rupture of the cerebral bridging veins due to violent shaking. Neuroimaging is crucial for the diagnosis of AHT. The presence of SDHs, especially in multiple locations, such as the interhemispheric region, over the convexity and in the posterior fossa, is significantly associated with AHT. CT is the first-line imaging modality for suspected AHT, particularly in case of acute or subacute symptoms. CT exquisitely demonstrates intracranial haemorrhages, skull fractures and soft tissue swelling of the scalp. In addition of CT, early MRI within the first week provides a better estimation of parenchymal injuries (hypoxic-ischaemic insult, contusions). MRI can also disclose subtle key signs for the diagnosis of AHT such as rupture/thrombosis of bridging veins at the convexity and/or ligamentous cervical injuries. Both CT and MRI offer wide ranges for dating the causal event. In particular, mixed density/intensity pattern of SDHs is frequent and provides no reliable clues for assessing repeated violence. Only the finding of different density in two distant SDHs argues in favour of "age-different" injuries. As a reminder, in all cases of suspicion of AHT, the full skeletal survey is also mandatory.

Learning Objectives:

1. To discuss the role of CT and MRI in imaging of abusive head trauma (AHT).
2. To give an overview of common CT and MRI findings in AHT.
3. To understand the strengths and limitations of CT and MRI in imaging AHT.

A-387 09:30

C. Imaging in hypoxic-ischaemic injury and hypothermia: an update

F.M. Triulzi; *Milan/IT (Fabio.triulzi@policlinico.mi.it)*

The incidence of hypoxic ischaemic encephalopathy (HIE) ranges from 1 to 8 per 1000 live births in developed countries, it accounts for approximately 15%-20% of neonatal mortality in full-term neonates. Differently from adults, in whom acute anoxic-ischaemic injury causes diffuse brain injury predominantly involving gray matter, neonatal HIE is generally more selective. The most frequent type of injury on MRI in term newborns consists of selective involvement of areas with higher energy requirements, i.e. the lateral thalami, posterior lentiform nuclei, hippocampi and perirolandic cortex. Moreover, the absence of a normal PLIC on T1-weighted images in asphyxiated infants has a high positive predictive value (100% of abnormal neurodevelopmental

outcome). In order of frequency, other locations of brain involvement in full-term newborns with HIE include the perirolandic and primary auditory cortex and optic radiation, the hippocampal formation and limbic cortex and the dorsal mesencephalic structures. Conventional MR sequences, diffusion, spectroscopy and more recently perfusion have been widely used in the last twenty years to find out the more reliable prognostic biomarker. There are now several evidences of benefits in neuroprotection by cooling treatment. No major complications are associated with therapeutic hypothermia and the predictive value of MRI for subsequent neurological impairment seems to be not affected by this kind of therapy. Being cooling therapy effective in the acute phase of HIE the role of MRI is now predominantly related to a better assessment of the brain damage in the subacute phase of asphyxia, when lesion load is well established.

Learning Objectives:

1. To discuss the role of US, (CT) and MRI in hypoxic-ischaemic injury (including advanced MR techniques).
2. To give an overview of common imaging findings in hypoxic-ischaemic injury (HIE).
3. To understand the importance of timing and prognostic value of imaging in HIE.

08:30 - 10:00 **Room N**

Cardiac

RC 903

Novel ways to assess myocardial tissue

Moderator:
O. Duvernoy; Uppsala/SE

A-388 08:30

A. T1 mapping: technical considerations
M.R. Makowski; *Berlin/DE (marcus.makowski@charite.de)*

In this refresher course, the current role of cardiac MRI for the characterisation of myocardial diseases with a focus on novel mapping techniques will be discussed. The limitations of current imaging techniques will be highlighted. The potential of novel T1 mapping technical approaches will be introduced. This refresher course will finish with clinical case examples.

Learning Objectives:

1. To learn about the principles of T1 mapping.
2. To learn about specific issues of T1 mapping.
3. To learn how to do and assess T1 mapping.

A-389 09:00

B. T2 mapping: technical considerations
C. Tessa; *Lido di Camaiore/IT (ctessa@sirm.org)*

Cardiac T2 mapping represents an alternative approach to traditional T2-weighted imaging that allows to quantify myocardial T2 relaxation times. Parametric T2 maps are obtained by collecting multiple images with different T2-weighting, providing multiple points along the T2 decay curve for fitting of an exponential signal decay model. To this purpose, T2-prepared steady-state free precession (SSFP) sequences as well as multi-echo-spin-echo (MESE) or gradient-spin-echo (GRASE) sequences can be employed. They can be acquired both in breath-hold and during free breathing, utilizing respiratory navigators. Optional motion correction algorithms may be applied to compensate for mis-registrations between the images used to generate the parametric maps. The maps are usually acquired in diastole, but they can also be obtained in systole to reduce partial-volume effect. T2 maps can be analysed both visually and quantitatively, by means of ROIs or automatic thresholds. T2 mapping sequences are less prone to artefacts than traditional T2-weighted sequences, and their reproducibility is very good. However, T2 relaxation time is very sensitive to co-factors and it is, therefore, necessary to generate reference values specific for each site, technique and imaging setting. Furthermore, studies in healthy controls have found a relatively large inter-subject variability in T2 measures that may potentially cause problems when trying to define cutoff values at single subject level. To date, there have been only a few single-centre studies. Further multi-centres trials in larger sample are needed to fully explore the potential of T2 mapping techniques.

Learning Objectives:

1. To learn about the principles of T2 mapping.
2. To learn about specific issues of T2 mapping.
3. To learn how to do and assess T2 mapping.

A-390 09:30

C. Clinical use of T1 and T2 mapping
H.J. Lamb; *Leiden/NL (h.j.lamb@lumc.nl)*

This lecture will provide an overview of the current and future application of MR multi-parametric imaging using T1- and T2-mapping techniques. The main field of application in cardiology is to determine tissue properties in a broad range of cardiomyopathies and metabolic disease such as metabolic syndrome and diabetes type 2. Based on an MR physics of multi-parametric MR imaging, first clinical applications will be discussed, followed by more advanced future application of T1-/T2-mapping. The overview aims in general to show the potential of quantitative MR imaging, which is also applicable in other organs than the heart, such as liver and kidney.

Learning Objectives:

1. To learn about the main fields of application for T1-T2 mapping.
2. To learn the specific parameters useful for the clinical implementation of T1-T2 mapping.
3. To understand the incremental value of T1-T2 mapping over current methodologies.

08:30 - 10:00 **Studio 2017**

Professional Challenges Session

PC 9

Implementing and evaluating clinical decision support (CDS) for imaging referral guidelines

A-391 08:30

Chairman's introduction
L. Oleaga Zufiría; *Barcelona/ES (lauraoleaga@gmail.com)*

Clinical decision support systems (CDS) represent computer application systems to enhance decision-making in the clinical workflow. These tools include clinical recommended guidelines, condition-specific order sets, computerized alerts and relevant reference information. Among the benefits of the use of CDS, we can include increase of quality and safety of care, avoidance of errors and improved efficiency. Implementation strategies and outcomes in the hospitals depend on their culture and resources. The introduction of a CDS includes a number of steps, such as identifying the needs and functional requirements, designing or configuring the system for use in the local environment, planning the implementation process and determining how to assess the needs identified. Most research has evaluated the effects of CDS, it has been focused primarily on clinician decision-making, but little has been published on how those decisions affect patient's outcomes. It is important to involve clinicians to avoid misconceptions about the use of CDS. Finally, an application of the CDS includes its application in medical schools to train students on the appropriateness of the imaging techniques in the clinical setting.

Session Objectives:

1. To understand the challenges to implementing CDS.
2. To learn from practical experiences of CDS implementation.
3. To understand how a CDS implementation can be evaluated and impact measured.
4. To understand the perspective of CDS users: referring physicians.

A-392 08:35

The role of basic and advanced CDS in value-centred radiology
H.-U. Kauczor; *Heidelberg/DE (Hans-Ulrich.Kauczor@med.uni-heidelberg.de)*

Radiologists are participating in the transition from the volume-centred pay-for-service to the value-centred pay-for-performance. Thus, clinical and economic outcomes are driving the reimbursement. However, the definition of metrics to measure performance, quality and outcome within the complex web of the healthcare system is challenging. Overall, the goal-directed behaviour of patients, ordering physicians, radiologists and specialists has to be aligned. As workflow is critical, incentives for improvements in collaborative care are pivotal. CDS will play an important role in improving quality and efficacy of the workflow and the radiology service in value-centred medicine. Basic CDS will check the appropriateness of CT or MRI for a given clinical scenario, mainly based on evidence and guidelines. Major challenges of CDS are 1) the deep integration into an existing multi-vendor environment of HIS and RIS as well as image acquisition devices and PACS; 2) data security and patient privacy issues between different health care providers and the integration of a cloud-based service into the system; 3) the adaptation of the basic "guidelines" of the CDS provider to the specific requirements of the institution and its imaging

department(s). This in particular relates to the level of healthcare (in- or outside, prevalence of disease), complexity of cases, comorbidities, local, regional and national standard of care and operating procedures. Advanced CDS should also check for already available imaging studies and reports as well as whether intravenous contrast should be given. If yes, contraindications (allergies, renal insufficiency, etc.) should automatically be checked from the electric patient record.

Learning Objectives:

1. To learn about challenges in the implementation of CDS.
2. To understand the opportunities of advanced functions of CDS.
3. To appreciate the contribution of CDS to value-centred radiology.

A-393 08:50

Evaluating CDS implementation and measuring outcomes

M.G.M. Hunink; *Rotterdam/NL (m.hunink@erasmusmc.nl)*

Background: guidelines and appropriateness criteria have been published to help physicians choose the right test for the right patient at the right time. These are typically implemented through computerized decision support systems (CDSSs) so that the advice is presented at the point-of-care. ACR select and ESR iGuide are such systems. The results of implementation of CDSSs for guiding imaging referrals is, however, not (yet) convincing: are CDSSs really cost-effective in guiding the justified use of imaging procedures? Study designs to evaluate CDSSs: to evaluate interventions, ideally a parallel group double-blinded RCT is performed but this is not feasible in this context given the nature of the intervention. A pragmatic parallel group RCT may be feasible but contamination effects between care-givers could easily occur invalidating such a study and this study design would be logistically difficult to perform. More realistic is a stepped-wedge cluster RCT or a matched pair cluster RCT. So far single-centre before-after studies have been published with their limitations. Outcome measures to evaluate CDSSs: ideally mortality, morbidity, quality of life and costs are evaluated to determine the cost-effectiveness of implementing CDSSs, requiring large studies with long follow-up. More realistic is to measure short-term quality of life, complications of testing and costs of the diagnostic workup. So far studies have focused on diagnostic yield and the number of exams ordered which provides only a very limited picture.

Learning Objectives:

1. To understand the difficulties in evaluating the impact of CDS and guideline use.
2. To learn about what can be measured and how.
3. To understand how comparisons between different hospitals can be drawn and lessons learned.

Author Disclosure:

M.G.M. Hunink: Advisory Board; ElBIR. Grant Recipient; ESR iGuide. Other; CUP: Royalties for textbook.

A-394 09:05

Using CDS: referring physicians' perspective: GPs

J.F.M. Metsemakers; *Maastricht/NL*

"no abstract submitted"

Learning Objectives:

1. To understand how referrers view and what they expect from imaging referral guidelines.
2. To learn how CDS can best be integrated into referral workflows and what to avoid.
3. To learn how general practitioners can best be involved in the process of introducing CDS.

A-395 09:20

CDS implementation in the classroom: ESR eGuide

L. Donoso; *Barcelona/ES (ldonoso@clinic.ub.es)*

Imaging referral guidelines are not only a legally recognised concept to ensure imaging is used appropriately or an evidence-based tool to improve clinical practice, but also a vital educational tool. Over the past years, the ESR has worked to create CDS-compatible guidelines based on the American College of Radiology Appropriateness Criteria which are now available at the point of care through ESR iGuide. Building on this effort, the ESR eGuide project aims to reap the educational benefits of referral guidelines and clinical decision support. An ESR Education Committee Taskforce is creating case studies on appropriate imaging to be solved with decision support using the ESR's referral guidelines. Taking a long-term approach to improving appropriateness in medical imaging, the overall purpose of this project is to educate doctors-in-training about appropriate imaging using evidence-based referral guidelines, while introducing the concept of clinical decision support and familiarising them with a technology they will encounter in their professional careers. The ESR eGuide project is part of the implementation of the EuroSafe Imaging Call for Action with regard to Action 1 on Clinical Decision Support and Action 6 focusing on educational activities including the development of e-learning tools. The objectives of ESR eGuide are: improving the quality of medical education with regard to diagnostic imaging, educating medical students about the appropriateness of different imaging modalities for given clinical indications, familiarising medical students with CDS technology, demonstrating the efficacy and utility of CDS, reinforcing the concept of evidence-based medicine.

Learning Objectives:

1. To understand how guidelines and CDS can be used for education.
2. To understand how test cases are developed and hear about user experiences.
3. To learn about the ESR eGuide project and how to participate.

09:35

Panel discussion: Introducing CDS for medical imaging referrals: what to do and how to measure

08:30 - 10:00 **Room E1**

Breast

RC 902

Minimally-invasive local treatment of breast cancer: the time is now

A-396 08:30

Chairman's introduction

M. Sklair-Levy; *Tel Aviv/IL (mirisklair@gmail.com)*

Breast cancer is the most common cancer among women in the western world. The aim of early diagnosis is to detect smaller cancers.Since we can detect smaller tumours, there is a shift towards less invasive treatment. With a transition from Radical mastectomy to breast conserving therapy is a well established practice. The question is are we ready for the next step to minimally/non-invasive therapy of small breast cancer. Are we ready to the NEXT REVOLUTION of Non-Surgical Ablation of breast cancer. Using minimally invasive image-guided tumour ablation techniques. There are many techniques available, such as radiofrequency ablation (RFA); laser ablation (ILT); microwave ablation; focused US ablation - high-intensity focused (MR-guided focused ultrasound - MRgFUS); cryoablation - ablates tumour tissue by cooling; MRg-FUS - is a noninvasive thermal ablation method using high-intensity focused ultrasound - US thermal ablation beam that heats and destroys targeted tissue, non-invasively using an accurate MRI guidance. It can achieve precise thermal ablation following target definition, treatment planing and control of energy deposition during treatment. Integrating FUS and MRI as a therapy delivery system enables to localise, target, treat, monitor in real time without damaging surrounding tissue. The different techniques will be described in detail.

A-397 08:35

A. High intensity focused ultrasound (HIFU) therapy

B. Cavallo Marincola; *Rome/IT (beatrice.cavallomarincola@gmail.com)*

Surgical treatment of breast cancer has changed overtime, evolving from radical mastectomy to more conservative approaches. This has been possible thanks to technical advantages in the field of diagnostic imaging that allowed early diagnosis of breast cancers with very small dimensions. Mini-invasive technologies (radiofrequency ablation, cryoablation, etc.) can preserve the original breast volume avoiding glandular resections and surgical scars and ensuring at the same time complete tumour ablation. Ablation with high-intensity focused ultrasound (HIFU) is based on the use of an extra-corporeal ultrasound transducer that selectively destroys target tissue avoiding thermal damages to surrounding structures. The technique can be performed under ultrasound or magnetic resonance (MR) guidance. MR guidance offers several advantages that improve safety and efficacy of the procedure: a visualization of the planned US beam during each phase of the procedure, a real-time monitoring of the progressive temperature increase within the target tissue and surrounding tissues, an accurate treatment planning, an evaluation of the treatment efficacy thanks to the use of intravenous gadolinium-based contrast agent. HIFU ablation of breast cancer is a new and promising technique that deserves large interest in the field of clinical research in order of its potential application in the clinical practice.

Learning Objectives:

1. To learn about the basics of HIFU therapy.
2. To become familiar with the different types of imaging guidance.
3. To appreciate its role in treating benign and malignant lesions.

A-398 09:00

B. Radiofrequency ablation therapy

B. Brkljačić; *Zagreb/HR (boris@brkljacic.com)*

Radiofrequency ablation (RFA) is a promising but quite rarely used minimally invasive modality to treat small breast cancer in patients in whom general anaesthesia is contraindicated or who refuse surgery. In most studies, cancers were surgically excised shortly after RFA. In very few studies, RFA was used as the only treatment modality, instead of surgery. The procedure is most conveniently performed under ultrasound guidance, in local analgesia, which allows constant contact with the patient during the procedure. Precise preprocedural imaging is crucial, and should include contrast-enhanced MRI in addition to mammography and ultrasound. Preprocedural core biopsy is mandatory, with the precise assessment of the tumour type, grade, and immunohistochemical features. Typical US findings of hyprechogenicity of ablated mass are noted during the procedure. Postprocedural mammographic and MRI findings are characteristic and will be presented. The complete ablation can be achieved in small T1-2 N0 M0 breast cancers that present as masses of maximum 2-3 cm in diameter, with the sufficient distance from the skin and pectoral muscle to avoid the thermal lesion of these tissues. In larger lesions only partial ablation may be achieved. Only solitary, unicentric, invasive ductal cancers, preferably ER/PR positive should be treated. Invasive lobular cancers should not be treated with RFA. Our results will be presented in a small group of patients who were treated with RFA, and who refused surgery, had contraindication to general anaesthesia and opted for RFA. The technique, preprocedural, intraprocedural and postprocedural imaging findings, as well as long-term result will be presented.

Learning Objectives:

1. To learn about how radiofrequency works.
2. To become familiar with its use in clinical practice.
3. To appreciate the advantages and disadvantages.

Author Disclosure:

B. Brkljačić: Speaker; Guerbet, Bayer.

A-399 09:25

C. Cryotherapy

M.H. Fuchsjäger; *Graz/AT (michael.fuchsjaeger@medunigraz.at)*

Cryotherapy is a new, minimal-invasive image-guided treatment option for breast tumours. A specific 12-17G probe is applied into the tumour. Argon gas making use of the Joule-Thomson effect cools down the needle tip to minus 187 degrees centigrade. An ice ball covering lesion and an adequate safety margin is formed. Coagulative necrosis of the tumour cells after two freezing cycles is the result. Cryoablation for breast tumours can be performed under US, CT or MRI guidance. Several studies showed an overall success rate of more than 90%. Indications for cryotherapy are small tumours, contraindications to general anaesthesia or increased risk of complications, support of standard therapies and palliative approach. Cryotherapy can be performed under local anaesthesia on out-patient basis with a potential better cosmetic outcome than standard surgical therapies. Minimal-invasive therapies ask for a paradigm-shift as the eradicated tumour is left in situ and resection with clear margins will not be proven histopathologically but functionally by MR imaging. It is important to emphasize that radiology is not aiming to take over therapy of breast cancer patients but to help with innovative, less invasive treatment options as a member of a multidisciplinary team. Close cooperation with our clinical partners (surgery, gynaecology, oncology, radiation therapy, etc.) is the key to success and avoidance of turf battles. The goal for the future should be minimal-invasive ablation therapy for breast cancer as a valid therapeutic option.

Learning Objectives:

1. To learn about cryotherapy technique.
2. To become familiar with its use in clinical practice.
3. To appreciate its role in treating benign and malignant lesions.

09:50

Panel discussion: How can we overcome resistance of clinical partner specialties to refer eligible women to radiology?

Neuro

RC 911

Cerebrovascular disease

Moderator:
A. Krainik; Grenoble/FR

A-400 08:30

A. Vascular distribution territories: arterial and venous

A. Dörfler; *Erlangen/DE (arnd.doerfler@uk-erlangen.de)*

After a short overview on the vascular anatomy of the brain with a focus on vascular distribution territories, the main aim of this presentation is to present different neurovascular pathologies closely associated with arterial and venous vascular distribution territories. A focus is here put on acute stroke and particularly imaging-based patient selection for interventional stroke therapy and venous pathologies. Another aim is to provide a better understanding of pathophysiology of different neurovascular disease in an interactive matter. In addition, advantages and limitations of CTA and MRI compared to conventional angiography are presented.

Learning Objectives:

1. To become familiar with a comprehensive vascular anatomy of the brain.
2. To understand the advantages and limitations of CTA and MRA.
3. To recognise the different imaging patterns in stroke and their prognostic value.

A-401 09:00

B. Arterial dissection and vasculitis

P.C. Maly Sundgren; *Lund/SE (Pia.Sundgren@med.lu.se)*

This lecture will focus on imaging findings with arterial dissection and the best method of choice for diagnosis. Also underlying causes will be briefly reviewed. Vasculitis is a rare condition. It is not always easy to diagnoses and multiple imaging modalities might be needed to come to final diagnosis. In this lecture, typical imaging patterns of the more common disease with vasculitis changes will be discussed, as well as discussion over which imaging method to use and the clinical implications for patients with vasculitis.

Learning Objectives:

1. To learn how to image dissections of the neck vessels and intracranial arteries.
2. To learn about the imaging features of cerebral vasculitis and how to differentiate it from reversible cerebral vasoconstriction syndrome.
3. To become familiar with the most important causes of secondary vasculitis, including infectious causes such as TB and HIV.

Author Disclosure:

P.C. Maly Sundgren: Research/Grant Support; SUS donation founds Lund, Sweden, Gustav V 80 years foundation, Swedish rheumatology Foundation, Kocks foundation, Sweden.

A-402 09:30

C. Cerebral perfusion studies in cerebrovascular disease: techniques, indications and applications

H.R. Jäger; *London/UK*

"no abstract submitted"

Learning Objectives:

1. To understand how imaging can help select patients for treatment of acute ischaemic stroke.
2. To show the importance of collateral flow in ischaemic patients.
3. To discuss the current evidence-based medicine (EBM) for treatment of patients with acute ischaemic stroke.

08:30 - 10:00 **Room F1**

Joint Session of the ESR and ESOR

Radiologic anatomy: lower extremities

Moderator:
U. Aydingoz; Ankara/TR

A-403 08:30

Hip

A.H. Karantanas; *Iraklion/GR (akarantanas@gmail.com)*

The painful hip is a common clinical problem in all age groups. Magnetic resonance imaging (MRI) is an invaluable tool to assess the hip joint because of its ability to directly visualize bone marrow, cartilage and soft tissues in multiple planes. MR arthrography (MRa) using intra-articular contrast material is the standard method for imaging labral lesions and cartilage degeneration. Understanding normal hip anatomy and common variants is important, to accurately detect and localize areas of pathology and to prevent misinterpreting normal structures as abnormal ones. Plain radiographs should always be available when reporting MRI because basic measurements allow assessment of underlying deformities which might explain the clinical and MRI findings. The most important to know are: joint space width (JSW), CE angle, VCA angle, alpha angle, acetabular retroversion and ischiofemoral space. Among the disorders causing hip pain, osteoarthritis (OA) is the most common one. Age is a risk factor strongly correlated with OA. Early OA is related to CAM type femoroacetabular impingement, developmental dysplasia and previous trauma. The diagnosis of OA is based on a combination of radiographic findings and characteristic subjective symptoms. The progression of OA traditionally has been measured using radiographic JSW. Weight-bearing radiographs centred on the hip are the most reproducible and reliable ones. The sequence of degeneration includes the following radiographic findings: joint space narrowing, osteophyte formation, subchondral sclerosis and cyst formation. In cases that radiographs show minor changes and high clinical suspicion of early disease, OA can be confirmed with MRI and/or MRa.

Learning Objectives:
1. To identify intra- and extra-articular anatomy on MRI.
2. To learn what we see and what we miss on plain film.
3. To understand osteoarthritis and learn its key features on imaging.

A-404 09:00

Knee

M. Klontzas; *London/UK (miklontzas@gmail.com)*

The prevalence of knee pain is constantly increasing worldwide, together with life expectancy and the prevalence of obesity. Advances in imaging technology over the last decades have rendered MRI the modality of choice for the evaluation of knee disorders. The use of MRI offers a comprehensive evaluation of the cartilage, the bone marrow and the soft tissues of the knee, providing high sensitivity and specificity for the diagnosis of common pathology such as cruciate ligament and meniscal tears, which cannot be visualized with plain radiographs. Knowledge of the normal cross-sectional anatomy of the knee is, therefore, of utmost importance for the evaluation of knee disorders and the discrimination between anatomical variations and clinically significant knee lesions. Menisci are among the most commonly injured knee structures, with a low signal intensity on MRI. Understanding of the variants of normal meniscal anatomy and awareness of meniscal injury patterns on MRI, combined with clinical history and examination data, can prove indispensable for the diagnosis of meniscal injuries and the avoidance of unnecessary diagnostic arthroscopic procedures.

Learning Objectives:
1. To identify intra- and extra-articular anatomy on MRI.
2. To learn what we see and what we miss on plain film.
3. To understand and learn the key features of meniscal injury.

A-405 09:30

Ankle

M. Maas; *Amsterdam/NL (m.maas@amc.nl)*

Injury of the ankle joint is a common entity, of which inversion is the most frequently seen trauma mechanism. This means that after applying Ottawa ankle rules conventional radiology of the ankle still occurs often in every day practice. And then things become difficult. Identifying a fracture on conventional AP, AP-Mortise (20 degrees of endorotation) and lateral views, being mainstay, is not that difficult, yet ruling out a fracture anywhere along the inversion line of the lateral ankle and foot is a challenge. In this presentation, anatomical landmarks will be provided to ease assessment and to aid structured reporting. So why is this difficult? Many bony landmarks that get injured are easily obscured on standard conventional radiology. Understanding biomechanics of this inversion trauma helps to analyse the images. Assessing according to the Lauge Hansen Classification of ankle trauma and subsequently ankle fracture makes things a bit better to understand. But the most important problem is the limitation of plain radiology in identifying soft tissue injury. Since both the lateral ligamentous complex, the syndesmotic network as well as the medial deltoid ligamentous network are prone to injury in inversion trauma, we need to be able to assess these soft tissue structures. For this purpose, cross-sectional imaging, preferably with MRI, yet also possible to a lesser extent with the use of CT scanning, is extremely helpful. Finally, cartilage injury of the talar dome might be caused by ankle inversion injury and needs assessment, preferably with MRI.

Learning Objectives:
1. To identify intra- and extra-articular anatomy on MRI.
2. To learn what we see and what we miss on plain film.
3. To understand and learn key features of ankle sprain.

08:30 - 10:00 **Room F2**

Special Focus Session

SF 9

The revival of lymphangiography

A-406 08:30

Chairman's introduction

B.A. Radeleff; *Heidelberg/DE (Boris.radeleff@med.uni-heidelberg.de)*

For decades, conventional bi-pedal lymphangiography has been considered the preferred technique for the evaluation of the lymphatic system and its disorders. Lymphangiography provides excellent architectural detail of the lymph nodes and lymphatic ducts. Intranodal lymphangiography (INL) was first reported in 1967 but the technique has been refined in the last 5 years. The lymph nodes are entered with ultrasound with a 25-23 G needle which provides an easy access to inject lipiodol and opacify the lymphatic system. This approach has simplified the technique, has shortened the time required for the procedure and, finally, has made it reproducible. Non-contrast MR lymphography is a new imaging technique and may be used for the diagnosis and classification of primary and secondary upper and lower limb lymphoedema. Therefore, it can be used for positive diagnosis, differential diagnosis and specific evaluation of lymphoedema pattern. Non-contrast MR lymphography may also be used as the modality of reference for the diagnosis of the so-called cystic lymphangioma but also for various lymphatic disorders such as lymphatic injuries resulting in chylous collections, chylous ascites and chylothorax. A postoperative (most common after oesophagectomy) or posttraumatic thoracic chyle leak is highly morbid and can carry significant mortality, if treatment is delayed. The gold standard for treatment of a chyle leak or postoperative chylothorax (e.g. after oesophagectomy) is a re-operation, either open or thoracoscopic, to ligate the thoracic duct. In this talk, I will discuss the technique of thoracic duct embolisation in cases of chyle leak and chylothorax.

Session Objectives:
1. To learn and to become familiar about the radiological diagnostic tools and therapy options (indication, technique and success) of lymphatic disease.
2. To understand the most important sequences and tricks for MR-lymphography for diagnosis and treatment steps leading to occlusion of chyle leaks.
3. To appreciate that diagnostics by non-contrast magnetic resonance lymphography in a near future could become the imaging modality of reference for investigation of lymphatic disorders.

A-407 08:35

"Theranostic" lymphangiography

E. Santos Martín; *New York, NY/US (ernessantos@gmail.com)*

Lymphangiography is a radiological image technique in which a radiopaque contrast medium (ethiodized oil) is injected into the lymphatic system. Lymphangiography provides excellent architectural detail of the lymph nodes and lymphatic ducts. For decades, conventional bipedal lymphangiography has been considered the preferred technique for the evaluation of the lymphatic system and its disorders, particularly in patients with lymphomas. The number of lymphographic studies performed in oncology centres has declined since the advent of simpler, less difficult and less morbid diagnostic tests (CT, MRI and PET), which have rendered the technique obsolete. Lymphangiography still has a role in the diagnosis, management and treatment of the lymphatic disorders, particularly in patients with lymphatic leaks and obstruction of the lymphatic vessels. Intranodal lymphangiography (INL) was first reported in 1967 but the technique has been refined in the last 5 years. The technique appears to be safer and faster than the old method. The lymph nodes are

entered with ultrasound with a 25-23 G needle which provides an easy access to inject lipiodol and opacify the lymphatic system. This approach has simplified the technique has shortened the time required for the procedure and, finally, has made it reproducible. INL has allowed to streamline the management of the patients with chylous leaks. Due to embolic properties of the lipiodol, lymphangiography can have therapeutic properties in patients with chylous effusions, ranging from 51% to 97%. This success is linked to the volume of the lymphatic drainage per day.

Learning Objectives:

1. To learn and to become familiar about the indication, technique and success of intranodal lymphangiography (INL).
2. To understand that intranodal lymphangiography is an effective option for further treatment method e.g. for chyle leaks.
3. To appreciate that if conventional lymphography is impossible, percutaneous intranodal lymphangiography is a valuable alternative.

A-408 09:00

MR lymphangiography

L. Arrivé; *Paris/FR (lionel.arrive@sat.aphp.fr)*

Non-contrast MR lymphography uses very heavily T2-weighted fast spin echo sequences with 3D acquisition and very thin section source images which obtain a specific display of lymphatic vessels. The raw data can be processed with different algorithms such as maximum intensity projection (MIP) algorithm. Lymphatic vessels are demonstrated with MR lymphography as alternating areas of constriction and dilatation representative of valves and contractile units. Non-contrast MR lymphography may be used in different fields. It is a unique non-invasive imaging modality for the diagnosis and classification of upper and lower limb lymphoedema. It can be used for positive diagnosis, differential diagnosis and specific evaluation of lymphoedema pattern (aplasic, hypoplasic and hyperplasic). Non-contrast MR lymphography is the modality of reference for the diagnosis of the so-called cystic lymphangioma which is a developmental abnormality characterised by lack of communications of regional lymphatic vessels resulting in marked dilatation. Non-contrast MR lymphography demonstrates that there is a continuous spectrum of change from normal variants to cystic lymphangioma. Non-contrast MR lymphography may also be used in various lymphatic disorders such as lymphatic injuries resulting in chylous collections, chylous ascites and chylothorax but also in lymphatic pathology of liver, spleen, kidney and chest. Non-contrast MR lymphography is a relative new imaging technique. The main limitation today is still the suboptimal spatial resolution. However, because of ongoing advances in software and hardware, in a near future it could become the imaging modality of reference for investigation of lymphatic pathology.

Learning Objectives:

1. To learn and to become familiar about the indication, technique and success of non-contrast magnetic resonance lymphography.
2. To understand the most important sequences and tricks for the non-contrast magnetic resonance lymphography.
3. To appreciate that non-contrast magnetic resonance lymphography in a near future could become the imaging modality of reference for investigation of lymphatic disorders.

A-409 09:25

Thoracic duct embolisation

H.H. Schild; *Bonn/DE (Schild@uni-bonn.de)*

Interventional thoracic duct occlusion has become an established alternative to surgical thoracic duct ligation in patients with a chylothorax that does not respond to conservative treatment. The first step of the procedure involves lymphographic delineation of abdominal and thoracic lymphatics. A lymph vessel that by course and size is a suitable access route to the thoracic duct is punctured transabdominally under fluoroscopy (or CT) with a 22 G needle. After insertion of a microwire, the puncture needle is removed, and a microcatheter advanced over the guide wire into the thoracic duct. After delineation of the anatomy to exclude anatomic variants, the duct is then occluded using first coils and then tissue adhesive. If for anatomical reasons the thoracic duct cannot be entered, percutaneous destruction of lymph vessels (by “scratching”) may be performed, or it may be tried to enter the duct transvenously in a retrograde fashion. Reported clinical success rates vary between 55 and 90%, depending on anatomy and cause of the chylothorax. The complication rate of the procedure is around 7%, with major complications being rare.

Learning Objectives:

1. To learn and to become familiar about the indication, technique and success of minimal-invasive therapies for thoracic chyle leaks.
2. To understand that thoracic duct embolisation is an effective treatment method for chylothorax.
3. To appreciate that if thoracic duct embolisation is impossible, percutaneous lymphatic destruction or injection of sclerosants/tissue adhesive next to the thoracicare valuabe therapeutic alternatives.

09:45

Panel discussion: Lymphangiography, are you convinced?

08:30 - 10:00 **Room D**

Multidisciplinary Session

MS 9

Primary bone tumours

A-410 08:30

Chairman's introduction

A.M. Davies; *Birmingham/UK*

Session Objectives:

1. To recognise the importance of a multidisciplinary approach to the diagnosis of bone tumours.
2. To appreciate the challenges faced by pathologists in making a diagnosis.
3. To appreciate the role of imaging from diagnosis to surgical planning.

A-411 08:35

Fundamental imaging

S.L.J. James; *Birmingham/UK (stevenjames@nhs.net)*

In this session, the fundamental requirements for bone tumour imaging will be discussed. The importance of radiographs will be stressed along with the important radiographic features to describe within a report. Local, regional and distant staging will also be described including a review of the current literature regarding the optimal modalities to perform this.

Learning Objectives:

1. To appreciate the diverse radiographic appearances of bone tumours.
2. To understand the importance of reviewing all imaging when making a diagnosis.
3. To become familiar with local and distant imaging strategies for staging.

A-412 08:55

Why I need the radiologist: the pathologist's perspective

L.-G. Kindblom; *Billdal/SE*

"no abstract submitted"

Learning Objectives:

1. To provide a reasoned differential diagnosis based on imaging findings.
2. To communicate the precise anatomical location and origin of the tumour.
3. To correlate imaging features of malignancy with histological findings.

A-413 09:15

The surgeon's perspective

L. Jeys; *Birmingham/UK (lee.jeys@nhs.net)*

"no abstract submitted"

Learning Objectives:

1. To orchestrate the multidisciplinary discussion of management based on combined imaging and histological findings.
2. To appreciate the significance of local and distant extent on management.
3. To learn about the imaging requirements for robotic surgery.

09:35

Multidisciplinary case presentation and discussion

08:30 - 10:00 **Room G**

EFOMP Workshop: Radiation incidents and accidents in medical imaging: can we prevent them?

EF 1

Radiation incidents and accidents in medical imaging and their management (part I)

Moderators:
J. Damilakis; Iraklion/GR
A. Torresin; Milan/IT

A-414 08:30

Chairman's introduction
J. Damilakis; *Iraklion/GR*

There are radiation incidents involving the exposure of a patient to a dose much greater than intended. Main reasons for these very high doses are a) lack of knowledge in medical radiation protection, b) poor equipment knowledge and c) use of inappropriate protocols. Accidental irradiation of pregnant patients during the first post-conception weeks leads to unnecessary termination of pregnancies. To avoid these radiation accidents, proper pregnancy screening is needed. In fluoroscopically guided interventional procedures with very long screening time, there is a possibility of cell killing sufficient to result in radiation-induced injuries in certain tissues of patients. There are also other causes of accidental exposure, for example, failure of staff to properly check the identity of patients. This may lead to radiation exposure of a patient who undergoes an x-ray procedure intended for another patient. Accidental medical exposures are a source of continuing concern. All measures should be taken to minimise the probability of accidental or unintended exposures of individuals subject to medical exposure.

Session Objectives:
1. To learn about the common reasons for radiation incidents and accidents in CT and interventional suites.
2. To learn about the common reasons for accidental exposure during pregnancy.
3. To be informed about the EU BSS requirements on radiation incidents and accidents in medical imaging and their management.

A-415 08:35

Radiation incidents and accidents in CT
M. Mahesh; *Baltimore, MD/US (mmahesh@jhmi.edu)*

Radiation incidents in diagnostic radiology are rare and may not be as life threatening as in radiation oncology, yet it is equally important to devise plans of action to address radiation incidents in diagnostic radiology. This talk will discuss various measures medical physicists can do to address such situations with focus on CT studies. Radiation incidents/accidents can lead to deterministic effects such as hair loss or skin erythema, which are rare but possible in CT scans (CT perfusion studies) due to incorrect settings or improper scanning. When radiation incidents occur, a physicist can do the following. First, physicist should record details of scan settings that have led to the radiation incident. Next, assess and make necessary changes to avoid future incidents. This should be followed by detail assessment of radiation exposure to patients (skin dose and organ dose) and work with the radiologists and other physicians to address the radiation events. Further, medical physicists can take precautions to avoid such incidents in future. Recently introduced 'CT dose alert' can be customized for each CT protocol such that incorrect settings that could lead to unintended high radiation exposure can be flagged prior to CT scan. In addition, features such as CT dose notification can further assist in periodic CT dose audits. This presentation will discuss in detail about the CT dose alert and CT dose notifications, which are key to avoid unintended radiation exposure to patients undergoing CT studies.

Learning Objectives:
1. To give an overview of radiation incidents and accidents in CT.
2. To discuss the lessons learnt from these incidents and accidents.
3. To learn how to manage incidents and accidents in CT.

A-416 09:05

Radiation incidents and accidents in interventional suites
R.W.R. Loose; *Nürnberg/DE (Loose@klinikum-nuernberg.de)*

The majority of radiation incidents and accidents in interventional suites are related to patients. Radiation accidents of staff members are very rare but may occur under specific circumstances. For example, staff members are at risk if parts of their body are for too long in the primary beam or if safety measures for new practices like SIRT with 90-Y are inadequate. A radiation accident to a patient means normally a deterministic injury - in most cases of the skin. Depending on the individual patient condition the threshold dose for accidents with skin injuries is above 2-5 Gy. Incidents may be unintended overexposures in the dose range of stochastic effects without injuries or "near miss" events without patient exposure. Incidents and accidents during interventional procedures can be avoided by precise and comprehensive standard operating procedures (SOP) and extensive training of all staff members involved. Every incident or accident should trigger a workup of the team to minimize the risk of a second occurrence. After a patient injury the patient and/or his relatives and the referring physician should be informed about recommendations for follow-up of possible lesions. The time delay in the occurrence of lesions may be in the range between 2 weeks and one year. Until February 6th 2018, the Council Directive 2013/59/Euratom has to be transposed into national regulations of member states requiring a recording and reporting of accidental and unintended exposures. Up to now, the approach of this transposition is unclear for many member states.

Learning Objectives:
1. To give an overview of radiation incidents and accidents in interventional radiology.
2. To discuss the lessons learnt from these incidents and accidents.
3. To learn how to manage incidents and accidents in interventional radiology.

A-417 09:35

Accidental exposure during pregnancy
J. Damilakis; *Iraklion/GR*

Accidental irradiation of pregnant patients occurs during the first weeks of gestation. During the first 2 weeks postconception, radiation will terminate pregnancy or the embryo will either recover completely (all or nothing effect). From the 3rd to 8th week postconception, the most possible form of damage is organ malformations. However, these effects are not likely to be observed after diagnostic imaging. After accidental exposure of pregnant patients, conceptus dose estimation is needed. CODE (COnceptus Dose Estimation) is a free web-based software tool for the estimation of embryo dose from radiography, diagnostic fluoroscopy, CT and fluoroscopically guided procedures. For more information about CODE, please visit embryodose.med.uoc.gr. Careful screening is needed to avoid accidental irradiation during pregnancy. X-ray departments must have posters in the waiting area asking female patients to inform the radiographer or radiologist about a possible pregnancy. According to ICRP publication 84, 'investigation of the reproductive status of a female of childbearing age prior to x-ray imaging' is needed. Article 62 of the new EU BSS states that 'Member States shall ensure that the referrer or the practitioner, as appropriate, inquire, as specified by Member States, whether the individual subject to medical exposure is pregnant or breastfeeding, unless it can be ruled out for obvious reasons or is not relevant to the radiological procedure'.

Learning Objectives:
1. To provide information about the frequency of accidental exposure of pregnant patients in imaging departments.
2. To learn how cases of accidental exposure of pregnant patients in imaging departments can be reduced.
3. To learn how to manage pregnant patients in case of accidental exposure to x-rays.

P. Due-Tønnessen; Oslo/NO

A-418 08:30

A. Patient and staff safety in medical imaging: what can be done?
S. Mc Fadden; *Newtownabbey/UK (S.McFadden@ulster.ac.uk)*

A wide variety of legislation and guidelines exist internationally to ensure that patient and staff safety in medical imaging is maintained. The systems for radiation protection for the 28 member states of the EU were initially based on the requirements of Council Directive 96/29/Euratom, i.e. European basic safety standards (EU BSS). The more recent Council Directive 2013/59/Euratom revises these standards and contains important changes to the legislation. In addition, a deadline of February 6, 2018 has been set whereby each member state must bring into force the laws and regulations necessary to comply with the new requirements. Free movement of health professionals within the European Union was established by Directive 2005/36 of the European Commission. This directive states that EU countries should recognise professional qualifications from other member states. However, the profession of radiography does not have specific requirements regarding training and education, or identification of required competencies defined at European level. Current research highlights great variation in the different education frameworks and competencies acquired during training by radiographic staff across the EU. Further work is required to standardise these qualifications and ensure safe movement of radiographic staff across member states. As technology continues to advance, the practice of radiography is continually evolving and new staff roles are emerging across all departments to accommodate these changes. A clear standardised framework recognising the different roles/competencies of radiographic staff, i.e. referrers, practitioners and operators across the EU is required to ensure safe autonomous practice is maintained.

Learning Objectives:
1. To appreciate the current guidelines and legislation across the EU.
2. To learn about current research and different roles of the radiographer.
3. To discuss different ways to ensure patient safety is maintained.

A-419 08:55

B. Aspects of safety: what should be considered?
K. Azevedo[1], C.A. Silva[2], A.F.C.L. Abrantes[1], L.P.V. Ribeiro[1], A.M. Ribeiro[1]; [1]*Faro/PT*, [2]*Évora/PT (kbazevedo@ualg.pt)*

The radiographer is a key element in the radiology department. To perform the examinations, from their programming, to their execution and evaluation, there are several factors that may influence patient safety, not only at the department level, but also at the healthcare facility level. It is clear that the main goal is to diagnose and treat the patient, but at the same time do no unnecessary harm. Incidents or accidents, more commonly seen as errors are one of the most assessed measurements when the topic is patient safety; however, as James Reason alerted, to err is human and healthcare is always a potentially hazardous sector. To maximize patient safety, the first step is to make it a cultural issue in the department and in the institution. Only if every healthcare worker understands the importance of this subject and feels like a link in the chain of safety, it becomes possible to achieve higher levels of safety. The professional responsibility in safety starts even before the first contact with the patient and ends after the last contact with the patient. During this period, several steps can be taken to increase safety and it is always important to check the progress in patient safety, by looking at indicators and to the healthcare worker perceptions.

Learning Objectives:
1. To appreciate the core competencies and the radiographer's role as a key element to ensure patient safety at the imaging department.
2. To learn about the main concepts of patient safety related to the radiographer's professional responsibility and ethics outlines at the imaging department level from a public or private hospital or even at the private practice level.
3. To discuss ways to promote patient safety and quality in imaging.

A-420 09:20

C. Patient safety: opportunities and challenges ahead in medical imaging
J. McNulty; *Dublin/IE (jonathan.mcnulty@ucd.ie)*

Patient safety is a major priority for all healthcare professions and undergraduate health professions education has the potential to improve patient safety. While patient safety curricula have been developed by many organisations to help support the introduction and promotion of patient safety within educational curricula, patient safety in medical imaging requires particular attention. There is a paucity of reports regarding the inclusion of patient safety topics within undergraduate radiography curricula and within radiology training programmes. We have reached a point where a comprehensive approach to patient safety from education and training through to service delivery cannot be viewed as optional. While some patient safety topics within medical imaging are stated to be comprehensively addressed across Europe, such as radiation protection, other topics may be being neglected. The starting point for addressing patient safety and any associated challenges is through an initial mapping exercise of how and where all topics are addressed in education and training programmes and how risk is minimised in clinical departments. While resourcing of new initiatives is often problematic, it would be negligent of educational and clinical service providers to overlook initiatives targeting patient safety on this basis. Education and training providers should actively engage with clinical departments and professional bodies to ensure the medical imaging department so that risks are minimised. European professional societies such as the European Federation of Radiographer Societies (EFRS) and European Society of Radiology (ESR) have significant roles to play in driving this activity.

Learning Objectives:
1. To appreciate the current status and challenges ahead with ensuring patient safety in medical imaging.
2. To learn about new ways of addressing the challenges ahead.
3. To discuss the implementation of patient safety focused curricula and the benefits for clinical departments.

Post-treatment evaluation: what every radiologist should know

A-421 08:30

Chairman's introduction
P. Haage; *Wuppertal/DE (patrick.haage@helios-kliniken.de)*

Suitable post-treatment evaluation after any intervention is crucial for a good outcome and high long-term success rates. Consequently, it is necessary to supervise the outcomes, define follow-up strategies and to identify potential complications and possibly prepare for re-intervention. Herein most common complications after thoracic aortic interventions, abdominal aorta surgical and endovascular repair and endovascular peripheral arterial disease treatment will be presented including imaging specifics, i.e. normal and pathological appearances and indications for reintervention. Information on the selection of modality (ultrasonography, CT, MRI), the typical phase interval between follow-up examinations and some specific suggestions including items to cover in a structured report will be delivered.

Session Objectives:
1. To briefly introduce the distinctive role of proper post-treatment evaluation after intervention.
2. To control the results and to know possible complications - to prepare re-intervention.

A-422 08:35

A. Thoracic aorta
T. Leiner; *Utrecht/NL (t.leiner@umcutrecht.nl)*

Cross-sectional imaging techniques play an important role when following up patients after endovascular or surgical repair of aortic disease. Depending on the disease in question, imaging is indicated at regular intervals after intervention and in many cases for the rest of a patients' life. Structured evaluation and reporting is very important to standardize the follow-up and to minimize interobserver variation. In my presentation, I will discuss the various endovascular and surgical techniques used to repair aortic disease and their

normal post-operative appearance. I will also discuss the most common complications and potential imaging pitfalls in the postoperative period including mimickers of pathologic processes such as felt pledgets, graft folds, and nonabsorbable haemostatic agents. Postoperative complications that may be encountered include pseudoaneurysms, infection, prosthetic valve dysfunction, dehiscence as well as graft kinking, stent fracture and endoleak. Specific attention will be paid to follow up intervals and which findings necessitate reintervention.

Learning Objectives:

1. To learn about the most common complications after thoracic aortic interventions.
2. To understand imaging specifics after thoracic aortic interventions.
3. To know indications for re-intervention.

Author Disclosure:

T. Leiner: Board Member; Society of Cardiovascular Magnetic Resonance (SCMR); European Society for Magnetic Resonance in Medicine and Biology (ESMRMB). Grant Recipient; Netherlands Heart Foundation, Technology Foundation STW, Netherlands Organisation for Scientific Research,. Research/Grant Support; Bayer, Bracco, Philips. Speaker; Philips.

A-423 08:58

B. Abdominal aorta

C. Loewe; *Vienna/AT (christian.loewe@meduniwien.ac.at)*

The endovascular treatment of infrarenal aortic aneurysms (EVAR) has become a well-established treatment option. On the contrary to patients after surgical repair, patients after EVAR require lifetime follow-up imaging since the chronic and progressive character of atherosclerosis can cause progression of aortic dilatation leading to prosthesis movement or insufficient aneurysm exclusion with time. Additionally, persistent perfusion of the aneurysm sac (endoleaks) can occur even years after stentgraft placement. Finally, the life expectancy of the materials used for endovascular treatment might be limited. CT angiography was established as the first method of choice for follow-up after abdominal aortic repair. The advantages of CT angiography are manifold and include optimal comparability with the pre-treatment examination (usually done by means of CT angiography), high resolution, direct visualization of the device itself and the possibility of multiphasic acquisition to detect even slow flow endoleaks. As its true for all treatment follow-up examinations, knowledge about primary procedure and typical post-therapeutic findings as well as about most common complications is a prerequisite in patient care after abdominal aortic repair. Device migration, device fracture and/or persistent sac perfusion - in most of the cases related to each other and - are the most common procedure-related complications. In this presentation, different therapeutic means for abdominal aortic disease will be presented as well as the typical, normal findings after treatment. Furthermore, most common complications will be introduced and discussed based on clinical examples. Finally, possible follow-up strategy depending on disease and procedure should be proposed.

Learning Objectives:

1. To learn about the most common complications after abdominal aortic interventions.
2. To understand imaging specifics after thoracic aortic interventions.
3. To know indications for re-intervention.

Author Disclosure:

C. Loewe: Speaker; GE Healthcare, BRACCO, Medtronic.

A-424 09:21

C. Peripheral arterial disease

M. Anzidei; *Rome/IT (michele.anzidei@gmail.com)*

CT and MR angiography (CTA and MRA) substantially changed the diagnostic approach in planning and follow-up of treatment for peripheral arterial disease (PAD), enabling early identification of treatment failure or treatment-related complications after endovascular and surgical procedures. Doppler Ultrasound is the first-line imaging modality during follow-up after treatment, but CTA and MRA enable more detailed and panoramic imaging that is extremely valuable in the assessment of treatment outcome. The aim of this presentation is to review the imaging findings in the most common complications after endovascular treatment for PAD, to discuss the best imaging modality in the various clinical scenarios and to explain when and how to re-intervene on the basis of imaging findings.

Learning Objectives:

1. To learn about the most common complications after PAD endovascular repair.
2. To understand what imaging technique is preferred (any diagnostic).
3. To explain when to re-intervene and how to prepare it?

EIBIR Session

EIBIR 2

EU Research on cancer imaging

A-425 08:30

Introduction

Y. Liu; *Brussels/BE (yan.liu@eortc.be)*

Imaging biomarkers are involved throughout cancer research, and serve many purposes other than providing surrogate endpoints. Nevertheless, novel imaging biomarkers must be qualified before they can be used to reliably guide clinical decisions. Imaging biomarker qualification requires strong collaboration between imagers in industry and academia, as well as insight from regulators and payers, utilizing the different strengths of each stakeholder. The European Union has launched Horizon 2020, the biggest EU Research and Innovation programme with nearly €80 billion of funding available over 7 years (2014 to 2020), in calls for proposals or actions. Of the total Horizon 2020 budget, around € 6.8 billion has been committed to fund "Health, demographic change and well-being" research, which is one of the seven challenges of the Societal Challenges pillar of Horizon 2020. The Innovative Medicines Initiative (IMI) is a partnership between the European Union and the European pharmaceutical industry, and it is also the world's biggest public-private partnership in the life sciences. Through the IMI 2 programme, it has a €3.3 billion budget for the period 2014-2024. The European Institute for Biomedical Imaging Research (EIBIR) has a significant amount of experience in the field of biomedical imaging research funding, and has achieved high successful rates in the past Horizon 2020 calls. It is in a stronger position to provide knowledgeable support for imaging proposal preparation and project management. Three granted imaging projects will be introduced in this session.

Session Objectives:

1. To understand cancer imaging research in Europe.
2. To learn about current funding opportunities for cancer imaging research in Europe.

A-426 08:45

Multimodal imaging with diffuse optics for cancer theranostics

T. Durduran; *Barcelona/ES (turgut.durduran@icfo.es)*

Near-infrared diffuse optical methods provide unique contrasts based on haemodynamics (microvascular blood flow, blood oxygen saturation and blood volume) and tissue structure (cell density, size) as well as the water and other chromophore concentrations. These can be measured in a non-invasive, relatively safe manner. I will describe the current state-of-the-art in the context of theranostics for oncology and relate them to ongoing European projects. In particular, the focus of my research is on the development of hybrid technologies that combine diffuse correlation spectroscopy (DCS) and diffuse optical spectroscopy (DOS) to be utilized in biomedicine. Our international efforts involve the validation, research as well as clinical translation of these technologies from "mice to men". The translational aspect of this effort is strengthened by the utilization of same/similar instrumentation on both small animals and on clinical feasibility testing. I will describe the background physics, the basics of the technology, different approaches to probes and illustrate the state of the art using examples from different studies. Finally, I will describe the LUCA project (http://www.luca-project.eu) where a European consortium is working towards building and validating a prototype that combines optics with ultrasound.

Learning Objectives:

1. To understand a new multimodal imaging technology.
2. To learn about the Horizon 2020 research project LUCA.

Using GlucoCEST MRI to visualise cancer

X. Golay; *London/UK (x.golay@ucl.ac.uk)*

Cancer accounts for 13% of all deaths worldwide and despite recent medical improvements remains one of the most deleterious diseases in the world. Early detection is very important as it increases the chances of survival. In addition, the high level of sophistication towards treating cancer has generated a new problem: the differentiation between treatment effect, regrowth or pseudo-progression of the tumour, which are all poorly differentiated on most imaging methods. Tumour cells preferentially uptake glucose over normal cells, as they rely on enhanced aerobic glycolysis for their energy supply, which distinguishes them from normal tissue (the Warburg effect. We have exploited this finding to both develop and demonstrate the sensitivity of a new radiation-free magnetic resonance imaging (MRI) technique, named glucose-based chemical exchange saturation transfer (GlucoCEST), which will provide additional information over and above current medical in vivo imaging techniques in oncology (1). GlucoCEST has been shown to detect both native glucose and glucose (Glc) analogues such as 3-O-methyl-D-glucose (3OMG) uptake in tumour models. We, therefore, established a consortium (GlucoCEST imaging of neoplastic tumours - GLINT) to bring the combination of Glc and 3OMG as a combined exam to the clinics, thereby providing a wide-ranging new diagnostic tool for one of the most devastating diseases in the world. Thus, GLINT aims, therefore, to provide a cheap, available, comprehensive, non-invasive, radiation-free complementary method to nuclear medicine techniques currently used for cancer assessment. Ref: 1) Walker-Samuel et al, Nature Medicine, 19(8):1067-73 (2013).

Learning Objectives:

1. To discover an innovative MRI method to visualise cancer.
2. To learn about the Horizon 2020 research project GLINT.

RC 906

Translational research in molecular imaging: how to do the translation

A-429 08:30

Chairman's introduction

J. Hodler; *Zurich/CH (juerg.hodler@usz.ch)*

Radiologists are good organisers with excellent knowledge of technology and with an important role in patient care. They are not necessarily at the forefront of basic research. Although radiologists do not all need to perform animal studies, we need to understand methodology, to recognize new findings with clinical potential and to reduce the well-known time lag between “bench and bedside”. This session contributes knowledge about preclinical imaging and its translation into clinical radiology by experts in their fields.

Session Objectives:

1. To learn the translational potential of preclinical research.
2. To understand the needs of preclinical research.
3. To know the physiological differences between small animals and humans.

Author Disclosure:

J. Hodler: Research/Grant Support; Bayer, Guerbet, Siemens.

A-430 08:36

A. Preclinical MR/PET imaging of cancer

C. Kuntner-Hannes; *Seibersdorf/AT (claudia.kuntner@ait.ac.at)*

Small animal molecular imaging has become an important technique for the development of new drugs, radiotracers and therapies. Positron emission tomography (PET) together with magnetic resonance imaging (MRI) provides unique in vivo information about specific molecular pathways in different diseases. How to decide what settings or conditions to use is not straightforward, as the experimental design is dependent on the particular science being investigated. In small animal imaging there are different multi-modal techniques available starting from using two stand-alone scanners to fully integrated PET/MRI scanners. From physics to physiology, there are many factors to consider when setting up an experiment, each of which can have a significant impact upon quantitative PET/MRI data. Standardization from animal models, animal handling, data acquisition protocols, and image data analysis should help to generate data that can be reproduced by the same or other laboratories to enhance scientific importance. This talk examines the most common factors related to all types of quantitative PET imaging.

Learning Objectives:

1. To learn the use of preclinical PET/MR imaging.
2. To understand the needs of standardisation in preclinical imaging.
3. To understand the challenges in quantitative preclinical PET imaging.

A-431 08:59

B. What about nanotechnology?

F.M.A. Kiessling; *Aachen/DE (fkiessling@ukaachen.de)*

The design of a molecular imaging agent should follow its clinical demands. This sounds trivial but often basic questions are not asked, which leads to failure in translation. Therefore, the following questions should be answered positively before starting research and development: is there a clinical need for the envisioned diagnostic procedure? Does its application impact the therapeutic conduct? Are all alternative drug designs less promising? Will the agent fulfil the required pharmacokinetic demands? Are toxic side effects not expected? Is the imaging method sufficiently robust and sensitive to draw a clear conclusion from the application of the nanodiagnostic agent also when analysing individual patients instead of comparing groups? Is there sufficient market potential for commercialisation and can the production be controlled and upscaled? Asking these questions will substantially help researchers to find ideal indication for nanomedicines and nanodiagnostics. For example, if fast compartmental exchange and renal clearance are required, the nanoparticles must be below 5 nm. If EPR-dependent accumulation is desired, the particles should be larger but neutrally charged. In turn, charged particles are preferred for labelling the MPS (mononuclear phagocyte system) and cells in vitro. Active targeting, may be used to enhance local retention and cellular uptake but it will not improve (even rather decrease) accumulation due shortening blood half-life. Using examples of our and others research on nanodiagnostics, nanotherapeutics and theranostics, the above questions will be addressed and according concepts and their strengths and limitations will be explained and discussed in detail.

Learning Objectives:

1. To understand advantages and limitations of nanomedicines.
2. To gain knowledge on elimination routes of nanoprobes.
3. To understand the potential benefit of active targeting.

Author Disclosure:

E³ - ECR Academies: Spinal Imaging

E³ 919

Degenerative cervical spine

A-433 08:30

Chairman's introduction

V.N. Cassar-Pullicino; *Oswestry/UK (Victor.Pullicino@rjah.nhs.uk)*

The degenerative process targeting the intervertebral discs and synovial joints can affect single or multiple levels in the cervical spine with variable severity. The changes are usually progressive and proliferative promoting instability and encroachment on the cord and exiting nerve roots. However, imaging evidence of these changes even when severe is not always related to symptoms. The objective of this session is to specifically focus on the relevant imaging features that a) are likely to be clinically relevant, b) require treatment and c) aid in treatment planning.

A-434 08:35

A. Normal ageing process

C.W.A. Pfirrmann; *Zurich/CH*

Ageing of the spine is a normal process, occurring in any subject. The prevalence of neck problems accounts for 1% of all health issues. Normal ageing; however, is not necessarily linked to symptoms. Ageing of the cervical intervertebral disc involves several processes, such as decrease of proteoglycan content and decrease of water content. Ageing of the disc starts with adolescence. The prevalence is around 16% in adolescence and close to 90% in subjects over 60 years. Already at 40 years of age, at least one finding representing a degenerative phenomenon is seen on two thirds of MR images of the spine. Cross-sectional studies have shown that all factors but age, such as physical activity, gender, smoking, body mass index are not significantly linked to the progression of degeneration. About one third of previously asymptomatic subject develops symptoms over a 10-year period. The most common MR imaging findings in the 10-year follow-up of an asymptomatic cohort are drop in signal of the nucleus pulposus, narrowing of the interspace, compression of the dural sac or the spinal cord and formational stenosis.

Learning Objectives:

1. To understand normal ageing process.
2. To describe biomechanical spinal changes with ageing.
3. To learn MR age-related findings.

A-435 09:03

B. MR findings: what's relevant?

M.-A. Weber; *Heidelberg/DE (MarcAndre.Weber@med.uni-heidelberg.de)*

This lecture will summarise typical MRI patterns of degenerative cervical spine disease, will explain which imaging findings may explain pain and are useful in planning treatment and will also include a discussion of the role of the different modalities, especially MRI vs. CT. Modern CT and MRI techniques provide excellent anatomical images of the cervical spine. MRI is best suitable for evaluation of the soft tissues, including the intervertebral discs, ligaments, bone marrow and spinal cord, whereas CT offers delineation of osseous components with high spatial resolution. MR imaging has a key role for exploration of spine degenerative disease. Intervertebral disc fissures are optimally depicted on T2-weighted imaging. Disc herniation and neural foraminal stenosis are common changes seen associated with neck pain with or without radiculopathy. Questions concerning pathologies of the neuroforamina, multiplanar reconstructions and/or additional angulated imaging sequences of the spine should particularly be included in routine examinations for improved delineation and depiction of neuroforaminal pathologies, especially if there is a need to evaluate surgical therapy. Whenever possible, a 3D sequence is preferred and thus post-imaging reconstructions can be compiled that not merely reduce examination time but also offers advantages for multiple planar reconstructions as well as simplifying the MR exam. Kinematic MRI might be beneficial for revealing disc bulges, which are not shown by traditional neutral views and should be considered in dedicated cases for the evaluation of the cervical spine. Cervical spine MRI should systematically be performed for cases of neck pain associated with neurologic deficit.

Learning Objectives:

1. To summarise typical MRI patterns of degenerative cervical spine disease.
2. To identify which imaging findings explain pain and are useful in planning treatment.
3. To discuss the role of the different modalities, MR vs CT.

A-436 09:31

C. Spinal stenosis: what is it?

M. Muto; *Naples/IT (mutomar2@gmail.com)*

Spinal canal stenosis represents a frequent cause of pain with relevant impact on the quality of life and daily activities. Spondylosis, trauma and malignancies are the most frequent causes and their incidence depends on patient age. Radiology has a crucial role in the diagnosis of spinal stenosis as well as in the recognition of the aetiologies using different imaging modalities: x-ray, CT, MR and dynamic studies. Furthermore, mini-invasive image-guided treatments are nowadays commonly included in the clinical practice dedicated to this category of patients. This presentation aims to describe the most frequent causes of spinal stenosis, to propose a correct diagnostic approach and planning the treatment strategies.

Learning Objectives:

1. To learn the most frequent causes of spinal stenosis.
2. To learn how to make a correct diagnosis of spinal stenosis using different imaging modalities.
3. To identify imaging features of spinal stenosis that determine outcome and treatment strategies.

A. Ultrasound: making a more specific diagnosis

M. Weston; *Leeds/UK (michael.weston2@nhs.net)*

Acute conditions in the female pelvis may be related to the gynaecological tract, namely ectopic pregnancy, ovarian cyst accidents, adnexal torsion, fibroid degeneration and pelvic inflammatory disease. Or, they may be related to other systems within the pelvis such as appendicitis, diverticulitis, urinary tract infections and stones, aneurysms and musculoskeletal conditions. The patient history and clinical findings are an important part of the differential diagnosis. However, having taken these into account it is important to be familiar with the typical ultrasound appearances of the common presentations and to keep an open mind regarding atypical alternatives. Ultrasound may be enough to make the diagnosis and guide treatment and follow-up, typically in self-limiting conditions such as a cyst accident. It is important to be aware of limitations and to know when other imaging modalities are needed.

Learning Objectives:

1. To be familiar with common and uncommon clinical scenarios in acute female pelvis.
2. To know the typical and atypical imaging findings.
3. To review the influence of findings on patient management.

A-438 09:00

B. When can CT give a definite answer?

I. Millet; *Montpellier/FR (milletingrid@wanadoo.fr)*

In the acute female pelvis setting, transvaginal and transabdominal pelvic sonography is the preferred imaging modality especially when gynaecologic causes are suspected. However, enhanced computed tomography (CT) can be helpful if the sonography is not conclusive or in a first line if the clinical symptoms are non-specific. Many gynaecologic causes of pain can be detected with some specific CT findings at enhanced CT and conversely, no additional imaging is recommended if pelvic CT examination is normal. Pelvic inflammatory disease should be considered if there is a symmetric low epiploic fat haziness especially when the fallopian tubes are thickened and enhanced. Adnexal torsion should be considered when an enlarged asymmetric ovary is adjacent to a thickened fallopian tube. CT can assert the gynaecologic origin of a haemoperitoneum by identifying the sentinel clot and/or an active bleeding in the pelvis. In pregnant women, CT remains the primary diagnostic tool in case of hypovolemic blunt or penetrating trauma or severe sepsis. CT may also be needed during pregnancy to assess common causes of acute abdominal pain such as suspected appendicitis, bowel obstruction, obstructing urinary tract calculi and pancreatitis especially if other imaging techniques such as ultrasound and magnetic resonance imaging are inconclusive. Protocols should then minimize the use of multi-phase studies and should use optimized settings to reduce the dose as much as possible without losing image quality. The estimated foetal dose using a single CT phase remains always below the 50-mGy limit above which there is a statistically higher risk of teratogenesis.

Learning Objectives:

1. To understand the role of CT in different female pelvic pathologies.
2. To become familiar with CT findings useful for differential diagnoses.
3. To know the strict indications for the use of CT in pregnant women.

A-439 09:30

C. Is MRI a game-changer?

G. Masselli; *Rome/IT (gabrielemasselli@libero.it)*

Rapid and accurate diagnosis is essential for the appropriate management of acute female pelvic conditions in the emergency department. Magnetic resonance (MR) imaging provides an additional imaging alternative to CT that does not involve the use of ionizing radiation or iodinated contrast material. MR imaging has several advantages over CT in terms of safety profile, diagnostic efficacy and ease of use. An issue that is causing increasing concern, both in the general population and in the medical community, is the potential adverse effects of overuse of ionizing medical radiation, of which CT remains the primary source. MR imaging does not make use of ionizing radiation, which is of particular concern in young women and pregnant patients. Recent advances in MR imaging hardware and software have allowed the development of rapid

imaging techniques that are particularly suited for emergency department indications. MR imaging enables assessment of the entire pelvis within several minutes without ionizing radiation and due MR to its high contrast resolution the administration of contrast agents is not mandatory. The value of MR imaging has been assessed in many acute conditions of the lower abdomen and pelvis, in particular MRI is accurate in differentiating gynaecological from no gynaecological disorders. Due to its advantages, depending on the local availability, MR imaging may be considered as the modality of first choice in the patients with acute pelvic pain.

Learning Objectives:

1. To be familiar with clinical conditions which are the clear indications for MRI examination.
2. To learn MRI protocols which are used in imaging of acute pelvic diseases.
3. To comprehend the advantage of MRI over US and CT in particular clinical settings.

10:30 - 12:00 **Room B**

ESR meets Belgium

EM 1

Emergency radiology

Presiding:
G.M. Villeirs; Gent/BE
P.M. Parizel; Antwerp/BE

A-440 10:30

Introduction

G. Villeirs; *Gent/BE*

Introduction to the "European Society of Radiology (ESR) Meets Belgium" session, by the President of the Belgian Society or Radiology. During this session, various topics in emergency medicine will be presented and illustrated by eminent Belgian radiologists. The session will also be animated by an interlude about radiology of Belgian food and a video about the Belgian Museum of Radiology.

Session Objectives:

1. To learn more about various topics presented by eminent Belgian radiologists.
2. To illustrate imaging applications in the Belgian context.
3. To show the diversity of emergency radiology.

A-441 10:35

Additional value of dual-energy CT in abdominal emergencies

E. Danse; *Brussels/BE (etienne.danse@uclouvain.be)*

CT plays a major role in the management of emergency situations. Its role is increased because the diagnostic performance of imaging methods takes benefit of the continuous technological CT improvements. Our goal is to present our recent experience of using spectral CT for the diagnostic workup of adult patients admitted for acute abdominal disorders. This presentation will be focused on the main applications of the spectral modalities for the diagnostic management of patients having severe trauma with abdominal consequence, suspicion of acute intestinal ischaemia, bowel obstruction, acute renal disorders (renal colic, acute pyelonephritis, renal infarct), acute pancreatitis and biliary tract disorders and some uncommon situations. Some basic key points about the spectral technique and the imaging flow management will also be presented.

Learning Objectives:

1. To explain the basics of dual-energy CT.
2. To illustrate the application of dual-energy CT in the abdominal emergency setting.
3. To demonstrate the incremental value of dual-energy CT in abdominal emergencies.

A-442 10:55

High-end CT imaging in forensic medicine: experience after recent Brussels terror attacks

W. Develter; *Leuven/BE*

"No abstract submitted."

Learning Objectives:

1. To learn more about the challenges in forensic medicine after major calamities.
2. To explain the need for high-end CT imaging in forensic medicine.
3. To illustrate the value of high-end CT in the aftermath of the Brussels terror attacks.

A-443 11:15

Interlude: Imaging Belgian food

K. Verstraete; *Ghent/BE (koenraad.verstraete@ugent.be)*

The purpose of this lecture is to present the imaging characteristics of a classical Belgian meal, including delicious Belgian desserts and beers. The methods used are plain radiography, CT and MR imaging. Results show the different absorption and resonance characteristics of Belgian food and drinks. Attendants should try to guess what we eat and drink by analysing the images.

Author Disclosure:

K. Verstraete: Other; Part of Belgian Food presented was prepared by Sodexo.

A-444 11:25

Imaging genetics and beyond: facial reconstruction and identification

P. Claes; *Leuven/BE (peter.claes@kuleuven.be)*

The phenotypic complement to genomics is phenomics which aims to obtain high-throughput and high-dimensional phenotyping. The paradigm shift is simple and similar to the one made in the human genome project, instead of 'phenotyping as usual' or measuring a limited set of simplified features that seem relevant, why not measure it all? With the advent of ever more consumer-worn sensors, the technological hardware exists for extensively (wide variety of measurements from different sensors) and intensively (in great detail and high resolution) collecting quantitative phenotypic data. In my research, e.g. 3D surface imaging and medical scanning devices, provide the optimal means to capture information of human morphology and appearance to the level of phenomics. In this seminar, I guide you through the science and the complexities of imaging genetics and elaborate on the genetic architecture of the human brain and face captured using MRI and 3D surface scanning, respectively. I will illustrate a computational framework that is able to match given faces to probe DNA. This facilitates the ability to perform facial identification and/or verification from DNA. Towards the future, this will generate innovative applications in forensics and biometrics, arming investigators with new and powerful tools to establish human identity from DNA.

Learning Objectives:

1. To demonstrate the application of imaging in genetic assessment.
2. To illustrate the use of imaging for identification.
3. To illustrate the use of imaging after facial reconstruction.

A-445 11:45

Interlude: The Belgian Museum of Radiology

R. Van Tiggelen; *Brussels/BE (info@radiology-museum.be)*

Some years ago, the Science Museum of London performed a survey among the visitors on the most important discoveries in medicine. Out of over 40,000 answers, radiology was number one. Radiology came ahead of, e.g. the discovery of penicillin of the description of DNA. This was a supplementary reason why we created, in 1990, the Belgian Museum of Radiology. Remember also that radiology is used in many fields in medicine and in many fields different from medicine . It is a fact that due to radiology, more than 30 Nobel Laureates have gained their prizes with the practical implementation of this technology. In the world, museums of radiology are rather scarce. What we do and what you can see in our institution is developed with the projection of our short video. We hope to see you in the near future.

11:50

Panel discussion: Acute pathology: emergency radiologists or organ subspecialists?

10:30 - 12:00 **Room G**

EFOMP Workshop: Radiation incidents and accidents in medical imaging: can we prevent them?

EF 2

Radiation incidents and accidents in medical imaging and their management (part II)

Moderators:
M. Brambilla; Novara/IT
D.J. Lurie; Aberdeen/UK

A-446 10:30

Chairman's introduction
M. Brambilla; *Novara/IT (marco.brambilla@maggioreosp.novara.it)*

This session will review the current safety issues related to MRI and nuclear medicine environment for both the patients as well as the staff members. Hazards intrinsic to the MRI and nuclear medicine environment must be understood, acknowledged and respected. Incidents occurring in imaging departments shall be properly documented and reported. An overview of incidents and accidents in MRI and nuclear medicine will be provided together with a critical discussion of the lessons learnt from these incidents and accidents. Information and guidelines will be provided on how to properly manage and report incidents and accidents. Finally, the role of the medical physicist in managing incidents and accidents in imaging departments will be outlined by identifying duties and responsibilities of medical physicists associated with the management of radiation incidents and accidents.

Session Objectives:
1. To learn about the common reasons for radiation incidents and accidents in MRI and nuclear medicine departments.
2. To appreciate why we need to manage radiation incidents and accidents properly.

A-447 10:35

Incidents and accidents in MRI
D.J. Lurie; *Aberdeen/UK (d.lurie@abdn.ac.uk)*

MRI is considered “safe”, due to the lack of ionising radiation and the absence of cumulative “dose” from the scanner’s static, switched and radiofrequency magnetic fields. Nevertheless, hazards associated with MR scanning exist and accidents and incidents of varying severity do occur. The most obvious hazard arises from the “missile effect”, whereby large ferromagnetic objects (chairs, compressed gas tanks) are accelerated into the magnet bore. More common, and harder to control, are the effects of the static magnetic field on small, treatment-related objects (e.g. endotracheal tube components) and on non-MR-safe implanted devices including pacemakers, stents, aneurysm clips or capsule-endoscopy devices. The most significant hazard from MRI is associated with radiofrequency pulses transmitted by the scanner. Non-resonant absorption of energy can potentially cause overheating of tissues, but these effects are well controlled by scanner software. Burns may arise from the unintended concentration of radiofrequency fields. This may be caused by conductive (non-ferromagnetic) objects within or near to the patient, including implanted pacemaker leads (remaining after pacemaker removal), non-MR-compatible or wrongly placed ECG leads, and drug-delivery patches. Burns may also arise from malfunction or incorrect setup of radiofrequency coils. The primary means of minimising adverse incidents are the design and control of MR facilities, education of all staff (from radiologists to cleaners) with regular updates, patient screening techniques and the flagging of patient notes and request forms. It is vital that all incidents are recorded and discussed locally and that lessons learned are disseminated to the wider MRI community.

Learning Objectives:
1. To give an overview of radiation incidents and accidents in MRI.
2. To discuss the lessons learnt from these incidents and accidents.
3. To learn how to manage incidents and accidents in MRI.

A-448 11:05

Radiation incidents and accidents in nuclear medicine
M. Brambilla; *Novara/IT (marco.brambilla@maggioreosp.novara.it)*

In addition to hazards associated with every imaging modality, such as patient’s over or underexposure due to non-optimized acquisition protocols, defective equipment, wrong manoeuvres, there are specific hazards in nuclear medicine procedures associated with the storage, manipulation and administration of unsealed radioactive sources, targeted with radiopharmaceuticals. As a consequence, accidents of varying severity do occur which involves not only patients but also staff workers. All the steps involved in the nuclear medicine workflow are subjected to potential accidents: from patient reception, to patient preparation, radiopharmaceutical preparation, administration and uptake phase of the examination, examination and quality controls of the equipment. The potential accidents must be understood, acknowledged and respected. The most diffuse accidents in nuclear medicine are contamination events, followed by overexposure of patients and failure in the managements of radioactive materials. The primary means of minimising adverse accidents are education of all staff (from nuclear medicine doctors, to radiographers and nurses) with regular updates, blank or dry tests during radiopharmaceutical preparation, clear identification of duties and responsibilities of the staff involved, traceability of procedural steps from patient reception to patient leaving the department, and the flagging of patient notes and request forms. Incident reporting is crucial. Accidents should be discussed locally and lessons learned should be disseminated to the wider NM community. Nuclear medicine departments may also be involved in the health managements of nuclear incidents and accidents in emergency scenarios occurring in nuclear power plants and during radioactive transportation.

Learning Objectives:
1. To give an overview of radiation incidents and accidents in nuclear medicine.
2. To discuss the lessons learnt from these incidents and accidents.
3. To learn how to manage incidents and accidents in nuclear medicine.

A-449 11:35

Management of incidents and accidents in imaging departments: the role and responsibilities of medical physicists
V. Tsapaki; *Athens/GR (virginia@otenet.gr)*

Modern imaging systems such as CT, MR, nuclear medicine machines and other interventional x-ray equipment are widely used by clinicians to pledge a more successful clinical outcome. There are occasionally cases, though, that incidents and accidents can occur during the use of these highly sophisticated systems. Medical physicists are working with technologists, radiologists, regulators, as well as various imaging systems manufacturers to ensure that such incidents and/or accidents do not occur in imaging departments. They are also cooperating closely with x-ray technologists and radiologists, cardiologists and other related physicians to reduce the radiation dose to the patient as well as to the staff. The role of medical physicists in ensuring high-quality and low-risk management system is vital in the attempt to build up a robust safety structure and culture and reduce or prevent radiation incidents/accidents or reduce hazards in MR departments both for the patients and also for the staff. All these issues will be discussed in more detail in the particular lecture. A number of recommendations will be given to guide all related imaging department personnel on the responsibilities of medical physicists regarding the management of incidents and accidents in imaging departments.

Learning Objectives:
1. To provide information about the role of medical physicists in managing incidents and accidents in imaging departments.
2. To identify the duties and responsibilities of medical physicists associated with the management of radiation incidents and accidents.

10:30 - 12:00 **Room M 2**

Professional Issues and Economics in Radiology (PIER)

PIER 1

Improving efficiency in radiology departments

Moderators:
J.A. Brink; Boston, MA/US
S. Morozov; Moscow/RU

A-450 10:30

A. How to identify radiology productivity bottlenecks?
S. Morozov; *Moscow/RU (npcmr@zdrav.mos.ru)*

The shared radiology workflow consists of physician’s referral, study approval, scheduling, patient arrival, imaging, reporting, validating, and results distribution. The performance of this process can be measured on different levels: resources utilization, current operations and outcomes. The end-result of the process is defined by the goal, which can also vary. The major goals are effectiveness (e.g. high-quality, high-safety, high-volume, high-accessibility services, patients’ and physicians’ satisfaction), efficiency (cost-effectiveness, cost-control, revenue generation) and health improvement (better treatment because of accurate diagnostics, less morbidity and mortality because of early diagnostics). The problem with the radiology services is that we often incorrectly measure incorrect metrics. Wherever we see systematic measurement of results in health care—no matter what the country—we see

those results improve (R.S. Kaplan, M.E. Porter). Hence, we should move from current radiology operational metrics (report turn-around-time, back-log time, discrepancies, equipment utilization rate, revenue) to clinical operational metrics (diagnosis-related delays of treatment, time to begin treatment) and outcome measurements (patients' and clinicians' satisfaction, gross margin of services, involvement in disease-specific clinical teams). The best method for tackling 'bottlenecks' is time-driven activity-based costing (TDABC) through better resource utilization, standardized processes, proper staffing, and logistics optimization. Building an enabling IT platform is the key for embedding the changes in the system. Ideal physician measurements are aligned to electronic data collection, attributable to individuals, cascade from organizational goals, supported by evidence and physicians, comparative, and transparent.

Learning Objectives:

1. To review the metrics of shared radiology workflow in the domains of efficiency, quality and safety (what).
2. To demonstrate various methods and techniques for total productivity improvement (how).
3. To delineate the roles of individuals and teams in productivity improvement cycle (who).

A-451 10:48

B. How to optimise radiology with big data: Medical Analytics Group (MAG) project

O.S. Pianykh; *Newton Highlands, MA/US (opiany@gmail.com)*

With medical technology becoming increasingly complex, and expected outcomes - more demanding, the cost of medical errors, delays and guesswork grows prohibitively high. To deal with these challenges, contemporary radiology has to rely on objective metrics and knowledge, applied to optimize its operations and decision-making. These metrics and their performance patterns can be most efficiently learned from the (big)data that our hospitals have been accumulating since the beginning of the digital era. Currently, most of these data are recorded and used only when the patients are examined; then it gets warehoused in the RIS, PACS and similar databases, remaining completely idle and forgotten. Transforming these data into the most effective and objective problem solver was the main idea behind the Medical Analytics Group (MAG) project, recently launched by the Department of Radiology at Massachusetts General Hospital. The principal purpose of MAG is to apply data science to routine radiology problems, looking for the best possible solutions. In this presentation, we will share our most interesting results, important successes, and thought-provoking challenges.

Learning Objectives:

1. To highlight the need for big data analysis in radiology management.
2. To provide examples of already implemented data-driven radiology optimisation.
3. To illustrate the challenges of big-data analysis and project implementation.

A-452 11:06

C. How to implement system changes?

G. Paulo; *Coimbra/PT (graciano@estescoimbra.pt)*

Health care organizations are complex sociotechnical environments where highly differentiated health professionals come together to provide, what is expected to be, the best quality of care to the patients. However, it is important to be aware that an asymmetric scientific and professional knowledge between health professionals and even inside each profession is a reality and consequently a barrier to implement a harmonized practice. To improve efficiency in radiology departments it is crucial to deliver patient care based on a well-established teamwork model, by providing team members with clear guidance, as a tool to allow them to be capable to undertake their role with professionalism and be able to identify when errors occur and how to recover and correct those errors. The department leaders have the responsibility to create and maintain a good working atmosphere by developing well-established communication channels and by empowering all staff members. Implementing system changes demands for understanding the paradigm shift of the social behaviour, influenced by the digital era and make adequate adaptations. Health care organizations are opened systems, influencing and being influenced by the internal and external environments. It is crucial for radiology departments to adapt to the new era. The challenges are manifold: to improve efficiency; to increase visibility in patient clinical workflow; to avoid commoditization, amongst other important aspects that will be presented during this session.

Learning Objectives:

1. To learn about the importance of teamwork towards the establishment of a good work environment.
2. To understand the impact of good communication strategies in increasing staff satisfaction.
3. To discuss about the influence of the organisational culture in professional empowerment.

A-453 11:24

D. Making the business case for patient-centred imaging care

M.H. Maurer; *Berne/CH (martin.maurer@insel.ch)*

Patient-centred health care aims to organize health care facilities around the needs of patients and their families. Also in radiology, the traditional business model of radiologists being "doctors to other doctors" is changing towards a patient-centred imaging care where the patient is placed at the centre of the health care environment and the imaging service is organized around the patient's needs and preferences. In this talk, the different dimensions of patient-centred imaging care (e.g. effective communication, education of the patient, emotional support) will be discussed to empower patients to participate in their medical care and decision-making. Several key indicators to build a patient-centred environment such as appropriateness of imaging procedures, scheduling and registration, physical comfort during imaging procedures, management of radiation exposure, and development of reporting programs will be presented as well as methods to redesign radiology processes towards a patient-centred imaging care.

Learning Objectives:

1. To identify health system priorities around patient-centred care.
2. To develop reporting and improvement programmes that align with health system priorities.
3. To build influence through leadership and performance in patient-centred care.

11:42
Panel discussion

10:30 - 12:00 **Room M 4**

E³ - ECR Academies: Spinal Imaging

E³ 1019
Spinal cord abnormalities

A-454 10:30

Chairman's introduction

S. Gaudino; *Rome/IT (simona.gaudino@gmail.com)*

Spinal imaging is a very wide and challenging topic and requires an integrated approach of clinical data, traditional and so-called advanced protocols. The objective of this academies course is to provide a deep and comprehensive discussion of the different fields of the spine/spinal cord pathology that are more frequently observed in clinical practice. The aim of the organizers was to provide a complete discussion on how to integrate the technical aspects of MRI examination of the spinal cord, the MRI semeiotics of both intradural extramedullary and intramedullary lesions, and the "pattern" approach to intramedullary lesions, to ultimately offer a helpful overview of the spinal pathologies that a radiologist may encounter during his professional career. Prof. Van Goethem will address the technical aspects of the MRI study of the spinal cord, discussing how to exploit MRI ranging from the basics to the most updated state-of-the-art techniques. He will specifically discuss the importance to include the "advanced" techniques in the evaluation of the spinal cord diseases. In the second lecture, Dr. Lycklama will discuss the fundamental topic of differential diagnosis between intra- and extra-medullary tumours, discussing semiotic, pathology and MR features. Finally, during the closing lecture, Prof. Turner will address one of the most difficult scenario that a neuroradiologist may deal with, non-tumoural spinal cord lesions, with the objective to make the audience familiar with the "pattern" approach, with whom, at least, reduce the number of differential diagnosis.

A-455 10:35

A. MR imaging of the spinal cord: how to do it?

J. Van Goethem; *Antwerp/BE (johan.vangoethem@uantwerpen.be)*

Magnetic resonance imaging (MRI) of the spinal cord is challenging in many ways. The spinal cord is a small structure and is located in an environment prone to artefacts. I will cover many types of artefacts, including truncation artefacts, motion artefacts caused by breathing and swallowing, CSF pulsation artefacts, aliasing artefacts, susceptibility artefacts and radiofrequency artefacts. The origin of these artefacts and the countermeasures that can be

taken will be discussed. I will also provide an overview of the different sequences that should be used in basic and advanced spinal cord imaging, briefly touching upon diffusion and perfusion imaging, spectroscopy and fMRI of the spinal cord.
Learning Objectives:
1. To understand the challenges for acquiring high-quality MR images of the spinal cord.
2. To learn current state-of-the-art sequences for spinal cord imaging.
3. To be aware of the importance of advanced neuroimaging techniques for the evaluation of spinal cord diseases.

A-456 11:03

B. Differentiating intradural mass lesions
G. Lycklama à Nijeholt; *The Hague/NL (g.lycklama@mchaaglanden.nl)*

Intradural lesions are primarily characterized by their location: intra- vs extramedullary. Intramedullary tumours will expand the spinal cord, while extramedullary lesions will deform it. MRI workup should include high-resolution axial T2 (for example, CISS) to better differentiate intra- from extramedullary. Susceptibility sensitive images show blood products as found, for example, in ependymoma and cavernoma. In addition, MRA may be useful, for example, to demonstrate vessels in a haemangioblastoma. Repeat MRIs are often needed to make a diagnosis and to rule out 'tumour mimickers'. The most common intramedullary tumour in adults is ependymoma. Usually they present with an enhancing component, some haemorrhage and cysts, and for the surgeon it is important to define the cystic components into tumour cyst, peritumoural cyst and secondary syringomyelia. Usually, the whole neuraxis is imaged to detect 'drop' metastases. In children, spinal cord tumours are very rare, and when occurring, astrocytoma is the most common - presenting with less strong enhancement and more vaguely defined than ependymoma. Other primary spinal cord tumours are rare - and 'tumour mimickers' should always be considered. Extramedullary tumours are most often benign: meningioma and Schwannoma. These can usually be distinguished by their growth pattern and signal characteristics, Schwannoma usually following the nerve root into the neuroforamen and expanding it. Other extramedullary lesions include metastasis, haemangioblastoma and cavernoma. It is, however, important to realize that some tumours which usually occur extramedullary, may also occur within the cord, for example, Schwannoma and haemangioblastoma.
Learning Objectives:
1. To understand how to differentiate intradural-extramedullary mass lesions from intrinsic spinal cord tumours.
2. To become familiar with the most common types of tumours arising within the spinal canal, both in children and in adults.
3. To learn the typical MR imaging features of these lesions.

A-457 11:31

C. Pattern recognition of non-tumoural spinal cord lesions
M.M. Thurnher; *Vienna/AT (majda.thurnher@meduniwien.ac.at)*

The choice of strategy for diagnostic problem solving depends on the perceived difficulty of the case and on knowledge of content. The list of non-tumoural pathology affecting the spinal cord includes demyelinating, vascular, metabolic and degenerative conditions. However, MR imaging findings are overlapping and sometimes confusing. Knowledge of coexisting brain lesions is crucial for narrowing the differential diagnosis. Clinical information (onset of symptoms, history of travels, immune status, etc.) will be helpful to confirm or exclude specific diagnoses. In this lecture, a simplified approach including tips and tricks to non-tumoural spinal cord lesions will be presented.
Learning Objectives:
1. To become familiar with the epidemiology and clinical manifestations of the most common diseases affecting the spinal cord.
2. To recognise the most common intramedullary lesions.
3. To learn how to identify these lesions based on the pattern of involvement.

Reporting interstitial lung disease made easy

Moderator:
N. Howarth; Chêne-Bougeries/CH

A-462 12:30

A. Five golden rules
S.R. Desai; *London/UK*

"no abstract submitted"
Learning Objectives:
1. To review diagnostic signs of common interstitial lung disease.
2. To learn how to avoid overdiagnosis.
3. To know the limitations of radiological diagnoses.

A-463 13:00

B. Multidisciplinary approach to diagnosis in interstitial lung disease: the role of HRCT
N. Sverzellati; *Parma/IT*

Surgical lung biopsy is no longer the reference standard for histological diagnosis in interstitial lung disease (ILD). Indeed, its traditional role has been supplanted by multidisciplinary diagnosis, over the last 15 years. It was shown that multidisciplinary discussion between clinicians, radiologists, and pathologists may often change initial individual subspeciality diagnosis. Interpretation of high-resolution computed tomography (HRCT) plays pivotal role in the multidisciplinary diagnosis. A number of scenarios can be outlined in the ILD, in which, clinical, HRCT, and histologic information can be combined in a complementary fashion: 1. HRCT appearance is pathognomonic in the correct clinical context. 2. The combination of HRCT and clinical features, including bronchoalveolar lavage, is sufficient for diagnosing ILD. 3. Clinical features and HRCT appearance can be combined to any biopsy to secure the diagnosis.
Learning Objectives:
1. To understand the role of radiologists in diagnosing interstitial lung disease.
2. To know the limitations of radiological diagnoses.
3. To understand what to say when the diagnosis is not obvious.

12:30 - 13:30 **Room D**

E³ - The Beauty of Basic Knowledge: A Survival Guide to Musculoskeletal Imaging

E³ 24C

Bone tumours

Moderator:
V.N. Cassar-Pullicino; Oswestry/UK

A-464 12:30

Bone tumours
K. Wörtler; *Munich/DE (klaus.woertler@tum.de)*

The diagnosis of a bone tumour is based on clinical findings, the age of the patient, the location of the lesion, its radiologic appearance, and, if imaging does not allow for a specific diagnosis, its histopathologic features. Radiography remains the initial imaging modality for evaluation of the localisation of the lesion with respect to the longitudinal and axial planes of the involved bone, for the depiction of matrix mineralisations, and for estimation of biologic activity by analysing the patterns of bone destruction and periosteal response. CT is typically used to obtain “radiographic” information in regions of complex skeletal anatomy such as the skull, spine, pelvis and shoulder girdle. MR imaging is best suited to determine the local extent of a bone tumour (local staging), but can also be helpful to narrow the differential diagnosis in specific lesions such as cysts and cartilage-forming tumours. With a clear emphasis on conventional radiography, this course will review the basic imaging features of benign and malignant bone tumours. Important radiographic findings, such as bone destruction patterns, types of periosteal reactions and matrix mineralisation, will be explained in correlation with histopathology as well as advanced imaging techniques.

Learning Objectives:
1. To become familiar with the imaging features of benign and malignant bone tumours.
2. To appreciate their imaging characteristic hallmarks on plain film radiography.
3. To learn how best to use imaging modalities in differential diagnosis.

13:00 - 13:30 **Room A**

P.M. Parizel; Antwerp/BE

A-465 13:00

The future of CT: from hardware to software
M. Prokop; *Nijmegen/NL (mathias.prokop@radboudumc.nl)*

The introduction of computed tomography in the 1970s has changed the field of radiology for good: we radiologists became cross-sectional imagers and moved to the center of the diagnostic process for millions of patients worldwide. CT became one of the exponential technologies in medicine: from the 1980s to the 2000s, speed and longitudinal spatial resolution doubled every two years. Since roughly 2010, this development has slowed down considerably, and the focus shifted from slice wars towards radiation dose reduction and dual energy imaging. While CT is nowadays a mature technology, further improvements in spatial resolution, photon counting detectors and overall optimization of the imaging chain will push its performance forward. Phase contrast imaging, x-ray lasers and inverse geometry scanners are far on the horizon. In the coming decades, however, technological progress in CT will shift from hardware solutions to software and novel applications. Already now, iterative reconstruction has reduced dose requirements more profoundly than most hardware solutions. Novel software techniques for motion correction offer temporal resolutions that outperform the most advanced hardware technology. Subtraction imaging becomes a competitor for contrast-enhanced dual energy CT. The main break-through for our patients, however, will come from a shift from morphological analysis to functional analysis for risk prediction and selection of appropriate treatments. Software solutions that keep radiation dose at bay, use radiomics and deep learning will transform the way we do radiology in the future. The same economic pressure that makes us report ever faster and cheaper will push automated image analysis forward for most of our routine work. By embracing the novel functional and predictive diagnostic opportunities of CT and MR, we will be able to remain at the center of the diagnostic process.

14:00 - 15:30 **Room K**

EFRS meets Belgium

EM 4
EFRS meets Belgium

Presiding:
S. Bogaert; Ghent/BE
H.H. Hjemly; Oslo/NO
A. Tempels; Lodelinsart/BE

Moderators:
G. Alleman; Beernem/BE
J.-L. Greffe; Lodelinsart/BE

A-466/A-467/A-468 14:00

Introduction
H.H. Hjemly; *Oslo/NO (Hakon@radiograf.no)*
S. Bogaert; *Ghent/BE*
A. Tempels; *Lodelinsart/BE (atempels@hotmail.be)*

The European Federation of Radiographer Societies has since 2013 had the pleasure and honour of being invited by the European Society of Radiology to host this dedicated 'EFRS meets' session at ECR. During the EFRS meets sessions, radiographers have the opportunity to get information about the role and education of radiographers in the different European countries. In line with the tradition, we choose as our guests the home country of the ECR Congress President. Previous EFRS meets session was in 2013 dedicated Spain, 2014 it was Russia, 2015 we met Germany and last year we met Sweden, and for 2017 EFRS welcomes you all to EFRS meets Belgium. The EFRS meets session will give a picture of the history and challenges of the radiographers profession and education in Belgium and the aims to achieve in the near future. Important items as patient safety, quality improvement and radiation protection will be presented. There will also be focus on Belgium itself, cultural highlights and how Belgium sees the world.
Session Objective:
1. To give an overview of Belgian radiographers and the radiographers' profession in Belgium.

A-469 14:05

A picture of the radiographers' profession and education
P. Van Laer; *Lovendegem/BE (Philippe.vanlaer@odisee.be)*

The Belgian radiographers educational system as well as the radiographers profession are relatively young in comparison with the rest of Europe. Belgium, with its multilingual organisation, is very complex. To get an overview on both themes, education and profession, it is necessary to look at Belgium as a country, to look at the different parliaments/legislation throughout Belgium and to look at how the profession has developed over the last 20 years. Furthermore, we have to look at the changes that have been realised in legislation during the last four years and at the opportunities that are in front of us.
Learning Objectives:
1. To learn about the education system for radiographers in Belgium.
2. To understand the history of the profession and the complexity of the legislation system in Belgium.
3. To become familiar with what has changed in Belgium in the last five years and what aims are to be achieved in the near future.

A-470 14:23

Belgium: the beautiful 'city'
K. Van Belle; *Sint-Andries/BE (kurt.vanbelle@odisee.be)*

What to say about Belgium? Is it as abstract as we think? Not that long ago Belgium was formed, so you would think not a great story. But before that, the Belgians had a great and rich history in Europe as it was the centre for trading luxury goods and great architecture. Today, Belgium is still known as a country with high standards and has many desirable goods such as chocolate and diamonds. On a cultural level, Belgium has many great artists from our medieval Van Eyck, modern Magritte and even Tintin from Hergé could conquer the world. Belgium is seen by the world as very Burgundian. Which is true: the highest density in high-end culinary and gastronomical cuisine can be found in our little country. Conclusion: Belgium stands for a cultural, gastronomical, rich history and a place to discover with many fantastic treats.
Learning Objectives:
1. To arouse curiosity about Belgian cultural highlights.
2. To explain how Belgium sees Belgium.
3. To discuss how the world sees Belgium.
4. To understand how Belgium sees the world.

A-471 14:41

Patient safety and quality improvement in Belgian radiology departments
S. Germonpré; *Brussels/BE (sofie.germonpre@odisee.be)*

In this study, we focus on the use of fluoroscopy-guided positioning (FGP) techniques in radiography. In Belgium, FGP is common practice. We investigate the importance of knowledge, skills and attitudes of imaging staff and organizational factors with respect to applying non-FGP. In addition, we study the usefulness of the UTAUT-model to investigate the acceptance of non-FGP by Belgian radiographers. A mixed method approach was used. To develop an in-depth understanding of imaging practices, radiographers and radiologists were interviewed (n=40), complemented with non-participative observations (200 hours) and image and document analyses. To study the usefulness of the UTAUT-model, we applied a cross-sectional survey research at 17 Belgian radiology departments. Clinical leadership of radiologist and chief radiographers as well as suitable x-ray devices and positioning aids were identified as important determinants. Furthermore, a lack of skills and knowledge of (advanced) positioning techniques and negative attitudes towards non-FGP was present. More precisely, staff expressed concerns with respect to the impact on the workload and workflow. Adequate supervision, regularly feedback and coaching were identified as important enabling factors for increasing the quality of the applied imaging techniques. The UTAUT model proved to be an adequate model for predicting the acceptance to use non-FGP. The intention to use non-FGP depends on the usefulness, the ease of use of and the positive attitudes towards non-FGP. A holistic approach considering knowledge, attitudes and contextual-organizational factors is needed to improve imaging practices. Clinical leadership of physicians, supervisor and peers are important enablers.

Learning Objectives:
1. To promote the implementation of best professional practices in patient positioning; knowledge, attitudes, organisational factors.
2. To highlight the usefulness of the UTAUT model to study professional behaviour outside the context of new technology.

A-472 14:59

Radiation protection in Belgium
O. Bran; *Louette-Saint-Pierre/BE*

"no abstract submitted"
Learning Objectives:
1. To learn about dose limits and radiation protection regulations in Belgium.
2. To explain the daily practice of radiographers in Belgium under the present laws.
3. To promote implementation of radiation protection best practice for radiographers.

15:17
Panel discussion

14:00 - 15:30 **Room M 1**

EuroSafe Imaging Session

EU 4

European CT dose repository

Moderators:
J.A. Brink; Boston, MA/US
J. Damilakis; Iraklion/GR

A-473 14:00

The technical implementation of dose tracking tools
A. Torresin; *Milan/IT (alberto.torresin@unimi.it)*

In the medical area, technological and scientific developments have led to a remarkable increase in radiation exposure. The need to implement radiation-dose-index monitoring (RDIM) systems for the most important ionizing radiation procedures in connection with stochastic and deterministic risks has become important. RDIM systems are software which passively or actively collect all the radiation-dose-index (RDI) from ionizing radiation modalities. RDIM systems store RDI data in a database along with patient demographic and exam information allowing the final user to visualize the RDI according to study type and patient. These data can be used both for quality assurance procedures in the diagnostic department and as a benchmark in the regional and national registries. To successfully implement an RDIM system, careful commissioning, testing and data analysis are needed in advance in full collaboration with the manufacturer. An interdisciplinary team of lead radiologist, lead medical-physics-expert, lead technologist, PACS IT leader and clinical engineers need to work together to choose, implement and ensure the proper use of the RDIM software based on the specific needs of the institution. RDIM systems are not intended solely as databases for patient exposure: collected RDIs do not represent the absorbed dose in an individual patient because they are related to the x-ray beam output and absorption at the image receptor.
Learning Objectives:
1. To discuss the strategy of implementation in the PACS.
2. To understand the open issues of the integration (standards, reporting, etc.).

A-474 14:15

How do dose tracking tools change the practice of radiographers?
S.J. Foley; *Dublin/IE (shane.foley@ucd.ie)*

This presentation aims to discuss the features of dose tracking systems that can be practically useful to radiographers in their role within CT. In particular, the radiographers' responsibility regarding dose optimisation will be examined, considering how dose tracking tools can influence behaviour and encourage protocol optimisation and support quality improvement initiatives.
Learning Objective:
1. To understand the impact of dose tracking tools on the radiographer's responsibility and behaviour towards CT protocols.

A-475 14:30

How do dose tracking tools change the practice of radiologists?
F. Zanca; *Leuven/BE (federica.zanca@ge.com)*

Dose tracking systems and their utilisation are an emerging topic of interest, with focus being on whether to track or not dose, what to track and how. However, another important aspect is how a dose tracking system can impact the practice of radiologists. This talk will identify and report examples of outcomes related to the implementation of a dose tracking system in a radiology department. We will talk about the role of such a tool for procedures standardization and optimisation, legislation compliance, individual patient risk assessment and research purposes. The primary rationale is indeed to avoid exposing patients to unnecessary radiation by engaging radiologists in a new practice of exams justification, protocols standardisation and optimisation. Such a system is also helpful for being compliant with the coming EU directive 2013/59/Euratom. A dose tracking system can also help in: identifying unusual high radiation dose and implementing patient follow-up process (patient safety); identifying studies with parameters outside pre-defined reference levels and optimize protocols (optimisation); identifying patient populations that receive a relatively large number of imaging studies and propose patient-specific protocol development; standardizing the workflow and operator-dependent protocol parameters; optimising dose level versus image quality. Similarly, it can act as a conduit of data to national benchmarking databases or as a tool to support the tracking of radiological procedures of individual patients and radiation dose. This presentation will end with some examples of dose tracking systems implementations in clinical practice.
Learning Objective:
1. To understand the impact of dose tracking tools on the radiologist's daily practice and behaviour towards CT protocols.
Author Disclosure:
F. Zanca: Employee; GE Healthcare.

A-476 14:45

European CT Dose repository working group: summary of activities
E. Neri; *Pisa/IT*

The CT Dose repository is the 3rd EuroSafe imaging subgroup, whose members are D. Caramella (IT), G. Paulo (PT), J. Damilakis (Gr) and A. Torresin (IT), with S. Ebdon-Jackson, a co-opted member from HERCA (European Radiological protection Competent Authorities). The subgroup was created and aimed at exploring the clinical impact of tools for automatic dose monitoring and provide recommendations, best practice in CT, to reassure radiologists about the reliability of statistics obtained from such systems. To reach that goal, the subgroup drafted a questionnaire that will be distributed to ESR members. The results of the questionnaire could be helpful to prepare recommendations on how to improve the CT dosimetric behaviour in radiological departments (with the help of such tools). The dose monitoring tools allows a precise internal audit of the dose behaviour in the radiological department, tracking the general dosimetric trend that mainly depends on the adopted imaging protocols. Such imaging protocols are frequently designed by an anatomical orientation with few concern about the specific clinical context in which the exam is performed. In parallel the attention of dose reference levels (DRL) is oriented to the anatomical segments, and not the clinical context. One example: lung CT for screening has the same scan length of a lung CT for nodule characterisation, as well as for pulmonary embolism, but the 3 exams are strongly different by indication and as a consequence by imaging protocols that influence the dose levels. Therefore it is clear that the actual dose reference levels, based on the anatomical focus, do not reflect the standard of dose anymore. Even more, in a same clinical context, there is a potential variability of patients anatomy, physiology, and target disease, which influences the CT imaging protocols. Dose monitoring systems could be therefore a helpful tool for building new dose reference levels based on the clinical indications and on the patient's specific factors, driving the actual DRL based on anatomy toward clinical indication reference levels.
Learning Objective:
1. To become familiar with the summary of activities of the working group.

A-477 15:00

The ACR Dose Index Registry
R.L. Morin; *Jacksonville, FL/US (morin.richard@mayo.edu)*

The ACR Dose Index Registry (DIR) is designed to assist practices, and institutions in comparison of dose indices with national values. The DIR was conceived in 2004 to address the uncertainty of dose in various imaging examinations. The key features of the DIR is the automatic extraction of dose indices, patient features (e.g. gender, age, exam type, etc.) and technical parameters. Facilities can then compare their values with national or local values to make decisions on altering their protocols to optimise the use of radiation for each examination. The DIR was launched in May 2011 and now has over 1600 institutions participating, both domestic and international. Over 33 million exams are currently in the DIR. The biggest challenge that was discovered was the large variation in examination names. This was narrowed by providing registry users with a mapping tool to map each examination name to the standardised RSNA RadLex® terminology. The other challenge was the automatic modulation of the x-ray beam as the tube circulates about the patient; hence, indices are larger for big patients than small patients. This is being addressed by the automatic measurement of the patient thickness and calculation of the size-specific dose estimate (developed by the AAPM). These solutions have improved the accuracy and utility of the DIR. In the future, the

DIR will address CR/DR, then fluoroscopy and it is hoped that the widespread use will contribute significantly to the management of radiation dose in medical imaging.
Learning Objective:
1. To learn the impact of the ACR Dose Index Registry in the clinical practice.

Professional Issues and Economics in Radiology (PIER)

PIER 2

Perspectives on radiology equipment management

Moderators:
B. Brkljačić; Zagreb/HR
P. Leander; Malmö/SE

A-478 14:00

A. Renewal of equipment and procurement: central vs local procedures
B. Brkljačić; *Zagreb/HR (boris@brkljacic.com)*

Advances in radiology equipment provide accurate and fast diagnosis, and offer new options for treatment guidance, thus improving the health outcomes and quality of life for the patients. The fast development of technology also resulted in accelerated technical and functional obsolescence of imaging equipment, consequently creating a need for renewal. Radiological equipment has a definite life cycle span and older equipment has a high risk of failures and breakdowns. The unavoidable decrease or loss of image quality renders equipment useless after the certain period. This may cause delays in diagnosis and treatment of the patient and safety problems both for the patient and the medical staff. European society of radiology is promoting the use of up-to-date equipment, especially in the context of the EuroSafe imaging campaign, as the use of up-to-date equipment will improve quality and safety in medical imaging. Reduction in radiation dose when utilising state-of-art equipment is of utmost clinical importance. Every healthcare institution or authority should have a plan for medical imaging equipment upgrade or renewal, since the equipment older than ten years is no longer state-of-the art equipment and the replacement is essential. Operating costs of older equipment will be high when compared with new one and sometimes maintenance will be impossible if no spare parts are available. Public procurement is another important issue in the renewal of equipment. Situation in Europe is very heterogeneous and often long and complicated procurement procedures hinder timely equipment renewal. The issues of different procurement strategies will be discussed.
Learning Objectives:
1. To discuss the need for the regular renewal of radiology equipment.
2. To present controversies in public procurement of radiology equipment.
3. To discuss advantages and disadvantages of different types of procurement.
Author Disclosure:
B. Brkljačić: Speaker; Guerbet, Bayer.

A-479 14:18

B. Utilisation of equipment: what is appropriate? The public healthcare system's perspective
P. Leander; *Malmö/SE (peter.leander@med.lu.se)*

Medical imaging equipment utilisation needs to be optimised for managing capital equipment budgets. Health economics talk about scarcity and that economics are needed for the only reason of scarcity of resources. Cost analysis for imaging equipment is a straightforward analytic task. Fixed costs are mainly the initial investment and service contracts. Running costs are mainly personnel and contrast media (CM). Personnel costs are not fully proportional to worked hours, as early and late hours are more costly. For MRI and CT, CM costs are relatively small but for PET/CT this a substantial part of the exam cost. On the other hand, if cyclotron is in-house this may come into another situation. All together the different costs can be put down in spread sheets showing cost per exam in relation to operating hours. Other factors to consider are the willingness of personnel to work and the possibility to have the imaging facility open at non-office hours. Traditionally personnel in imaging departments work daytime beside their duty on call. There may be an educational challenge to explain why the funder/hospital have such an urge to open up scanners early in the morning and run them into the evening. In addition, aside ER imaging the departments are often not built to be open at non-office hours. All stated above need to be worked through to come to best practice and a reasonable compromise between the radiological department and the public funder.
Learning Objectives:
1. To describe how a cost analysis of system utilisation can be performed.
2. To discuss how other factors than economical influence the utilisation.
3. To come to a reasonable common goal of utilisation between the radiological department and the public funder.

A-480 14:36

C. Utilisation of equipment: what is appropriate? The private healthcare system's perspective
A. Palkó; *Szeged/HU (palkoand@gmail.com)*

Private companies tend to be more sensitive to cost and efficacy than community/government-financed service providers. It explains why several of the key focus points from management point of view, in their case, are cost management, optimisation in scheduling and patient involvement, and best practice maintenance concepts. The purpose of this lecture is to explain the paradigm shift in cost management from traditional cost management to total cost of ownership and optimization of company-owned inventory; from breakdown or corrective to preventive maintenance; from traditional to lean-based scheduling, workflow-optimisation and patient satisfaction-based management.
Learning Objectives:
1. To understand the basics of cost management.
2. To learn about optimisation in scheduling and patient involvement.
3. To present best-practice maintenance concepts.
Author Disclosure:
A. Palkó: Advisory Board; Affidea.

A-481 14:54

D. Radiology: a cost factor? The hospital manager's perspective
P. Garel; *Brussels/BE (sg@hope.be)*

In-house and outsourced radiology are often opposed on different grounds, for example, on: quality and patient safety, availability of human resources, financial incentives, organisational reasons, etc. Those different elements should be perceived through the huge diversity of the healthcare systems in place in Europe. Success or failures of both options will depend much more on context factors than on theoretical approaches. Not only this cannot be anymore limited to the local or even national context as cross-border care is developing but this has to be perceived in the context of the development of integrated concept diversely defined and put in place. Integrated care is bringing new issues of collaboration, coordination between the different levels of care as well as new ways of financing.
Learning Objectives:
1. To discuss reasons for in-house vs outsourced radiology.
2. To explain cost-models (e.g. internal budgeting).
3. To discuss new concepts for integrated care and the consequences for radiology.

M. Smits; Rotterdam/NL

A-482 14:00

Preclinical MRI: multimodal markers for neuroscience drug discovery?
M. von Kienlin; *Basle/CH (markus.von_kienlin@roche.com)*

One of the biggest bottlenecks in drug development for brain disorders is the lack of reliable and predictive biomarkers during early clinical testing; this makes very difficult the development of novel therapies which respond to the huge unmet medical need in many neurological or psychiatric diseases. Pharmacological magnetic resonance imaging and spectroscopy (phMRI/MRS) have the potential to serve as early indicators for target engagement or proof of mechanism studies in clinical phase I/II trials. This contribution will address the topic from a preclinical perspective, i.e. how MR approaches in rodents can elucidate pharmacologically induced changes in structure or function, and how confidence can be increased that preclinical results are relevant to the patient situation. Preclinical imaging in drug discovery serves three main purposes. First, it is used to qualify animal models, ensuring that the molecular

mechanisms in the model appropriately reflect human disease processes; whenever possible, this “back-translation” is based on genetic and proteomic evidence, and is also linked to further phenotypic characteristics of the model. Second, phMRI supports milestone transition decisions for advanced compounds in the discovery portfolio, by characterising the mechanistic and functional properties of potential new medical entities. Last but not least, preclinical results identify imaging biomarkers to be deployed in early clinical development. These three domains will be illustrated with examples from neurodegenerative and neurodevelopmental disorders.

Learning Objectives:

1. To become familiar with potential MR biomarkers for diagnosis and therapeutic monitoring of specific brain diseases.
2. To learn about advanced MR techniques and methods providing quantitative biomarkers.
3. To learn how MR imaging biomarkers can help to evaluate specific effects of novel pharmaceuticals upon brain function in preclinical animal models.
4. To understand how brain imaging markers could be included in clinical trials.

A-483 14:30

Clinical MRI: whole-body markers for cancer detection/response

F. De Keyzer; *Leuven/BE (frederik.dekeyzer@uzleuven.be)*

While T1- and T2-weighted magnetic resonance imaging has been feasible in the body for several decades, anatomical information does not always reflect underlying biological information, which limits its diagnostic and prognostic value. In the last decade, hardware and software improvements have led to applicability of functional MR techniques that fill in that gap. At the same time, there has been a huge expansion of possible treatments and combinations, whereby optimal treatment success very much depends on patient-specific information, of which imaging is an important part. In this session, we will focus mainly on applications of diffusion-weighted (DW-) and dynamic contrast-enhanced (DCE-) MR imaging and the biomarker information these can provide, both as a diagnostic tool, and as a tool for predicting and evaluating response to therapy. While the strengths of these techniques make them worthwhile in a whole range of oncologic applications, they also have drawbacks regarding standardization of acquisition, handling of motion effects, use of post-processing strategies and image interpretation. These drawbacks need to be discussed and overcome to set up multicentre studies aiming to bring these imaging biomarkers into widespread clinical domain.

Learning Objectives:

1. To become familiar with the biomarker content of WB-MRI protocols.
2. To review the literature showing that WB-MRI biomarkers can aid in the detection and characterisation of cancers and by extension to response assessment to therapies.
3. To highlight that WB-MRI BM qualification requires frameworks for development and that we are now at efficacy testing stage.

A-484 15:00

Molecular MRI: where are the limits for MRI biomarkers?

L. Schröder; *Berlin/DE (lschroeder@fmp-berlin.de)*

MRI suffers from intrinsic low sensitivity and relies on abundant tissue water as the signal source in most conventional imaging applications. However, there are two emerging concepts that can improve this situation and thus contribute to the field of molecular and metabolic imaging for advancing the understanding of many diseases on a molecular level. The first one is CEST (chemical exchange saturation transfer) that amplifies the signal from dilute metabolites or contrast agents through labile protons or exchangeable water molecules by encoding it as signal loss in the abundant tissue water signal. CEST works both with certain endogenous substances and synthetic contrast agents that can also sense the presence of distinct analytes. The second technique is based on increasing the detectable magnetization through special preparation of the spin system prior to the encoding and detection. The achieved condition outside the thermal equilibrium is called hyperpolarization. Though being of transient nature, it is a powerful approach that has enabled various applications for metabolic, molecular and cellular imaging. Both approaches can be combined in the so-called hyper-CEST approach that is currently under investigation for ultra-sensitive MRI that visualizes the distribution of targeted sensors in the picomolar concentration range. Altogether, clinical and preclinical imaging applications will benefit significantly from specific contrast agents or metabolites with enhanced sensitivity since a biochemical or cell biological response to a certain treatment usually occurs much earlier than mesoscopic changes in morphology.

Learning Objectives:

1. To become familiar with the wide range of new potential markers provided by new contrast mechanisms for MR imaging, in particular chemical exchange saturation transfer (CEST) and hyperpolarisation.
2. To understand the role, benefits and limitations of molecular imaging.
3. To learn about the potential future use of targeted contrast agents that combine the benefits from both CEST and the sensitivity gain of hyperpolarised agents.

E³ 1221

Basic breast imaging

A-485 16:00

A. Calcifications in mammography

C.S. Balleyguier , S. Moalla, J. Arfi-Rouche, A.-M. Tardivel, M. Attard, M.-C. Mathieu; *Villejuif/FR (Corinne.BALLEYGUIER@gustaveroussy.fr)*

Breast calcifications are common findings detectable on mammography. Breast calcifications are most likely benign; nevertheless irregular microcalcifications cluster may be the only imaging findings suggesting a ductal carcinoma in situ (DCIS). Analysis of microcalcifications on mammography remains on magnification views; size, density, number, pleomorphism and distribution within the breast have to be carefully analysed to differentiate benign and suspicious microcalcifications clusters. Benign calcifications are categorised as BI-RADS 2 and are more likely round, regular, with a calcified rim, tea-cup or egg-shell shape. Suspicious microcalcifications may be amorphous, irregular, with a linear or segmental distribution. When a microcalcifications cluster is categorised as BI-RADS 4, a stereotactic biopsy should be performed. Ultrasound may be performed first to detect non-calcified mass. Vacuum assisted stereotactic biopsy with at least 6 11 Gauge samples must be performed. New technologies such as BLES biopsy, associating biopsy and radiofrequency can be performed to entirely remove the cluster. In this topic, biopsy techniques and diagnostic strategies to diagnose microcalcifications will be presented on a basis of clinical cases.

Learning Objectives:

1. To become familiar with different types of calcifications.
2. To learn the differential diagnosis of different calcifications.
3. To learn the different tools to biopsy calcification clusters.

A-486 16:45

B. Asymmetry and architectural distortion

L.J. Pina Insausti; *Pamplona/ES (ljpina@unav.es)*

Asymmetries are unilateral deposits of fibroglandular tissue not conforming to the definition of a mass. Four types of asymmetries can be considered: asymmetry as an area of fibroglandular tissue visible on only one mammographic projection, mostly caused by superimposition of normal breast tissue. Focal asymmetry visible on two projections, hence a real finding rather than superposition. Global asymmetry consisting of an asymmetry over at least one quarter of the breast and is usually a normal variant. Developing asymmetry new, larger and more conspicuous than on a previous examination. After the detection of one of the previous asymmetries, it is mandatory to compare with previous mammograms, if available. Palpation and additional techniques can be used to study the lesion, such as spot compressions, tomosynthesis, US and in some cases MRI. A biopsy is needed if malignancy cannot be excluded. The term architectural distortion is used when the normal architecture is distorted with no definite mass visible. This includes thin straight lines or spiculations radiating from a point and focal retraction, distortion or straightening at the edges of the parenchyma. Architectural distortion can also be seen as an associated feature. Tomosynthesis is a very sensitive technique to detect architectural distortions. Surgery, radial scar and carcinoma are the most common causes of distortions. A biopsy is mandatory if a surgical scar is excluded. The management of radial scars needs further workup after a core needle biopsy: both surgery or vacuum-assisted biopsy can be used.

Learning Objectives:

1. To understand the concept of asymmetry and architectural distortion.
2. To become familiar with the respective imaging features.
3. To learn about the diagnostic approach using all breast imaging modalities.

16:00 - 17:30 **Room B**

New Horizons Session

NH 12
The increasing clinical impact of MR/PET

A-487 16:00
Chairman's introduction
L. Umutlu; *Essen/DE (Lale.Umutlu@uk-essen.de)*

Within the past 5 years, simultaneous PET/MRI has been successful introduced into clinical oncologic imaging. It has demonstrated its strength and superiority, particularly in application fields that require high soft tissue contrast imaging such as head and neck cancers or cardiac imaging, questioning the need and or benefit for PET/CT imaging in particular clinical investigations. Apart from its high soft tissue contrast, the interchange from CT to MRI for morphological correlation facilitates another favourable topic, by means of the reduction of the applied ionizing radiation. The applied amount of ionizing radiation can be reduced to 1/3 of the amount in full-dose diagnostic PET/CTs. This is of particular interest for paediatric imaging as well as in the setting for therapy monitoring, when repetitive scans are required.

Session Objectives:
1. To understand the increasing clinical impact of MR/PET in diverse application fields.
2. To understand the benefits of MR/PET over PET/CT in paediatric and head and neck imaging.
3. To become familiar with indications for MR/PET in cardiac and musculoskeletal imaging.

A-488 16:05
MR/PET in paediatric oncology?
P.D. Humphries; *London/UK (humphriespaul@gmail.com)*

Advances in paediatric oncology over the past decades have led to a much improved success rate in the treatment of children with cancer, with some tumours having a 5-year survival over 90%. This success increases the relevance of diagnostic radiation exposure, given the greater radiosensitivity of children and, therefore, increased chance of inducing a second malignancy following treatment. Imaging modalities that can reduce ionising exposure are, therefore, very attractive for paediatric imaging. MRI has been a preferred method of imaging childhood tumours for some time, owing to excellent soft tissue depiction, lack of ionising radiation and the ability to derive “functional” data from DWI and spectroscopy, for example. PET imaging is well established for some paediatric tumours, notably FDG-PET in lymphoma, but is also gaining traction in other cancers, such as sarcomas and choline-PET for CNS neoplasms. Given the above considerations a hybrid platform of PET-MRI is particularly relevant for paediatric oncology, with the potential for future multi-parametric tumour modelling allowing evaluation at both at staging and therapy response assessment.

Learning Objectives:
1. To understand the gain of using MRI instead of CT together with PET.
2. To become familiar with current application fields in paediatric imaging.
3. To give an insight into future application fields.

Author Disclosure:
P.D. Humphries: Grant Recipient; Great Ormond Street Hospital Charity Grant.

A-489 16:25
MR/PET in cardiac imaging?
M. Dewey; *Berlin/DE (marc.dewey@charite.de)*

MR/PET is the new kid on the block, enabling hybrid imaging of anatomy and function. I will summarise the new horizons of MR/PET for providing clinical impact in patients with known or suspected cardiac diseases. For this purpose, we will discuss myocardial area-at-risk definition, differentiation of cardiac tumours (from thrombus) and assessment of myocarditis by MR/PET. Finally, technical challenges and potential solutions will be discussed together with patients’ experience of the examination.

Learning Objectives:
1. To understand the gain of using hybrid MR/PET in cardiac imaging.
2. To become familiar with current application fields in cardiac imaging.
3. To give an insight into the clinical impact and potential future applications of MR/PET in cardiac imaging.

MR/PET in head and neck imaging?
M. Becker; *Geneva/CH*

PET/CT and MRI with diffusion-weighted imaging (DWI) are complementary techniques for the assessment and staging of head and neck tumours. This lecture focuses on clinical applications of MR/PET in head and neck tumours with special emphasis on multiparametric imaging using high-resolution morphological MRI, DWI and perfusion imaging. First, advantages of using MRI instead of CT in head and neck oncology are summarized and current evidence regarding clinical feasibility, image quality, optimized imaging protocols and quantification with MRI-based attenuation algorithms and with DWI in the head and neck is reviewed. Then the current state of knowledge regarding the diagnostic performance of MR/PET in head and neck cancer is discussed and typical tumour manifestations are presented. The appearance of primary and recurrent squamous cell cancers, lymph node metastases and distant metastases on MR/PET, as well as the value of multiparametric imaging are summarized. The variable appearance of functional phenomena mimicking disease, as well as potential pitfalls of image interpretation due to morphological or functional post-treatment changes are addressed. Illustrative cases of concordant and discrepant multiparametric evaluations are discussed, as well as the dilemma how to deal with discrepant multiparametric data in clinical routine.

Learning Objectives:
1. To understand the gain of using MRI instead of CT together with PET.
2. To become familiar with current application fields in head and neck imaging.
3. To give an insight into the clinical impact of MR/PET in head and neck imaging.

MR/PET in musculoskeletal imaging?
G. Andreisek; *Münsterlingen/CH (gustav@andreisek.de)*

Hybrid MR/pet is an increasing and fast-growing topic in musculoskeletal research. This talk will highlight current applications in the field of musculoskeletal imaging and gives an insight into potential future applications of MR/PET in musculoskeletal imaging. Therefore, a short introduction is provided about the necessity for MR/PET in certain musculoskeletal pathologies. After that, the current gold standard imaging modalities and their limitations are reviewed, and then potential advantages of MR/PET are discussed. Examples for clinical applications are provided as well as a review of the corresponding literature. The audience should get an impression what is clinically available, what is “evidence-based” and what applications are currently purely reserved for research.

Learning Objectives:
1. To understand the gain of using hybrid MR/PET in MSK imaging.
2. To become familiar with current application fields in MSK imaging.
3. To give an insight into the clinical impact and potential future applications of MR/PET in musculoskeletal imaging.

Thoracic manifestations of systemic disease

Moderator:
A. Chodorowska; Wroclaw/PL

A-492 16:00

A. Systemic sclerosis
M. Silva; *Parma/IT (mariosilvamed@gmail.com)*

Systemic sclerosis (SSc) is variably associated with pulmonary involvement, which is a paramount prognostic factor. Interstitial fibrosis and small vessel abnormalities are the two elementary lung wounds in SSc, they can occur independently of each other. Chest radiograph has low sensitivity in the assessment of early interstitial lung disease (ILD) associated with SSc. Whereas, basal symmetric reticulonodular opacities and bronchiectasis, even honeycombing can be seen in advanced SSc-ILD. Oesophageal dilation can be the only apparent finding. High-resolution computed tomography (HRCT) is pivotal in baseline staging and follow-up of lung involvement. HRCT findings of SSc-ILD include confluent ground-glass opacities, traction bronchiectasis/bronchiolectasis, fine reticulation and honeycombing. The HRCT pattern of non-specific interstitial pneumonia (NSIP) is common, actually reflecting 75% frequency of histologic NSIP. The combination of HRCT and pulmonary function tests (PFTs) has been proposed for prognostication of SSc. ILD extent <10% has lower risk compared to >30%, with minor influence from PFTs. On the other hand, PFTs can further stratify prognosis among subjects with ILD extent 10-30%. Quantitative CT methods are being developed to measure ILD extent. SSc patients are at increased risk of lung cancer, its surgical treatment is mostly prevented by extensive ILD. Pulmonary hypertension (PH) can occur independently of ILD, reflected by isolated reduction of DLCO at PFTs. In particular, PH is more common in the limited cutaneous systemic sclerosis, also known under the acronym CREST syndrome. Echocardiography is used for indirect non-invasive assessment of PH, whereas right heart catheterization is more accurate albeit invasive.
Learning Objectives:
1. To learn about the typical radiological appearances.
2. To be aware of the clinical relevance of scoring.
3. To know how vascular complications affect patient prognosis.

A-493 16:30

B. Granulomatosis and polyangiitis
S. Bayraktaroglu; *Izmir/TR (selenb2000@gmail.com)*

Granulomatosis with polyangiitis (GPA) is characterized by chronic granulomatous necrotizing vasculitis that involves mainly small and medium-sized vessels. It is the most common of the ANCA-associated vasculitis. The classic clinical triad includes upper airway diseases (such as sinusitis, nasalmucosal ulcerations, subglottic stenosis), lower respiratory tract involvement and glomerulonephritis. The upper respiratory tract is affected in almost all patients, and the lungs and kidneys are involved in 90% and 80% of patients, respectively. The most common findings with GPA are nodules and masses of varying sizes, seen in up to 70% of the patients. Cavitation within these lesions may be seen due to the necrotic nature of the disease. Diffuse ground-glass opacity and consolidation occur in 25-50% of patients representing DAH secondary to capillaritis. Tracheobronchial involvement is also common typically occurring at the subglottic area in the form of circumferential thickening. Patients are treated with immunosuppressive therapy. Ground-glass attenuation, cavitated nodules and masses appear to represent active inflammatory lesions. In patients treated with immunosuppressive therapy, the ground glass areas, nodules and mass lesions generally decrease or resolve.
Learning Objectives:
1. To learn about the radiological appearances of small-vessels vasculitis.
2. To learn how clinical and radiological features help in differential diagnosis.
3. To appreciate the actual role of imaging in assessing disease activity.

A-494 17:00

C. Histiocytosis and lymphangioleiomyomatosis
A. Oikonomou; *Toronto, ON/CA (anastasia.oikonomou@sunnybrook.ca)*

PLCH is a rare type of histiocytosis occurring in smokers, characterized by infiltration of tissues with dendritic Langerhans cells. PLCH may exclusively involve lungs or rarely be part of multisystem disease. HRCT findings include nodules, combination of nodules and cysts or only cysts with upper lobe distribution and sparing of lung bases. Coexistence of cysts with GGO is common. Cysts are bizarre-shaped, thin or thick-walled and variable in number and size. Nodules with or without cavitation have a centrilobular location. Pneumothorax may be the initial manifestation. Lymphangioleiomyomatosis (LAM) is a rare cystic lung disease caused by infiltration of the lungs with smooth muscle cells. It occurs in patients with tuberous sclerosis (TSC-LAM) and in a “sporadic” form (S-LAM), exclusively seen in women of reproductive age. Parenchymal lesions in LAM mainly include cysts, which are thin-walled, well-defined, rounded, may reach large numbers and have no zonal predominance. Nodules are extremely rare in S-LAM and may be seen in TSC-LAM. They represent multifocal micronodular pneumocyte hyperplasia. Chylothorax and pneumothorax are common. When both cysts and nodules coexist then PLCH has to be differentiated from LIP, amyloidosis or light-chain disease. When only nodules or only cysts are present then differential diagnosis includes nodular diseases (only for PLCH) such as sarcoidosis, silicosis, tuberculosis, amyloidosis and metastases or cystic lung diseases (both for PLCH and LAM) such as LAM and PLCH, respectively, Birt-Hogg-Dube, LIP and amyloidosis. If cysts coexist with GGO then PLCH is differentiated from PJP, DIP and LIP.
Learning Objectives:
1. To learn about the typical radiological features and complications.
2. To discuss the possible overlap with other cystic and non-cystic lung diseases.
3. To appreciate the clinical relevance of differentiating these two entities.

Headline Session

European Radiology 25th Anniversary Session

Moderators:
M.F. Reiser; Munich/DE
A.L. Baert; Kessel-Lo/BE
A.K. Dixon; Cambridge/UK

A-500 16:00

Introduction: 25 years of European Radiology
M.F. Reiser; *Munich/DE (Maximilian.Reiser@med.uni-muenchen.de)*

At this ECR, we celebrate the 25th anniversary of European Radiology. For this occasion, 25 articles published during the past 25 years were picked to reflect the immense progress radiology and imaging sciences have made over this period. The selection was based on number of citations and whether the work was influential for the development and changing practise of imaging and image guided interventions. Furthermore, we attempted to achieve a balance and to represent the diversity within the different subspecialties. 10 of these 25 articles are presented in this session. We invite you to join this journey through time with a perspective towards the future.

A-501 16:05

How to present research data consistently in a scientific paper
M. Laniado; *Dresden/DE (Michael.Laniado@uniklinikum-dresden.de)*

Scientific writing is an integral part of academic radiology, and it is professionally rewarding. One of the duties of academic mentors is to motivate and help young radiologists to successfully pass the primary hurdle of knowing how to begin. As with the research project as such, thoughtful planning of the manuscript is an important step. There are many ways to begin but the writer typically drafts the methods section first, followed by the results, the discussion, and the introduction. Information given in both the introduction and the discussion may function as a clip between which data provided in materials and methods and results are embedded. The conclusions should exactly reflect what was reported in the results section. The abstract has to be written as a comprehensive but very short summary of purpose, materials and methods, results, and conclusions. It is of utmost importance that the author edits the manuscript carefully and follows the target journal's instructions to contributors. Once the manuscript has gone through peer review and revisions are requested (provisional acceptance) it is recommended to respond to the comments point by point. This will facilitate reevaluation of the manuscript by the same reviewer(s) and enhances the likelihood that the revised version will be accepted for publication. In conclusion, writing scientific articles is a form of mental exercise that has to be practised to be successful.

A-502 16:13

Cost considerations regarding an integrated CT-PET system

G.K. von Schulthess; *Zurich/CH (gustav.vonschulthess@usz.ch)*

Integrating two modalities into one system, like PET and CT into PET/CT has advantages and drawbacks. The advantages are: the patient gets "two examinations in one", which is time efficient (patient preparation in the scanner is half), a hybrid exam is more agreeable to the patient, and there are synergies in siting and technology. The disadvantages are mainly due to added inflexibility. Separate modalities can be used in parallel for two patients, scheduling is much more flexible and, therefore, amortization of equipment and revenue generation may become easier with separate systems. It turns out that PET/CT seems quite efficient. First, all oncologic PET (the majority) examinations require PET and CT. Second, the time gained in pre-and post-scan patient handling using PET/CT is a critical bonus. CT being so fast makes PET/CT cost-effective. Cost-effectiveness with SPECT/CT (e.g. in cardiac imaging) or in PET/MR are much more difficult to attain. In summary, when purchasing a hybrid system, one has to carefully weigh advantages and disadvantages, so as to stay on the cost-effective side.

Role of contrast-enhanced helical CT in the evaluation of acute thoracic aortic injuries after blunt chest trauma

M. Scaglione; *Naples/IT (scaglionefun@gmail.com)*

The purpose of this retrospective study was to determine the value of contrast-enhanced helical CT for detecting/managing acute thoracic aortic injury (ATAI). Between June 1995 and February 2000, 1419 consecutive chest CT examinations were performed in the setting of major blunt trauma. The following CT findings were considered indicative of ATAI: intimal flap; pseudoaneurysm; contour irregularity; lumen abnormality; extravasation of contrast material. On the basis of these direct findings no further diagnostic investigations were performed. Isolated mediastinal haematoma on CT scans was considered an indirect sign of ATAI. In these cases, thoracic aortography was performed even if CT indicated normal aorta. Seventy-seven patients had abnormal CT scans: among the 23 patients with direct CT signs, acute thoracic aortic injuries was confirmed at thoracotomy in 21. Two false-positive cases were observed. The 54 remaining patients had isolated mediastinal haematoma without aortic injuries at CT and corresponding negative angiograms. The 1342 patients with negative CT scans were included in the 8-month follow-up program and did not show any adverse sequela. Contrast-enhanced helical CT has a critical role in the exclusion of thoracic aortic injuries in patient with major blunt chest trauma and prevents unnecessary thoracic aortography. Direct CT signs of ATAI do not require further diagnostic investigations: isolated aortic bands or contour vessel abnormalities should be first considered as possible artefacts or related to non-traumatic aetiologies especially when mediastinal haematoma is absent. In cases of isolated mediastinal haematoma other possible sources of bleeding should be considered before directing patients to thoracic aortography.

A-504 16:29

CT angiography of pulmonary embolism in patients with underlying respiratory disease: impact of multislice CT on image quality and negative predictive value

M. Remy-Jardin; *Lille/FR (martine.remy@chru-lille.fr)*

Our objective was to evaluate the impact of multislice CT (MSCT) on image quality and diagnostic value of spiral CT angiograms. Over an 8-month period (January 2000 to August 2000), 134 consecutive patients, including 55 patients with underlying lung disease, underwent MSCT (group 1). Image quality and diagnostic results of CT angiograms were compared with those obtained in 125 consecutive patients, including 58 patients with underlying lung disease, evaluated with thin-collimation single-slice CT (SSCT; group 2) over a similar period of time (January 1999 to August 1999). A 3-month clinical follow-up was systematically obtained in all patients who were not anticoagulated in the two groups. For a significantly longer mean z-axis coverage, the mean duration of data acquisition was significantly shorter with MSCT. The frequency of examinations devoid of motion artefacts was significantly higher in group 1 than in group 2. In the absence of significant difference in the quality of vascular enhancement, mainly coded as good or excellent, the proportion of examinations interpretable down to the subsegmental arteries was higher in group 1 (57.5%) than in group 2 (13%) ($p<0.0001$). The benefits of MSCT were more marked for patients with underlying respiratory disease and did not lead to a higher detection rate of peripheral pulmonary embolism. The negative predictive values of single-slice and multislice CT were 100 and 99%, respectively. Improvement in image quality on MSCT scans accounts for the improved diagnostic accuracy of CT angiography, in particular for patients with impaired respiratory function.

CT colonography: effect of experience and training on reader performance

S. Halligan; *London/UK (s.halligan@ucl.ac.uk)*

The purpose of this paper was to investigate the effect of radiologist experience and increasing exposure to CT colonography on reader performance. Three radiologists of differing general experience (consultant, research fellow, trainee) independently analysed 100 CT colonographic datasets. Readers had no prior experience of CT colonography and received feedback and training after the first 50 cases from an independent experienced radiologist. Diagnostic performance and reporting times were compared for the first and second 50 datasets and compared with the results of a radiologist experienced in CT colonography. Before training only the consultant reader achieved statistical equivalence with the reference standard for detection of larger polyps. After training, detection rates ranged between 25 and 58% for larger polyps. Only the trainee significantly improved after training ($P=0.007$), with performance of other readers unchanged or even worse. Reporting times following training were reduced significantly for the consultant and fellow ($P<0.001$ and $P=0.03$, respectively), but increased for the trainee ($P<0.001$). In comparison to the consultant reader, the odds of detection of larger polyps was 0.36 (CI 0.16, 0.82) for the fellow and 0.36 (CI 0.14, 0.91) for the trainee. There is considerable variation in the ability to report CT colonography. Prior experience in gastrointestinal radiology is a distinct advantage. Competence cannot be assumed even after directed training via a database of 50 cases.

First performance evaluation of a dual-source CT (DSCT) system

T. Flohr; *Forchheim/DE (thomas.flohr@siemens.com)*

We present the first performance evaluation of a new dual source CT (DSCT) system equipped with two x-ray tubes and two corresponding detectors that are mounted onto the rotating gantry with an angular offset of 90°. We introduce the system concept and potential benefits for ECG-controlled cardiac CT and for general radiology applications. We evaluate both temporal and spatial resolution by means of phantom scans. We present first patient scans to illustrate the performance of DSCT for ECG-gated cardiac imaging, and we demonstrate first results using a dual-energy acquisition mode. The evaluated DSCT system provides 83 ms temporal resolution independent of the patient's heart rate for cardiac CT. In a centred z-resolution phantom, 0.4-mm cylinders can be resolved at all heart rates, owing to the z-flying focal spot technique. The scan time to cover the heart volume (12 cm) is 5-9 s, depending on the patient's heart rate. First clinical experience shows a considerably increased robustness of the method for the imaging of patients with high heart rates. As a potential application of the dual-energy acquisition mode the automatic separation of bones and iodine filled vessels, e.g. for CT angiographic examinations, is demonstrated. Retrospect after 10 years: DSCT has been a significant step in introducing cardiac CT into clinical routine. Dual-energy CT has been reinvigorated by DSCT, resulting in some applications on their way to mainstream clinical use.

Gd-EOB-DTPA-enhanced magnetic resonance images of hepatocellular carcinoma: correlation with histological grading and portal blood flow

T. Murakami[1], Y. Imai[2]; [1]*Osaka/JP*, [2]*Ikeda City/JP*
(murakami@med.kindai.ac.jp)

The objective of this study is to retrospectively investigate enhancement patterns of hepatocellular carcinoma (HCC) and dysplastic nodule (DN) in the hepatobiliary phase of gadolinium-ethoxybenzyl-diethylenetriamine (Gd-EOB-DTPA)-enhanced MRI in relation to histological grading and portal blood flow. Sixty-nine consecutive patients with 83 histologically proven HCCs and DNs were studied. To assess Gd-EOB-DTPA uptake, we calculated the EOB enhancement ratio, which is the ratio of the relative intensity of tumorous lesion to surrounding non-tumorous area on hepatobiliary phase images (post-contrast EOB ratio) to that on unenhanced images (pre-contrast EOB ratio). Portal blood flow was evaluated by CT during arterial portography. Post-contrast EOB ratios significantly decreased as the degree of differentiation declined in DNs (1.00 ± 0.14) and well, moderately and poorly differentiated HCCs (0.79 ± 0.19, 0.60 ± 0.27, 0.49 ± 0.10, respectively). Gd-EOB-DTPA

uptake, assessed by EOB enhancement ratios, deceased slightly in DNs and still more in HCCs, while there was no statistical difference in the decrease between different histological grades of HCC. Reductions in portal blood flow were observed less frequently than decreases in Gd-EOB-DTPA uptake in DNs and well-differentiated HCCs. Reduced Gd-EOB-DTPA uptake might be an early event of hepatocarcinogenesis, preceding portal blood flow reduction. The hepatobiliary phase of Gd-EOB-DTPA-enhanced MRI may help estimate histological grading, although difficulties exist in differentiating HCCs from DNs.

A-508 17:01

ESUR prostate MR guidelines 2012

J.O. Barentsz; *Nijmegen/NL (j.barentsz@rad.umcn.nl)*

The aim was to develop clinical guidelines for multi-parametric MRI of the prostate by a group of prostate MRI experts from the European Society of Urogenital Radiology (ESUR), based on the literature evidence and consensus expert opinion. True evidence-based guidelines could not be formulated, but a compromise, reflected by “minimal” and “optimal” requirements has been made. The scope of these ESUR guidelines is to promulgate high-quality MRI in acquisition and evaluation with the correct indications for prostate cancer across the whole of Europe and eventually outside Europe. The guidelines for the optimal technique and three protocols for “detection”, “staging” and “node and bone” are presented. The use of endorectal coil vs. pelvic phased array coil and 1.5 vs. 3T is discussed. Clinical indications and a PI-RADS classification for structured reporting are presented.

A-509 17:09

Nephrogenic systemic fibrosis and gadolinium-based contrast media: updated ESUR Contrast Medium Safety Committee guidelines

H. Thomsen; *Aalborg/DK*

The purpose of the session is to update the guidelines of the Contrast Media Safety Committee (CMSC) of the European Society of Urogenital Radiology (ESUR) on nephrogenic systemic fibrosis and gadolinium-based contrast media. Topics reviewed include the history, clinical features and prevalence of nephrogenic systemic fibrosis and the current understanding of its pathophysiology. The risk factors for NSF are discussed and prophylactic measures are recommended. The stability of the different gadolinium-based contrast media and the potential long-term effects of gadolinium in the body have also been reviewed.

A-510 17:17

Iterative reconstruction techniques for computed tomography Part 1: Technical principles

M.J. Willemink; *Utrecht/NL (m.willemink@umcutrecht.nl)*

The objectives are to explain the technical principles of and differences between commercially available iterative reconstruction (IR) algorithms for computed tomography (CT) in non-mathematical terms for radiologists and clinicians. Technical details of the different proprietary IR techniques were distilled from available scientific articles and manufacturers' white papers and were verified by the manufacturers. Clinical results were obtained from a literature search spanning January 2006 to January 2012, including only original research papers concerning IR for CT. IR for CT iteratively reduces noise and artefacts in either image space or raw data, or both. Reported dose reductions ranged from 23% to 76% compared to locally used default filtered back-projection (FBP) settings, with similar noise, artefacts, subjective, and objective image quality. IR has the potential to allow reducing the radiation dose while preserving image quality. Disadvantages of IR include blotchy image appearance and longer computational time. Future studies need to address differences between IR algorithms for clinical low-dose CT.

Dose reduction: tips and tricks

Moderator:

C. Granata; Genoa/IT

A-511 16:00

A. Dose reduction in paediatric CT

D. Aadnevik; *Bergen/NO (daniel.aadnevik@helse-bergen.no)*

Computed tomography (CT) is an invaluable tool in diagnostics and the use of CT has rapidly increased since the 1970s. Ionising radiation can damage human tissues, and is associated with an increased risk of cancer. The effect is of particular concern in children as they have a higher radiosensitivity and longer life expectancy. Modern CT scanners have a high level of automatisation regarding acquisition parameters which may leave the imaging professionals insecure whether the radiation dose is appropriate for the diagnostic task at hand. Studies have shown that in some cases adult protocols are directly implemented in paediatric imaging, resulting in unnecessary high doses. As radiation professionals, it is our duty to keep the radiation dose as low as reasonably achievable (ALARA). It is important to have a basic understanding of how technical factors influence image quality and how to properly balance the output parameters of the scanner in accordance with the ALARA principle. The benefits of low tube voltage, automatic exposure control (AEC), helical pitch and iterative reconstruction techniques will be discussed with respect to radiation dose and examples from local optimisation studies will be presented. Vendor-specific solutions for dose reduction will be explained.

Learning Objectives:

1. To explain the factors that affect patient radiation exposure from CT exams.
2. To discuss the importance of dose reduction in paediatric CT.
3. To give an overview of CT dose reduction strategies and techniques.

A-512 16:30

B. Diagnostic reference levels in paediatric imaging: international recommendations

R. Seuri; *Helsinki/FI (raija.seuri@hus.fi)*

In many institutions the number of paediatric patients is fairly small, which makes optimization challenging. Diagnostic reference levels are an important method for optimization. The DRLs offer a way to compare institution's own patient dose levels, which are expected to comply with good practices. In this comparison dose should always be considered together with the indication of imaging and image quality. DRLs are used by collecting patient dose values and comparing their median values to DRLs. Paediatric DRLs have usually been established for different age-groups. Both ICRP and EC now recommend the use of weight for grouping of paediatric patients. Instead of different groups, also a continuous DRL-curve can be used. The guidelines also provide recommended dose metrics for each modality to be used in DRL comparison. Quite a few countries have set their national DRLs (NDRLs) for at least the most common paediatric examinations, mostly for radiography. By European recommendation the NDRLs should be based on collection of doses from representative institutions in the country, not phantom measurements. The NDRL is then determined by calculating the third quartile level of the collected doses, or the local median values. The PiDRL project was organized by EC to collect the existing national DRLs in Europe to establish European DRLs for optimization in those countries, which have not established their own NDRLs. The report with the European DRLs for the most common paediatric radiological procedures including all modalities was published in 2016.

Learning Objectives:

1. To discuss the need for establishing diagnostic reference levels (DRLs) in paediatric diagnostic imaging.
2. To give an overview of DRL values for typical paediatric examinations.
3. To understand the way of implementation and use of DRLs in dose reduction and protocol optimisation.

A-513 17:00

C. The impact of dose management systems

L.A. Rainford; *Dublin/IE (louise.rainford@ucd.ie)*

The importance of radiation dose monitoring, particularly for high-dose medical examinations, is clearly stated in international radiation protection guidelines, with specific reference to paediatrics. It is mandated by European Directive that the establishment and use of DRLs is fulfilled by all member states. Existing levels of dose information varies across imaging sub-specialities, as evidenced by the recent European PiDRL project. Specific challenges continue to

confound paediatric dose data collections, including reduced frequency of examinations compared to adults, patient age/weight/size variations, procedural variability and varied data survey methodologies. Increasing numbers of dose tracking software packages, including those providing web-based dose data collection, tracking and analytics are available. These systems although varied in scope of content offer services, including dose documentation, dose reference levels setting, performance benchmarking, imaging protocol management and outlier identification. A summary overview of products and their management of big data will be provided. Furthermore, the current clinical reality that substantial amounts of both unstructured and structured dose data are routinely being captured, with the employment of varied mechanisms of data recording, will be evidenced. Why this information is potentially not being used optimally will be discussed, as will communication matters relevant to dose management products. Practical issues relevant to clinical data required for dose and imaging protocol evaluation will be incorporated. Finally, the role of dose management systems in the review of population dose data and protocol optimisation will be discussed and the potential barriers to the successful completion of multi-centre surveys will be considered.

Learning Objectives:

1. To discuss the importance of dose monitoring in paediatric imaging.
2. To have an overview of the features and functions of dose monitoring systems.
3. To understand the role of dose monitoring systems in the evaluation of population dose and protocol optimisation.

16:00 - 17:30 **Room N**

Special Focus Session

SF 12a

My most scary head and neck mistakes

A-514 16:00

Chairman's introduction: Misses, misinterpretations and mistakes

A. Borges; *Lisbon/PT*

At the same time imaging became a major player in the diagnostic process it has also become a major source of diagnostic error. Although errors in radiology are multifold, most are attributable to image interpretation errors by radiologists which can grossly be subdivided into perceptual and cognitive. Radiologists are put under a great amount of pressure by the urgency of the diagnosis requiring rapid reporting, on top of increasing workload, increasing complexity of imaging techniques and increasing complexity of clinical cases. While the number of images and post-processing requirements have increased dramatically in the past decades the reporting time has decreased at the same pace, leaving more room for error. This session will cover misses, perceptual errors defined as important imaging findings that are not seen by the radiologist and mistakes, cognitive errors defined as visually detected findings which are misinterpreted by the radiologist, in head and neck imaging using illustrative clinical cases. We will also provide strategies both at the individual and departmental level to prevent these mistakes in a solution-oriented approach and to cope with mistakes once they eventually occur.

Session Objectives:

1. To become familiar with the most common mistakes in head and neck imaging and their causes.
2. To learn strategies to avoid mistakes.
3. To learn how to deal with different types of mistakes.

A-515 16:05

What I missed and why

M.G. Mack; *Munich/DE (m.mack@radiologie-muenchen.de)*

This lecture will give you an overview of diagnosis which can be missed easily. The reason for missed diagnosis can be variable and includes the following: the radiologists know only common disease; radiologists are only able to diagnose lesions, which they have seen before; radiologist did not get the full clinical Information; lack of time; radiologists can have the "hammer-and-nail" bias; radiologists want to save money by not doing an additional examination (e.g. with another modality); radiologists have different skill levels.

Learning Objectives:

1. To become familiar with different types of missed findings.
2. To appreciate common radiologist's bias.
3. To learn strategies to avoid different categories of misses.

A-516 16:28

What I misinterpreted and why

L. Ginsberg; *Houston, TX/US (lginsberg@mdanderson.org)*

Head and neck cancer imaging is fraught with opportunity for error. These errors include but are not limited to failure to observe, failure to synthesize and integrate findings into the correct interpretation and various types of knowledge gaps that can produce an incomplete, inaccurate or otherwise inadequate reading. This presentation will reflect on my own personal shortcomings in several cases, serving as a cautionary tale to others.

Learning Objectives:

1. To appreciate different causes of misinterpretation of imaging findings in the head and neck.
2. To review common misinterpreted findings in the head and neck.
3. To learn how to avoid misinterpretations.

A-517 16:51

How to deal with mistakes: the report, the radiologist and the department

S.J. Golding; *Oxford/UK (stephen.golding@nds.ox.ac.uk)*

Errors always occur in radiology, as a result of the nature of the subject, clinical circumstances and the complexity of human individuality. Individuals and departments must have a strategy for dealing with these incidents. The initial question to address is whether an error has actually occurred and whether it is clinically significant. Radiological reporting is open to discrepancies (a better description than "errors") in medical opinion and each discrepancy should be graded in a system which allows for justifiable variation in opinion and judges the potential clinical impact. Where a significant discrepancy is found the appropriate action potentially involves the radiologist, the referring clinician and the patient. It also depends on the grade of discrepancy. Any actions taken should be documented at the time: retrospective alteration of medical records should be avoided. Departments should have methods of recording discrepancies that change the impact of previously issued reports, whether or not these have impact extending to duty of disclosure to the patient. Where an individual radiologist is found to generate an excessive number of discrepancies the grading system can be used to evaluate their competence objectively, but must be statistically robust, i.e. it employs a sufficient number of blinded viewers who independently grade an adequate number of the same reports, randomly selected. Regular evaluation of all radiologists in this way could be used to demonstrate the overall clinical performance of individual departments. Where substandard performance is found departments must have arrangements for retraining or altering the content of that radiologist's practice.

Learning Objectives:

1. To learn how to deal with mistakes: your own and other's.
2. To understand the value of clinical audits.
3. To become familiar with different steps of clinical action.

17:14

Panel discussion: Mistakes - can they be avoided and how?

MRI for gynaecologic imaging: how I do it

A-518 16:00

Chairman's introduction

K.H. Härmä; *Berne/CH (kirsihannele.haermae@insel.ch)*

Optimising gynaecologic magnetic resonance imaging (MRI) incorporates the understanding of the concepts of multiparametric MRI, the combination of thin section high-resolution T2-weighted anatomical sequences and diffusion-weighted imaging (DWI). In DWI, the random Brownian motion of water molecules is measured within a voxel of tissue, being related to cellularity and the integrity of the cellular membranes of tissues providing qualitative and quantitative information compared to morphologic criteria only. DWI has potential to differentiate between malignant and benign tumours, to monitor therapy response or to detect recurrence. It also may have its value in predicting tumour aggressiveness or heterogeneity. Patient preparation includes intramuscular antispasmodic drug administration to last through the scanning. Indications of using MR-contrast media vary among different gynaecologic diseases. Contrast agents are not recommended in pregnancy, despite of lacking evidence of adverse foetal effects. Linear gadolinium chelates should be avoided when imaging breast feeding mothers. MRI has a growing role as a non-invasive diagnostic tool while decisions of treatment management move towards personalised medicine, for example, in ovarian

cancer patients. Developed methods in debulking surgery, such as peritonectomy, resection of diaphragm or suspicious cardiophrenic lymph nodes via thoracoscopy, aimed to optimal debulking without any residual tumour, require accurate pre-operative knowledge of the tumour extent. Increasingly used whole body DW-MRI may have potential in assessing disease extent, also in supradiaphragmatic tumour sites. Radiologists should be active in interdisciplinary workshops to communicate the new development and possibilities of multiparametric MRI in gynaecologic imaging.

Session Objectives:

1. To learn how to optimise MRI of the female pelvis.
2. To understand the diagnostic benefit of integration of advanced techniques.

A-519 16:05

A. Basics of patient preparation and T2W-imaging

N.M. deSouza; *Sutton/UK (nandita.desouza@icr.ac.uk)*

T2-W MR imaging provides exquisite soft tissue contrast for diagnosis and evaluation of benign and malignant pelvic pathology. It is essential to achieve images free of artefact with maximal spatial and optimal contrast resolution. Sequence acquisition parameters that deliver the best tissue contrast must be implemented and image degradation by patient-related factors must be avoided. Physiological motion in the pelvis arises largely from bowel peristalsis and bladder filling. Intramuscular administration of antiperistaltic agents (Buscopan [hyoscine butylbromide] 20mg or glucagon 1mg) is important; intravenous delivery results in a very short period of antiperistaltic action insufficient to last through the scanning period. Bladder filling during the scan also degrades image quality. An empty bladder at the outset is preferred. To minimise diuresis during scanning, diuretic-inducing caffeine containing drinks or excessive fluid intake should be discouraged for 4 hours prior. Images dedicated to a particular anatomical structure, e.g. uterus should be acquired in planes along the long and short axis of the organ, with as small a field-of-view as feasible without compromising signal-to-noise ratio. For large field-of-view images, T2-W scans in true orthogonal planes to the B0 field are preferred. The sagittal plane is best for visualising the uterus, while the transverse plane is ideal for assessing parametria, adnexae and pelvic side wall. For the ovaries, the coronal plane may be helpful. High-quality T2-W imaging in orthogonal planes are usually sufficient for detecting, characterising, staging pelvic malignancy, monitoring treatment response and assessing disease recurrence of a range of gynaecological pathologies.

Learning Objectives:

1. To understand the value of patient preparation.
2. To learn how to optimise and tailor protocols in female pelvic imaging.
3. To understand the role of T2WI, and how and when to use 3D techniques.

A-520 16:28

B. Contrast agents

R.A. Kubik-Huch; *Baden/CH (rahel.kubik@ksb.ch)*

Gadolinium-based contrast material is not usually necessary for evaluating benign uterine disease, but is recommended in fibroid evaluation. Gadolinium-enhanced sequences are performed for staging endometrial carcinoma, being useful in the assessment of the depth of myometrial tumour invasion. The optimal tumour/myometrial contrast timing was reported between 90 and 150 seconds. Thus, the utility of dynamic acquisition has been debated. Contrast-enhanced imaging will not be routinely performed in cervical carcinoma. It is recommended that the MR assessment of sonographically indeterminate adnexal masses are mandatory for staging ovarian carcinoma. Dynamic contrast-enhanced MRI may provide quantitative information about tumour perfusion, being useful for monitoring therapeutic effects and predicting therapeutic outcome. MR angiography should be performed in patients scheduled for fibroid embolization or in suspected pelvic congestion syndrome. Gadolinium-based contrast agents will cross the placenta and enter the foetal bloodstream. The agents are excreted into the amniotic fluid and will not be removed effectively from the foetal environment. Although there is currently no evidence of adverse foetal effects, contrast agents should be avoided in the pregnant patient. Only a small amount of gadolinium is excreted into the breast milk and absorbed by the infant, without any adverse effects being reported. Therefore, breast feeding can be continued, but it might be the preference of the mother to discard the breast milk in the 24 hours after contrast medium. If contrast agents need to be administered in these patients, linear gadolinium chelates should be avoided.

Learning Objectives:

1. To become familiar with the safety considerations and guidelines for the use of gadolinium with a special focus on imaging pregnant and lactating patients.
2. To learn why, how and when to use IV contrast-enhanced imaging in MRI of the female pelvis.
3. To understand different gadolinium T1W techniques and their clinical value in routine imaging, as well as to become familiar with quantification techniques.

A-521 16:51

C. Diffusion and ADC

E. Sala; *New York, NY/US (salae@mskcc.org)*

DW-MRI is a functional imaging technique that displays information about water mobility, tissue cellularity and the integrity of the cellular membranes. It also permits the quantitative evaluation of the apparent diffusion coefficient (ADC) from images with different b-values. The ADC value is measured in mm^2/s and is calculated by the slope of the line of the natural algorithm of signal intensity versus b-values. DW-MRI should be performed at two or more b-values, which include one or more low b-values (50-100 s/mm^2) since perfusion contribution to diffusion is then eliminated and a very high b-value (750-1000 s/mm^2). Both breath hold and non-breath hold DW sequences can be used. However, the type of DW sequence differs among manufacturers and the radiologist should be familiar with the strengths and limitations of their own scanners. Combination of DWI with conventional MRI sequences improves lesion detection and radiologist confidence in imaging interpretation. DW-MRI can be useful for accurately determining the depth of myometrial invasion in endometrial cancer. This can be particularly helpful in cases of tumours that are either iso- or hyper-intense relative to the myometrium or when the use of intravenous contrast medium is contraindicated. In addition, ADC values are inversely related to the cellularity of tumours which may be useful for distinguishing between benign and malignant tissues and for monitoring tumour response to treatment in cervical and ovarian cancer.

Learning Objectives:

1. To understand the technical principles of DWI.
2. To learn how to optimise and integrate DWI in pelvic imaging.
3. To illustrate the added diagnostic value of DWI in female pelvic imaging.

17:14

Panel discussion: Multiparametric MRI of the female pelvis - should it replace tailored protocols?

16:00 - 17:30 **Room E1**

Special Focus Session

SF 12b

Challenges in the diagnosis of acute appendicitis

A-522 16:00

Chairman's introduction

J. Stoker; *Amsterdam/NL (j.stoker@amc.uva.nl)*

Acute appendicitis is the most common urgent cause of acute abdominal pain at the emergency department. Ultrasound and computed tomography play an important role in diagnosing acute appendicitis, while magnetic resonance imaging can be considered in certain situations. Knowledge on the accuracy, pros and cons and cost-effectiveness of either technique and the possible imaging strategies (e.g. in specific groups or clinical settings) are crucial for proper management, including discriminating between complicated and uncomplicated appendicitis.

Session Objectives:

1. To become familiar with the topics on imaging in acute appendicitis discussed in this session.
2. To learn the optimal diagnostic strategy in diagnosing acute appendicitis in specific populations (paediatric, pregnant, obese, elderly).
3. To understand the role of imaging in the management of acute appendicitis in specific populations (paediatric, pregnant, obese, elderly).

Author Disclosure:

J. Stoker: Research/Grant Support; Robarts Clinical Trials.

A-523 16:05

Acute appendicitis during pregnancy: high-end ultrasonography, ultra-low dose CT or unenhanced MRI?

P.-A. Poletti; *Geneva/CH (pierre-alexandre.poletti@hcuge.ch)*

Imaging is important in the diagnostic management of pregnant patients with suspicion of appendicitis, since the risk of foetal loss dramatically increases (20-25%) in case of perforation, when compared to unperforated appendicitis (3-5%). Ultrasonography is unanimously advocated as first-line imaging; however, this operator-dependent technique is limited by an uncertain sensitivity (20-100%) and by a high rate of indeterminate results (88-96%), especially in the last trimester of pregnancy. MRI is often recommended to be used as second-line imaging method, because it has a good sensitivity (80-100%) and specificity (93-98%) for appendicitis and delivers no ionizing radiations. However, there are many drawbacks to its use: MRI is not available

24/24 in every centre, being absolute innocuous for the foetus is not demonstrated, it is time consuming, requires patients collaboration and its value for identifying alternative diagnoses is debated. Because of reluctance to ionizing radiation exposure, especially during the first trimester, i.v. contrast-enhanced CT is usually only recommended when ultrasonography and MRI are inconclusive or unavailable. The accuracy of CT is equivalent to that of MRI for the diagnosis of appendicitis, but has been reported better for alternative diagnoses. Preliminary, not yet published series suggest that ultra-low-dose unenhanced CT (<2mSv), with iterative reconstruction, might be a practical alternative to MRI and to standard dose i.v. enhanced CT, as second-line imaging tool, after an indeterminate ultrasound, for an acceptable dose of radiation. This will be discussed in the presentation.

Learning Objectives:

1. To learn about the pros and cons of high-end ultrasonography, ultra-low dose CT and unenhanced MRI in diagnosing appendicitis in pregnancy.
2. To appreciate the role of high-end ultrasonography, ultra-low dose CT and unenhanced MRI in diagnosing appendicitis in pregnancy.
3. To understand of the role of high-end ultrasonography, ultra-low dose CT and unenhanced MRI in relation to clinical findings to differentiate between diagnosing appendicitis uncomplicated vs complicated appendicitis in pregnancy.

A-524 16:23

Imaging algorithms for acute appendicitis in difficult patients (obese, elderly, other)

J.B.C.M. Puylaert; *The Hague/NL (dr.jbcmpuylaert@wxs.nl)*

The clinical diagnosis of appendicitis is classically unreliable: 25% of appendectomies are unnecessary, while significant surgical delay occurs in 20% of patients with appendicitis. US, CT and MR have brought down these numbers to 3% and 5%, respectively, by accurately diagnosing both acute appendicitis as well as many of its clinical masqueraders. The inflamed appendix presents as a blind-ending, concentrically layered, firm sausage-like structure, often surrounded by inflamed fat. This is in contrast to the normal appendix, which is compressible, mobile and usually, but not always, smaller than 7mm. Appendicitis can be excluded by demonstrating a normal appendix over its full length or by reliably demonstrating an alternative diagnosis. This may involve principally conservatively manageable conditions such as Crohn's disease, infectious ileocolitis, haemorrhagic follicle, pneumonia, necrotic myoma, non-perforated peptic ulcer, pyelonephritis, ureterolithiasis, right colonic and sigmoid diverticulitis, rectus sheath haematoma, familial Mediterranean fever, adnexitis, ovarian cyst, segmental omental infarction and primary epiploic appendagitis, or principal surgical conditions such as perforated peptic ulcer, ectopic pregnancy, ovarian torsion, cholecystitis, small bowel obstruction, colonic carcinoma, intussusception, ruptured aneurysm and Meckel diverticulitis. Various imaging appearances of appendicitis and its differential diagnosis will be shown as well as many possible pitfalls. Specific pitfalls and management in difficult patients (obese, the elderly and the pregnant patient) will be highlighted.

Learning Objectives:

1. To learn about the pros and cons of high-end ultrasonography, ultra-low dose CT and MRI in diagnosing appendicitis in 'difficult' patients.
2. To appreciate the role of high-end ultrasonography, ultra-low dose CT and unenhanced MRI in diagnosing appendicitis in 'difficult' patients.
3. To understand the role of high-end ultrasonography, ultra-low dose CT and unenhanced MRI in relation to clinical findings to differentiate between uncomplicated vs complicated appendicitis in 'difficult' patients.
4. To understand the pros and cons of different imaging strategies in diagnosing appendicitis in 'difficult' patients.

A-525 16:41

What is the cost-effectiveness of different imaging modalities in acute appendicitis?

M. Zins; *Paris/FR (mzins@hpsj.fr)*

Use of imaging in the diagnostic workup of patients with clinically suspected appendicitis reduced the rate of negative appendectomies, surgical complications and the costs. There is a high level of evidence that the most cost-effective method of imaging appendicitis is to start with a US study and follow each negative US study with a CT examination (conditional CT strategy). During pregnancy, following indeterminate US, magnetic resonance imaging is the most cost-effective strategy. For pregnant women with suspected appendicitis, an extremely high level of clinical diagnostic certainty must be reached prior to proceeding to operation without pre-operative imaging. In the general population, the accuracy of conditional or immediate MR imaging is similar to that of conditional CT in patients suspected of having appendicitis. Paradigm shifts to MRI owing to concerns over radiation should be considered only if high MRI test performance is reliably achievable.

Learning Objectives:

1. To learn about the level of evidence concerning cost effectiveness of imaging in acute appendicitis.
2. To learn about the cost effectiveness of high-end ultrasonography, ultra-low dose CT and MRI in diagnosing appendicitis (including uncomplicated vs complicated).
3. To understand the cost-effectiveness of different imaging strategies in diagnosing appendicitis in the general population, in pregnancy and in 'difficult' patients.

A-526 16:59

Evidence-based treatment of acute appendicitis: conservative vs surgical management?

M.A. Boermeester; *Amsterdam/NL (m.a.boermeester@amc.uva.nl)*

In the past only clinical evaluation was used to evaluate patients with suspected appendicitis, but this is imperfect. Unnecessary surgical exploration is not without downsides. It carries an increased risk of mortality, of prolonged hospital stay, and of wound infections. Based only on clinical evaluation, 10-20 per cent of patients with appendicitis would be missed. Such a missed diagnosis results in a treatment delay. Perforated appendicitis is associated with higher mortality and morbidity rates. Because of negative appendectomy rates, missed appendicitis cases and differentiation between uncomplicated and complicated appendicitis, imaging has become widely used in first world countries to aid the clinical evaluation of acute abdominal pain. Appendiceal perforation has long been considered an advanced state of acute appendicitis. However, the relation between time and progression of disease (from simple uncomplicated to gangrenous or perforated appendicitis) is being questioned. Perforated and non-perforated appendicitis are suggested to have different pathophysiologies. Conservative management has been proposed as an alternative for selected patients with uncomplicated or simple appendicitis. Several randomized trials have indicated that treatment with antibiotics is as safe and effective as appendectomy for patients with uncomplicated appendicitis, with low failure rates which then can be treated with appendectomy without a higher complication rate. However, preoperative identification of patients with uncomplicated appendicitis has proven to be a challenge.

Learning Objectives:

1. To learn about the evidence concerning conservative vs surgical management in acute appendicitis.
2. To learn about the role of clinical history, physical examination and laboratory findings in the management of acute appendicitis.
3. To appreciate the role of imaging in management of acute appendicitis (including uncomplicated vs complicated).

Reporting the degenerative lumbar spine

Moderator:
E.T. Tali; Ankara/TR

A-527 16:00

A. Disc nomenclature: how I make my report

E. Arana; *Valencia/ES (aranae@uv.es)*

For the clinical management of degenerative spine lesions, the radiologist is of major importance for the discrimination of normal ageing and probable relevant imaging findings. A systematic review will include key anatomic and radiologic features in disc pathology. Standardized disc nomenclature (version 2.0) is mandatory and its key imaging characteristics are showed. Emphasis is placed on pain generators and clear-cut imaging findings such as neural compression. Elusive relationship among other imaging findings and symptoms are also explained. Overall, challenges and pitfalls will be reviewed for the management of potentially relevant lesions using MRI on the background of symptoms relevance. Hints are provided to increase reproducibility and consistency of radiological reports and what clinicians need in our report.

Learning Objectives:
1. To become familiar with the different nomenclatures in degenerative disc disease and their anatomic substrates.
2. To learn how to differentiate between the different types of disc disease.
3. To appreciate how the different types of degenerative disc diseases determine the therapeutic approach.

A-528 16:30

B. Don't forget the facet joints and posterior elements
L. van den Hauwe; *Antwerp/BE (lucvdhauwe@mac.com)*

Many radiologists reading imaging studies of the spine performed in patients with low back pain (LBP), neck pain, and radicular symptoms tend to focus on the anterior part of the spine, and more specifically on the intervertebral disc. They are often unaware that the posterior elements (facet joints, pedicles, spinal ligaments, spinous processes, etc.). may also be a source of pain. Moreover, radiologists are faced with the low specificity of the morphological abnormalities found on plain film radiography, computed tomography (CT) and magnetic resonance (MR) imaging which are also a frequent finding in the general - often asymptomatic - population. Conversely, the source of LBP (and neck pain) may remain unrecognized unless more dedicated MR imaging sequences such as fat-suppressed (FS) T2-weighted images (e.g. short-tau inversion recovery (STIR)) and FS contrast-enhanced (CE) T1-weighted images are added to the standard spinal MR imaging protocol. These FS-sequences are more sensitive in demonstrating bone marrow oedema, soft tissue inflammation, and hypervascularity that are often associated with degenerative changes of the posterior elements, e.g. facet joint osteoarthritis, synovitis, neural arch intervertebral or spinous process neoarthrosis, etc. Also nuclear medicine techniques such as single-photon emission computed tomography (SPECT), SPECT/CT, etc. are additional imaging techniques that may correctly identify the source of the pain.
Learning Objectives:
1. To become familiar with the anatomy of the facet joints and the posterior elements.
2. To understand the pathophysiological principle underlying the degenerative changes of these structures.
3. To appreciate the effect of these changes on the therapeutic approach.
Author Disclosure:
L. van den Hauwe: Consultant; icometrix, Leuven/BE.

A-529 17:00

C. What to say and not to say in your report
M.M. Thurnher; *Vienna/AT (majda.thurnher@meduniwien.ac.at)*

Following a degenerative spine diagnosis, many issues can be successfully treated with various conservative treatments. These options do not work for every patient, some will need surgical pain relief. Variability in radiologists' reporting styles and recommendations for spinal studies can lead to confusion among clinicians and may contribute to inconsistent patient care. Reporting spine studies requires a systematic approach. The report on MRI of the spine should have following elements: perispinal tissue, bones, disks, spinal canal, facet joints, spinal cord and cauda equina. Adequate techniques and sequences are mandatory for optimal evaluation of spinal structures. In this lecture, the recommendations to improve documentation and reporting of spine MRI will be discussed.
Learning Objectives:
1. To understand the legal value of a report.
2. To demonstrate how detailed a report should be.
3. To understand the importance of a clinical information and the relevance of assessing previous examinations.
Author Disclosure:
M.M. Thurnher: Consultant; Guerbet.

Cortical anatomy and primary functional areas
T.A. Yousry; *London/UK (t.yousry@ucl.ac.uk)*

The anatomy of the brain is often perceived as being complicated. Especially the cortex is seen as an irregular arrangement of variable structures, which are difficult to differentiate and to identify. We will review the overall subdivision of the brain into lobes and describe their boundaries and their major gyri and sulci. We will then describe the location of specific functions. 1. Primary sensorimotor cortex: motor is located in the precentral gyrus, sensory in the postcentral gyrus around the central sulcus (CS), hence the importance of always correctly identifying the CS. We will present 4 interlocked methods to identify the CS in the axial plane: a) knob, b) lateral axial, c) medial axial and d) gyral/cortical thickness and 3 to identify it in the sagittal plane: a) lateral sagittal, b) hook and c) medial sagittal. 2. Primary auditory cortex (A1): centred at the postero-medial part of Heschl's gyrus (HG), we will present simple landmarks in each of the 3 planes: a) axial: adhaesio interthalamica, b) sagittal: omega/heart shape of HG, c) coronal: omega shape of HG. 3. Primary visual cortex (V1): centred on the calcarine sulcus, we will discuss the characteristic shape that allows the identification of this structure in all 3 planes. At the end of this lecture, you will know the subdivision of the cortex; the methods and landmarks necessary to identify the primary sensorimotor, speech, auditory and visual areas.
Learning Objectives:
1. To understand the basic concepts of cortical subdivision.
2. To be able to identify critical cortical structures.
3. To learn to localise primary functional areas.
Author Disclosure:
T.A. Yousry: Advisory Board; Biogen Idec; Genzyme. Board Member; Neuroradiology. Grant Recipient; Medical Research Council, MS Society of Great Britain and Northern Ireland, Stroke Association, British Heart Foundation, Wellcome Trust. Research/Grant Support; BRC. Speaker; ESOR, Novartis.

A-531 16:30

Vascular distribution territories: arterial and venous
A. Dörfler; *Erlangen/DE (arnd.doerfler@uk-erlangen.de)*

After a short overview on the vascular anatomy of the brain with a focus on vascular distribution territories, the main aim of this presentation is to present different neurovascular pathologies closely associated with arterial and venous vascular distribution territories. A focus is here put on acute stroke and particularly imaging-based patient selection for interventional stroke therapy. Another aim is to provide a better understanding of pathophysiology of different neurovascular disease in an interactive matter. In addition, advantages and limitations of CTA and MRI compared to conventional angiography are presented.
Learning Objectives:
1. To become familiar with a comprehensive vascular anatomy of the brain.
2. To recognise patterns of various pathologies attributed to vascular distribution territories.
3. To recognise the different imaging patterns in stroke and their prognostic value.

A-532 17:00

The basal ganglia of the brain revisited
D. Zlatareva; *Sofia/BG (dorazlat@yahoo.com)*

The deep grey matter nuclei include the basal ganglia and thalamus. These paired symmetric structures are located in the telencephalon, diencephalon, and mesencephalon. The lenticular nucleus includes putamen and globus pallidus. Together with caudate nucleus these structures are named corpus striatum. The term "basal ganglia" refers to caudate nucleus, putamen, globus pallidus, substantia nigra and subthalamic nucleus. All these structures are part of extrapyramidal system and have wide connections not only with each other but also with the midbrain, thalamus and cerebral cortex. The striatum is the main recipient of afferents from the entire cerebral cortex and from thalamus to the basal ganglia. In the motor regions of the basal ganglia, there is a motor homunculus similar to that seen in the primary motor cortex. The major output structures of the basal ganglia are the globus pallidus internal

segment and the substantia nigra pars reticulate. Both of these structures make GABAergic, inhibitory connections on their targets. The basal ganglia and thalami have five functional divisions which are sensorimotor, supplementary motor, premotor, association and limbic territories. These divisions take part in functional cortical-basal-ganglial-thalamocortical circuits which enable the execution of automatic and semi-automatic motor programs, modulation of muscle tone and the harmonisation of movement. If one or more of these regulatory circuits are interrupted the result will be either a net removal of inhibition, leading to excessive movement like tremor or dystonia, or a net decrease in motor activation causing impaired movement (e.g. rigidity, akinesia).

Learning Objectives:

1. To recall the basal ganglia nuclei and their topography.
2. To identify the classic functional organisation of the basal ganglia and its current concepts.
3. To elucidate the pathophysiology of various movement disorders.

16:00 - 17:30 **Room F2**

Oncologic Imaging

RC 1216

Monitoring response: the essential guide for all radiologists

A-533 16:00

Chairman's introduction

P. Brader; *Graz/AT (peter@brader.md)*

Imaging-based therapy monitoring is essential to visualise and quantify the effect of cancer therapy. Therefore, criteria-based reporting methods were established to ensure standardised and reproducible results for response evaluation of oncologic patients. Response evaluation criteria in solid tumours (RECIST) as the most widely accepted morphologic, size-based evaluation system is based on imaging assessment of change in tumour burden, to determine if the tumour has shrunk or grown. However, they only evaluate the size of the lesion, not its viability, proliferative rate or physiologic state. In recent years, a broad range of novel molecular cancer therapeutics were introduced into clinical use. These new therapy regimes demonstrated significant effects on tumour angiogenesis and tumour metabolism, but often only subtle effects on tumour morphology. Established methods of monitoring cytotoxic tumour therapies such as RECIST have been shown to be not sufficiently sensitive for monitoring the therapeutic effects of molecular anti-cancer agents to allow for a timely differentiation of responders from non-responders because such treatments are less likely to result in tumour shrinkage. The complementary acquisition of morphological, functional and molecular information using advanced imaging methods such as diffusion-weighted imaging or perfusion imaging as well as hybrid imaging techniques (PET/CT, PET/MRI) allows for a higher sensitivity and specificity in the timely differentiation of responders from non-responders. The tremendous development in oncology and technical innovations in imaging present a particular challenge for radiology.

Session Objectives:

1. To understand the correlation of functional imaging evaluation with the pathophysiological effect of treatment on oncological pathology.
2. To understand the necessity of functional imaging for an accurate (early) evaluation of the therapy regimen on the response (or non-response) of oncological disease.
3. To learn about the added value of functional imaging for evaluating treatment (e.g. anti-angiogenic treatment).
4. To learn about the technical principles of functional imaging in correlation with the impact of therapy on tumour cells and neo-vasculature.

A-534 16:05

A. RECIST made easy

A.G. Rockall; *London/UK (a.rockall@imperial.ac.uk)*

A significant part of modern-day cancer imaging involves the assessment of change in the extent of tumour in the context of a clinical trial or research study. The reporting requirements for these imaging studies are documented in the research protocol. A standardized response assessment is important to be able to collate data between different centres, as well as to evaluate published data from different studies. Response evaluation criteria in solid tumours (RECIST) were developed and published in 2000. RECIST criteria have been widely adopted for the evaluation of treatment response in the clinical trial setting. A revised version, RECIST 1.1 was subsequently published in 2009, to address several problems that had been encountered with RECIST 1.0. New studies frequently use RECIST 1.1 but in some cases, new studies will still use RECIST 1.0 to allow direct comparison with a previous similar study. In this lecture, the key features of RECIST will be presented with worked examples. Selection of appropriate target lesions will be illustrated. Frequently asked questions will be addressed and the criteria for response will be illustrated.

Learning Objectives:

1. To learn about the basic idea of RECIST.
2. To understand how to use RECIST in daily clinical practice.
3. To become familiar with the detailed rules of RECIST.

A-535 16:28

B. PERCIST: PET response criteria

C.C. Cyran; *Munich/DE (clemens.cyran@med.uni-muenchen.de)*

With the implementation of novel oncologic strategies and prolonged survival of cancer patients, early and longitudinal monitoring of therapy response to treatment in individual patients has become a key request to imaging. Known limitations of morphological size-based criteria (e.g. RECIST) for the monitoring of tumour response led to the investigation of additional functional and molecular imaging techniques to allow for a reliable and timely distinction of responders and non-responders, particularly under novel molecular cancer therapies. Particularly hybrid imaging techniques, such as PET/CT or PET/MRI, demonstrated significantly improved diagnostic accuracy for the evaluation of treatment response in different tumour entities under a variety of treatments with a reported change-in-intended management of up to 35% in oncologic indications compared to conventional imaging alone. To allow for a standardised evaluation of therapy response, criteria-based reporting of target and non-target lesions has been established to classify therapy response into different categories ranging from complete response to progressive disease and has found broad application particularly within clinical studies. Similar to the size-based RECIST (response criteria in solid tumours) criteria, PERCIST (PET response criteria in solid tumour) criteria were developed to provide a systematic, standardised approach for the criteria-based evaluation of metabolic tumour response to therapy using 18F-FDG PET. Studies evaluating PERCIST criteria suggest that the inclusion of standardised metabolic criteria may allow for an increased sensitivity, specificity and diagnostic accuracy in the evaluation of therapy response compared to morphological imaging criteria alone.

Learning Objectives:

1. To learn about the basic principles of PERCIST.
2. To understand how to use PERCIST for structured quantitative research and clinical reporting.
3. To appreciate the advantages of PERCIST over mere morphological methods.

C. Assessment of response using functional MR and CT imaging: the essentials

C.A. Cuénod; *Paris/FR (ca@cuenod.net)*

The assessment of the morphological changes detected by imaging is the most common way to evaluate response to treatment. The most frequently used criteria being the RECIST criteria. However, changes in cell metabolism and tissue physiology, which precede morphological changes, cannot be detected by the conventional imaging techniques. The development of functional imaging techniques such as dynamic contrast-enhanced CT (DCE-CT) or MRI (DCE-MRI) and diffusion MRI has enabled the assessment of information such as tumour vascularity, permeability and cellularity non-invasively. Therefore, there is a growing interest in using these new techniques to early assess the response of treatment as well as to follow patients during treatment. These methods may be of great help, not only to test the effect of new drugs and determine the groups of patients and tumours that could benefit from a new drug, but also to monitor the treatment of an individual patient. After reviewing the basic principles and the theory involved in DCE-CT, DCE-MRI and diffusion

MRI, we will address the technical aspects and requirements of these functional imaging methods. The spread of these techniques, however, is slowed down by many limitations that will be discussed. Not only they tend to be more complex to implement than routine morphological protocols, but they are very sensitive to the acquisition parameters and the mathematical models and software models used to extract the parameters. Consensus and normalization are still required.

Learning Objectives:

1. To learn about the portfolio of functional imaging response methods in CT and MRI.
2. To understand the current clinical value of each technique.
3. To appreciate potential advantages compared to PERCIST.

Imaging the hip and thigh

Moderator:

V. Njagulj; Sremska Kamenica/RS

A-537 16:00

A. Femoroacetabular impingement: what is it, how do I image it and does it matter?

R. Sutter; *Zurich/CH*

The last decade has seen a constant rise in the number of patients diagnosed and treated for femoroacetabular impingement (FAI). However, there are ongoing controversies about the accuracy of measurements for assessing FAI and an associated overdiagnosis of FAI. This refresher course covers the pathophysiology of FAI, the classic osseous hallmarks, and the characteristic damage to the articular cartilage and labrum. It gives an overview of state-of-the-art FAI imaging with different radiological modalities, including the use of traction at MR arthrography, and addresses possible pitfalls when evaluating the hip joint. Additional anatomical factors are described that contribute to the development of FAI, such as abnormal femoral antetorsion and acetabular version, and finally the relevance of the different parts of the diagnostic algorithm for evaluating FAI are discussed.

Learning Objectives:

1. To understand the mechanism of femoroacetabular impingement.
2. To learn about the imaging findings in patients with femoroacetabular impingement.

A-538 16:30

B. Groin pain in the athlete: what causes it and what does imaging contribute?

M. Maas; *Amsterdam/NL (m.maas@amc.nl)*

The diagnosis and classification of groin pain in athletes is a topic of ongoing debate and extensive research, since groin pain comprises 2 to 5 percent of all sports injuries that is potentially career-ending. How come the trouble arriving at an easy to treat diagnosis? First of all there is a very complex anatomy. Besides the complex anatomy that will be discussed in the presentation, differential diagnosis is quite broad, including intra-abdominal pathology, genitourinary abnormalities, referred lumbosacral pain and hip joint disorders. Secondly, in the field of sports medicine only recently there is an improvement of diagnostic dedicated tests allowing better narrowing of the differential. Adductor strains and osteitis pubis are the most common musculoskeletal causes of groin pain in athletes. And then there still is the debatable sportman's hernia. In the field of imaging, the mainstay is to start with pelvic radiography, also in young athletes. The not completely matured symphysis pubis will not be easy to distinguish normal from abnormal. Features will be discussed. In the field of MRI recently The Copenhagen standardized MRI protocol is launched that can assess the pubic symphysis and adductor regions in athletes. We will provide details on this strategy. We also will enlighten on the role of US imaging and US-guided intervention in this specific population. Most important topic is to stress the team effort in this complex type of injury in these athletes. We will illustrate this with our initiatives in the IOC centre of scientific excellence ACES in Amsterdam.

Learning Objectives:

1. To understand the anatomy of the groin region.
2. To learn about the imaging findings in athletes with groin pain.

A-539 17:00

C. Muscle injury of the hip and thigh

M.-A. Weber; *Heidelberg/DE (MarcAndre.Weber@med.uni-heidelberg.de)*

This lecture will focus on MRI for the assessment of muscle injuries at the hip and thigh using fluid-sensitive sequences. Muscle injuries include a large variety of imaging patterns from occasionally subtle changes in muscle strain to complete muscle tears. Exercise-related chronic changes such as delayed onset muscle soreness, compartment syndrome and muscle hernias, as well as complications of muscle injuries such as myositis ossificans may be encountered. The MRI appearance of a muscle contusion may be similar to a muscle strain/tear. Mild post-exercise oedema can persist for some time and can mimic a low-grade muscle strain injury. 35% of all soccer injuries are muscle injuries and they are the most frequent cause for missing a game. The myotendinous junction is the weakest link in the muscle-tendon-bone chain. The widely used grading system for muscle injuries divides muscle injuries into four grades (grade 0: normal MRI, i.e. functional injury of the muscle, grade 1: oedema, grade 2: partial rupture, grade 3: complete tear). However, this grading system is only a rough estimate, because grade 2 injuries comprise a wide range from tiny fibre discontinuities to subtotal muscle ruptures. Measures of the longitudinal length as well as the percentage and volume of the muscle injury in MRI have some predictive value with respect to time to return to sports activities. Moreover, injury to the intramuscular component of the tendon has prognostic significance. A complete tear (grade 3) may require surgery.

Learning Objectives:

1. To understand the imaging patterns of muscle injury at the hip and thigh.
2. To learn about grading and prognostic values of muscle injuries.

16:00 - 17:30 **Room G**

Multidisciplinary Session

MS 12

Transcatheter aortic valve implantation (TAVI)

A-540 16:00

Chairman's introduction: A brief history of TAVI

A. Cribier; *Rouen/FR (alain.cribier@chu-rouen.fr)*

Aimed at redressing the limitations of balloon aortic valvuloplasty developed by our group in 1985 for the treatment of inoperable patients with aortic stenosis (AS), TAVI (transcatheter aortic valve implantation) emerged in 2002 to profoundly alter the landscape of cardiovascular medicine. This new disruptive technology is among the important "medical breakthroughs" till date. It evoked scepticism and criticism in the beginning. But, thanks to innumerable clinical trials and evidence-based investigations, it is widely accepted by the medical community now and this acceptance is continuing to grow. In the last decade, TAVI has been performed in about 300 000 patients around the world and its use keeps growing 40% annually. The field of TAVI is rapidly evolving, with major refinements in technology and procedural techniques, patient selection and biomedical engineering.With the development of better devices, new approaches and new implantation strategies, TAVI has become much simpler and safer. The indications were initially limited to elderly AS patients with multiple co-morbidities. The same are now cautiously and appropriately growing to include a broader population of patients with lower surgical risk and degenerated surgical bioprosthesis. There are few examples of clinical fields in medicine that match the rapid and careful evolution of TAVI.

Session Objectives:

1. To understand the clinical needs of non-surgical techniques for aortic valve replacement.
2. To understand the difficult process of developing a breakthrough innovative technology in interventional cardiology.
3. To understand the importance of "translational research" for the success and expansion of TAVI.

Author Disclosure:

A. Cribier: Consultant; Edwards Lifesciences.

A-541 16:15

The TAVI procedure

H. Eltchaninoff; *Rouen/FR (helene.eltchaninoff@chu-rouen.fr)*

In 2016, TAVR is clearly turning into a routine procedure. This is driven by a number of factors: increased operator's experience, better patient selection and improved 3D adjunctive imaging. But, mainly, striking technology enhancements have changed the world of TAVR with improved systems, and the development of "minimalist strategies" making the procedure faster, simpler safer and more cost-effective. In 2016 was demonstrated the efficiency of new devices provided by the two leading companies, Edwards Lifesciences with its balloon-expandable Sapien 3 valve, and Medtronic with its self-expanding Evolut-R valve. With these new devices, the main complications of TAVR, mortality, paravalvular regurgitation (PV), vascular complications and stroke have been considerably improved. In the US, PARTNER Sapien 3 trial reported this year (583 patients), all cause mortality has decreased at 1 month to 1.1% (13% at 1 year), disabling stroke to 1.0%, PV leak to 3%, major bleeding and vascular complications to 5%. Similar improved results with the Evolut-R in a smaller series of patients were reported. In 2016, with the decreased size of the new devices, TAVR can now be performed using the transfemoral approach (the default access site) in almost 90% of cases, under local anaesthesia, allowing early discharge home within 3 days in a majority of cases (60% in Rouen). In patients non-suitable for transfemoral approach, alternative approaches include trans-aortic, trans-apical, trans-carotid and subclavian routes. TAVR is confirmed to be a breakthrough technology addressing an unmet clinical need validated by rigorous evidence-based studies.

Learning Objectives:

1. To learn the current indications of TAVI and the process of patient selection.
2. To learn the different phases of the procedure using the transfemoral approach.
3. To learn the prevention and treatment of complications.

Author Disclosure:

H. Eltchaninoff: Speaker; edwards lifesciences.

A-542 16:30

The cardiac surgeon's perspective

P.-Y. Litzler; *Rouen/FR (pierre-yves.litzler@chu-rouen.fr)*

During many years, the only treatment of calcific aortic stenosis was surgical aortic valve replacement. Despite excellent results, numerous patients were not eligible to surgery due to comorbidities or frailty. In April 2002, the first human transcatheter aortic valve implantation(TAVI) was performed in Rouen leading to a new era in the treatment of aortic stenosis. The first cases of TAVI were performed with a surgical cut down of the groin under local anaesthesia. But, due to the large diameter of the first catheters (24Fr) and the presence in numerous patients of small calibre vessels, the idea of a transapical approach emerged and, the first patients were implanted in 2005. Few years later, new surgical approaches were developed with transaortic, trans-sub-clavian or transcarotid artery procedure. Transapical approach could be a secure procedure if a perfect analysis of the aortic valve is managed prior to surgery to avoid drastic complication. The measurement of the distances between annulus and coronary ostia, the aortic valve area and the annulus plan are the key points of procedural success. At the beginning of the procedure, a transthoracic echocardiography to determine the position of the apex of the heart is strongly recommended. Multiple studies have reported excellent results whatever the approach (transfemoral, transapical, etc.) and the initial goal, i.e. "to provide an alternative to non-surgical patients" has been reached. However, the long-term durability of the transcatheter valves still unknown and today, the use of TAVI in low risk or younger patients remains controversial.

Learning Objectives:

1. To learn the different mini-surgical approaches for TAVI and the current indications.
2. To learn the different phases of TAVI using the mini-surgical approaches.
3. To learn from a cardiac surgeon the perspectives of surgical valve replacement in the TAVI era.

Author Disclosure:

P. Litzler: Other; Edwards Proctor.

A-543 16:45

Pre-interventional assessment by CT

J.-N. Dacher; *Rouen/FR (Jean-Nicolas.Dacher@chu-rouen.fr)*

In recent years, transcatheter aortic valve intervention (TAVI) gained wide acceptance in patients with severe aortic stenosis contraindicated to surgical valve replacement. Pre-operatively, CT of the heart, aorta and iliac vessels is recommended. Various CT techniques can be performed depending on CT generation. Basically, ECG-gated examination of the heart and aortic root should be performed, completed by non-gated coverage of the abdominal aorta and ilio femoral vessels. Systolic reconstruction of the heart should be obtained to evaluate the aortic valve area and measure the annulus (diameters and planimetry). Diastolic reconstruction can be used for evaluating distances between annulus and coronary ostia, the sub-aortic septum, the calcification and cuspidity of the valve, the extent of the calcification (i) to the annulus (increasing the risk of per procedural rupture) (ii) to the septum (risk of conduction abnormality) and (iii) mitral valve. Vascular route should be evaluated from the access up to the aortic valve. All images should be transmitted to the Cath. Lab. with a structured report, including any other thoraco-abdominal abnormality/disease, a frequent situation is those elderly patients.

Learning Objectives:

1. To learn about the technical principles of MDCT acquisition in pre-TAVI assessment.
2. To learn about the advantages of a structured MDCT report (including key images) validated by the cardiology team.
3. To know the medical impact of the radiology team in the management of TAVI patients.

A-544 16:58

Why use dual-energy CT in TAVI patients?

B. Dubourg; *Rouen/FR (benjamin.dubourg@chu-rouen.fr)*

Since the first introduction of transcatheter aortic valve implantation (TAVI), the number of procedures has increased worldwide. A comprehensive cardiac and aorto-iliac arteries CT angiography before the procedure has become a common and recommended clinical practice. Dual-energy CT (DECT) allows to quantify iodine within a voxel and to display two different data sets : (1) virtual monoenergetic images and (2) Iodine maps. The virtual monoenergetic images allow to increase iodine attenuation at post-processing hence to reduce the injected iodine load. This property is of importance in TAVI population with frequent impaired renal function. Up to 50% reduction of iodine volume can be attained at the expense of an increased image noise which remains acceptable for diagnosis. The iodine maps allow to measure iodine concentration within a voxel. Myocardial extracellular volume fraction (ECV) is a validated myocardial fibrosis marker; it is directly measurable from iodine maps. The ECV calculated from DECT is comparable and/or highly correlated to ECV calculated from MRI. A single delayed post-contrast DECT acquisition could add a prognosis value to the actual standard anatomic comprehensive CT evaluation.

Learning Objectives:

1. To know how to decrease the dose of iodine with new CT technology including dual-energy.
2. To know how to control the radiation dose with new CT technology.
3. To know how to characterise the myocardium with new CT technology.

A-545 17:11

Common and uncommon complications seen by CT

J. Caudron; *Rouen/FR (drjeromecaudron@gmail.com)*

Computed tomography angiography (CTA) is a suitable technique for assessing potential vascular and cardiac complications occurring after TAVI thanks to its good spatial and contrast resolution. Vascular complications are easily evaluated by CTA. Some cardiac complications can be assessed by CT. The cardiac CTA (CCTA) protocol will depend on the clinical context and the degree of emergency. A retrospectively ECG-gated CCTA is adapted in these patients with frequent tachycardia and difficulties to use beta-blockers. Prior acquisition without injection can be useful in case of suspicion of annulus rupture to distinguish the calcifications from extravasation of contrast agent. A normally implanted valve is properly deployed (i.e. with diameter and surface in adequation with the valve size implanted), with good circularity. Its basal portion is located at the level of the native annulus, often some millimetres below. The coronary ostia are free, distant from native valvular calcification. The main complications leading the realization of CTA are 1) vascular complication, often at the point of puncture; 2) malpositioning and/or misdeployment in the aortic root which can lead to paravalvular leak or disturb the opening/closing of the valvular leaflets; 3) valve migration or embolization; 4) annulus rupture, the most severe complication with poor prognosis.

Learning Objectives:

1. To learn the basic cardiac CTA protocol in implanted patients.
2. To know the normal CT findings in implanted patients.
3. To know the complications of TAVI and potential yield of CT.

17:24

Multidisciplinary case presentation and discussion

16:00 - 17:30 **Room K**

Pros & Cons Session

PS 1227

Providing an effective ultrasound service: how and by whom?

Moderators:
L.E. Derchi; Genoa/IT
V. Gibbs; Bristol/UK

A-546 16:00

A. Who provides US services? The situation in Europe
H. Edwards; *Stevenage/UK (hazel.edwards@nhs.net)*

For many years, the majority of ultrasound examinations in the United Kingdom (UK), both obstetric and non-obstetric, have been performed by radiographers who have undergone post-graduate training in ultrasound. These 'sonographers' scan, interpret and report their own examinations. Today, sonographer-led ultrasound services are essential and well established. The second largest professional group performing ultrasound in the UK is radiologists. Other groups including midwives, obstetricians, emergency physicians and aortic screening technicians also contribute to services. This model is successful yet it appears to be unique. No other country relies so heavily on sonographers. Throughout mainland Europe physicians and general practitioners perform the majority of ultrasound examinations. In countries like Australia, Canada and the United States, ultrasound may be performed by sonographers but reporting remains the domain of the overseeing physician. However, as demand for ultrasound services continues to escalate, changes are afoot with small numbers of sonographers now practising in Sweden, Denmark and The Netherlands, some as part of pilot studies. Furthermore, physicians in Germany are beginning to view UK ultrasound services with interest. Evidence supporting the success of UK ultrasound practice will be offered in this presentation. Possible reasons behind the historical development and emerging trends will be discussed. Recommendations for supporting future practice of sonographers outside the UK will be made.
Learning Objectives:
1. To discuss the three models of ultrasound scanning undertaken across Europe.
2. To outline the differences in ultrasound services provided across European countries.

A-547 16:15

B. Should US services be provided by radiologists? (performed and reported on)
M. Claudon; *Vandoeuvre-les-Nancy/FR (m.claudon@chu-nancy.fr)*

Ultrasound (US) is an imaging technique which is now widely expanded among countries and specialties. The increase in daily activity as well as off-hours requests are a challenge for most teams. The possibility of educating technicians for doing the first part of examination has been raised in several European countries on a model partly inspired from the position of sonographers in UK and the USA. However, there are still some challenges which should moderate such an evolution: the level and control of competences and practice of such new activities for technicians, the way technicians should be covered by radiologists in case of complex cases, the difficulty in checking the content of the examination performed by the technician and compared to previous examinations. Therefore, caution should be emphasized before going in this direction, and a careful control of US should be maintained by radiologists
Learning Objectives:
1. To discuss why US examinations should be performed directly by the radiologist.
2. To underline why US examinations should be reported only by the radiologist.
Author Disclosure:
M. Claudon: Speaker; Philips Ultrasound.

A-548 16:30

C. Can or should US services be provided by radiographers/sonographers? Educational needs
G. Harrison; *London/UK (G.Harrison@city.ac.uk)*

In 1977 the College of Radiographers set the standard for ultrasound training in the UK by launching the highly respected Diploma of Medical Ultrasound (DMU). Then, in the early 1990s, radiography education changed to degree level and universities were able to develop their own post-graduate ultrasound programmes, set standards and assessments, independent of the professional body. This allowed entry into ultrasound training to MSc level for radiographers and other health care professionals, such as nurses and midwives. In 1993 the Consortium for the Accreditation of Sonographic Education (CASE) was formed by a number of professional bodies and ultrasound interest groups, to ensure that the standards of these postgraduate programmes met the needs of the health care service. The current remit of CASE includes ensuring high standards of training for ultrasound practitioners and stipulates that reporting should be an integral part of the examination. Ultrasound education is changing to meet the growing demands on the ultrasound service in the UK. There are new programmes being delivered as direct entry programmes at undergraduate and postgraduate levels, for non-health care professionals, and some training is being provided outside the university setting. These will be discussed in relation to other international training models.
Learning Objectives:
1. To outline ultrasound training programmes and curricula in countries where US is undertaken and reported by sonographers.
2. To compare this with other international training models available.

A-549 16:45

D. Is it possible to standardise a 'real-time' examination? Sometimes it is possible, but not always
C. Nyhsen; *Sunderland/UK (nyhsenc@doctors.org.uk)*

Ultrasound is a real-time investigation and has a great variety of indications and uses. The advantage is that practitioners can directly communicate with patients, which allows tailoring of scans for each individual case. This can be very helpful allowing areas to be scanned that may not even have been requested, but on the other hand a thorough investigation is still needed as important pathology may otherwise be missed. This presentation will focus on the ability and limitations of standardising exams and highlight the importance of good team working between sonographers and radiologists.
Learning Objectives:
1. To discuss when and how this is possible.
2. To be able to recognise when an additional examination by the radiologist is needed.

A-550/A-551 17:00

Discussion on the pros and cons
L.E. Derchi; *Genoa/IT*
V. Gibbs; *Bristol/UK (vivien.gibbs@uwe.ac.uk)*

This session will include invited speakers presenting their views on which are the most appropriate groups of healthcare professionals to provide an effective ultrasound service. An overview of the current models in places across Europe will be explored. This will be followed by a facilitated discussion on the advantages and disadvantages of each model.

16:00 - 17:30 **Room M 1**

EuroSafe Imaging Session

EU 5

EuroSafe Imaging Stars

Moderators:
L. Bonomo; Rome/IT
S. Ebdon-Jackson; Didcot/UK

A-552 16:00

Value and limitations of the 'Is your Imaging EuroSafe' surveys
L. Bonomo; *Rome/IT (lorenzo.bonomo@unicatt.it)*

Eurosafe imaging stars is an initiative designed to identify and recognize imaging facilities worldwide that embody best practice in radiation protection. One important contribution Eurosafe imaging stars is making is to participate in the data collection efforts through the "Is your imaging Eurosafe" surveys on CT doses making the resulting benchmarks more reliable. "Is your imaging Eurosafe" comprises a series of surveys on CT DRLs for different indications.The core aim of "Is your imaging Eurosafe" is to build a European repository based on dose exposures for specific clinical indications that would be most useful for self-benchmarking and for future establishment of DRLs. In addition, this repository would provide insights into the influence of the age of the equipment on dose exposures which may be helpful at the local level to stimulate a policy of upgrading or replacing equipment. Finally, repeating the survey in the same centre over a period of three years will provide important information on the evolution of DRLs.

Learning Objectives:
1. To learn about the value of EuroSafe Imaging surveys.
2. To understand how useful the EuroSafe Imaging surveys' findings in our daily clinical activity can be.
3. To understand how data can be collected and what actions are needed to enhance radiation protection of patients.

A-553 16:15

Integration of the 'EuroSafe Imaging Clinical Audit Pack' in imaging departments

B.E. Kelly; *Belfast/UK (barryekelly@mac.com)*

Audit simply means comparing an element of clinical practice against an agreed standard. In radiological practice, this might mean what we do; how we do it; what equipment we use; how we interact with our patients; our colleagues and our environment. To put it another way, audit asks one question: 'are we safe?' Audit should be achievable, local, practical, inexpensive, non-threatening and easy (ALPINE). In February 2018, the Euratom 2013/59 Directive will come into effect. This directive will set comprehensive standards for radiological best practice across the European Union. These standards will become the benchmarks against which our practice is measurable. The audit subcommittee, under the auspices of the ESR, has designed an audit pack to help you get started and to demonstrate how easy audit can be. The purpose of this lecture is not only to do that, but also suggest why you should do it, how it protects you, your patients, optimizes your equipment and your working environment.

Learning Objectives:
1. To gain an appreciation of the place for audit in radiological practice in the 21st century.
2. To understand the difference between audit and research.
3. To appreciate the importance of re-audit in the audit spiral (helix).

A-554 16:30

Benchmarking: why, how and when?

J. Hakumäki; *Kuopio/FI (juhana.hakumaki@kuh.fi)*

Benchmarking is the comparison of processes and performance with peer organizations. The objectives are usually threefold: to determine what type of functions need to be improved, how top performers achieve their performance, and to use this information for performance improvement. In the context of radiation protection, the main goal is not only the reduction of radiation in particular imaging studies but also the employment of alternative imaging techniques with significantly lower (CBCT) or negligible dose (MRI/US), and how this is best done. The employees and the organization using radiation are ultimately responsible for radiation protection and employment of the ALARA (as-low-as-reasonably-achievable) principles. Guidelines, regulations or vendor efforts always require implementation and may not always be sufficient. Benchmarking serves this goal well by providing performance data from peers to peers. Collection of dosage data is usually simple and standardized, and modern imaging information systems store these data already. Data inspection and analysis, however, usually requires dedicated professionals, such as a medical/hospital physicists to partake in the process. The Eurosafe imaging initiative provides guidelines for compatibility, which is introduced in more detail. Scheduling is governed usually by combination of benchmarking requests initiated by authorities, self-initiated assessment work, as well as those implemented or recommended by the Eurosafe imaging initiative for compatible institutions. The extent of this will naturally be limited by personnel and time devoted to such activity. Benchmarking is normally not especially cost-intensive and integrates well into workflow.

Learning Objectives:
1. To understand why to benchmark radiation doses among institutions.
2. To learn how to collect and compare data and how to be compatible with the EuroSafe Imaging initiative.
3. To understand the scheduling and motives for benchmarking.

A-555 16:45

The value of achieving star status

D. Akata; *Ankara/TR (dakata@hacettepe.edu.tr)*

Stars are often used as symbols for classification and ranking purposes. It is a way to announce publicly the level of quality of the service provider. For the first time in radiology, it is used by ESR to promote and endorse institutions for safer and better radiological practice as part of the Eurosafe imaging campaign. The number of examinations using ionizing radiation is tremendously increasing each year. In this regard, justification of the exams and maintaining doses within diagnostic reference levels, to develop a patient safety culture in medical imaging is highly important. When an institution applies to become a EuroSafe imaging star, it revisits the most updated principles for radiation protection to perform safe imaging. Although one of the goals is to harmonize the patient safety standards, it should be regarded differently from an accreditation process. It is not a pass or fail system. It is a system aiming to achieve for the better. With this voluntary action, an institution can do self-auditing and learn their weaknesses, but also in a way declares to be bound and determined to improve. With the star project, awareness of the basic concepts for safe imaging is created not only by the providers, but also for the patients. Moreover, it will be a motivation for institutions to be in the network of imaging departments committed to best practice in radiation protection for future cooperation in projects.

Learning Objectives:
1. To cause awareness of the basic concepts for safe imaging in order to harmonize patient safety standards.
2. To understand criteria and goals to perform the best clinical practice in radiation protection.
3. To learn to do self-auditing and to identify strengths and weaknesses.
4. To gain an insight in the network of imaging departments committed to best practice in radiation protection for future cooperation in projects.

A-556 17:00

How to improve the EuroSafe Imaging Stars concept?

L. Donoso; *Barcelona/ES (ldonoso@clinic.ub.es)*

Launched in February 2016, the EuroSafe imaging stars initiative has been designed to identify and recognise imaging facilities that embody best practice in radiation protection and that are committed to putting the principles advocated and concepts developed by the European society of radiology into practice. By recruiting a network of imaging departments committed to best practice in radiation protection, the stars initiative will give radiation protection efforts greater visibility, have a direct impact on clinical practice, and enable the ESR to collect data for analysis and benchmarking. To become a EuroSafe imaging star, the applicant facility has to perform a self-assessment according to a list of criteria defined by the ESR. The list of criteria is divided into five sections and imaging facilities will be awarded up to five Stars depending on how many criteria of a certain level they fulfil, i.e. from 'EuroSafe imaging star *' to 'EuroSafe imaging star *****'. After the first year of implementation, it is now time to consider the first experiences and lessons learnt, as well as to review the current criteria; e.g. the EuroSafe imaging stars initiative is currently not targeted towards specialised hospitals, like orthopaedic or paediatric hospitals. These facilities cannot complete the current 'Is your imaging EuroSafe?' surveys, although participation is a prerequisite for becoming a star. Thus, measures have to be considered to improve the EuroSafe imaging stars initiative, e.g. the establishment of additional surveys to collect paediatric patient data.

Learning Objectives:
1. To review the current criteria for the different levels of accreditation.
2. To present the experience and the lessons learned after the first year of implementation.
3. To discuss the possible ways for the improvement of the EuroSafe Imaging Stars initiative.

A-557 17:15

Improving the integration of radiation protection in the clinical setting

G. Frija; *Paris/FR (guy.frija@egp.aphp.fr)*

The basic principles of radiation protection are justification, optimisation and dose limitation. The optimisation process is essential to ensure the necessary image quality with minimal exposure of the patient to radiation dose and to maintain diagnostic efficacy at the same time. The ALARA principle ("as low as reasonable achievable") is followed in the optimisation process, which also has to consider different factors, e.g. equipment, type of examination and body region. Image quality in relation to clinical need would be much more relevant than only dose reduction as part of the optimisation process. When a CT is performed, it is clear that the technical protocol is driven by the clinical indication. The resultant image quality needed for a reliable interpretation is consequently also directly linked to the clinical indication. Therefore, it is very important to record the dose exposure on the basis of the clinical indication rather than on technical and/or anatomical protocols. The development of automatic dose recording systems would also facilitate the establishment of local diagnostic reference levels (LDRLs), which have the advantage of better reflecting the distribution of the patient's body characteristics as well as the disease's prevalence and the performance of the used modalities. In addition, it has already been shown that LDRLs would be an effective tool for improving the clinical practice, as one can only improve what one can measure.

Learning Objectives:
1. To clarify the concept of optimisation in relation to the clinical indication.
2. To show why local diagnostic reference levels are appropriate.

16:00 - 17:30 **Room M 2**

Professional Issues and Economics in Radiology (PIER)

PIER 3

Tailoring radiology departments towards patients' needs

Moderators:
C.D. Becker; Geneva/CH
H. Hricak; New York, NY/US

A-558 16:00

A. Visibility of radiology

N.H. Strickland; *London/UK (nicola.strickland@imperial.nhs.uk)*

Radiologists must raise their visibility with their patients, clinical peers and managers if they are to survive as doctors in the hospital environment, and not be relegated to distant report-producing commodities, or be replaced by non-radiologist doctors and/or non-medical personnel. Their reports must add value by being diagnostic and actionable, and not merely observational descriptions devoid of medical interpretation. Their interventions must be based upon their own informed, collaborative clinical assessment of their patients, not carried out in response to directed instruction from their clinical peers. Diagnostic and interventional radiology underpins the whole of modern medicine and surgery. Radiologists must raise their profile by actively involving themselves in a wide gamut of clinical activity including: medical student and postgraduate teaching, advising upon the patient pathway, multidisciplinary team meetings, patient interactions, multidisciplinary research and managerial decisions. Visibility, accessibility and excellent communication skills are key to raising radiologists' profile and making them an indispensable and valued part of the clinical team.

Learning Objectives:

1. To discuss ways of raising the visibility of radiology with our clinical colleagues.
2. To explore the pros and cons of raising the visibility of radiology with patients.
3. To consider how to make radiology the centre of managers' vision.

A-559 16:18

B. Outsourcing in radiology: costs and quality matters

A. Giovagnoni; *Ancona/IT (a.giovagnoni@univpm.it)*

Outsourcing is defined as buying labour, parts or services from a source outside the company rather than using the company's own staff or resources. Over the last five years, outsourcing has become a global trend in business because, when performed properly, it can produce efficiencies not attainable when these functions are performed internally by an organization. Outsourcing in hospitals is becoming more and more popular. The most common services that are outsourced are non-medical tertiary services; in recent years, however, hospitals have started to outsource medical services, so-called "secondary services", which include laboratory, pathology as well as radiology services. Structured and operated effectively, outsourcing can produce significant benefits while enabling hospitals to focus limited resources and management efforts on other areas. Radiology is increasingly being considered for outsourcing due to its unique operating and funding challenges and because of interest expressed by radiologists and outside vendors. The challenge of responding to constant technological advancement, labour shortages and increasing customer service expectations in the face of declining reimbursement, managed care, capital constraints and outpatient competition are compelling hospitals to consider outsourcing. Moreover, the daunting financial and operational challenge of transitioning radiology from an analogue world to a digital one makes management and funding of radiology even more of a challenge for hospitals. Radiology outsourcing arrangements can be tremendous win-win opportunities for radiologists and hospitals; they are very significant undertakings and should be entered into only with realistic goals, commitment, due diligence and confidence by both parties.

Learning Objectives:

1. To define the various types of outsourcing and discussing advantages and disadvantages.
2. To know and analyse the different stages of the outsourcing process.
3. To analyse the legal issues and professional responsibility.

A-560 16:36

C. Demonstrating the added value of the radiologist: the European approach

P.M.A. van Ooijen; *Groningen/NL (p.m.a.van.ooijen@umcg.nl)*

We live in a world that is constantly changing at a high pace. Many of these changes are related to the advances in computer science and can be quite disruptive and turn things around. These changes also have their effects on healthcare in general and radiology in particular. Many technologies have a disruptive effect on the way radiology is practised now and in the near future. The tasks in the patient treatment process will be re-distributed among healthcare professionals and radiologists should understand this and claim their part of this workload based on their knowledge and experience in medical imaging. This will pose threats to the radiological speciality but it also holds tremendous opportunities that will allow radiology to keep adding value to patient care in the future.

Learning Objectives:

1. To know and acknowledge which disruptive technologies will influence future radiology.
2. To know about different workload distribution models between professionals.
3. To determine new possibilities for radiology to add value to patient care.

A-561 16:54

D. Demonstrating the added value of the radiologist: the US/Canadian approach

G. McGinty; *New York, NY/US (geraldinemcginty@gmail.com)*

Advances in technology such as PACS and voice recognition have made radiologists more efficient and productive but have rendered them largely invisible to their referring physician colleagues and patients. Whereas in the past consultation in the radiology department was common, now many physicians do not know where the radiology department is located and worse, if they find it, the door might be locked because the radiologist is too busy to talk to them! As the US healthcare system has sought to embrace value rather than volume in the "Obamacare" era, radiologists risked being considered a commodity and indeed reductions in reimbursement reflected this misperception. The ACR's imaging 3.0 initiative ignited a culture change among radiologists and has led to greater visibility for radiologists. The radiology community has used its advocacy efforts to shape payment policy to incentivise even more engagement with patients and colleagues as well as provide meaningful metrics and reporting methodologies by which radiologists can demonstrate their value. This presentation will discuss the journey that has taken radiologists "out of the shadows" and provide a vision of the future where the value of radiologists is not only recognised but rewarded.

Learning Objectives:

1. To see the change of radiology as a discipline over the last decades and threats out of this.
2. To learn about opportunities of radiology today.
3. To understand about the continuity of care and the role of radiology in this context.

17:12
Panel discussion

16:00 - 17:30 **Room M 3**

Interventional Radiology

RC 1209
Portal hypertension and interventional radiology (IR)

A-562 16:00
Chairman's introduction
V. Vilgrain; *Clichy/FR (valerie.vilgrain@aphp.fr)*

Portal hypertension (PHT) is a common complication of chronic liver cirrhosis. It is defined by an increase in portal pressure. Complications occur (mostly gastro-oesophageal bleeding and ascites) when the portal pressure exceeds 10 mmHg. The role of imaging is twofold: diagnosis of PHT using morphologic imaging and tissue elasticity and performing interventional procedures (TIPS) when indicated. Such procedures are decided in multidisciplinary team sessions.
Session Objectives:
1. To appreciate the role of multidisciplinary treatment of portal hypertension.
2. To learn about imaging and intervention in portal hypertension.
3. To discuss outcomes of interventions in portal hypertension.

A-563 16:05
A. Imaging of portal hypertension
I. Bargellini; *Pisa/IT (irenebargellini@hotmail.com)*

Portal hypertension (PH) represents a fearful complication of several diseases (most frequently liver cirrhosis), being associated with a significant increase in morbidity and mortality. Ultrasound and cross-sectional imaging (CT and MR) are required to evaluate presence and extent of PH complications (such as varices, splenomegaly, ascites), providing essential information for patient's management and treatment planning. Moreover, several surrogate signs have been described in the attempt to reach a confident non-invasive diagnosis of PH. Nonetheless, as of today, definitive diagnosis of PH is based on the measurement of hepatic venous pressure gradient (HVPG). PH is diagnosed by an HVPG higher than 6mmHg, it is considered clinically significant when HVPG is higher than 10mmHg and severe when HVPG is higher than 12mmHg. A direct relation has been demonstrated between HVPG and risk of variceal bleeding, hepatic decompensation and liver-related mortality, and HVPG has become a surrogate endpoint in the assessment of treatment response and reduction of risk of liver-related mortality. However, HVPG measurement is invasive and is routinely available and reliably standardized only in expert centres. Thus, non-invasive methods, such as elastography, are under investigation, able to identify PH, grade its severity and predict presence, extent and risk of variceal bleeding.
Learning Objectives:
1. To appreciate imaging features of portal hypertension.
2. To discuss the appropriate choice and timing of imaging technique in investigation of portal hypertension and its complications.
3. To learn about relevant findings that influence therapy choice in portal hypertension.
Author Disclosure:
I. Bargellini: Advisory Board; Bayer. Speaker; Bayer, Ge Healthcare, Biocompatibles UK Ltd, Sirtex,.

A-564 16:28
B. Embolisation of varices and splenic artery in portal hypertension
I.E. Keussen; *Lund/SE (inger.keussen@med.lu.se)*

Portal hypertension is the most common secondary to liver cirrhosis; however, it can also be caused by portal/splenic vein thrombosis or occlusion. A bleeding secondary to portal hypertension usually originates from esophageal or gastric varices, other sites may be duodenal, stomal or rectal varices. A bleeding from oesophageal varices is primarily most often treated endoscopically with sclerotherapy or rubber banding. Gastric varices are less prevalent but more difficult to treat endoscopically. If medical and endoscopic treatment methods fail, interventional treatment is the next option, which includes embolisation of varices, TIPS, BRTO and partial splenic arterial embolisation. Embolisation of varices may be performed by percutaneous or transjugular-transhepatic approach, but trans-splenic route or direct puncture of the stomal varices are also reported. A BRTO may be applied in patients with a spleno-renal shunt and secondary gastric varices. Partial splenic embolisation may decrease inflow of blood to the portal vein and secondary decrease the portal hypertension. In most cases, a combination of different techniques is necessary to achieve good results.
Learning Objectives:
1. To discuss the rationale for embolisation.
2. To learn about the selection of technique and choice of material.
3. To understand outcomes from embolisation techniques.

A-565 16:51
C. Transjugular intrahepatic portosystemic shunt (TIPS): critical appraisal of techniques and guidelines for treatment
A. Krajina; *Hradec Králové/CZ (antonin.krajina@fnhk.cz)*

TIPS is a percutaneous, minimally invasive method of creating a portosystemic shunt for decompression of portal hypertension (PH). Using transjugular approach, long needle, balloon angioplasty, and stent-graft, a side-to-side shunt of determined diameter is created to shunt blood flow from the portal vein (PV) to hepatic vein or inferior vena cava above the liver. The most often indication for TIPS is cirrhotic ascites, which is sometimes combined with severe hydrothorax. However, TIPS should be used only in those patients who are intolerant of repeated large-volume paracentesis. TIPS has been used as a rescue treatment in rare cases of endoscopically uncontrollable variceal bleeding, especially from gastric fundal varices. Emergent TIPS (in 72 hours) performed in patients with severe PH and high risk of early rebleeding has been proved to have better bleeding control and survival in 1 year. Partial or complete PV thrombosis does not change usual technique of TIPS. TIPS is technically difficult in chronic extrahepatic PV obstruction, in children, and in patients with massive hepatic veins thrombosis (Budd Chiari Syndrome - BCS). The absence of hepatic veins and distorted anatomy due to the caudate lobe hypertrophy requires sometimes direct transcaval approach to the PV in patients with BCS. Moreover, these patients must be anticoagulated life long due to underlying hypercoagulopathy. TIPS demonstrated good control of ascites and reversal of liver failure in large series of patients with BCS. All patients with TIPS must be followed regularly in specialized multidisciplinary centre, and the surveillance of TIPS function is mandatory.
Learning Objectives:
1. To discuss the selection of patients for TIPS.
2. To learn about the techniques for TIPS formation.
3. To discuss outcomes of TIPS and role of imaging surveillance.

17:14
Panel discussion: Appropriate selection of patients for IR including the role of balloon-occluded retrograde transvenous obliteration (BRTO) for gastric varices

16:00 - 17:30 **Room M 4**

Special Focus Session

SF 12c
Gadolinium contrast agents: a Yin and Yang story

A-566 16:00
Chairman's introduction
B. Hamm; *Berlin/DE (bernd.hamm@charite.de)*

Reports that gadolinium is deposited in the body (e.g. brain, bone and skin), though in very small amounts, have shaken the radiological community. This session will first present the latest preclinical data on gadolinium deposition and possible mechanisms of gadolinium tissue accumulation. Next, we will proceed from preclinical insights to the latest clinical findings regarding gadolinium deposition and possible strategies to deal with the challenges faced by radiologists using gadolinium-based contrast agents in MR imaging. Finally, for our daily clinical work, we are also interested in possible future guidelines of the regulatory authorities. The session will conclude with a discussion among the speakers and the audience.
Session Objectives:
1. To become familiar with our current understanding of gadolinium deposition in the body.
2. To learn about the latest clinical and preclinical findings regarding gadolinium deposition.
3. To understand possible mechanisms underlying gadolinium deposition in the body.
4. To learn about the current opinion and strategy of the regulatory authorities.
5. To learn about possible strategies to deal with the challenge of gadolinium deposits.
Author Disclosure:
B. Hamm: Board Member; Deutsche Röntgengesellschaft, ECR, ESR, ESMRMB, ESOR, Deutsche Forschungsgemeinschaft. Grant Recipient; Abbott, Kendle/MorphoSys AG.

A-567 16:05

Latest preclinical data on gadolinium deposition

H.A. Rowley; *Madison, WI/US (hrowley@uwhealth.org)*

This section will provide an update and synthesis of basic science aspects and preclinical studies relevant to gadolinium deposition, with an emphasis on brain findings. To understand gadolinium deposition we must first understand the physiology of transportation, uptake, elimination, localization, and potential retention for metals in general, not just gadolinium. Animal investigations, clinical MRI, and pathologic studies show evidence for iron, calcium, and manganese preferentially localizing to the same deep grey nuclei in the brain as those areas 'stained' with gadolinium, suggesting shared mechanisms of deposition. Tissue levels of gadolinium deposition seen after clinically relevant doses are far below known toxic thresholds, and to date, no signs of tissue damage (e.g. gliosis or neuronal dropout) or corresponding neurologic deficits have been observed. It is important to recognize that all marketed gadolinium agents have been linked to varying levels of gadolinium retention in the body, regardless of specific agent or structural class (e.g. linear vs macrocyclic). Due to underlying physics and chemistry, we must recognize that MRI metrics (T1 signal hyperintensity or relaxometry changes) and tissue data may or may not be well correlated. MRI detection of T1 shortening relies on gadolinium species that are bound to either a chelate or macromolecules; gadolinium phosphates and other salts do not contribute to MRI signal changes but can still be detected using tissue assays. Levels of deposition depend on the organ, cumulative dose, time after injection, the specific pharmaceutical agent, and host factors including prior radiation or chemotherapy.

Learning Objectives:

1. To become familiar with the latest preclinical data on gadolinium deposition.
2. To learn about possible mechanisms of gadolinium deposition in tissues.
3. To be informed about ongoing preclinical studies to avoid gadolinium deposition.

Author Disclosure:

H.A. Rowley: Consultant; GE, Bracco, Bayer, Guerbet, Gore, Genentech.

A-568 16:28

Current clinical situation based on published data

V. Runge; *Berne/CH*

Omniscan, Magnevist, and MultiHance (all being linear gadolinium chelates) are now known to be associated with dentate nucleus hyperintensity, specifically high signal intensity within the dentate nucleus on T1-weighted scans seen pre-contrast after 5 or more prior injections. Dotarem, Gadovist and ProHance, the macrocyclic chelates, are not so associated. Dentate nucleus hyperintensity is likely to reflect more general gadolinium deposition throughout the body in these patients with normal renal function. In patients receiving a very high number of injections, hyperintensity is observed in many other nuclei and structures within the brain. Initial reports suggest associated clinical symptomatology, but are not definitive. The following recommendation has been made by the National Institutes of Health - "When GBCAs are required, consider the use of a macrocyclic GBCA (e.g. gadobutrol, gadoteridol, gadoterate meglumine) rather than a linear agent". The EMA is likely soon to act, with a possible outcome of this and other actions being the withdrawal of multiple agents.

Learning Objectives:

1. To learn about the latest clinical findings regarding gadolinium deposition.
2. To be informed about the latest trends concerning gadolinium deposition in academia.
3. To learn about possible strategies to deal with the challenge of gadolinium deposits.

Author Disclosure:

V. Runge: Advisory Board; Bayer. Research/Grant Support; Bayer, Guerbet. Speaker; Bayer.

A-569 16:51

What is the position of the regulatory authorities?

O. Clément; *Paris/FR*

There are a considerable amount of studies published in the last 3 years showing hyperintensities in the dentate nucleus in patients having received multiple injections of gadolinium chelates, especially with linear chelates. This new safety concern about gadolinium chelates is happening 6 years after the nephrogenic systemic fibrosis crisis where the European Medicines Agency (EMA) released decisions concerning the classification and use of gadolinium chelates in renal insufficiency. Here, new clinical aspects have to be taken into account: who are the populations at risks? Which chelates are involved? Should the marketing authorisations be changed? On March 2016, the European Commission triggered a procedure under article 31 of Directive 2001/83/EC and asked the Pharmacovigilance Risk Assessment Committee (PRAC) to assess the impact of the new findings on the benefice/risk balance of gadolinium chelates and to issue recommendation concerning the marketing authorisations. The procedure included questions to the pharmaceutical companies, and the organisation of an ad hoc expert group at the EMA. The final conclusions are still awaited at the time of writing this abstract, but might be public during ECR 2017.

Learning Objectives:

1. To learn about the current opinion and strategy of the regulatory authorities.
2. To learn about possible strategies to deal with the challenge of gadolinium deposits.
3. To learn whether alternative contrast agents will become available in the near future.

17:14

Panel discussion: After all that, what are you doing?

16:00 - 17:30 **Room M 5**

Joint Session of the ESR and the EANM

Common diagnostic guidelines on diabetic foot, osteomyelitis and prosthetic joint infection

Moderators:
V.N. Cassar-Pullicino; Oswestry/UK
A. Signore; Rome/IT

A-570 16:00

Guidelines on osteomyelitis (part 1)

L.M. Sconfienza; *San Donato Milanese/IT (io@lucasconfienza.it)*

Although the bone was one of the first organs to be evaluated in radiology, the diagnosis of osteomyelitis still remains a challenge. Over time, plain radiography, computed tomography and magnetic resonance imaging have been variously used to detect acute and chronic osteomyelitis in different locations of the body. On the other hand, nuclear medicine has been also used with good diagnostic performance. From 2013 onwards, a collaboration between ESR, EANM and the relevant clinical societies has taken place to develop common guidelines on the topic. In this session, we present the process which led to the development of these guidelines and the results of such a work.

Learning Objectives:

1. To learn about the current literature evidence on the diagnosis of osteomyelitis using radiological and nuclear medicine modalities.
2. To understand the consensus process that led to build common diagnostic flowcharts on osteomyelitis.
3. To become familiar with diagnostic flowcharts on osteomyelitis involving radiological and nuclear medicine modalities.

Author Disclosure:

L.M. Sconfienza: Equipment Support Recipient; Travel grants by Bracco Imaging Srl / Esaote.

A-571 16:15

Guidelines on osteomyelitis (part 2)

A. Glaudemans; *Groningen/NL (a.w.j.m.glaudemans@umcg.nl)*

In this session the latest version of the joint guidelines on the imaging of peripheral bone infection are presented. These guidelines have been prepared with the collaboration of delegates from ESR, EANM, ESCMID and EBJIS. The focus in this nuclear medicine part will be on the statements presented in the guidelines that focus on nuclear medicine techniques.

Learning Objectives:

1. To learn about the current literature evidence on the diagnosis of osteomyelitis using radiological and nuclear medicine modalities.
2. To understand the consensus process that led to build common diagnostic flowcharts on osteomyelitis.
3. To become familiar with diagnostic flowcharts on osteomyelitis involving radiological and nuclear medicine modalities.

A-572 16:30

Guidelines on prosthetic joint infection (part 1)

L.M. Sconfienza; *San Donato Milanese/IT (io@lucasconfienza.it)*

With ageing of general population, prosthetic substitution of joints has become extremely diffuse. Prosthetic joint infection (PJI) is a complication occurring in about 3% of patients undergoing prosthetic substitution of joints. The diagnosis of PJI still remains a challenge. Over time, plain radiography, computed tomography and magnetic resonance imaging have been variously used to detect the presence of infection around metallic implants. On the other hand, nuclear medicine has been also used with good diagnostic performance. From 2013 onwards, a collaboration between ESR, EANM and the relevant clinical

societies has taken place to develop common guidelines on the topic. In this session, we present the process which led to the development of these guidelines and the results of such a work.

Learning Objectives:

1. To learn about the current literature evidence on the diagnosis of prosthetic joint infection using radiological and nuclear medicine modalities.
2. To understand the consensus process that led to build common diagnostic flowcharts on prosthetic joint infection.
3. To become familiar with diagnostic flowcharts on prosthetic joint infections involving radiological and nuclear medicine modalities.

Author Disclosure:

L.M. Sconfienza: Equipment Support Recipient; Travel grants Bracco Imaging / Esaote.

A-573 16:45

Guidelines on prosthetic joint infection (part 2)

O. Gheysens; *Leuven/BE (olivier.gheysens@uzleuven.be)*

The number of joint prosthesis replacements is still increasing due to an increased life expectancy. Even though in the majority of patients, better joint function and pain relief is obtained, prosthetic joint infection (PJI) is a complication with an incidence between 2 and 4%, which leads to a high socio-economic burden. Early diagnosis of PJI is of utmost importance to save the prosthesis and joint function. In this session, we will present the latest joint guidelines for the diagnosis of PJI. These guidelines have been prepared in collaboration between EANM and ESR as well as the clinical societies (EBJIS and ESCMID).

Learning Objectives:

1. To learn about the current literature evidence on the diagnosis of prosthetic joint infection using radiological and nuclear medicine modalities.
2. To understand the consensus process that led to build common diagnostic flowcharts on prosthetic joint infection.
3. To become familiar with diagnostic flowcharts on prosthetic joint infections involving radiological and nuclear medicine modalities.

A-574 17:00

Guidelines on diabetic foot complications (part 1)

A. Leone; *Rome/IT (a.leonemd@tiscali.it)*

Soft tissue and bone superimposed infection involving the foot is one of the most common long-term complications of diabetes mellitus. Diagnosing these complications is crucial to make proper decisions regarding therapeutic strategies, and should be clinically based on the presence of local or systemic signs or symptoms of inflammation. However, a probable diagnosing is reasonable if there are positive results on a combination of diagnostic tests such as probe-to-bone, serum inflammatory markers, and imaging modalities. Each imaging modality, however, does not provide enough information alone and a multimodal approach should be used for an accurate diagnosis. In an effort to provide guidance for diagnosing diabetes-related foot complications, this presentation is divided into 3 parts: part 1 will review diabetic foot complications and illustrate their major radiological imaging features. Part 2 will present the consensus process that led to build common diagnostic flowcharts on diabetic foot complications. Part 3 will illustrate some cases to become familiar with these diagnostic flowcharts.

Learning Objectives:

1. To learn about the current literature evidence on the diagnosis of diabetic foot complications using radiological and nuclear medicine modalities.
2. To understand the consensus process that led to build common diagnostic flowcharts on diabetic foot complications.
3. To become familiar with diagnostic flowcharts on diabetic foot complications radiological and nuclear medicine modalities.

A-575 17:15

Guidelines on diabetic foot complications (part 2)

A. Signore; *Rome/IT (alberto.signore@uniroma1.it)*

In this session, we will present the latest version of the joint guidelines prepared in collaboration between EANM and ESR on the imaging of infections in several musculoskeletal diseases, such as the diabetic foot, spondylodiscitis, prosthetic joint infections and peripheral bone osteomyelitis. These guidelines have been prepared also with the collaboration of other clinical European societies such as the EASD, the ESCMID, the ESNR and the EBJIS.

Learning Objectives:

1. To learn about the current literature evidence on the diagnosis of diabetic foot complications using radiological and nuclear medicine modalities.
2. To understand the consensus process that led to build common diagnostic flowcharts on diabetic foot complications.
3. To become familiar with diagnostic flowcharts on diabetic foot complications radiological and nuclear medicine modalities.

Saturday, March 4

08:30 - 10:00 **Room A**

E³ - ECR Academies: Interactive Teaching Sessions for Young (and not so Young) Radiologists

E³ 1321
Imaging of abdominal tumours

A-576 08:30
A. Liver tumours
A. Luciani; *Créteil/FR (alain.luciani@aphp.fr)*

Imaging of liver tumours relies on optimal imaging instrumentation, thorough understanding of the key underlying liver diseases, and on key diagnostic elements. This session should provide attendees with the main elements allowing an accurate management of patients suspected of baring liver tumours. Current guidelines recommend that MRI and ultrasound, especially contrast-enhanced ultrasound (CEUS) should be preferred to CT for the diagnosis of benign liver tumours. The lecture will provide the opportunity to review key diagnostic features of liver cysts, haemangiomas and focal nodular hyperplasia (FNH). The differential diagnosis with liver hepatocellular adenomas and the specific role of hepatobiliary contrast agents in that context will also be discussed. Current guideline for the detection and characterisation of patients with underlying chronic liver disease will be reviewed, including the most up-to-date criteria for non-invasive HCC characterisation. Last, the imaging management strategies of liver metastases will be presented.
Learning Objectives:
1. To become familiar with the differential diagnosis.
2. To identify the key imaging findings.
Author Disclosure:
A. Luciani: Grant Recipient; Bracco. Investigator; GEMS. Research/Grant Support; GEMS, Siemens Helathcare. Speaker; GEMS.

A-577 09:15
B. Pancreatic tumours
C. Matos; *Lisbon/PT (celso.matos@fundacaochampalimaud.pt)*

Despite the advent of more and more sophisticated imaging techniques (US, CEUS, EUS, MDCT, MRI, PET-CT) the diagnosis and staging of pancreatic solid lesions remains a challenge. As for other organs and disease entities no single imaging modality is perfect. Differential diagnosis and management decisions are based on a mixture of clinical information and imaging findings involving multiple modalities. This lecture will familiarise the attendees with old truths, main challenges and new trends in the diagnosis of pancreas tumours, differential diagnosis with pancreas inflammation, and in identifying features that may help to select surgical candidates.
Learning Objectives:
1. To become familiar with the differential diagnosis.
2. To identify the key imaging findings.

08:30 - 10:00 **Room B**

GI Tract

RC 1301
Difficult challenges in imaging the acute abdomen
Moderator:
S.K. Puri; New Delhi/IN

A-578 08:30
A. Perforation of the GI tract
V. Maniatis; *Aabenraa/DK (vmaniatis67@gmail.com)*

Perforation of the gastrointestinal tract represents an emergency and life-threatening condition. Causes of perforation may be traumatic (endoscopy, blunt trauma, ingested foreign body), inflammatory (peptic ulcer disease, diverticulitis, appendicitis, Crohn's disease or other enteritis), bowel ischaemia and neoplasms. Clinical diagnosis may be difficult and patients may be first radiologically evaluated with plain radiographs or ultrasound but with limited information in cases of perforation. CT scanning is by far the imaging method of choice in cases of perforation. CT findings of gastrointestinal tract perforation can be direct or indirect. Direct findings include free air or/and oral contrast either intra- or retroperitoneal. Indirect findings comprise inflammatory mass surrounding an appendicolith or a radiopaque foreign body. Non-specific findings include bowel wall thickening, mesenteric infiltration, interloop free fluid and abnormal bowel wall enhancement. With the use of both direct and indirect findings, the sensitivity of CT in diagnosing gastrointestinal tract perforation is up to 92%. False-positive results usually occur in post-operative patients, where free air as a result of previous operation can be misdiagnosed as a sign of anastomotic leak or iatrogenic bowel trauma. CT is also able to depict the site of perforation with an overall accuracy between 82 and 90% and the cause of perforation in up to 67% of cases. It is well documented that CT plays a crucial role in the assessment of patients with gastrointestinal tract perforations, by offering fast and accurate essential information to the clinicians and enabling the most correct therapeutic choice.
Learning Objectives:
1. To learn about the main causes and clinical symptoms of GI tract perforation.
2. To become familiar with the imaging methods used to detect GI tract perforation and with relevant diagnostic algorithms.
3. To appreciate the important imaging appearances indicative of GI tract perforation. What should radiologists not miss?

A-579 09:00
B. Bowel obstruction
A.J.B.S. Madureira; *Porto/PT (ajbmadureira@gmail.com)*

Bowel obstruction is an important cause of surgical admissions for acute abdominal pain, with high morbidity and mortality if left untreated. The diagnosis can be suggested by plain abdominal films but CT plays a crucial role in the diagnosis and management of these patients. It can confirm the diagnosis, grade the severity of the obstruction, locate it, and provide the aetiology. A dedicated technique is necessary and multiplanar reconstructions are mandatory. The causes of small bowel obstruction can be divided into intrinsic (inflammatory diseases, neoplasia), extrinsic (adhesions, hernias), and intraluminal (gallstones, bezoars). The three most frequent causes of large bowel obstruction are neoplasm, volvulus, and diverticulitis. The imaging findings vary according to the cause, and some are very specific. CT can provide a quick diagnosis and allow an early and optimal management of these patients, contributing to an improved survival.
Learning Objectives:
1. To learn about the different types and causes of bowel obstruction.
2. To become familiar with relevant imaging signs in both small and large bowel obstruction including complications.
3. To appreciate the most widely used imaging approach for detection and evaluation of bowel obstruction.

A-580 09:30
C. Acute biliary conditions
C.D. Becker; *Geneva/CH*

Acute cholangitis is a serious condition which occurs most commonly in the context of bile duct obstruction du to stone disease or strictures. Unless diagnosed and treated correctly, acute cholangitis may lead to liver abscess formation, septicemia and multiorgan failure. The role of noninvasive imaging is to determine the presence of obstruction of the biliary tree, as well as its level and its cause. Although ultrasonography or computed tomography are most commonly used in the emergency situation, magnetic resonance imaging offers the most detailed diagnostic results, especially with regard to the cause obstruction. Depending on the level and the cause of bile duct obstruction, decompression of the biliary tree may be done by means of minimally invasive interventional techniques either via the endoscopic-retrograde or the percutaneous-transhepatic approach. Acute gallbladder disease is most often associated with calculous disease and obstruction of the cystic duct, although it may also occur without the presence of calculi (acalculous cholecystitis). Ultrasonography should always be used as the first line method in suspected gallbladder disease.
Learning Objectives:
1. To learn about the most common pathologies leading to acute biliary conditions.
2. To become familiar with the relevant multimodality imaging appearances in this group of patients.
3. To appreciate the role of interventional radiology in the management of these conditions.

08:30 - 10:00 **Room C**

Special Focus Session

SF 13a
Cases I'll never forget in chest imaging

A-581 08:30
Chairman's introduction
A.P. Parkar; *Bergen/NO (apparkar@gmail.com)*

Errors in radiology reporting occur regularly, and the underlying causes are well studied and documented. Most errors are recognized early and do not cause permanent harm, but sometimes the delays caused by errors lead to serious harm to patients. The errors can be divided into perceptual (observational) and cognitive (interpretative) errors, the prior being the most common, up to 80% of errors. The pathology is not seen or observed, often as it is hidden behind another structure or in an uncommon location. Sometimes the reason why it was missed initially cannot be found when reviewed retrospectively. In addition, an additional finding may be missed due to so-called “satisfaction of search”. Cognitive errors are when the pathology is seen but interpreted incorrectly. This may be because the reader is misled by irrelevant clinical information, or simply lacks the knowledge to understand the clinical relevance of the finding. In chest radiology, there are pitfalls in the plain radiographs related to certain anatomical areas, to the way the image has been performed (supine or with insufficient inspiration) or inherent limitations of the modality. Lung cancers are frequently missed, and up to 50% of nodules below 10mm are missed initially on radiography. A systematic approach to reading chest radiographs and CT images is necessary to avoid common reporting errors.
Session Objectives:
1. To become familiar with the common mistakes in chest imaging.
2. To understand the value and limitation of pattern recognition.
3. To appreciate the value of combing pattern recognition and clinical information.

A-582 08:34
Nodules (0.4-2 cm)
A.R. Larici; *Rome/IT (annarita.larici@unicatt.it)*

Errors in imaging interpretation are the principal causes that bring a radiologist to remember a certain case for the whole life, and this eventuality may occur both in chest radiographs and CT scans. Observer error is one of the most important mechanisms leading to a misdiagnosis of a pulmonary nodule and includes scanning error, recognition error, decision-making error and satisfaction of search. Technical considerations, such as image quality and patient positioning and movement, are also factors that can contribute to the likelihood of missing lung nodules, mainly on chest radiographs. Nodule characteristics also play a critical role and include size, conspicuity and location. Up to 96% of nodules are less than 10 mm, with a reported malignancy rate of 1-12%. These nodules may be easily missed on chest radiographs, particularly if they show ill-defined margins or ground-glass density, or if they are masked by superimposed chest structures or have endobronchial location. To learn about chest anatomical details and to become familiar with the possible appearance and differential diagnosis of pulmonary nodules is helpful in avoiding misinterpretation. This presentation will cover the learning objectives using side-by-side plain films and CT scans in most of the selected cases, to help understand how to systematically review chest x-ray and improve radiologist’s accuracy in interpreting this challenging topic.
Learning Objectives:
1. To understand the anatomical and pathological basis.
2. To learn about typical diagnoses and differentials.
3. To appreciate typical caveats and pitfalls.

A-583 08:43
Masses and consolidation (> 2 cm)
C.P. Heussel; *Heidelberg/DE (heussel@uni-heidelberg.de)*

A mass is any pulmonary, pleural, or mediastinal lesion seen on chest radiographs as an solid or partly solid opacity greater than 3 cm in diameter (Fleischner Society: Glossary of Terms for Thoracic Imaging, Radiology 246). Radiologists are expected to identify masses sensitive and easy on chest x-ray; however, detectability might be difficult due to, e.g. superimposition. Consolidations, however, suffer mainly from correct differential diagnosis taking clinical information into account. Knowledge of anatomy, sensibility to the weaknesses of conventional radiology, and differential diagnoses are helpful for correct image reading and interpretation. Similar to masses, a consolidation appears as a homogeneous increase in pulmonary parenchymal attenuation that obscures the margins of vessels and airway walls usually giving an positive pneumobronchogram. Therefore, a series of abnormal chest x-ray is demonstrated with giving the audience the possibility for own image analysis like a quiz. Furthermore, characterization will be discussed in other lesions.
Learning Objectives:
1. To understand the anatomical and pathological basis.
2. To learn about typical diagnoses and differentials.
3. To appreciate typical caveats and pitfalls.

A-584 08:52
Ground glass opacity
M.-P. Revel; *Paris/FR (marie-pierre.revel@aphp.fr)*

Ground glass opacity (GGO) is defined by a hazy increased opacity which does not obscure the underlying vascular markings of the lung parenchyma. It may result from a partial filling of the alveolar spaces, a thickening of the alveolar walls or septal interstitium, or from a combination of these changes. On CT, it is important to evaluate whether the GGO is focal or diffuse, and in diffuse forms to look for homogeneity, distribution and ancillary findings such as traction bronchiectasis, intralobular lines resulting in a crazy-paving pattern, the presence of cysts, of lobule sparing. The main differential diagnosis is mosaic perfusion, characterized by an asymmetry of vessels between the low and high attenuating areas. Diffuse GGO may also be overlooked, but can be suspected if the “dark bronchus sign” is present. To find out the cause, it is important to take into account the chronicity of symptoms, the patient's immune status, smoking history and preexisting medical condition.
Learning Objectives:
1. To understand the anatomical and pathological basis.
2. To learn about typical diagnoses and differentials.
3. To appreciate typical caveats and pitfalls.

A-585 09:01
Reticular pattern
J. Coolen; *Leuven/BE (johan.coolen@uzleuven.be)*

When a collection of innumerable small linear opacities on CXR or HRCT merges into an network we speak about reticulation. On HRCT it is one of the imaging findings that may suggest the presence of a diffuse interstitial lung disease (ILD). The Fleischner Society propose this ‘reticular pattern’ in the glossary of terms, because this pattern approach is not purely descriptive but already contains some interpretation of what is seen and hence narrows the differential diagnosis. The key points are to identify the dominant types of linear opacities (interlobular/perilobular/intralobular), to establish what portion of the lung is predominantly involved (central/peripheral and upper/mid/lower zone) and to describe the appearance of reticulation (smooth/nodular/irregular). When all the radiological patterns (ground glass/nodular/honeycombing/mosaic attenuation) or other radiological signs are correctly interpreted, the radiologist must be aware whether these findings fit with acute disease or are more likely to be associated with chronic inflammatory or even fibrotic change of lung tissue. This format provides mostly a pattern-based specific diagnosis or a shortened list of differential diagnoses. However, in ILD establishing the correct diagnosis, mostly an integrated pathologic-radiologic-clinical correlation is mandatory.
Learning Objectives:
1. To understand the anatomical and pathological basis.
2. To learn about typical diagnoses and differentials.
3. To appreciate typical caveats and pitfalls.

A-586 09:10
Cystic pattern
S.R. Desai; *London/UK*

"no abstract submitted"
Learning Objectives:
1. To understand the anatomical and pathological basis.
2. To learn about typical diagnoses and differentials.
3. To appreciate typical caveats and pitfalls.

A-587 09:19
Airway abnormalities
E. Castañer; *Sabadell/ES (ecastaner@tauli.cat)*

Radiologists are crucial in the diagnosis of airway abnormalities. Conventional radiography is the first step but often lesions are identified only when large. MDCT plays an important role in the characterization of lesions and improved planning for interventional procedures. The radiologist is often the first to suggest the diagnosis of a diffuse tracheal disease. A systematic approach to a large-airway lesion considers the focality or diffuseness of the lesion, the airway that is involved, and whether the posterior airway membrane is

involved. By noting the wall portion affected and its abnormal characteristics sometimes a diagnosis can be suggested. Some entities cause circumferential wall thickening (Wegener´s granulomatosis, amyloidosis, intestinal inflammatory disease), whereas others affect mainly the tracheal cartilage (relapsing polychondritis, tracheobronchopathia osteochondroplastica). We will review the anatomy and histology of the airways, and present some demonstrative cases. Most errors in diagnosing central airway disease are caused by our failure to look at these structures. If we remember to look at the airways, we usually have no difficulties in recognizing disease.

Learning Objectives:

1. To understand the anatomical and pathological basis.
2. To learn about typical diagnoses and differentials.
3. To appreciate typical caveats and pitfalls.

A-588 09:28

Vascular abnormalities

M. Das; *Maastricht/NL*

"no abstract submitted"

Learning Objectives:

1. To understand the anatomical and pathological basis.
2. To learn about typical diagnoses and differentials.
3. To appreciate typical caveats and pitfalls.

A-589 09:37

Pleural disease

C. Beigelman; *Lausanne/CH*

Common reporting errors regarding pleural disorders may be related to the difficult recognition of findings with chest x-ray such as those related to a pneumothorax in supine position or intrafissural in location. The projection of a device or the presence of an underlying lung disease such as bullae of emphysema may also be responsible of an underestimation (satisfaction of search) of a pneumothorax. All these mistakes are usually solved using CT. Errors in interpretation may also delay the accurate diagnosis. This is especially the case for focal pleural thickening (PT) that may be related to typical pleural plaques, but may also correspond to normal structures, previous tuberculosis, pleural metastasis, silicosis, or other rarer conditions. Furthermore, postero-basal PT in supine examination may be reversible on prone position. In all cases, a careful analysis of other CT findings, of previous imaging studies and the clinical history (previous malignancy, talc pleurodesis) are determinant for the final diagnosis. Features suggestive of malignancy include circumferential pleural thickening, nodular pleural thickening, parietal pleural thickening greater than 1 cm and mediastinal pleural involvement. However, atypical aspects such as pleural effusion even without plaque and pleural irregularity may be observed in mesothelioma and slight changes in the mediastinal or interlobar pleura should be considered suspicious of this diagnosis. The correct recognition of such potential pitfalls will ensure the best diagnostic quality for the patients.

Learning Objectives:

1. To understand the anatomical and pathological basis.
2. To learn about typical diagnoses and differentials.
3. To appreciate typical caveats and pitfalls.

09:46

Panel discussion: How to avoid common mistakes in the interpretation of chest imaging?

08:30 - 10:00 **Room O**

Special Focus Session

SF 13b

Cardiac imaging in prevention and screening: who, when and how?

A-590 08:30

Chairman's introduction

T. Leiner; *Utrecht/NL (t.leiner@umcutrecht.nl)*

The widespread availability of ultrasonography, multidetector row CT and fast-gradient MR systems has enabled high-quality cardiac imaging in many centres. This has converged with the recognition that early and subtle alterations in cardiac structure and function can be detected before becoming clinically relevant. In this session, we explore the role of cardiac imaging in prevention and screening. In the first part, the role of cardiac imaging in athletes is discussed, including the ability of imaging techniques to differentiate effects of physical training from cardiac disease. The second lecture will focus on the complementary role of imaging in individuals with elevated cardiac risk factors over clinical risk scoring systems. The third lecture will cover the role of imaging in screening for cardiac disease of suspected or known genetic origin.

Session Objectives:

1. To recognise and interpret cardiac alterations in athletes, individuals with elevated cardiac risk factors and patients with suspected genetic cardiac disease.
2. To understand when and in whom cardiac imaging is indicated according the best available evidence today.
3. To perscribe practical MR and CT approaches in populations that qualify for prevention and screening using imaging.

Author Disclosure:

T. Leiner: Board Member; Society for Cardiovascular Magnetic Resonance (SCMR), European Society for Magnetic Resonance in Medicine and Biology (ESMRMB). Grant Recipient; Netherlands Heart Foundation, Technology Foundation STW, Netherlands Organisation for Scientific Research,. Research/Grant Support; Bayer, Bracco, Philips. Speaker; Philips.

A-591 08:35

Cardiac imaging in athletes: what is normal, what is abnormal?

B.K. Velthuis; *Utrecht/NL (b.k.velthuis@umcutrecht.nl)*

High levels of sports training generate physiological cardiac adaptation with balanced increase in biventricular size and ventricular hypertrophy. The degree of ventricular dilatation and myocardial wall thickness depends on several factors, including sex, ethnicity, sport discipline, training level and doping. Understanding these changes is essential to distinguish normal variance and sport-adaptation from mild forms of cardiomyopathy. The largest dimensions are usually seen in male endurance athletes. African/Afro-Caribbean athletes can show higher wall thickness and more hypertrabeculation which should not be confused with hypertrophic or non-compaction cardiomyopathy. Long-term high-level endurance sports can induce atrial fibrillation, myocardial fibrosis, more coronary artery calcification and ARVC-like right ventricular dilatation and arrhythmias. Cardiac events in young athletes (<35 years of age) are rare and mostly caused by cardiomyopathy, channelopathies, malignant coronary artery anomalies and myocarditis. Echocardiography is the first imaging investigation if screening reveals abnormalities or athletes are symptomatic, but cardiac MRI is the most all-round imaging modality. Cardiac MRI is better for assessing possible cardiomyopathies, myocardial fibrosis and ischaemia detection. Most cardiac events occur in older male recreational sportsmen and the majority are related to atherosclerotic coronary artery disease (CAD). Low-dose coronary CT, with non-contrast CT to evaluate coronary artery calcium and CT angiography to assess the full extent of the atherosclerotic burden and degree of stenosis, has additional value to a sports-medical examination for screening older athletes or in athletes with atypical complaints. Cardiac events can be triggered by demand ischaemia, even without a significant coronary stenosis.

Learning Objectives:

1. To recognise the spectrum of cardiac alterations due to physical activity and how to differentiate these from disease.
2. To understand the differences in cardiac alterations due to different types of physical activity and training duration.
3. To understand the benefits and limitations of coronary CT in athletes.

A-592 08:58

Screening of individuals with cardiac risk factors: what to look for?

M. Dewey; *Berlin/DE (marc.dewey@charite.de)*

Addressing patients with an increased cardiac risk clinically is difficult. Magnetic resonance (MR) imaging and/or computed tomography (CT) might improve the discrimination of patients with an increased cardiac event risk from those without. The strengths and weaknesses of MR imaging and CT will be discussed. Randomised controlled trials such as PACC, FACTOR-64 and EISNER as well as large-scale population studies such as MESA, SHIP, SCAPIS, UK Biobank, German NaKo, and ROBINSCA will be introduced. Finally, I will outline when and in whom cardiac imaging might be beneficial as a screening approach to better target preventive therapies.

Learning Objectives:

1. To understand the role of imaging techniques in patients with elevated risk for cardiovascular events.
2. To understand the strengths and weaknesses of different imaging modalities.
3. To understand when and in whom cardiac imaging is indicated.

Author Disclosure:

M. Dewey: Author; “Coronary CT Angiography”, Springer, 2009, “Cardiac CT”, Springer 2011 and 2014. Consultant; Guerbet. Terms of arrangements are managed by the legal Dept. of Charité Berlin.

A-593 09:21

Evidence base and guidelines for screening genetic cardiac diseases

J. Moon; *London/UK*

"no abstract submitted"

Learning Objectives:

1. To review cardiac imaging findings that can provide clinically important information in patients with suspected genetic cardiac disease.
2. To understand when and in whom cardiac imaging is indicated for screening for manifestations of genetic diseases involving the heart.

09:44

Panel discussion: Who, when and how to screen?

08:30 - 10:00 **Room N**

Head and Neck

RC 1308

Post-treatment imaging of the head and neck

A-594 08:30

Chairman's introduction

H.B. Eggesbø; *Oslo/NO (h.b.eggesbo@medisin.uio.no)*

Head and neck cancer in the Western countries accounts for 3-4% of all cancers. Worldwide incidence is estimated to be 500,000, in Europe 250,000. Three times as many men as women are affected. Squamous cell carcinoma constitutes more than 80% of the head and neck cancers. Though, the histopathology depends on the anatomical region. At the time of the diagnosis 1/3 is in stage I or II and 2/3 in stage III or IV. The recurrence rates for stage I and II is relatively low, with 5-year survival of 70-90%. However, the risk of a secondary primary cancer after radiation therapy (RT) may be higher than the risk of recurrence. For stage III and IV, the local recurrence rates vary from 25 to 80%, and metastases from 10 to 30%. 5-year survival is 10-55%. For stage I and II, the treatment options are surgery and/or RT, while for stage III and IV chemo- and RT are the main options. Common for all treatments are major alterations to the treated tissue that challenge the post-treatment imaging interpretation, independent of modality. This session will focus on expected changes after RT and surgery, including the most frequent surgical procedures. Then finally, when and how to perform post treatment imaging, to depict early cancer recurrence.

Session Objectives:

1. To become familiar with different ways of treatment.
2. To understand post-surgical and post-RT complications.
3. To know how to follow-up patients in order to depict early recurrence.

A-595 08:35

A. Normal findings after radiotherapy

R. Hermans; *Leuven/BE (Robert.Hermans@uzleuven.be)*

After radiotherapy, imaging may be used to monitor tumour response, and to detect recurrent or persistent disease before it becomes clinically evident. Early tumour recurrence may be difficult to distinguish from treatment-induced tissue changes. Therefore, the expected imaging changes after radiotherapy of a head and neck cancer should be well known. These tissue changes depend on the radiation dose, the irradiated volume, and the time elapsed since treatment. Reticulation of fat layers, retropharyngeal space oedema, postirradiation sialadenitis, lymphatic tissue atrophy, and thickening of the pharyngeal and laryngeal structures may be seen. These expected tissue changes often appear symmetrical, unless asymmetric radiation portals were used. However, at the site of a bulky tumour, scar tissue may cause an asymmetric appearance also after successful treatment. Therefore, obtaining a baseline CT or MR study after therapy for a neoplasm with a high risk for recurrence is recommended, best 3-6 months post-treatment. By comparing subsequent studies with this baseline study, tumour recurrences or treatment complications can be detected with more confidence. Some recommend PET-CT as initial baseline study, as this technique has a high negative predictive value; the positive predictive value is lower, as therapy-induced inflammatory changes may cause false-positive results. Tissue necrosis is a rare complication of radiotherapy in the head and neck region, usually appearing late after treatment. Both soft tissue, cartilage and bone necrosis may be encountered; differentiation from tumour recurrence at an early stage may be difficult. Other long-term complications may occur, such as development of a secondary tumour.

Learning Objectives:

1. To get acquainted with changes in tissues during and after radiotherapy.
2. To understand expected changes after radiotherapy in CT and MR imaging.
3. To recognise treatment complications from expected tissue changes after radiotherapy.

A-596 08:58

B. Normal findings after surgery

A. Trojanowska; *Lublin/PL (agnieszka30@yahoo.com)*

Nowadays, the management of head and neck cancer involves multidisciplinary evaluation and treatment, which usually includes surgery, radiation therapy and chemotherapy. The various approaches to surgical resection and tissue reconstruction, the types of neck dissection, different radiation therapy techniques and the addition of concurrent and neoadjuvant chemotherapy regimens may complicate imaging findings. Differentiating post-treatment changes from tumour recurrence with the use of different imaging modalities is challenging because of the presence of altered anatomy secondary to resection, flap reconstructions, oedema, inflammation and the presence of scar tissue. Therefore, it is essential to be familiar with normal findings after surgery and radiotherapy, to distinguish these characteristics from tumour recurrence and treatment-related complications.

Learning Objectives:

1. To get acquainted with most frequent surgical procedures in head and neck.
2. To understand how to evaluate post-surgical patients.
3. To learn how to assess microvascular flaps.

A-597 09:21

C. Treatment monitoring for early detection of recurrence

A.D. King; *Hong Kong/HK (king2015@cuhk.edu.hk)*

Head and neck tumour recurrence occurs in ~25-50% of patients with squamous cell carcinoma treated by CRT, the majority occur “in field” and are detected on the post-treatment assessment or within 3 years of follow-up. Imaging aims to identify early recurrence amenable to curative salvage surgery and avoid unnecessary biopsy or surgery. Reported size criteria for recurrence include ≥1cm primary focal mass and ≥1cm nodal short axis/<75%-90% size reduction. However, size criteria have limitations, notably in HPV+ disease which is associated with large sterile post-treatment nodes. Extracapsular tumour spread and persistent necrosis are also inaccurate signs of persistent nodal disease. The main advantages of MRI over CT are T2 and diffusion-weighted images. Tumour recurrence has similar signal intensity to the pre-treatment tumour, T2 intermediate signal and restricted diffusion (b-1000 high + ADC map low signal), compared to inflammation (high signal) or mature scar tissue (low signal) on the T2 images and ADC maps. Contrast enhancement tends to be moderate in recurrence and between that of mature scar tissue (mild/absent) and granulation tissue/inflammation (marked), but there is overlap on the conventional T1W post-contrast images. False-negative findings arise from microscopic disease such as that found at tumour margins or in pre-treatment occult nodal metastases, and also from small/infiltrating tumours mixed with benign post-treatment change. False-positive findings arise from post-treatment changes, especially granulation tissue/inflammation, sterile component of necrotic node (ADC map low signal) and complications such as radionecrosis, radiation-induced tumours and granulomatous polyps.

Learning Objectives:

1. To get acquainted with problem of recurrence in imaging studies.
2. To understand how to estimate signs of recurrence on CT and MRI.
3. To learn about false positive and false negative findings.

09:44

Panel discussion: What are the challenges in differentiating post-treatment changes from tumour recurrence?

08:30 - 10:00 **Studio 2017**

Genitourinary

RC 1307

Management of incidental findings in the genitourinary tract

Moderator:
R.H. Oyen; Leuven/BE

A-598 08:30

A. Adrenals
L.E. Derchi; *Genoa/IT (derchi@unige.it)*

Adrenal gland abnormalities are unexpectedly identified in 5% to 8% of abdominal imaging studies. Most of them are benign and a source of little or no concern; others are potentially fatal. Clinical and imaging criteria make differentiation between benign and malignant lesions possible in most cases. When there is no history of malignancy, adrenal lesions are almost always non-malignant (usually an adenoma), while in subjects with known malignancy up to 50% of them are malignant, and most metastatic. Imaging criteria based on macroscopic appearance of these lesions can easily identify those containing mature fat (myelolipomas), the hyperdense haematomas and fluid-filled cysts. However, when lesions have non-specific appearance it is necessary to analyse their structure with lipid-sensitive techniques (density measurement at unenhanced CT; chemical shift evaluation at MR), using perfusion/wash-out imaging after contrast medium injection (absolute or relative percentage wash-out calculation) or with metabolic imaging during PET and CT/PET studies. This presentation will discuss how to behave when an unexpected adrenal lesion is detected and how to proceed in its diagnostic workup.

Learning Objectives:
1. To understand the definition of incidental findings in adrenal pathology.
2. To learn about the imaging characteristics of common adrenal incidental masses.
3. To become familiar with the algorithm approach and evidence-based recommendations for management of adrenal incidentalomas.

A-599 09:00

B. Kidneys
H.C. Thoeny; *Berne/CH (harriet.thoeny@insel.ch)*

Cystic and small solid renal masses are frequently detected incidental renal lesions with increasing incidence in the elderly population. Therefore, renal cell carcinomas are also increasingly detected as incidental findings on imaging. Nephron-sparing surgery has been the method of choice for the treatment of small solid renal masses. However, a large percentage of these solid renal lesions is benign and most of the incidentally detected malignant renal tumours such as renal cell carcinomas (RCCs) are smaller, with lower stage and are less aggressive than symptomatic RCCs. In addition, a correlation with size of the solid lesion and growth rate has been described ranging from 0.13 to 0.31 cm per year. Therefore, active surveillance is now a more frequently applied approach to deal with these incidentally detected small solid renal lesions (<3-4cm). Whereas in solid enhancing lesions <1cm in diameter active surveillance is the treatment of choice at any age, in larger lesions management is mainly depending on clinical factors including the age and the performance state of the patient. The role of the radiologist is to exclude benign lesions such as Bosniak I and II cysts and angiomyolipomas as well as non-neoplastic conditions mimicking a tumour (infection, infarct, vascular anomalies and aneurysms). In patients with small solid renal lesions stratified for active surveillance close follow-up with note of the growth rate has to be performed not to miss the time point of delayed treatment in case of a fast growth rate or clinical progression.

Learning Objectives:
1. To understand the definition of incidental findings in renal pathology.
2. To learn about the imaging characteristics of common renal incidental masses, namely cystic.
3. To become familiar with the algorithm approach and evidence-based recommendations for management of renal incidentalomas.

A-600 09:30

C. Adnexa
C.S. Balleyguier [1], T.M. Cunha[2], N. Perrot[3], F.M. Danza[4], I. Thomassin-Naggara[3]; *[1]Villejuif/FR, [2]Lisbon/PT, [3]Paris/FR, [4]Rome/IT (Corinne.BALLEYGUIER@gustaveroussy.fr)*

Incidental adnexal lesions are non-symptomatic lesions diagnosed on ultrasound, CT or MRI performed for an unrelated reason. They have increased in frequency with increased use of cross-sectional imaging. The majority is benign, even in patients with known malignancy or postmenopausal women. However it is important to reliably differentiate malignant from benign lesions to avoid delays in treating ovarian cancer and prevent unnecessary interventions in benign lesions. To try to characterise these findings, age, menopausal status, previous medical and family history and tumour marker such as CA 125 have to be known. Further management will depend on whether the lesion is clearly benign or malignant, or indeterminate. Specific diagnoses have to be suggested in case of fatty content (teratoma, lipoid cell tumour, ...), calcified content (ovarian leiomyoma, teratoma, brenner struma, ...), and in extra-gynaecological origin (lipoleiomyoma, pelvic teratoma, liposarcoma, ...). Diagnostic algorithms in cystic and solid incidentaloma will be presented in this session, including differential diagnoses. A specific focus will be made on diagnostic strategy in post-menopausal cystic ovarian lesions. Treatment strategy will also been described.

Learning Objectives:
1. To understand the definition of incidental findings in adnexal pathology.
2. To learn about the imaging characteristics of common adnexal incidental masses.
3. To become familiar with the algorithm approach and evidence-based recommendations for management of adnexal incidentalomas.

08:30 - 10:00 **Room L 8**

E³ - Rising Stars Programme: EFRS Radiographers' Basic Session

The professional roles of the radiographer

A-601/A-602 08:30

Introduction
H.H. Hjemly; *Oslo/NO (hakon@radiograf.no)*
D. Katsifarakis; *Athens/GR (d_katsifarakis@yahoo.gr)*

The session will highlight the variety of professional pathways radiographers have the opportunity to persuade, emphasising how to conduct service need analysis as a driver for development and the education required to underpin radiographer advanced and consultant practice. It will present and discuss the pathway from clinical practice to management, requirements to ensure a successful transition from clinical practice to management and challenges encountered during the transition and at management level. It will also present how radiographers can have an academic career and/or become a researcher, the main areas of work for radiographer academics in research, teaching and administration. Radiographers are attractive for vendors of medical imaging industry and an experience-based presentation on this possibility will discuss why radiographers should make the move, the breadth of available opportunities, demands of industry and role progression opportunities.

A-603 08:35

Becoming a clinical radiographer: role, role development and specialisation
N.H. Woznitza; *London/UK (nicholas.woznitza@nhs.net)*

Worldwide there has been sustained and significant increases in the number of imaging investigations, driven by an ageing population, new and emerging technologies and dissemination of practice. Radiographers are fundamental to the diagnostic pathway, are integrated into clinical teams and have a unique position from which to improve patient care and outcomes. Clinical radiographers have a varied career pathway, from graduate radiographer to consultant practitioner. Key opportunities for career development will be discussed, as well as an introduction to the evidence base that underpins radiographer reporting. To facilitate role development for radiographers, an outline of service need analysis will be included. The education required to underpin radiographer advanced and consultant practice will be identified. Key points covered: challenges facing a newly qualified radiographer in settings with limited radiologist cover. Becoming a reporting radiographer, with education and audit requirements. Progression from advanced to consultant practice, including research evidence to support role development.

Learning Objectives:
1. To understand the opportunities for different career pathways across the radiography profession.
2. To be aware of the educational requirements underpinning each of the different careers which will be presented within the session.
3. To support radiographers in making choices about their own career development and career pathway.

Author Disclosure:
N.H. Woznitza: Research/Grant Support; College of Radiographers.

A-604 08:53

Becoming a clinical manager

E. Kelly; *Galway/IE (eileenma.kelly@hse.ie)*

Making the transition from clinical practice into clinical management requires extensive consideration. For some the transition results from 'stepping up' into the role of clinical manager while others actively pursue promotion to management and undertake formal managerial studies in preparation for the challenges encountered in a management role. Pre-requisites for a managerial role include excellent communication and people skills, excellent organisational, administrative and project management skills and the ability to adapt in a rapidly changing environment. While it is not essential in Ireland to possess a managerial postgraduate qualification a manager does require six years of post-graduate experience. The role of a clinical manager can be extremely fulfilling with the ability to improve the service provided to patients and support and develop staff in their own professional roles. Managers also encounter many challenges including budget restrictions which impact on technology advances and education and development and ultimately on the quality of service delivery. However, a successful clinical manager overcomes those daily challenges through continued commitment in effective leadership and by empowering and motivating staff.

Learning Objectives:
1. To understand the opportunities that may be available for clinical managers.
2. To be aware of the requirements and qualifications needed for this role.
3. To support prospective radiographers when choosing a managerial role.

A-605 09:11

Becoming an academic and/or researcher

S.J. MacKay; *Liverpool/UK (S.Mackay@liverpool.ac.uk)*

This talk will begin with a description of the role of the radiographer as an academic/researcher drawing on the recognised role from the UK experience. It will explain the main areas of work for radiographer academics in research, teaching and learning and administration. It will then describe the educational requirements to obtain an academic/research post in the UK. Finally, it will discuss the opportunities available for a career in research and academia.

Learning Objectives:
1. To understand the role of the radiographer as an academic person and researcher.
2. To be aware of the educational requirements underpinning this career pathway.
3. To support radiographers by providing the required information on the opportunities in these fields.

A-606 09:29

Working in industry

P. Doherty; *Forchheim/DE (doherty.patrick@siemens.com)*

The healthcare environment is one which is rapidly changing. Consolidation and industrialisation of services are changes which are evident worldwide. Industry partners are evolving to meet these changes. This evolution places unique demands on these companies and one integral cohort of employees for such companies are those who have clinical training. For imaging companies, radiographers are uniquely positioned to leverage their extensive training in a wide variety of areas. The potential for radiographers is vast, but it is imperative that radiographers entering into industry are not only aware of the unique challenges associated with the transition but also of the unlimited rewards that can be attained.

Learning Objectives:
1. To understand the opportunities of working in industry.
2. To be aware of the fast developments that take place in industry and be knowledgeable of the requirements to occupy such a post.
3. To provide the necessary support for radiographers in making the choices to pursue a career in industry.

RC 1302

Rethinking ductal carcinoma in situ (DCIS)

Moderator:
F. Pediconi; Rome/IT

A-607 08:30

A. New radiologic-pathologic knowledge on DCIS

A. Frigerio; *Turin/IT (alfonso.frigerio@gmail.com)*

A modern rethinking of ductal carcinoma in situ must take off from the awareness of the utter inadequacy of the terminology currently in use. Already in 1976, Jensen, Rice and Wellings remarked that "ductal carcinoma in situ of the human breast is of lobular (acinar) origin". While the latest (2012) WHO Classification decided to omit the name 'ductal' from the definition of the most common type of invasive breast carcinoma, it still failed to recognize the inconsistency of this descriptor for its intra-epithelial counterpart. It is time to move to a new inter-disciplinary approach where a mutually respectful interaction between radiologists and pathologists should take full advantage of new imaging techniques and new pathologic methods to achieve better characterization of the different types of breast lesions and their clinico-biological potential. A new classification and terminology based on the site of tumour origin (acinar vs ductal), as best displayed by diagnostic imaging paired with modern pathologic techniques as large-format histologic sections, should open the way to a better understanding of the lesion biology, eventually improving treatment planning decisions. This lecture will include a discussion of different subtypes of in situ lesions neoductgenesis as an important feature that should be recognized and reported, the potential of mammographic tumour features as synergistic prognostic factors alongside classical pathological and modern molecular patterns. Overcoming long-lasting barriers to effective communication would be the prerequisite to a new professional setting where all specialists involved mutually enhance the benefits of their clinical knowledge.

Learning Objectives:
1. To learn about different types of DCIS.
2. To become familiar with risk of developing a cancer.
3. To appreciate the radiologic-pathologic correlations.

A-608 09:00

B. Diagnosing DCIS

S. Schrading; *Aachen/DE (sschrading@ukaachen.de)*

The presentation gives an overview over the current role and recent data of dynamic contrast-enhanced (DCE) breast MRI for diagnosis ductal carcinoma in situ (DCIS). Special attention is paid on the description and illustration of typical imaging features as well as pitfalls and difficult differential diagnosis of DCIS at MRI. In addition, the impact of DCE MRI on DCIS treatment and recent discussion on overdiagnosis and overtreatment of DCIS are discussed.

Learning Objectives:
1. To learn about the evidence based on MRI in evaluating DCIS.
2. To become familiar with different imaging appearance of DCIS.
3. To appreciate added value of MRI for diagnosis.

A-609 09:30

C. Reducing overtreatment of DCIS

M.G. Wallis; *Cambridge/UK (matthew.wallis@addenbrookes.nhs.uk)*

Breast screening has led to an inexorable rise in the number of women living with a diagnosis of DCIS predominantly but not exclusively as a result of the detection of micro-calcification. It is clear from long-term follow-up that conventional treatment fails the 15 to 20% who develop invasive disease a few of whom then die from breast cancer. There is larger group that never progresses with in their lifetime which means we have either cured them or just overtreated them. Traditional pathology and genetics suggest that there is a low-risk group that either never progresses or if they do, they develop 'low-risk' invasive disease. I will describe the 3 international trials LORIS (The LOw RISk DCIS trial), LORD (LOw Risk DCIS) & COMET (Comparison of Operative versus Medical Endocrine Therapy for Low-Risk DCIS); in particular, commenting on their differences. Using LORIS as my main example I will discuss how we have attempted to resolve the hurdles of setting up a 'no treatment trial' and talk about some of the lessons learnt from successfully steering LORIS from feasibility to full trial. Anecdotally patient views have been more entrenched than those of surgeons and to my surprise the radiology second opinion service set up to reduce the risks of 'active monitoring' up by annual VAB has not been overwhelmed.

Learning Objectives:
1. To learn about the risk of overdiagnosis and overtreatment.
2. To become familiar with the risk of avoiding surgery.
3. To appreciate the prospective for the future.

08:30 - 10:00 **Room E2**

RC 1311
White spots in the brain

Moderator:
E. Maj; Warsaw/PL

A-610 08:30
A. White spots and blots in the brain: what are they?
T.A. Yousry; *London/UK (t.yousry@ucl.ac.uk)*

White matter lesions (WMLs) often present a diagnostic challenge. They can be incidental, associated with ageing, or reflect an underlying disease. The differential diagnosis is, therefore, wide reaching from vascular, such as small vessel disease (SVD) to inflammatory causes, such as multiple sclerosis (MS). Although the clinical presentation often leads to the right diagnosis, overlap in the clinical presentation as well as in the MR findings is frequent. The correct interpretation of the corresponding imaging is, therefore, essential. To be able to put WMLs in the right context, they need to be categorised and related to their pathological substrate, which is the basis for the nomenclature that should be used. MRI criteria have been developed to support the differential diagnosis. They are based among other features on shape (oval in MS), distribution (subcortical in MS, basal ganglia in SVD), enhancement (MS), involvement of spinal cord (MS) and occurrence of other changes (lacunes and microhaemorrhages in SVD). New findings from 7T high-field MRI have contributed to the development of new criteria, such as the central vein in MS lesions, which can be also identified at 3T. These findings determine the imaging strategy that needs to be adopted. This strategy also needs to take into account the MRI criteria to diagnose MS - the 2010 “McDonald criteria” - which are based on the demonstration of dissemination in space (DIS) and time (DIT) and after exclusion of alternative causes.
Learning Objectives:
1. To understand what white spots are.
2. To make differential diagnoses in brain white spots.
3. To demonstrate how to study patients with brain white spots.
Author Disclosure:
T.A. Yousry: Advisory Board; Biogen Idec; Genzyme, Ixico. Board Member; Neuroradiology. Grant Recipient; Medical Research Council, MS Society of Great Britain and Northern Ireland, Stroke Association, British Heart Foundation, Wellcome Trust. Speaker; Novartis.

A-611 09:00
B. How can I improve my reporting of T2-hyperintense lesions?
A. Rovira-Cañellas; *Barcelona/ES (alex.rovira@idi.gencat.cat)*

Focal white matter bright spots on T2-weighted images (BS) are commonly observed on brain MRI, not only in the elderly, but also in middle-aged subjects, particularly those with migraine or chronic headache. In addition, a large list of different disorders should be considered in these patients as hypoxic-ischaemic vasculopathies, multiple sclerosis, primary and systemic vasculitis and acquired metabolic and toxic conditions, among others. While it is recognized that a combination of findings from clinical history, physical examination and laboratory tests is commonly required to correctly establish a firm and clear etiological diagnosis, a detailed analysis of different MRI features should also be considered essential, e.g. lesions shape, size and distribution; contrast-uptake; associated structural lesions (microbleeds, infarctions, etc.). Knowledge of these features, will assist the diagnostic workup of patients presenting with BS and should be considered a first step to take full advantage of the potential of MRI, and in doing so should result in a reduced chance of misdiagnoses and facilitate the correct diagnosis of sometimes treatable disorders. Detailed description of these features and their interpretation must be translated into a written and structured radiological report, which should be accurate with inclusion of relevant positive and negative findings and clinically focused, to properly assist with the further management of these patients. These standardized reports are more time-efficient than simply dictation, support analysis for research and decision support and improve communication of radiology results, which has important clinical implications in the management of patients presenting with brain BS.

Learning Objectives:
1. To understand if it is possible to use a structured report with white brain abnormality.
2. To learn how to define a comprehensive imaging protocol for those patients.
3. To appreciate the role of modern imaging techniques for defining white brain hyperintense T2 lesions.

A-612 09:30
C. Is there a need for quantitative reporting of white matter lesions?
W. van Hecke; *Antwerp/BE (wim.vanhecke@icometrix.com)*

Brain white matter lesions occur in different brain disorders, such as vascular disease, dementia, multiple sclerosis, etc. As the number, location, shape and size of these lesions are relevant for diagnosis, follow-up or clinical decision making, they should be assessed in the radiological report. However, studies have demonstrated that a visual evaluation of white matter lesions is labour intensive and observer dependent, leading to a low reproducibility of the reported values. In recent years, image processing techniques were developed to obtain quantitative white matter lesion information in a semi-automatic or automatic way. Some of these techniques are now also approved for and available in a clinical routine setting, allowing to integrate quantitative information on brain white matter lesions in the radiological report.
Learning Objectives:
1. To understand the importance of quantitative analysis in white matter lesions.
2. To show how to perform the quantitative analysis.
3. To understand the importance of follow-up in patients with white matter lesions.
Author Disclosure:
W. van Hecke: Board Member; icometrix. Founder; icometrix.

08:30 - 10:00 **Room F1**

E³ - European Diploma Prep Sessions

E³ 1323
Chest

A-613 08:30
Chairman's introduction
J. Vilar; *Valencia/ES*

Session Objectives:
1. To understand the most important signs in chest imaging.
2. To learn the imaging features of benign and malignant lesions of the lung.
3. To become familiar with the imaging appearance of common lesions of the mediastinum, pleura and chest wall.
4. To understand the role of different imaging modalities including hybrid imaging in diagnosing and staging neoplasms of the chest.

A-614 08:36
A. Fundamentals of chest imaging
D. Tack; *Baudour/BE (denis.tack@skynet.be)*

This lecture intends to review the basic technical requirements for performing chest radiographs and chest CT, the radiation dose descriptors suited for CXR and CT, the basic anatomical landmarks for image interpretation and numerous signs in chest imaging used for radiographic or CT examinations. In addition, rules for checking for lines and tubes will be illustrated with quiz cases.
Learning Objectives:
1. To learn the anatomy and normal variants of the respiratory system, heart and vessels, mediastinum and chest wall and to confidently identify these on radiographs, CT and MRI.
2. To understand the technical aspects, exposure doses and post-processing of radiographs and CT of the chest.
3. To gather an in-depth understanding of the most common chest radiography signs (including silhouette sign, air bronchogram, air crescent sign, cervicothoracic sign, tapered margins, gloved finger sign, golden sign, deep sulcus sign).
4. To learn the appearance and correct position of monitoring and support devices (tubes and lines).

A-615 09:04

B. Inflammation and tumours of the lung

H. Prosch; *Vienna/AT (helmut.prosch@meduniwien.ac.at)*

Inflammatory and neoplastic diseases of the lung are frequently encountered on chest CTs. As both inflammatory and neoplastic diseases, as well as some congenital disorders, present with an increase in lung density, the differential diagnosis is challenging. Increased lung densities may present as ground glass opacities or consolidations. Ground glass opacities are defined as an increase in lung density, with preservation of bronchial and vascular margins. Ground glass opacities may be caused by a thickening of the pulmonary interstitium or a partial filling of the air spaces with fluids or cells. Pulmonary opacities, in which the bronchial or vascular margins are obscured, are defined as consolidations. Consolidations are the result of a complete filling of the alveolar spaces with fluids or cells, or a thickening of the pulmonary interstitium with complete displacement of the air from the parenchyma. The diagnosis of diseases that present with an increase in lung density requires a systematic analysis of the predominant CT pattern and ancillary CT findings. Furthermore, clinical data, such as information on the immunological status of the patient as well as laboratory findings, have to be taken into account to narrow the differential diagnosis. If CT findings and clinical data are inconclusive, percutaneous or transbronchial biopsies are often required to confirm or rule out a presumptive diagnosis. Biopsies are particularly important in cases in which a presumed benign process does not respond to treatment or a malignant process is suspected.

Learning Objectives:

1. To understand the imaging features and differential diagnoses of diffuse infiltrative and alveolar lung disease and atelectasis.
2. To become familiar with thoracic diseases in immunocompetent, immunocompromised and post-transplant patients.
3. To become familiar with the differentiation of solitary and multiple pulmonary nodules, benign and malignant neoplasms, hyperlucencies and their potential aetiology and evaluation.
4. To understand the role of different imaging modalities including hybrid imaging in diagnosing and staging neoplasms of the chest.

Author Disclosure:

H. Prosch: Advisory Board; Boehringer Ingelheim, Roche. Speaker; Boehringer Ingelheim, Roche, Roche.

A-616 09:32

C. Mediastinum, pleura and chest wall

N. Howarth; *Chêne-Bougeries/CH (nigel.howarth@grangettes.ch)*

The presentation will cover the predefined learning objectives using side-by-side plain film and CT imaging to help understand the imaging features of common pathologies of the diaphragm, pleura and chest wall, concentrating on causes of mediastinal and hilar diseases, disorders of the pulmonary vascular system and great vessels and the postoperative chest. Although the clinical value of the chest x-ray remains undiminished, errors of interpretation of the chest x-ray remains one of the most frequent causes of malpractice issues. The skills required for accurate interpretation of imaging of the mediastinum, pleura and chest wall will be explored. The topics will be disease orientated. The objective is to help you improve your performance in plain film and CT imaging of the chest.

Learning Objectives:

1. To become familiar with the imaging features of common pathologies of the diaphragm, pleura and chest wall on radiography, CT and MRI of the chest.
2. To learn the imaging features and causes of mediastinal and hilar diseases.
3. To understand the imaging features of disorders of the pulmonary vascular system and great vessels.
4. To learn the typical imaging features of the postoperative chest.

08:30 - 10:00 **Room F2**

Emergency Imaging

RC 1317

Acute pain: hallmark in emergency radiology

A-617 08:30

Chairman's introduction: Management and therapeutic pathways in patients with acute pain

D.R. Kool; *Nijmegen/NL*

Acute pain in head, chest or abdomen is a common reason for patients to visit an emergency department. The differential diagnosis in these patients is often diverse and diagnostic imaging will help the clinician to make the correct diagnosis and start appropriate treatment. Depending on the available clinical information, the radiologist decides together with the treating physician what image modality or imaging pathway is the most suitable and efficient for that patient, with those symptoms, in that hospital, at that time. In this refresher course, the clinical conditions presenting with acute pain in head, chest and abdomen will be addressed. The ratio behind the choice of imaging modality will be discussed and the imaging findings will be demonstrated. In the panel discussion, the role of radiology and the radiologist in the diagnostic journey of these patients will be addressed.

A-618 08:35

A. Head

S. Wirth; *Munich/DE (stefan.wirth@med.uni-muenchen.de)*

Severe headache is a common reason for presentation to emergency services. While many headaches resolve spontaneously, some patients require further examination including neuroimaging. The international classification of headache disorders differentiates 1) primary headaches, 2) secondary types with a known structural or biochemical cause and 3) cranial neuralgias. Consequently, imaging has a relatively low diagnostic yield in primary headache whereas it plays an important role in the differential diagnosis of secondary forms. Worldwide, the most common form of headaches is caused by primary tension-type headaches and migraines (90%). Danger signs or other potential indicators of secondary headache are: history of recent head trauma, new onset or change in headache in patients over 50 years of age, time to peak intensity of less than 5 minutes, any new or worsened abnormal neurological examination. In such circumstances, patients should undergo neuroimaging. Typical imaging findings for the most common clinical scenarios will be presented. Particular attention will be paid to sudden onset (thunderclap) headache, which requires urgent evaluation as such headaches may be signs of intracranial and in particular of subarachnoid haemorrhage - mainly caused by trauma or aneurysm rupture. Besides traumatic and non-traumatic bleeding, typical other aetiologies of headache will be discussed: cerebral venous thrombosis, cervical artery dissection, spontaneous intracranial hypotension, pituitary apoplexy, retroclival haematoma, ischaemic stroke, acute hypertensive crisis, headache associated with sexual activity, third ventricular colloid cysts, meningitis, complicated sinusitis and reversible cerebral vasoconstriction syndromes.

Learning Objectives:

1. To become familiar with common clinical conditions resulting in acute headache.
2. To understand the choice of the best-suited imaging modality.
3. To learn about typical imaging findings in the most common clinical scenarios.

A-619 09:00

B. Chest

E. Dick; *London/UK (elizabeth.dick@imperial.nhs.uk)*

General radiologists need to be able to confidently review CT in patients with acute chest pain since this is a common emergency presenting complaint which is increasingly investigated with CT. This case-based talk will consider the cardiac, aortic, pulmonary, oesophageal and chest wall causes of pain. It will review the best imaging protocols for different patient groups according to their risk factors. Take-home tools will include a reporting pro forma and checklist of 'Don't miss' sites.

Learning Objectives:

1. To become familiar with clinical conditions resulting in acute pain.
2. To understand which additional data will influence the choice of the correct imaging modality.
3. To learn about typical imaging findings in patients with acute chest pain.

Author Disclosure:
E. Dick: Board Member; British Society of Emergency Radiology, European Society of Emergency Radiology.

A-620 09:25

C. Abdomen
R. Basilico; *Chieti/IT (rbasilic@unich.it)*

Acute abdominal pain is a common main complaint in patients examined in the emergency department and can be related to a wide range of diseases. On the basis of the results of the initial diagnostic steps for these patients, represented by clinical evaluation and laboratory investigations, the clinicians will consider imaging examinations to help establish the correct diagnosis. The diagnostic approach for acute abdominal pain is not only one of the most difficult for the clinician but it is also a great challenge for the radiologist because differential diagnoses include a myriad of disorders, ranging from life-threatening to benign self-limiting conditions. The diagnostic workup of patients admitted with acute abdominal pain is based on various imaging modalities such as abdominal plain film, ultrasound, CT and MRI: the topographic classification of acute abdominal pain (pain in one of the four abdominal quadrants, diffuse abdominal pain, flank or epigastric pain) with reference to the age and gender of patients, facilitates the choice of the imaging technique and allows to narrow the range of possible diagnoses. The most practical approach to acute abdominal pain is to confirm or to exclude the most common disease and to look for general signs of pathology such as inflamed fat, bowel wall thickening, ileus, free fluid and free air. Moreover, knowledge of atypical imaging findings is of great importance to improve the diagnostic orientation. In any case, results have to be confronted with clinical findings to obtain the correct diagnosis.
Learning Objectives:
1. To become familiar with common clinical conditions resulting in acute abdominal pain.
2. To understand what clinical information influences the choice of the best-suited imaging modality.
3. To learn typical and less typical imaging findings in patients with acute abdominal pain.

09:50
Panel discussion: Where does radiology fit in the pathway?

08:30 - 10:00 **Room D**

Musculoskeletal

RC 1310
Shoulder MRI: mastering technique and making my report relevant

A-621 08:30

Chairman's introduction
J. Kramer; *Linz/AT (kramer@ctmri.at)*

General considerations regarding the following lectures are made focused on the question: what the patient/surgeon want to know together with clues how to make a reasonable report. Beginning with demonstration of normal anatomy including subtle details and variants, new insights into rotator cuff disorders (from degenerative changes to full thickness tear) pathologic alterations in patients with shoulder instability are demonstrated and discussed.
Session Objectives:
1. To understand the level of expertise that patients expect for adequate performance and reading of shoulder MRI.
2. To gain insight into differentiating normal age-related changes from clinical relevant MR features.

A-622 08:35

A. The normal MRI: techniques and anatomy
E. Llopis; *Valencia/ES (evallopis@gmail.com)*

The shoulder has a large range of motion making it susceptible for instability. To maintain shoulder stability there are a combination of static and dynamic structures. Bone structures, humeral head and glenoid, are essential to keep shoulder normal function, and its role is being redefined as key for success of arthroscopy treatments. Intraarticular the glenoid ligaments, bicipitolabral complex and labrum help act in combination with the strong rotator cuff muscles (supraspinatus, infraspinatus, subscapularis and teres minor) to allow all the normal range of motion of the shoulder. We will review the normal anatomy and different techniques to study the shoulder, with especial emphasis on MR and MR arthrography. Including how to perform MR and CT arthrography in one single procedure. We will provide some tricks such as forced external rotation or ABER position that allow to diagnose small subtle lesions.
Learning Objectives:
1. To become familiar with MRI techniques for imaging the shoulder.
2. To understand normal MRI shoulder anatomy, and normal variants seen.

A-623 08:58

B. Rotator cuff tears: what are they and what do they look like?
K.-F. Kreitner; *Mainz/DE (Karl-Friedrich.Kreitner@unimedizin-mainz.de)*

Rotator cuff (RC) disease is common and may be a significant cause of shoulder pain. Thorough assessment of the RC by MR imaging may enable accurate diagnosis and facilitate appropriate management by the orthopaedic surgeon. The tendons of the rotator muscles are highly organized structures where five distinct histologic layers have been described. Over the last decade, the rotator cable has received increasing attention as it acts as a supporting limb of the cuff. The cable is adjacent to the crescent zone of the RC and can be seen on most MR imaging studies. Pathologically, tendinosis/tendinopathy can be differentiated from partial- and full-thickness tears of the cuff. Whereas tears at the rotator crescent are often due to ischaemia and degeneration, tears of the footprint have obtained increased attention as they affect younger patients and have implications on the appropriate operative procedure. Partial-thickness tears can be described as articular, bursal or intrasubstance partial tears and should be further characterized with regard to the degree of tendon involvement. Full-thickness tears allow communication between the glenohumeral joint and the subacromial-subdeltoid bursa and can be pinhole in size or involve an entire tendon. It is further of utmost importance to assess atrophy or fatty infiltration in case of an RC tear as these findings influence therapy and outcome of the affected patients. Tears of the subscapularis tendon typically begin in the cranial part of the tendon are often associated with lesions of the long biceps tendon and the rotator interval.
Learning Objectives:
1. To become familiar with the anatomical basis of rotator cuff tears.
2. To learn about the MRI findings of rotator cuff pathology.

A-624 09:21

C. Patterns of instability: what does the MRI show?
A.J. Grainger; *Leeds/UK (andrewgrainger@nhs.net)*

Two patterns of injury are seen in patients dislocating their shoulder. Younger patients will tend to disrupt the labroligamentous complex, whereas the older population tends to disrupt the integrity of the rotator cuff. In this latter group, tears of supraspinatus are seen along with tears of subscapularis and avulsion fractures of the greater tuberosity. Rotator cuff disruption forms the subject of other talks so will not be discussed further here. Anterior dislocation leading to avulsion of the anteroinferior labral-ligamentous complex from the glenoid is termed the Bankart lesion, or bony Bankart if accompanied by a fracture. Avulsion occurs due to the pull of the anterior band of the inferior glenohumeral ligament (AIGHL) at its attachment to the anteroinferior labrum. The AIGHL is the primary restraint to movement when the arm is abducted and externally rotated. Avulsion of the labrum is well shown at MR arthrography and a number of variants exist which will be discussed. Posterior dislocation will produce a reverse pattern of shoulder injury which will also be discussed.
Learning Objectives:
1. To become familiar with patterns of abnormality seen in shoulder instability.
2. To learn about the MRI findings of shoulder instability.
Author Disclosure:
A.J. Grainger: Consultant; medivir AB. Equipment Support Recipient; Siemens Healthcare. Speaker; GE Healthcare.

09:44
Panel discussion: How are the indications for MR arthrography in the shoulder changing?

08:30 - 10:00 **Room G**

Physics in Medical Imaging

RC 1313
Motion management in medical imaging

A-625 08:30
Chairman's introduction
A. Torresin; *Milan/IT (alberto.torresin@unimi.it)*

Motion management in medical imaging is very important for diagnostic and therapeutic application. Its quantification and control can increase image quality in diagnostic imaging and optimize the final results in radiotherapy for delivering ablative doses to tumours with limited normal tissue toxicity. The methods for quantification and control are modality and clinical application dependent. Respiratory induces motion artefacts, particularly those occurring in the abdomen and lung. It poses a hefty problem in diagnostic imaging and cardiac motion leads to blurred images with reduction of spatial and contrast resolution. In diagnostic application many methods can be applied in MRI, US, CT, CBCT, SPECT, PET where different image modalities should be registered in the same reference coordinates and a lot of methods have to be applied for different clinical applications. A modern radiotherapy tenet is to accurately identify the treatment target to follow and secure high-dose treatment target volume. Respiratory motion can induce errors in target volume delineation and dose delivery in radiation therapy for thoracic and abdominal cancers. 4D computed tomography and 4D magnetic resonance imaging are the most common contemporary imaging technique for identifying tumour motion. Radiotherapy application is not directly discussed during the section but imaging corrected for motion will support also this application.
Session Objectives:
1. To learn about the origins of motion management in medical imaging.
2. To understand image motion in medical imaging.
3. To learn about solutions and work-arounds.

A-626 08:35
A. Managing respiratory motion with CT and CBCT: conventional approaches and motion compensating techniques
J. Sijbers; *Antwerp/BE (jan.sijbers@ua.ac.be)*

Motion in x-ray imaging is a common problem. It generally leads to blurred images and loss of spatial resolution. In this talk, various strategies for motion compensation will be discussed, on acquisition as well as tomographic image reconstruction level. In addition, it will be shown that motion blur in the acquired x-ray projections can be beneficial instead of disadvantageous with respect to CT image quality.
Learning Objectives:
1. To learn about conventional techniques for respiratory motion compensation.
2. To learn about new methods for respiratory motion compensation.
3. To contrast the available and up-and-coming respiratory motion compensation methods.

A-627 08:58
B. Managing cardiac motion with CT and CBCT: conventional approaches and motion compensating techniques
M. Kachelrieß; *Heidelberg/DE (marc.kachelriess@dkfz.de)*

Diagnostic CT is the workhorse of the radiologist: highly quantitative images with very high spatial resolutions (0.3 mm isotropic) for complete anatomical areas are acquired in scan times as short as about 1 s. CT further routinely achieves an unprecedented temporal resolution of 63 ms, which is one quarter of the rotation time, for complete anatomical regions. For moving objects, however, even 63 ms may introduce motion blurring. Given the spatial resolution of 0.3 mm, objects moving at a speed of about 4 mm/s or faster will introduce blurring. Such velocities occur in the thorax due to breathing and, even more dominantly, in the heart, where velocities of 70 mm/s are typical. In CBCT, a slowly scanning non-diagnostic modality, the situation becomes even worse because not only the temporal duration of the scan is long but also because respiratory motion cannot be ignored anymore and will be superimposed with the cardiac motion. The simplest methods to manage cardiac motion are cardiac-correlated (prospectively or retrospectively gated) scans performed during a single breath-hold. Gating may include scanning during a single heart beat (either in circle, in spiral, or in high-pitch spiral mode) or during multiple heart beats. Recently, new algorithms that have the ability to compensate for the motion during image reconstruction are being developed: they have the potential to significantly increase the temporal resolution or to improve the dose usage to 100%. The lecture discusses the methods in use, and those that are being developed.
Learning Objectives:
1. To learn about conventional techniques for cardiac motion compensation.
2. To learn about new methods for cardiac motion compensation.
3. To contrast the available and up-and-coming cardiac motion compensation methods.

A-628 09:21
C. Motion compensation in MR and PET imaging
C. Kolbitsch; *Berlin/DE (christoph.kolbitsch@ptb.de)*

MR image quality and diagnostic accuracy can be considerably impaired by physiological organ motion (e.g. breathing, heartbeat or swallowing). Advances in MR hardware, plus novel image acquisition and reconstruction approaches, now allow for faster MR imaging; nevertheless, up to 20% of MR scans experience severe motion artefacts and require repeated data acquisition. A wide range of techniques to minimise motion artefacts has been developed for different MR applications. In clinical practice, this is commonly motion prevention (e.g. asking a patient to hold their breath) and motion gating (i.e. restricting data acquisition to a certain motion state). More advanced approaches measure displacement of organs due to physiological motion and utilise this information to correct motion artefacts. PET images are affected by motion twofold. Movement of organs can lead to blurring of the imaged structures and impair detectability, particularly of small features. In addition, quantitative PET requires correction for different tissue densities using so-called attenuation correction maps. Motion can lead to a mismatch between these and PET image data, resulting in severe errors in PET quantification. The recent introduction of simultaneous PET-MR now offers us the possibility to improve PET image quality and accuracy by utilising MR-based motion information.
Learning Objectives:
1. To learn about motion measurement and compensation in MR.
2. To understand how patient motion affects PET images.
3. To learn about how MR data can be used to motion-compensate PET images, in PET/MR.

09:44
Panel discussion: How to optimise motion management in different imaging modalities?

08:30 - 10:00 **Room K**

Professional Challenges Session

PC 13a
Radiography and radiology: more than the sum of their parts

A-629 08:30
Chairmen's introduction: Working together (part 1)
P. Bezzina; *Msida/MT (Paul.bezzina@um.edu.mt)*

To sustain a good medical imaging department and to ensure a positive atmosphere at work, a place where most of us spend the majority of our daily time, it is important to work together and support each other. It is only in a positive working environment that radiologists and radiographers can understand and respect each other, acknowledge the competences of all the individuals, and have joint goals to develop and strengthen radiology and radiography so as to improve practice in a department. Among many of the topics in which working together is practically important is patient safely where we all need to be on the same path and committed to this. The same goes for improvement of protocols, new ideas and testing of new sequences and method. In other words, it has to be done jointly if it is to work and has to be implemented with the support of all staff regardless of background. This session will focus on these topics as well as to give an insight into how you as radiologist and radiographers working together, with different but important skills and knowledge, can achieve a lot to improve your daily practice. For sure two work better than one.
Session Objectives:
1. To appreciate the challenges facing radiography and radiology.
2. To emphasise the importance of a patient safety culture.
3. To understand the need for care and compassion in medical imaging.

A-630 08:33

Chairmen's introduction: Working together (part 2)

P.C. Maly Sundgren; *Lund/SE (Pia.Sundgren@med.lu.se)*

This is a joint chairman session to introduce the following lectures that are focused on the need and benefits of working together as radiologists and radiographers in the clinical and research setting to improve quality, to learn from each other and to move the field forward with the best interest in patient care and quality.

Session Objectives:

1. To appreciate the challenges facing radiography and radiology.
2. To emphasise the importance of a patient safety culture.
3. To understand the need for care and compassion in medical imaging.

A-631 08:37

Opportunities and challenges facing radiography and radiology

G. Paulo; *Coimbra/PT (graciano@estescoimbra.pt)*

Medical imaging is the main pillar of modern health care systems. The equipment technological development combined with the new medical devices have increased medical importance in healthcare delivery. However, evidence shows an exponential growth of the number of medical imaging procedures and a decrease of radiographers and radiologists. One of the main reasons related to this evidence is related to the fact that medical imaging is slowly being fragmented and taken by others, which represents a real threat to our professions. This new reality calls for a development of a common strategy to make us more visible in the patient clinical pathway, enhancing our importance in patient care delivery avoiding medical imaging to be transformed into a commodity. Radiologists must increase their “clinical” role in the management of patient disease and radiographers must increase knowledge, skills and competences towards a consistent and structured role development into advance practice. The future of medical imaging professions depends on our capability of building a team-work model based on roles and responsibilities, as a tool to develop professional satisfaction and increase our visibility in healthcare systems.

Learning Objectives:

1. To highlight the current challenges facing radiographers and radiologists.
2. To discuss the opportunities for radiographers and radiologists.
3. To suggest approaches to meeting current and future needs for the delivery of effective patient care in clinical departments.

A-632 09:00

Patient safety culture: a combined responsibility

S.J. Foley; *Dublin/IE (shane.foley@ucd.ie)*

This presentation aims to familiarise attendees with the recent European Basic Safety Standards Directive (2013/59) which is due to be transposed by all member states into national law by February 2018. The directive consolidates five previous directives into one single document and aims to modernise radiation protection in Europe. It strengthens a number of key radiation protection principles such as justification, the need for and use of DRLs and the requirements for appropriate education of all individuals involved in the delivery of radiation. New requirements are also stipulated for the education of patients as to potential risks while undergoing radiological procedures, the need for dose monitoring devices on all CT and interventional equipment as well as the requirement to transfer patient dose data to the radiological report. In particular, new legislative requirements will be discussed with a particular focus on the increased responsibilities regarding patient safety that will be required of both radiographers and radiologists under the directive. Finally, the potential for the directive to improve the culture of radiation safety within clinical environments will be discussed by consideration of the cumulative effect of both the new and strengthened articles contained within, to change professional behaviours.

Learning Objectives:

1. To familiarise attendees with the European BSS Directive (2013/59).
2. To discuss the responsibilities for radiographers and radiologists within the Directive.
3. To consider how the Directive can improve the culture of radiation safety within the clinical environment.

A-633 09:23

Skills and competences in care and compassion

A. England; *Salford/UK (A.England@salford.ac.uk)*

Ever since Robert Francis QC published his report into the mid-Staffordshire NHS trust inquiry care and compassion have been the forefront of many public and professional debates. The subject of care and compassion is in itself huge and one which has implications for both undergraduate radiography education and post-qualification clinical practice. Questions have arisen as to how these two topics can be adequately embedded into high-quality radiographic practice. What skills are necessary to practice with appropriate care and compassion and how can these be assessed at both pre- and post-qualification levels. Care and compassion is highly topical but often difficult to quantify, will these two topics remain at the forefront of radiographic practice and what can we do as professionals to encourage this. This lecture serves to identify and discuss the key issues of skills and competencies in the delivery of care and compassion within radiographic practice.

Learning Objectives:

1. To focus on the specific aspects of care and compassion within radiography and radiology.
2. To discuss the issue of continuous professional development in care and compassion.
3. To emphasise the importance of care and compassion within training curricula.

Burnout of radiologists

A-634 08:30

Chairman's introduction

M.G.M. Hunink; *Rotterdam/NL (m.hunink@erasmusmc.nl)*

Do you feel more-and-more overwhelmed? Are you often physically and emotionally exhausted? Have you lost your passion and commitment? Are you not accomplishing what you could and should? Are you disillusioned with your job or career (or life in general)? Are you becoming cynical and emotionally detached? Insomnia, headaches, neck pain, GI upsets? You probably have burnout. If you recognise these signs in yourself, your colleagues or your employees, it is time to act. The cost of burnout is high: personally, to the department and to the hospital! Burnout among physicians is becoming an epidemic. Radiologists are particularly vulnerable to burnout due to a host of factors related to their work: declining income, limited interaction with patients and peers, severe time constraints, work overload, too many bureaucratic tasks, and too much computer work. About 50% of radiologists in the USA have at least one symptom of burnout. The percentage in Europe is unknown. Burnout has negative consequences for the individual and also for his/her practice and patients: it can have adverse effects on performance, professionalism, patient safety, relationships, personnel retention and patient satisfaction. Prevention is better than cure when it comes to burnout. Important preventive measures can and should be taken both at the personal and organisational level. Personal measures include mindfulness training, attention for work-life balance, and focusing on meaningful activities. Organisational measures include tracking and supporting physician well-being, monitoring physician burnout, implementing programs teaching personal preventive measures, leadership skills training and flexibility in work hours.

Session Objectives:

1. To learn about the silent epidemic of physician burnout.
2. To learn to recognise the symptoms of burnout.
3. To understand what factors contribute to burnout in radiologists.
4. To learn what preventive measures can be taken to prevent burnout in radiologists.
5. To understand what interventions work in treating burnout.

A-635 08:40

A personal story

M.F. Berger; *Nottwil/CH (mberger@access.ch)*

In this talk I shall present my own experience with burnout from a first person point of view: early warning signs, failed attempts at self-help, sudden break-out of symptoms, medical workup, interventions and, finally, resolution and consequences. I shall also briefly touch on how I witnessed burnout in two colleagues of mine. Mindfulness played a major role in the recovery of all three of us. I shall describe my personal approach to mindfulness and explain how the practice can not only improve your resilience to stressful life events, both private and professional, but also how it may actually help you become a better radiologist.

Learning Objectives:
1. To learn to recognise the early symptoms of burnout in oneself.
2. To understand how life events and work stress in radiology contribute to burnout.
3. To appreciate the challenges in dealing with burnout.
4. To learn how mindfulness can help in prevention and treatment.
5. To appreciate the value of mindfulness in being a better radiologist.

A-636 09:00

Mindfulness-based interventions for burnout of physicians

A. Speckens; *Nijmegen/NL (Anne.Speckens@radboudumc.nl)*

Mindfulness-based interventions (MBIs) are increasingly applied in health care settings to reduce psychological distress in both patients with psychiatric disorders and those with somatic illnesses. Originally, mindfulness-based cognitive therapy (MBCT) was offered to patients with recurrent depressive disorder to reduce relapse/recurrence. The current evidence suggests that MBCT might be at least as effective as antidepressant medication in preventing relapse/recurrence. Increasingly, MBIs are also offered to patients with other psychiatric disorders, such as somatoform disorders and ADHD. In addition, MBIs have demonstrated to be effective in reducing symptoms of anxiety and depression in patients with chronic somatic conditions, such as cancer and multiple sclerosis. MBIs have not only been applied in clinical populations, but also in health care professionals. Mindfulness-based stress reduction (MBSR) has been shown to reduce burnout and improve psychological well-being and empathy in medical students, residents, general practitioners and consultants. In this presentation, recent findings of two randomised controlled trials in 167 medical students and in 148 residents from different medical specialities will be presented. In addition, the results from two pilot studies in 50 general practitioners and 52 medical consultants will be discussed.

Learning Objectives:
1. To appreciate the impact of the practice environment and the risk factors that lead to physician burnout.
2. To understand the impact of physician burnout on patient care.
3. To learn what we can do to prevent and treat physician burnout.
4. To learn what the research says about the effectiveness of mindfulness for burnout.
5. To appreciate what leaders can do to enhance the lives of staff and residents.

A. Speckens: Employee; Radboudumc Nijmegen, the Netherlands. Founder; Radboudumc Centre for Mindfulness. Grant Recipient; Dutch Organisation for Scientific Research, Dutch Cancer Society, Dutch Assocation for Mental Health. Research/Grant Support; See above.

A-637 09:25

Interventions to prevent and treat burnout

B. Trück; *Brussels/BE (beate.trueck@brusselsmindfulness.be)*

Mindful awareness is about learning to pay attention. It is like training a muscle - training attention to be where you want it to be. This reduces our tendency to work on autopilot, allowing us to us choose how we respond and react in stressful situations. Mindfulness is cultivated in a variety of ways. This includes sitting down (on a chair) and observing your thoughts, emotions or your breath. But mindfulness can also be developed by simply focusing on the task at hand whether you are at work in a meeting or at home cooking a meal. In this talk we will be discussing what it means to be most of the time on autopilot and how this can lead to symptoms of stress and burnout. I will give a practical insight into how mindfulness helps to step out of the autopilot. We will be practising some short mindfulness meditations and share our experiences. We will also be talking about how one can be more mindful in daily life and how short moments of stopping and becoming aware can bring about a great change. I will present some concrete tips of how to integrate mindfulness in your daily life without much additional time.

Learning Objectives:
1. To learn what interventions are available to prevent and treat burnout.
2. To experience what mindfulness/meditation can do for you.
3. To appreciate that attention to the present moment enhances feelings of happiness.
4. To appreciate that mindfulness enhances focus in all activities.

09:50

Panel discussion and discussion with the audience

08:30 - 10:00 **Room M 2**

ESHI (European Society for Hybrid Medical Imaging) Session

Hybrid imaging: case-based diagnosis in PET/CT

Moderator:
K. Nikolaou; Tübingen/DE

A-638 08:30

FDG indications in oncology: case-based

K. Riklund; *Umea/SE (katrine.riklund@umu.se)*

Hybrid imaging with PET/CT and sometimes PET/MR is used on daily basis in the clinical workup, staging procedure, treatment planning and evaluation of several oncologic diagnoses. The most commonly used tracer is oncology is 18F-fluorodeoxyglucose (FDG) and the presented cases are examined with FDG. We will also discuss the evidence base for FDG PET/CT and the impact on clinical handling.

Learning Objectives:
1. To learn about the evidence for common indications.
2. To become familiar with PET and CT findings.
3. To learn about the impact on clinical decision.

A-639 09:00

Non-FDG indications in oncology: case-based

O. Ratib; *Geneva/CH*

Learning Objectives:
1. To learn about the evidence for common indications.
2. To get familiar with PET and CT findings.
3. To learn about the impact on clinical decision.

A-640 09:30

Pitfalls in PET/CT: case-based

G. Antoch; *Düsseldorf/DE (antoch@med.uni-duesseldorf.de)*

Coupling CT with PET adds additional information to morphologic and functional imaging alone. However, bringing both modalities together gives way to new types of image artefacts and pitfalls caused by interaction of morphology and function. In addition, pitfalls known from CT and PET alone still exist in hybrid imaging. The reader has to be aware of these pitfalls to avoid misinterpretation of the imaging data. This course gives an overview regarding different pitfalls in PET/CT imaging that have to be known and dealt with when reading an reporting hybrid imaging studies.

Learning Objectives:
1. To learn about the cause of pitfalls in PET/CT.
2. To get familiar with the appearance of pitfalls in PET/CT.
3. To learn about how to avoid pitfalls in PET/CT.

08:30 - 10:00 **Room M 3**

E³ 1326

Image-guided liver interventions: update and level of evidence

Moderator:
P.L. Pereira; Heilbronn/DE

A-641 08:30

A. Hepatocellular carcinoma (HCC)

L. Crocetti; *Pisa/IT (laura.crocetti@med.unipi.it)*

Hepatocellular carcinoma (HCC) represents one of the few cancers for which locoregional treatments are recognized as being able to cure and/or prolong survival and included in international guidelines. This is due to the unique nature of HCC, in most cases occurring in patients with underlying virus- or alcohol-related cirrhosis. Treatment choice in patients with HCC is, therefore, driven not only by tumour staging, but also by careful evaluation of liver function and physical status. These characteristics configure a complex scenario and prompt the need for close cooperation among interventional oncologists, surgeons and hepatologists. The Barcelona Clinic Liver Cancer (BCLC) classification has emerged during recent years as the standard classification that is used for clinical management of patients with HCC. This classification links stage stratification with a recommended treatment strategy and defines standard of care for each tumour stage. According to the BCLC

staging system, image-guided tumour ablation is recommended in patients with very early and early-stage HCC. Despite the widespread implementation of surveillance programs, more than half of the patients with HCC are diagnosed late, when curative treatments cannot be applied. For patients presenting with multinodular HCC and relatively preserved liver function, absence of cancer-related symptoms, and no evidence of vascular invasion or extrahepatic spread, i.e. those classified as intermediate-stage - transcatheter arterial chemoembolization (TACE) is the current standard of care. Transarterial radioembolization (TARE), despite non yet included in current guidelines, is a valuable treatment tool entering the clinical practice especially for the early advanced HCCs.

Learning Objectives:

1. To evaluate the clinical indication for interventional radiological approaches for HCC.
2. To evaluate pro and contra of endovascular vs percutaneous treatment options.
3. To highlight recent research and emerging developments in the treatment of HCC.

A-642 09:00

B. Liver metastases of colorectal cancer (mCRC)

T.K. Helmberger; *Munich/DE (Thomas.Helmberger@klinikum-muenchen.de)*

Among the approximately 450,000 colorectal cancer patients per year about 30% will present with synchronous, and 50% with metachronous metastases, whereas about 35% will have “liver only” metastases. Primarily, only up to 20% of the metastases will be resectable. According to current guidelines, various local and locoregional cytoreductive therapies might apply after primary systemic therapy for induction of response. Interventional oncology (IO) provides mainly three image-guided local and locoregional cytoreductive therapeutic approaches: (1) percutaneous thermal-ablation (mainly radiofrequency and microwave ablation) got established over the last 20 years. With current techniques 3 cm metastases can safely be coagulated achieving 5-year survival rates of around 50% - comparable to surgical results. (2) Transarterial chemo-ablation for larger, multifocal, or diffuse metastases is currently adopted parallel to the experiences made in the treatment of HCC. While the results of hepatic arterial infusion (HAI) are still not convincing, transarterial chemo-embolisation with drug-eluting beads (DEB-TACE) is gaining promising results with comparable response rates to systemic chemotherapy (sCTx) but less side effects. Nevertheless, long-term survival data are still lacking. (3) Transarterial radio-embolisation (TARE, SIRT) could prove its efficacy in chemo-refractory patients but also with sCTx in first-line therapy regimens achieving response rates over 90% and a significantly improved hepatic progression-free survival. Current research in IO focus on refinement of techniques and identifying (and probably utilising) secondary effects as immune-stimulation triggered, e.g. by thermal- or radio-ablation.

Learning Objectives:

1. To outline the current status of image-guided therapeutic approaches for mCRC.
2. To discuss the application of endovascular vs percutaneous treatment options in different clinical scenarios.
3. To highlight recent research and emerging developments in this field.

Author Disclosure:

T.K. Helmberger: Consultant; BTG, TERUMO, SIRTEX. Speaker; TG, TERUMO, SIRTEX.

A-643 09:30

C. Liver metastases of neuro-endocrine tumours (NET)

J. Kettenbach; *St. Pölten/AT (joachim.kettenbach@stpoelten.lknoe.at)*

Neuroendocrine tumours (NET) usually arise from the gastrointestinal tract or the pancreas and often metastasise in the liver. NETs are not easily detected and their clinical symptoms are often non-specific; thus, they pose a particular clinical challenge and most patients present with tumours at an already advanced stage. Incidence and prevalence of NETs have been increasing significantly over last decades and survival rates remain low. Somatostatin analogues have proven effective for several NET types. Recently, molecular targeted drugs against pancreatic NETs are also effective. Systemic chemotherapy may be beneficial, but often lacks clear supporting evidence. Attaching isotopes (such as ^{68}Ga, ^{90}Y or ^{177}Lu) to somatostatin-receptors makes them usable for both diagnosis and therapy, showing reduction in disease progression and no relevant toxicity. Since NETS metastasise in the liver, these metastases can be targeted by intra-arterial therapies such as chemo-, radio-, and bland embolisation as well. Radioembolisation has the advantage of not being affected by portal thrombosis, a contraindication to TACE/TAE. Currently grade 1-2, liver-only or liver-dominant disease, tumour progression and symptoms are defined as indications for embolotherapy. In addition, 18F-FDOPA PET/CT-guided RFA ablation has shown very promising results recently. There is no clear consensus which therapy technique for NETs to favour. However, these technique require careful consideration and dedicated patient care and there are still many diagnostic and therapy challenges. All local and systemic therapies do have specific characteristics and should not be seen as competing, as survival is linked to the number of treatment lines.

Learning Objectives:

1. To outline the current status of image-guided therapeutic approaches for NETs.
2. To discuss indications and advantages of endovascular vs percutaneous treatment options.
3. To evaluate literature data on interventional treatments of NETs.

08:30 - 10:00 **Room M 4**

E³ - ECR Academies: Multiparametric Ultrasound (MPUS)

E³ 1320

Multiparametric US in paediatric radiology

A-644 08:30

Chairman's introduction

K. Rosendahl; *Bergen/NO (karen.rosendahl@helse-bergen.no)*

Multi-parametric ultrasound (US) integrates B-mode anatomical information with information on an organ’s vascularity and stiffness. During this session, the role of contrast-enhanced US in paediatric imaging, focusing on trauma, liver and kidneys will be addressed, followed by a presentation on Doppler and CEUS in chest imaging. Moreover, issues on off-label use of CEUS in children will be discussed.

A-645 08:35

A. Contrast-enhanced US (CEUS) in paediatric trauma

M. Riccabona; *Graz/AT (michael.riccabona@medunigraz.at)*

The objective of this lecture is to present basic knowledge about the use, the findings and the limitations of contrast-enhanced ultrasound (CEUS) in paediatric trauma. First basics of CEUS will be revisited including a short discussion of visualization tools, implications of the off-label use of ultrasound contrast agents (UCA) in children and safety precautions. Then tips and tricks about “how to perform the exam” will be presented. Finally, indications when intravenous or intracavitary applications of UCA are useful will be listed - with examples of the typical imaging findings and discussion of restrictions of CEUS. The pros and cons of CEUS in children with trauma are discussed with respect to other imaging, particularly CT which remains the gold standard imaging technique particularly in severe and multiple trauma in childhood. CEUS is a promising option for imaging children with blunt abdominal trauma or for follow-up after trauma. When restrictions are respected, the non-ionizing nature of the investigation with a good safety profile suggest the use of CEUS in paediatric (mild to moderate) trauma as an alternative to standard CT imaging - in spite of the off-label application of UCA in Europe.

Learning Objectives:

1. To understand the role of off-label use of US contrast agents in paediatric patients.
2. To become familiar with CEUS in the assessment of paediatric trauma patients.
3. To learn about limitations of CEUS in trauma compared to CT.

A-646 09:03

B. CEUS in paediatrics: liver, kidney and beyond

E.-M. Jung; *Regensburg/DE (Ernst-Michael.Jung@klinik.uni-regensburg.de)*

The objective of this lecture is the comparison of the diagnostic liver findings of MRI, CT and CEUS in children. Methods include analysis of the diagnostic findings of CEUS, MRI and CT scans in 56 children (age 0-17 years) with a total of 60 benign and malignant liver lesions and anomalies of the portal vein/perfusion. All patients underwent CEUS using sulphur hexafluoride microbubbles and a multi-frequency probe (1-5 MHz, 6-9 MHz). MRI was performed in 38 lesions. CT was performed in 8 lesions. Out of the 56 patients, 49 liver lesions (48 benign, 1 malignant), 9 anomalies of the portal vein/perfusion and 2 of the biliary system were detected. 16/49 lesions were analysed histopathologically. Using CEUS, the characterisation of the lesions was possible in 45 out of 49 cases. In 32 cases, CEUS provided the exact diagnosis. Findings of MRI and CEUS were concordant in 84% of cases (n=32/38). CEUS considered 1 benign lesion to be malignant. 2 lesions were not detectable and in 3 lesions no definite diagnosis was established using MRI. Findings of CT and CEUS were concordant in 5 of 8 cases. In 21 lesions, CEUS as the only imaging modality was found to be sufficient. Despite the restricted indications for using CEUS in children, it offers a high diagnostic detection rate (93%) of liver lesions.

Learning Objectives:
1. To understand established indications for off-label use of CEUS.
2. To learn how to perform CEUS in different age groups.
3. To become familiar with US contrast enhancement in parenchymal organs.

A-647 09:31

C. Multiparametric US of the paediatric chest: more than effusion
P. Tomà; *Rome/IT (paolo.toma@opbg.net)*

Indications for use of thoracic ultrasound are (in descending order): to confirm and characterize pleural effusions, evaluation of a radiological opacities, follow-up of lung diseases in neonates, thoracic wall lesions (i.e. fractures, etc.), congenital malformations such as CPAM, and in several cases the pneumothorax. Colour and pulsed Doppler, wherever possible, due to motion artefacts (i.e. flash artefacts) are helpful to identify the vascular supply in congenital malformations, detection vascularity of consolidations and atelectasis. About CEUS, use in paediatrics is off label. In adults, pattern of enhancement detected by chest CEUS does not distinguish between CAP and lung cancer and overly optimistic beliefs on this matter should be debated. The limits about CAP are operator dependency, limited access of deeper areas hidden by aerated lung, no evaluation of air trapping, limited assessment of mediastinal and hilar lymphadenopathy, perihilar opacities, restrictions in appraising pulmonary vascularity, potentially non-recognition of other underlying pulmonary conditions. About the management of complicated paediatric pneumonia improving by CEUS the detection of ischaemia and necrotic tissue is useless as does not change the approach (CT experience).
Learning Objectives:
1. To understand established indications for chest US in children.
2. To learn the different roles of real-time US, Doppler and CEUS to diagnose pulmonary and mediastinal lesions, especially pneumonia.
3. To understand the limitations of percutaneous US of the chest.

08:30 - 10:00 **Room M 5**

E³ - ECR Academies: Neuroradiology: from Morphology to Function

E³ 1322
Cerebral blood flow quantification

A-648 08:30

Chairman's introduction
T. van der Zijden; *Edegem/BE (thijsvanderzijden@hotmail.com)*

Obviously, physiological and pathophysiological processes in the brain have repercussions on the cerebral perfusion. The cerebral perfusion is influenced by many regulatory mechanisms. Both systemic and local processes play a role in entities such as vasoreactivity, autoregulation and neurovascular coupling in the brain. Imaging of brain perfusion can play an important role in not only detecting pathological processes, such as stroke, neurodegenerative disease and tumour, but also in directing treatment of these diseases and in the follow-up after treatment. Nowadays, a shift from invasive to non-invasive CBF imaging has occurred. Several methodologies with different techniques have been developed to detect and measure variations in blood flow components. In this session, an overview of functional and physiological properties of cerebral vasculature in health and disease will be given. A demonstration of how to conduct functional imaging of perfusion will be given as well. In particular, the use of arterial spin-labelling techniques will be discussed. Last but not least an overview will be demonstrated of how these MRI-based cerebrovascular reactivity measurements can be implemented in a clinical setting.

A-649 08:36

A. Functional imaging of cerebral perfusion
A. Krainik; *Grenoble/FR (akrainik@chu-grenoble.fr)*

The lecture presents the functional properties of the cerebral vasculature, including neurovascular coupling, autoregulation and cerebral vascular reactivity (CVR) to circulating gases (CO2 and O2). We describe how to conduct functional imaging of perfusion, especially CVR mapping using MRI under hypercapnic challenge. We show that CVR fMRI allows to estimate the impact of functional changes of perfusion on activation BOLD fMRI in ageing and brain lesioned patients referred for stroke and tumour. CVR fMRI also provides interesting information on adaptative physiology in healthy subjects under hypoxia, and on pathophysiology in various diseases such as cerebral steno-occlusive disease, neurodegenerative diseases, brain tumour and seizure.

Learning Objectives:
1. To understand that functional imaging of perfusion enables the study of properties such as vasoreactivity to circulating gases, autoregulation and neurovascular coupling.
2. To show that functional imaging of perfusion can influence therapeutic strategy through estimation of the vascular reserve and the risk of ischaemia.
3. To learn that functional MRI of vasoreactivity is of value in understanding functional MRI activation.

A-650 09:04

B. Cerebral blood flow measurements with arterial spin-labelling
X. Golay; *London/UK (x.golay@ucl.ac.uk)*

Arterial spin labelling (ASL) is a magnetic resonance (MR) imaging technique used to assess cerebral blood flow non-invasively by magnetically labelling of the inflowing blood. One of the most attractive reasons to use ASL is that it can provide a quantitative assessment of cerebral blood flow (CBF). There are currently two main approaches used to implement ASL, pulsed ASL (PASL) and pseudo-continuous ASL (pCASL). A recent position paper has been published, indicating that the second one is preferred, as it provides a more robust SNR than PASL (1). Here, the basic model describing the biophysics of perfusion will be demonstrated and the assumptions behind its use will also be discussed. In particular, examples showing where such assumptions fail will be highlighted, so that they can be recognised and interpreted appropriately. Finally, examples of applications will be shown, in particular in stroke and as an early biomarker of disease onset in dementia. Ref: 1) Alsop et al, Magnetic Resonance in Medicine 73:102-116 (2015).
Learning Objectives:
1. To reveal how arterial spin labelling (ASL) can accurately measure cerebral blood flow (CBF).
2. To present an overview of the advantages and limitations of using ASL in adult and paediatric subjects.
3. To show that the use of subject-specific model parameters (for example particularly blood and tissue T1) can improve the accuracy of CBF estimates.

A-651 09:32

C. Cerebrovascular reserve imaging and the consequences of neurovascular uncoupling
J. Hendrikse; *Utrecht/NL (j.hendrikse@umcutrecht.nl)*

The presence of cerebrovascular reserve (CVR) can be assessed when a challenge is applied that causes a change in the cerebral vasculature (such as a vasodilation). For a patient with already a change (vasodilation) in the resting condition only a small change upon this challenge will be detected relative to a healthy subject with a normal baseline condition of the cerebral vasculature. To measure the cerebrovascular reserve two important parts can be distinguished. First, the type of challenge that is used. Second, the methods that are used to measure the cerebrovascular reserve. In the current presentation we focus on the MRI methods that used to measure the cerebrovascular reserve. Challenges that are most often used are either a carbon dioxide challenge, a breath-holding challenge, a simple functional MRI challenge (visual), or medication such as acetazolamide. For MRI measurement methods, a change in BOLD signal during the challenge is most often used. Other quantitative MRI methods that can be used are arterial spin labelling (ASL) perfusion MRI, or other quantitative methods such as phase-contrast MRA. Challenge of the CVR measurements is the setup of these measurements with, for the carbon dioxide, the delivery of the gas mixture to the patient in the MRI scanner during the MRI scan. The patient needs a gas mask and the images need to be processed after the MRI exam. In patients with cerebrovascular disease, the CVR may indicate the patients with the most severe haemodynamic impairment (reduced CVR) that might benefit most from revascularisation procedures.
Learning Objectives:
1. To understand the consequences of severely reduced CVR in terms of future risk of stroke as well as cortical thinning that can occur in the absence of acute ischaemic events.
2. To review the challenges facing clinical implementation.
3. To understand the potential of CVR for informing patient selection for revascularisation.

10:30 - 12:00 **Room A**

E³ - ECR Academies: Interactive Teaching Sessions for Young (and not so Young) Radiologists

E³ 1421

Genitourinary and gastrointestinal radiology

A-652 10:30

A. Prostate MRI using PI-RADS

H.C. Thoeny; *Berne/CH (harriet.thoeny@insel.ch)*

Prostate imaging is based on the so-called PI-RADS (prostate imaging and reporting data system) system that provides clinical guidelines for performing and interpreting multiparametric MRI (mpMRI) of the prostate. To perform correct mpMRI all sequences should be acquired with the same angle, slice thickness and location. PI-RADS is an objective tool based on a 5-point scoring system to define the probability of the presence of a significant prostate cancer and to exclude significant prostate cancer with a high likelihood. Furthermore, interreader variability should be decreased. PIRADS allows to improve and standardise communication between radiologists and urologists. In PIRADS vs 2 an overall score based on all mpMR techniques (high-resolution T2, DW-MRI and DCE-MRI) is provided for each detected lesion. PIRADS 1 and 2 mean that clinical significant cancer is unlikely to be present, PIRADS 3 means an indeterminate lesion and PIRADS 4 and 5 suggest that clinically significant cancer is highly likely to be present, in PIRADS 4 the size of the lesion is smaller than 1.5 cm, whereas PIRADS 5 means that the tumour is larger than 1.5 cm. Most of the prostate cancers are located in the peripheral zone and DW-MRI is the dominant sequence to detect a significant cancer in this location, whereas T2 is the dominant sequence to detect significant prostate cancer in the transition zone. If a sequence is technically inadequate, this should be assigned assessment category "X".

Learning Objectives:

1. To learn the clinical indications for prostate MRI.
2. To assess technical considerations for performance of multiparametric prostate MRI.

A-653 11:15

B. New aspects of renal tumours

N. Grenier; *Bordeaux/FR (nicolas.grenier@chu-bordeaux.fr)*

Renal tumours can be solid or cystic or mixed. Clear cell, papillary and chromophobe are the three most frequent types of carcinomas but many other types are possible. Angiomyolipomas, oncocytomas and leiomyomas remain the three most frequent types of benign tumours. New aspects of renal tumours include integrated MR and contrast-enhanced US criteria within Bosniak's classification for cystic masses and multiparametric MR patterns for solid tumours. These new imaging criteria should provide reliable criteria for patient management and decrease the number of inadequate follow-up and tumour biopsies. Separating atypical cystic masses and low- or non-enhancing solid tumours often requires contrast-enhanced US or MRI. One of these two techniques is now mandatory in CT-based type IIF cystic lesions for reclassification. In solid tumours, multiparametric MR imaging must include chemical shift gradient echo (GRE) sequences, signal intensity on T2-weighted images, dynamic contrast-enhanced sequences, diffusion-weighted sequences and late contrast-enhanced images. Using different combinations of two or several parameters, now makes it possible to clearly distinguish certain renal tumours. A larger validation of all these combinations is still necessary to define those having a clinical significance for routine practice.

Learning Objectives:

1. To become familiar with the different types and classifications of renal tumours.
2. To understand the key imaging findings of the different tumours.

Precision imaging and patient experience

Presiding:
J.A. Brink; Boston, MA/US
R.L. Ehman; Rochester, MN/US
P.M. Parizel; Antwerp/BE

A-654/A-655/A-656 10:30

Introduction

P.M. Parizel; *Antwerp/BE,*
J.A. Brink; *Boston, MA/US,*
R.L. Ehman; *Rochester, MN/US*

Session Objectives:

1. To document the growing significance of clinical decision support software for radiologists.
2. To demonstrate how radiologists can use quantitative imaging biomarkers to enhance their role in scientific research and clinical practice.
3. To illustrate how ACR and RSNA are helping radiologists to provide better patient-centred care and improve patient experience with medical imaging.

A-657 10:45

Clinical decision support

K.J. Dreyer; *Boston, MA/US*

As computers outperform humans at complex cognitive tasks, disruptive innovation will increasingly remap the familiar with waves of creative destruction. In healthcare, nowhere is this more apparent or imminent than at the crossroads of radiology and the emerging field of clinical data science. As leaders in our field, we must shepherd the innovations of cognitive computing by defining its role within diagnostic imaging, while first and foremost ensuring the continued safety of our patients. If we are dismissive, defensive or self-motivated - industry, payers and provider entities will innovate around us achieving different forms of disruption, optimised to serve their own needs. To maintain our leadership position, as we enter the era of machine learning, it is essential that we serve our patients by directly managing the use of clinical data science towards the improvement of care - a position which will only strengthen our relevance in the care process as well as in future federal, commercial and accountable care discussions. In this session, we will explore the state of clinical data science in medical imaging and its potential to improve the quality and relevance of radiology as well as the lives of our patients.

Learning Objectives:

1. To understand how decision support systems may improve appropriate utilisation of medical imaging.
2. To understand the role of decision support systems in reducing variation in radiologists' reporting.
3. To consider future opportunities for decision support for medical imaging.

Quantitative Imaging Biomarkers Alliance

E.F. Jackson; *Madison, WI/US (efjackson@wisc.edu)*

The RSNA quantitative imaging biomarkers alliance (QIBA, www.rsna.org/qiba) unites imaging scientists, healthcare professionals and industry and regulatory stakeholders to advance quantitative imaging and the use of quantitative imaging biomarkers (QIBs) in clinical trials and clinical practice. The QIBA mission is to improve the value and practicality of QIBs by reducing variability across devices, patients and time. This mission is accomplished by 1) collaborating to develop, test, and promulgate methods for obtaining consistent and valid QIB results across imaging platforms, clinical sites, and time and 2) accelerating the development and adoption of hardware and software standards needed to achieve accurate and reproducible QIB results. The work of QIBA is accomplished primarily by stakeholder volunteers who contribute to the efforts of four modality-specific coordinating committees (CT, MR, nuclear medicine, ultrasound) and twelve biomarker committees. In addition, a metrology work group has developed standard terminology and a rigorous statistical framework for research and clinical applications of QIBs. Selected QIBs that are considered to be transformational, translational, feasible, practical and collaborative are addressed by profiles, which are technical standards that include one or more performance claims and inform users what quantitative results can be achieved by following the profile. Sources of bias

and variance, and methods to minimize each, are considered in profile development. This presentation will summarize the goals and objectives of QIBA, including international efforts. The QIBA perspective on opportunities for QIB applications in the practice of precision medicine, challenges to be overcome, and approaches to addressing such challenges will be presented.

Learning Objectives:

1. To understand the need for quantitative imaging biomarkers in clinical trials and clinical practice.
2. To understand key challenges to the implementation of standardised quantitative imaging techniques.
3. To describe some of the current approaches to resolving such key challenges.

11:30

Interlude/Commentary: Future directions in quantitative imaging (ESR/ACR/RSNA Leaders)

Imaging 3.0/Radiology Cares

G. McGinty; *New York, NY/US (geraldinemcginty@gmail.com),*
R.L. Ehman; *Rochester, MN/US*

This session will describe campaigns that have been created by professional radiology organisations in the US to promote patient-centred practice and a thoughtful understanding of the radiologist's role in shaping care delivery and improving the health of the patients they serve. The session will describe resources and tools that have been created for these campaigns which may be useful to the radiology community worldwide. The radiology cares campaign, developed by the Radiological Society of North America (RSNA) focuses on optimising the experience of patients during their radiologic care. Through online resources and educational materials the initiative helps radiologists take patient-centred radiology from concept to practice. The imaging 3.0 campaign of the American College of Radiology (ACR) was designed as a blueprint for the future of radiology as the US healthcare delivery system transitions from a volume-based payment methodology to a value-based one. Its specific aim is to position the radiologist as the steward of appropriate imaging and an integral member of the care delivery team. Together these efforts aim to refocus radiologists' practice around the patient's needs rather than those of the physician and staff. An important component of both campaigns has been the development of tools such as the RadiologyInfo site that teaches patients about their imaging care as well as data registries such as the dose index registry that allows radiologists to benchmark against peers and measure quality improvement efforts. These campaigns have also helped promote advocacy efforts to include meaningful value-based incentives and metrics for radiologists.

Learning Objectives:

1. To understand the principles of the Imaging 3.0 initiative.
2. To understand the principles of the Radiology Cares initiative.
3. To consider potential opportunities for improved patient experience with medical imaging.

Ovarian cancer staging: where and what to look for?

M.M. Otero-García; *Santiago de Compostela/ES (milagros.otero.garcia@sergas.es)*

Ovarian cancer (OC) is the 5th most common cancer among women worldwide and the second most common gynaecological malignancy. More than 70% of women are diagnosed at an advanced stage (Stages III, IV) and, therefore, with a low 5-year survival rate. Imaging findings of OC depend on the route of dissemination. The first route is the direct extension to the pelvis and surrounding structures, followed by peritoneal extension with ascites and implants in abdominal gravity-dependent areas. Other routes include lymphatic spread throughout para-aortic and pelvic pathways, and haematogenous dissemination. OC treatment requires radical cytoreductive surgery followed by chemotherapy or neoadjuvant chemotherapy followed by interval debulking. An accurate mapping of tumour burden and distribution of disease by imaging plays a central role in treatment stratification. Contrast-enhanced CT is the first imaging technique to use in OC staging because it identifies eligible patients for complete cytoreductive surgery, establishes a precise mapping of peritoneal lesions, detects possibly non-resectable disease and possible complications (e.g. intestinal obstruction). MRI detects implants smaller than 1 cm, especially those adjacent to tissues with similar signal intensity and bladder or rectal involvement. MRI provides helpful functional information regarding response monitorization. An increase in the ADC value in the diffusion sequence indicates a good response to chemotherapy. MRI is the first imaging tool in pregnant women or those with allergy to iodinated contrast. PET/CT has the greatest utility in those patients with rising CA 125 levels and negative CT/MR imaging results during OC follow-up.

Learning Objectives:

1. To become familiar with the different radiological findings in ovarian cancer.
3. To learn where to look for metastatic ovarian cancer.
3. To investigate the role of different imaging modalities in ovarian cancer staging.
4. To understand the potential clinical impact of imaging in treatment planning.

A-662 11:00

Update in breast ultrasound

B. Brkljačić; *Zagreb/HR (boris@brkljacic.com)*

Modern US scanners use compound and harmonic imaging, and as colour Doppler for evaluation of vascularisation of lesions. High-frequency transducers may demonstrate most of lesions containing malignant microcalcifications. 3D ultrasound is available for hand-held and automated high-resolution linear 3D transducers. US-guided biopsies should be performed for all lesions visible by ultrasound. US-guided wire localisation and clip placement can be performed, as well as US-guided minimally invasive therapy, like RFA. Automated whole-breast ultrasound might have important role in screening. Fusion of ultrasound and MRI images, as second look US in MRI-examined patients decreases proportion of false-positive findings, increases specificity and decreases number of MR-guided biopsies. Hand-held ultrasound is highly operator dependent and requires proper examination technique, experience and education to visualise all breast parts and axilla. The best US scanner should be used, with high-frequency linear transducers for breast examination. Ultrasonographic findings should be compared with mammographic and MRI findings. Features of the breast lesions that need to be analysed are: shape, relation of anteroposterior to laterolateral diameter, margins, internal structure, sound absorption (distal acoustic phenomena), and stiffness. Sonoelastography is a dynamic technique that uses US to estimate the stiffness of tissues by measuring the degree of distortion under application of external force. Elastogram is superimposed over B-mode image in different colours depending on the type of elastography. Strain elastography requires compression with the transducer and is mostly qualitative, while shear wave elastography does not require compression and enables quantification of the stiffness of the lesion.

Learning Objectives:

1. To learn about technique and clinical applications of breast ultrasound.
2. To understand the role of ultrasound for guidance of breast biopsies and minimally invasive treatment.
3. To understand the role of ultrasound in screening for breast cancer.
4. To become familiar with clinical use of sonoelastography and automated whole-breast ultrasound systems.

A-663 11:30

Multiparametric MRI evaluation in brain tumours

A. Santa; *Sibiu/RO (adriansanta@ymail.com)*

MRI is definitely the method of choice in evaluating brain tumours, it is multiparametric approach permitting a very good characterisation and identification of many different types of brain masses. For the best diagnosis, one should have a good knowledge not only of what sequences are to be applied in the examination, but most importantly, what any of these sequences is really dealing with, what kind of information are they revealing and how to exploit such information for the better characterisation of tumour. The presentation explains via clinical examples the position and role of each sequence, from the morphological T1, T2 and FLAIR images to more sophisticated acquisitions, such as diffusion and ADC mapping, susceptibility weighted images, tractography, perfusion and rCBV, emphasising what properties of the mass these sequences are exploring. The multimodal approach to brain tumours is a speculative science, in which each sequence brings a different sort of data, the final result being "constructed" from the rapport that every sequence brings to the radiologist.

Learning Objectives:
1. To learn about how we assess MRI images regarding brain tumours.
2. To understand the role of each type of sequence in evaluating the pathology.
3. To appreciate how the decision of diagnostic progresses along with the various sequences acquired, the data that each sequence bring to the reader.
4. To become familiar with more sophisticated modalities of assessment of brain tumours, e.g. diffusion, ADC, spectroscopy, perfusion and with the way they add to positive and differential diagnosis.

10:30 - 12:00 **Room L 8**

ESR Patient Advisory Group (ESR-PAG)

ESR-PAG 1

Improving patient safety and quality of care in clinical radiology

A-664 10:30

Chairmen's introduction (part 1)

N. Bedlington; *Vienna/AT (nicola.bedlington@eu-patient.eu)*

This session will focus on improving patient safety and quality of care in clinical radiology. Different presentations will be included. The first one will present the work of the ESR Audit & Standards Subcommittee in collaboration with the ESR Patient Advisory Group. It will highlight methods and examples of good practice and how to improve the patient-doctor relationship. Thereafter, the patients' perspective will be provided with a focus on the driver diagram as well as on information over-/underload. The final presentation is dedicated to the implementation of a patient satisfaction questionnaire in the radiology department. It will point out the benefits of patient satisfaction assessment and how to understand the gathered feedback. The session will conclude with a panel discussion.

Session Objectives:
1. To understand how ESR is improving patient safety and quality of care through audit and standards.
2. To explore concrete examples of best practice on implementing these standards in the radiology department and how these might be replicated.

A-665 10:35

Chairmen's introduction (part 2)

B.E. Kelly; *Belfast/UK (barryekelly@mac.com)*

Audit measures something against an agreed standard. As radiological health care professionals, we tend to think of this as equipment and process driven. Whilst this is an important component, audit can, and should, also be used to measure our interaction with each other and with our patients. By doing this, we ensure that a patient-centred approach leads to a safe, professional and harmonious institution.

Session Objectives:
1. To understand how ESR is improving patient safety and quality of care through audit and standards.
2. To explore concrete examples of best practice on implementing these standards in the radiology department and how these might be replicated.

A-666 10:40

The work of the ESR Audit & Standards Subcommittee in collaboration with ESR-PAG

B.E. Kelly; *Belfast/UK (barryekelly@mac.com)*

A driver diagram (DD) is used to conceptualise an issue and to determine its system components, thus creating a pathway to achieve the goal of patient-centred care. The DD that shall be discussed provides guidance on how to embed this patient-centred care within radiology departments for the benefit of all. One way to measure patient contentment is with a patient satisfaction questionnaire. Such a document has been produced by Dr Dominque Carrie. This has been reviewed and refined by both the Patient Advisory Group and the Audit committees and will be disseminated to radiology departments throughout Europe. Overwhelming evidence shows that doctors are patients too. Ten percent of medical students and doctors have significant psychological and dependency issues. Two percent are bipolar and one percent suicidal. In addition it is known that these traits are longstanding, continuing from school, college, university through long medical careers. It is vital, for professional, pastoral and ethical reasons that these issues are recognised and treated.

Learning Objectives:
1. To become familiar with methods and examples of good practice and on how to improve the patient-doctor relationship.
2. To understand the need for balance between professional responsibility and patient autonomy.

A-667 10:55

Patients' perspective (part I)

D. Walsh; *Dublin/IE (executivedirector@efna.net)*

This presentation will explore what neurology patients view as 'quality care', using examples of good and bad radiology practice from relevant disease areas. It will then question if such good practice can be further enabled - and bad practice minimized - through patient involvement in monitoring the implementation of the driver diagram. To facilitate this process, good communication between doctor, patient and the wider multidisciplinary team is essential, and this will be considered from the patient perspective. The presentation will aim to analyse the potential phases of patient involvement, for example, including ways to identify the most relevant patient-reported outcome measures, and ways to collect and analyse patient-generated evidence. The evidence - in this case, a patient relevant audit of driver diagram implementation - must then be disseminated to allow prospective patients to engage in more informed decision-making in their approach to choosing treatment and management options, e.g. services, treatment centres and health care professionals.

Learning Objectives:
1. To learn that implementing the driver diagram in their department will be a step-by-step process that can be monitored by patients.
2. To learn that a fair knowledge of the upcoming procedure is part of feeling safe for the patient.
3. To learn that an overload of information is equally detrimental to a safe feeling as no information, putting the patient central means an adjusted offering of information.

Author Disclosure:
D. Walsh: Grant Recipient; EFNA, as an organisation, is funded - in part - by a consortia of pharmaceutical sponsors. The list can be found here: http://efna.net/about-us/finance-and-funding/. Speaker; As Executive Director of EFNA, I am occasionally invited to speak at events held by the pharmaceutical industry. However, no payment is received..

A-668 11:10

Patients' perspective (part II)

E. Briers; *Hasselt/BE (erikbriers@telenet.be)*

The perfect radiology department does not exist there is always room for improvement. The driver diagram can be seen as an inventory of good practice objectives. A comparison between this standard and the actual situation in the department should show weak point and elements to be improved. Ideally this is realised through a good set of procedures (ISO meaning) that guide the work in the department. These procedures need verification in the execution. In this, patients play a vital role as they go where radiologists do not go and they undergo the procedures. To ensure patients a safe and comfortable journey through the department they need to know and understand what they are up to. Patients present themselves to the department they are sent by a clinician with a diagnostic issue. The diagnostic issues are very diverse from a simple broken wrist to a cancer diagnosis. The patients on the other hand have different levels of literacy and on top of that different level of coping. This boils down to the fact that there is not one answer that will fit all patient and diagnostics needs. What is not enough information for one patient is an overload for another and overload is as bad as no information at all as it makes the patient deaf to new and potentially important info. Good information is provided at the level of the individual patient with adequate complexity, respect and compassion for the intellectually underprivileged.

Learning Objectives:
1. To learn that implementing the driver diagram in their department will be a step-by-step process that can be monitored by patients.
2. To learn that a fair knowledge of the upcoming procedure is part of feeling safe for the patient.
3. To learn that an overload of information is equally detrimental to a safe feeling as no information, putting the patient central means an adjusted offering of information.

A-669 11:25

Example of good practice: implementing a patient satisfaction questionnaire in your radiology department

D.-G. Carrié; *Toulouse/FR (dominiquecarrie@wanadoo.fr)*

Patients of modern medical imaging require from us doctors radiologists, very high-quality technical performances, carried out on the most modern equipment, in complete efficiency and safety. They also demand that they are carried out as quickly as possible, in pleasant places, by well-trained staff

attentive to all their requests. For 9 years, in our department of medical imaging in Toulouse (France), it has, therefore, appeared necessary to assess their satisfaction by a questionnaire after they benefited from a diagnostic or interventional (CT or MRI) imaging. This experience showed us that it is easy to implement such a questionnaire in any structure of medical imaging. The proposed items may be discussed between radiologists, with the service personnel, with patient-users organisations you know, in relation to the supposed expectations of your patients and potential problems or limits to each structure (for example, appointment delays, times of waiting, results retrieval, direct access to the radiologist). The questions must be simple and understandable by each patient. For the responses obtained to be sufficiently numerous and representative, incentives to respond to the questionnaires must be implemented (proposed systematically after any delivery of the result for instance). The results obtained must be regularly collated, their evolution over time analysed, modifications in your daily practice implemented, their presentation to the entire team regularly made. This allows us to better understand the expectations of our patients, to improve our practices to satisfy them better, and thus offer a radiology service closer to them.

Learning Objectives:

1. To understand the benefits of patient satisfaction assessment.
2. To learn how to implement a questionnaire (means to be used, items to estimate).
3. To understand the feedback you will obtain.

11:40

Panel discussion: Does your department perform well in patient-centred care?

10:30 - 12:00 **Room F1**

E³ - European Diploma Prep Sessions

E³ 1423
Gastrointestinal and abdominal

A-670 10:30

Chairman's introduction

C. Stoupis; *Männedorf/CH (c.stoupis@spitalmaennedorf.ch)*

The role of radiologist in the diagnosis of abdominal diseases is crucial. Knowledge of the key imaging features of the different abdominal disorders including the benign and malignant lesions of the parenchymal organs and the GI tract, based on the underlying anatomy, physiology and pathology is essential to approach the correct diagnosis. Awareness of strengths and limitations of the different imaging techniques will increase the diagnostic confidence of radiologist, providing important information about lesion detection and characterization and will guide to the specific diagnosis and the decision making in patient management.

Session Objectives:

1. To understand the typical imaging features of benign and malignant lesions of the hepatobiliary system.
2. To learn the typical imaging features of benign and malignant lesions of the pancreas and spleen.
3. To become familiar with the methodological basis and to differentiate typical features in imaging examinations of the gastrointestinal tract.
4. To understand the role of different imaging modalities including hybrid imaging in diagnosing and staging neoplasms, gastrointestinal and abdominal organ systems.

A-671 10:36

A. Hepatobiliary system

Y. Menu; *Paris/FR (yves.menu@sat.aphp.fr)*

Detailed understanding of liver and biliary anatomy and segmentation and vessel anatomy (hepatic artery, portal vein, hepatic veins, inferior vena cava) including variants in vascular anatomy that may affect surgical planning is critical. Focal liver lesions include benign and malignant tumours, as well as infections. Distinction can be done with imaging in most cases using an algorithmic approach, helped with clinical and biological data. Multimodality may be necessary, sometimes leading to the necessity of imaging-guided biopsy. Imaging is more and more prominent in the evaluation of diffuse liver diseases, based on morphological changes as well as quantification of fat, iron and fibrosis. Bile duct imaging requires relevant technique and good understanding of the appearance of main diseases like tumours and inflammation. Overall, imaging is a prominent step for the evaluation of hepatobiliary diseases, while the radiologist's role is also to choose the relevant method, or association of methods, for the clinical question.

Learning Objectives:

1. To learn the anatomy, normal variants and congenital disorders of the hepatobiliary system.
2. To become familiar with the primary and secondary imaging features of acute and chronic diffuse liver diseases.
3. To understand the causes and imaging features of benign and malignant focal liver lesions, including cysts, haemangiomas, adenomas, focal nodular hyperplasia, hepatocellular carcinomas and metastases.
4. To learn the various causes and imaging features of benign and malignant diseases of the biliary tract and gallbladder.

A-672 11:04

B. Pancreas and spleen

W. Schima; *Vienna/AT (wolfgang.schima@khgh.at)*

In general, contrast-enhanced MDCT is the primary tool of pancreatic imaging, and MRCP is very valuable for assessment of the ductal system. There is a variety of anatomic variants and anomalies of the pancreas and the ductal system. Pancreas divisum and annular pancreas are the result of either failure of fusion or of rotation of the pancreas anlagen during the foetal period. Both anomalies may result in significant morbidity. Ductal adenocarcinoma is by far the most common malignant tumour of the pancreas, with approximately 80% of patients having non-resectable (advanced) disease at the time of diagnosis. In patients with equivocal CT findings, contrast-enhanced MRI is the technique of choice for visualization of small tumours. A wide differential diagnosis exists for cystic masses: from benign pseudocysts to benign, borderline and invasive malignant neoplasms. Contrast-enhanced MRI is the best modality for characterization of these lesions and to guide follow-up in these patients. Acute pancreatitis is classified as interstitial oedematous or necrotizing pancreatitis according to the revised Atlanta classification, which has brought a consistent terminology for fluid collections and complications of pancreatitis. Imaging of splenic masses is one of the less esteemed tasks in abdominal imaging. The reason for this is that the imaging appearances of many splenic lesions may overlap, which makes noninvasive characterization quite challenging. However, imaging findings of the most important benign lesions such as haemangiomas, hamartomas and abscesses should be familiar. If noninvasive characterization of focal splenic lesions is not possible, US-guided core needle biopsy may be of help.

Learning Objectives:

1. To understand the anatomy, normal variants and congenital disorders of the pancreas.
2. To become familiar with the causes and imaging features of benign and malignant pancreatic tumours.
3. To understand the imaging features of acute and chronic pancreatitis and its potential complications.
4. To learn the causes and imaging features of focal and diffuse splenic abnormalities.

A-673 11:32

C. Imaging of the gastrointestinal tract

R.G.H. Beets-Tan; *Amsterdam/NL*

Fluoroscopy, US, CT and MRI are the cornerstones in GI tract imaging. Fluoroscopy has a role in congenital anomalies and functional disorders of GI tract. Transabdominal US is accurate to detect appendicitis and abdominal free fluid and fluid/abscess collections. Contrast-enhanced CT identifies post-traumatic complications such as lacerations, the causes of bowel obstruction and dilatation. CT shows postoperative complications such as leakage of surgical anastomosis, abscesses, internal herniation, bowel strangulations and bowel ischaemia. Inflammation of the bowel, diverticulitis, epiploic appendagitis are well detected on CT. In recent years, MR enterography has gained field for the assessment of Crohn's disease activity and extent. Endoscopic US is the mainstay in staging oesophageal and gastric tumours, CT is the method of choice for local and distant staging of duodenal, small and large bowel tumours, while endorectal US and MRI have been widely adopted for staging of rectal tumours. This lecture will deal with the various GI diseases and its imaging features.

Learning Objectives:

1. To become familiar with the anatomy, normal variants and congenital disorders of the oesophagus, stomach, duodenum, small bowel, colon, rectum and anal canal.
2. To understand the imaging features of colonic diverticulosis, diverticulitis, tumour stenosis, ileocolic intussusception, colonic fistula, paracolic abscess, epiploic appendagitis, intraperitoneal fluid collection, colonic pneumatosis and pneumoperitoneum.
3. To learn typical radiological manifestations of inflammatory bowel diseases, malabsorption syndromes, infection and bowel ischaemia.
4. To become familiar with the staging of tumours of the gastrointestinal tract, including features that indicate nonresectability, and to understand the role of different imaging modalities including hybrid imaging in diagnosing and staging.

10:30 - 12:00 **Room M 4**

E³ - ECR Academies: Multiparametric Ultrasound (MPUS)

E³ 1420
Multiparametric US of small parts

A-674 10:30
Chairman's introduction
D.-A. Clevert; *Munich/DE (Dirk.Clevert@med.uni-muenchen.de)*

Ultrasound is a sensitive and accurate technique for the evaluation of small part abnormalities, and is widely accepted as the first-line imaging technique and the gold standard for many common and uncommon small part diseases but does not provide a histological diagnosis. Due to the continuous development of modern ultrasonography, such as high frequency transducers, colour Doppler and real-time elastography, ultrasonography is considered the imaging modality of choice in small parts disorders. Real-time elastography has been introduced over 20 years ago for making non-invasive measurements of the mechanical properties of tissue and for imaging the elasticity of biological tissue. Real-time elastography in detection and differentiation of nodules in the breast, prostate, thyroid gland lymph nodes and scrotal mass has already demonstrated its promising value.
Author Disclosure:
D. Clevert: Advisory Board; Samsung, Siemens, Philips, Bracco. Speaker; Samsung, Siemens, Philips, Bracco.

A-675 10:35
A. Thyroid
S.S. Özbek; *Izmir/TR (sureyya.ozbek@ege.edu.tr)*

Thyroid nodules are detected in more than half of the general population. Given the fact that only about 5-15% of them are malignant, characterization of them during clinical management becomes highly important. Contrary to its high performance in detecting nodules, real-time grey-scale ultrasonography (US) is not perfect in differentiating malignancy. Nodular features including marked hypoechogenicity, solid structure, irregular margins, taller-than-wider shape, internal microcalcifications and evidence of extrathyroidal disease have been used for characterization. However, no single parameter has been shown to be completely reliable in this regard. Thus, some sonographic patterns and guidelines with combined use of these features have been suggested in recent years, resulting better rates of characterization. Up to now, research focusing on Doppler US and sonoelastographic techniques has yielded only complementary value to enhance the conclusion deduced from grey-scale examinations, rather than being a substitute. A sonoelastographic result in favour of a “soft” lesion is suggested to be used to impose benignancy, when grey-scale US results are inconclusive. Thanks to the gland’s superficial location, new generations of colour Doppler US systems provide highly detailed vascular depiction of nodular vascularity, which results in scarcity of contrast-enhanced US (CEUS) research in thyroid gland. Currently, the use of CEUS agents is largely limited to depiction of residual tissue following therapeutic ablation. In conclusion, the characterization of thyroid nodules are mainly based on combined use of grey-scale US criteria indicating highly suspicious for malignancy. In cases of equivocal results, sonoelastographic findings may be of value in enhancing diagnostic accuracy.
Learning Objectives:
1. To understand the current roles of real-time US, Doppler techniques, US elastography and CEUS to differentiate between benign and malignant thyroid nodules.
2. To learn about current guidelines for thyroid nodule assessment.
3. To become familiar with the advantages and limitations of the various US techniques.

A-676 11:03
B. Lymph nodes
P.-Y. Marcy; *Ollioules/FR (brozpy@gmail.com)*

Multiparametric ultrasound (MPUS) assessment of superficial lymph nodes (LN) is well established. This includes diagnosis, prognosis, selecting and monitoring treatment, beyond the diagnosis itself (cancer, lymphoma, or inflammatory nodes). Diagnosis of a unilateral metastatic N+ reduces by 50%/25% the epidermoid head and neck cancer patient's 5-year survival rate when ipsilateral/in the lower/contralateral neck. Metastasis is site specific with respect to H&N primary location. Differences between benign and malignant nodes are based upon size, shape, echotexture, echogenic hilum and vasculature. Malignant nodes are typically hypoechoic, without echogenic hilum, round shaped, with L/T ratio <2, and with vessels predominant in periphery. Typical US features of LN include reactive adenitis (germinative centres); cystic (tuberculosis, H&N & thyroid carcinomas) and reticulated patterns (malignant lymphoma), and microN+. Combining Fine Needle Aspiration Cytology (FNAC) increases US specificity up to 93%. US guided-FNAC makes the diagnosis of microN+ (subcortical foci), thus should improve oncology prognosis. FNA biopsy makes the subtype diagnosis of malignant lymphoma. Thyroglobulin/Calcitonin wash-out improves the diagnostic accuracy of N+ of follicular/medullary thyroid origin. CEUS can assess nodal architecture and depicts abnormal vascular patterns, where results are uncertain. Elastography may detect a subset of malignant LN. US landmarks knowledge of axillary and inguinal regions, and of the Robbins classification in the neck is mandatory to define the correct anatomical location of LN to the surgeon/oncologist. Assessment of sentinel lymph nodes is useful in breast/penile, vulva/head and neck, and thyroid cancers.
Learning Objectives:
1. To understand the current roles of real-time US, Doppler techniques, US elastography and CEUS to differentiate between benign and malignant superficial lymph nodes.
2. To understand MPUS criteria and their limitations.
3. To learn about MPUS in the assessment of sentinel lymph nodes.

A-677 11:31
C. Scrotum
M. Bertolotto; *Trieste/IT (bertolot@units.it)*

Ultrasonography (US) is the imaging modality of choice for examination of the scrotum. It can provide information valuable for the differential diagnosis of a variety of disease processes involving the scrotum with similar clinical manifestations. Beside grey-scale US, several modes have been adopted to improve characterization of scrotal lesions, including Doppler US modes, sonoelastography and CEUS. A multiparametric approach to scrotal pathologies has potential to improve the diagnostic performance of grey-scale US. Doppler modes are used in association with grey-scale investigation in virtually all patients. Their ability to demonstrate testicular perfusion aids in reaching a specific diagnosis in patients with acute scrotal pain, and in characterization of solid tumours. A number of hypovascular lesions, however, still appear avascular. Differentiation between truly avascular and hypovascular lesions is clinically important, since there is increasing evidence that the former are usually benign, while the latter are more often malignant. CEUS can be used to clearly demonstrate presence or absence of lesion vascularization when colour Doppler findings are equivocal. Reason for the use of elastographic modes stems from the existence of large differences in stiffness between surrounding normal and pathologic tissues that may otherwise possess similar image contrast with conventional modes. Generally speaking, when a hard lesion is identified malignancy is suspected, while soft masses are more often benign. However, exceptions exist to this rule. A variety of benign testicular lesions may appear hard at elastography and, on the contrary, malignant tumours may be softer than expected. Moreover, some lesions change consistency over time.
Learning Objectives:
1. To become familiar with the US morphology of the normal scrotal content as assessed by real-time US, Doppler techniques, US elastography and CEUS.
2. To learn the advantages and limitations of these US modalities in the assessment of the acute scrotum.
3. To understand the current roles of real-time US, Doppler techniques, US elastography and CEUS to differentiate between benign and malignant testicular and extratesticular scrotal mass lesions.

Advanced imaging techniques in brain tumours

A-678 10:30
Chairman's introduction
P.C. Maly Sundgren; *Lund/SE (Pia.Sundgren@med.lu.se)*

As session chairman, I will give a brief introduction to the topics related to advanced techniques in brain tumour imaging that will be discussed in this session and give some highlight as well as some future ideas regarding advanced brain tumour imaging with respect to new magnetic resonance imaging sequences.

A-679 10:36

A. Clinical utility of perfusion imaging for differentiating brain tumours
I.N. Pronin; *Moscow/RU*

"no abstract submitted"
Learning Objectives:
1. To provide practical tips and tricks for performing CT and MR perfusion in patients with brain tumours.
2. To illustrate how certain perfusion derived parameters (rCBV) can be correlated with tumour histology (e.g. angiogenesis, capillary leakage, malignancy grade).
3. To show that intense contrast enhancement is not identical to perfusion.

A-680 11:04

B. Clinical applications of amino acid PET in brain tumour patients
N. Galldiks; *Cologne/DE (norbert.galldiks@uk-koeln.de)*

In the last years, PET using radiolabelled amino acids has gained increasing interest in the diagnostics of brain tumour patients and has been established in many neurooncological centres as a complementary diagnostic tool to conventional MRI. Amino acid PET offers important additional information in the diagnosis of unclear space-occupying brain lesions and an improved delineation of glioma extent, which is helpful for biopsy guidance, planning of resection and radiation therapy. Furthermore, amino acid PET imaging may provide prognostic information in untreated, newly diagnosed glioma patients, helps to differentiate tumour progression or recurrence from treatment-related changes in low- and high-grade gliomas as well as in brain metastasis (e.g. pseudoprogression, radiation necrosis) and allows to evaluate the metabolic response following brain tumour therapy, particularly chemoradiation, alkylating chemotherapy and antiangiogenic therapy, earlier than with conventional MRI.
Learning Objectives:
1. To show that amino acid PET is gaining increasing importance in assessment of tumour activity and malignancy.
2. To demonstrate how amino acid PET can be useful in glioma delineation for treatment planning (e.g., resection, biopsy, radiation), detection of post-therapeutic effects, assessment of treatment response, and prognostication.
3. To provide information on new PET tracers (targeting tumour hypoxia, enzymes in neoplastic metabolic pathways, etc.) and the combination of tracers with therapeutic agents.

A-681 11:32

C. Assessment of brain tumour perfusion and abnormal vascular structure using arterial spin-labelling
X. Golay; *London/UK (x.golay@ucl.ac.uk)*

Haemodynamic alterations are present in many brain tumours, and in general, CBF and cerebral blood volume (CBV) increase with grade. Much of our MR imaging-based knowledge about these changes has been gained from Gd-based techniques, in particular dynamic susceptibility contrast (DSC) and dynamic contrast-enhanced (DCE) imaging. Thus, so far, most literature has focused on relative CBV changes, because it is easier to assess using such techniques than CBF, and most of the data available are of relatively poor spatial resolution and prone to artefacts, due to the rapid passage of the intravascularly confined tracer necessitates. ASL cannot measure relative CBV, but provides a straightforward assessment of CBF. In particular, since water has high permeability in the normal and neoplastic tissue, there is no need with ASL to use complicated leakage-correction algorithms to obtain quantitative results. Initial reports demonstrated that ASL and DSC show largely concordant results in glioblastoma multiformae (GBM) (for reference, see 1). Higher CBF in GBM correlates with genetic markers and is associated with shorter progression-free survival time. Lower grade tumours typically demonstrate lower CBF. In fact, some have suggested that CBF quantification provides a better estimate of event-free survival for a wide range of gliomas than does a histologic grading scale. Finally, CBF has also been used to assess metastatic disease and treatment response, in particular in the assessment of radiation necrosis vs. recurrence. Ref: 1) Haller et al., Radiology, 281(2):337-356 (2016).
Learning Objectives:
1. To offer a short update on the physical principles and technique of arterial spin-labelling in assessing brain tumour perfusion.
2. To review the advantages and disadvantages of ASL as compared to contrast-enhanced perfusion imaging.
3. To provide clinical examples where ASL has contributed significantly to management and clinical decision making in brain tumour patients.

A-682 12:15

From features to function: breakthroughs in breast imaging
F.J. Gilbert; *Cambridge/UK (fjg28@cam.ac.uk)*

The imaging phenotype of breast cancer is used to decide the likelihood of a lesion being invasive or in situ disease which affects the diagnostic approach. The morphological appearance can give a clue as to the grade or aggressiveness of a cancer. Functional imaging gives information about the vascularity, metabolism or cellular activity of a lesion or organ. Functional magnetic resonance imaging (MRI) techniques include dynamic contrast-enhanced (DCE) MR, diffusion-weighted imaging (DWI), blood oxygen level-dependent (BOLD) MR and these give insight into pathology and pathological processes that cannot be gained from traditional anatomical imaging. Molecular imaging with radioisotopes gives information on metabolism and proliferation and this has been exploited in PET using different radiotracers. Breast cancer has a marked degree of tumoural heterogeneity reflecting clonal diversity which exhibits various metabolic and functional phenotypic characteristics. This variation can result in different prognosis and also a differential response to treatment creating a challenge in the identification of the best therapeutic regimen for each patient. Vascular and proliferation measures can be used to predict response to treatment. This lecture will focus on the move from morphological imaging in breast cancer to a more functional approach and examine whether or not there is sufficient evidence for us to change our practice.

E³ - The Beauty of Basic Knowledge: Chest Imaging

E³ 25D

The most important measurements you need to know in chest radiology

Moderator:
N. Howarth; Chêne-Bougeries/CH

A-683 12:30

A. Heart and great vessels: how, why, when?
G. Fassa-Ashrafpoor; *Chêne-Bougeries/CH (golmehr.fassa@grangettes.ch)*

Cross-sectional imaging techniques such as computed tomography (CT) and magnetic resonance imaging (MRI) are increasingly being performed, allowing unrestricted assessment of the heart and great vessels. ECG-gated acquisition protocols are crucial in reducing motion artefacts. Measurement of the thoracic aorta is performed at different anatomic levels using a multi-plane double-oblique reconstruction perpendicular to the lumen, allowing for identification of patients requiring surgical management. Assessment of the heart includes measurement of right and left atrial areas, end-systolic and end-diastolic right and left ventricular volumes (allowing determination of ejection fraction) and left ventricular end-diastolic wall thickness, which are relevant for the diagnosis of cardiomyopathies. Moreover, structural analysis of the heart should also be performed. The anatomy, connections and dimensions of the pulmonary veins can be easily analysed. The presence of thrombosis in cardiac cavities, mainly in the left atrial appendage and the left ventricular apex should also be sought, most importantly in patients with a history of systemic embolism. Other structures, such as the coronary arteries and cardiac valves can also be accurately assessed by CT and MRI. Finally, cross-sectional techniques are indicated for follow-up of patients after surgical intervention of the heart and great vessels.
Learning Objectives:
1. To review the most useful measurements on cross-sectional imaging of the heart and great vessels.
2. To learn how to accurately perform these measurements.
3. To know when the measurements are of clinical importance.

A-684 13:00

B. Lung nodules: is volume better than size?

M. Prokop; *Nijmegen/NL*

"no abstract submitted"

Learning Objectives:

1. To review the management of pulmonary nodules seen on CT.
2. To learn how to accurately perform the measurement of nodule volume and size.
3. To know the limitations of the lung nodule measurement.

12:30 - 13:30 **Room D**

E³ - The Beauty of Basic Knowledge: A Survival Guide to Musculoskeletal Imaging

E³ 24D

Acute trauma: patterns in the peripheral skeleton

Moderator:
V.N. Cassar-Pullicino; Oswestry/UK

A-685 12:30

Acute trauma: patterns in the peripheral skeleton

J. Teh; *Oxford/UK (jamesteh1@googlemail.com)*

A systematic approach to analyse trauma imaging of the peripheral skeleton is presented. Typically, imaging begins with x-rays. A step-wise approach may reveal subtle abnormalities that should prompt further action. For example, the presence of a Segond fracture on x-ray suggests an ACL injury and thus should lead to an MRI scan. It should be recognized that in trauma, certain injuries cannot occur in isolation; therefore, a dislocated radial head on elbow x-ray should prompt imaging of the whole forearm, as Monteggia fracture-dislocation may be present. Understanding mechanisms of injury allows the radiologist to predict patterns of injury. So if bone bruising is present on MRI in the lateral femoral condyle and medial patella, a lateral patellar dislocation should be suspected and a specific search for an injury of the medial retinaculum should be made. Conversely, recognizing classic patterns of injury can allow the mechanism of injury to be deduced. This lecture will focus on classical patterns of acute trauma in the peripheral skeleton.

Learning Objectives:

1. To become familiar with the imaging manifestations of common important injuries in the upper and lower limb.
2. To understand the underlying mechanism that result in combination of injuries.
3. To learn how to best employ imaging modalities in their diagnosis.

14:00 - 15:30 **Room A**

E³ - ECR Academies: Interactive Teaching Sessions for Young (and not so Young) Radiologists

E³ 1521

Imaging of the skull base

A-686 14:00

A. Non-tumoural pathology of the temporal bone

B. Ozgen Mocan; *Ankara/TR (burce@hacettepe.edu.tr)*

The temporal bone has a complex anatomy but the pathologies involving the temporal bone structures are somewhat limited with specific and diagnostic imaging findings. During this lecture, the most common non-tumoural causes of conductive and sensorineural hearing loss will be reviewed in an interactive manner with an emphasis on the most commonly seen pathologies such as chronic inflammation, cholesteatoma, otosclerosis and labyrinthitis ossificans.

Learning Objectives:

1. To learn the most common inflammatory lesions of the temporal bone.
2. To become familiar with malformations and common pathologies.

A-687 14:45

B. Tumours of the skull base

T. Beale; *London/UK (timothy.beale@uclh.nhs.uk)*

The lecture will describe a classification system for tumours of the skull base that will aid in the differential diagnosis. Using clinical cases the imaging features of the common skull base tumours will be highlighted. The important review areas for the individual tumours will be discussed including those features that may alter the clinical management and help in the differential diagnosis. The common pitfalls and non-neoplastic differential diagnosis will be highlighted and an imaging technique for assessing the skull base will be discussed.

Learning Objectives:

1. To become familiar with the imaging technique of the skull base.
2. To identify imaging criteria for improved differential diagnosis.

14:00 - 15:30 **Room B**

Special Focus Session

SF 15a

My three top tips for abdominal imaging

A-688 14:00

Chairman's introduction

M. Zins; *Paris/FR (mzins@hpsj.fr)*

In this session including focused short lectures we will learn how to avoid common mistakes in abdominal radiology and we will understand how to get over an area of difficulty through the clinical expertise of selected abdominal radiologists. Common liver, pancreatic and biliary diseases will be discussed as well as Inflammatory bowel diseases and acute abdominal conditions.

Session Objectives:

1. To learn how to avoid common mistakes in abdominal radiology.
2. To understand how to get over an area of difficulty through the clinical expertise of selected abdominal radiologists.

A-689 14:05

Postoperative abdomen

D.J.M. Tolan; *Leeds/UK*

"no abstract submitted"

Learning Objectives:

1. To learn how to optimise detection of anastomotic leaks on CT using radiological signs and positive luminal contrast.
2. To recognise material in the abdomen surgeons may leave deliberately.
3. To recognise material in the abdomen surgeons may leave by accident.

A-690 14:13

Appendicitis

J.B.C.M. Puylaert; *The Hague/NL (dr.jbcmpuylaert@wxs.nl)*

Abdominal ultrasound plays a pivotal role in the imaging workup of patients with suspected appendicitis. It should be the primary modality, and only in case of a negative or inconclusive examination, should be followed by CT or MR. The specific advantages of US over CT are: US has an image definition in the close range which is much higher than that of CT. US is more interactive than CT. Patient's history as well as the painful area or palpable mass can directly be correlated with the US findings. US is real-time and shows peristalsis, pulsations and blood flow. US also shows the effects of respiration, Valsalva manoeuvre, gravity and compression with the probe, allowing to assess whether the appendix or other organs as bowel and gallbladder are soft or rigid. US allows immediate US-guided puncture of intraperitoneal fluid and drainage of pus. US in appendicitis should be performed with graded compression. Compression is necessary to displace or compress bowel to eliminate the disturbing influence of bowel gas and to approach the pathological structure closely. This allows the use of a high-frequency transducer with a better image quality. The final US report should be integrated with the clinical findings, laboratory data, CT scan and possible other radiological examinations. It is clear that the US examination, as described here, should not be performed by a technician nor by a clinician, but by an experienced (abdominal) radiologist.

Learning Objectives:

1. To learn that US has a pivotal and unique role in appendicitis and should be done prior to CT.
2. To learn that US in acute abdomen allows the radiologist to get closer to the patient than CT and MRI.
3. To learn that US should be performed by abdominal radiologists, and not by clinicians or technicians.

A-691 14:21

Bile duct stones

J.A. Guthrie; *Leeds/UK (Ashley.Guthrie@leedsth.nhs.uk)*

1. Whilst the investigation of choice for the diagnosis of gallstones within the gall bladder is US, it is less reliable for stones in the bile ducts. Risk factors in patients with known stones (either pre- or post-cholecystectomy) include right upper quadrant pain, deranged liver function tests and a dilated common bile duct. MRCP is a reliable quick non-invasive examination. 2. 2D HASTE/SS-FSE/FSE-ADA/FASE without fat saturation in 2 planes (oblique coronal and axial) will establish a diagnosis in most cases and are the “work horse” sequences in most patients, and can usually be acquired over a limited number of breathholds. The ducts are outlined by fluid in the lumen and fat outside the duct. Stones are identified as dependent filling defects on 2 planes. The lack of fat saturation allows for a better appreciation of the bile duct wall and adjacent anatomical structures. 3D sequences often take a long time to acquire and may yield poor images. 3. FISP/GRASS/FFE/SARGE (which can be gated) are a useful adjunct especially in those patients that have difficulty holding their breath, if they are struggling turn to this class of sequence before the patient is exhausted.

Learning Objectives:

1. To learn that in patients with a high index of clinical suspicion of bile duct stone, MRCP should be employed early.
2. To know that 2D HASTE/SS-FSE/FSE-ADA/FASE without fat saturation in 2 planes (oblique coronal and axial) - will establish a diagnosis in most cases and are the "work horse" sequences in most patients.
3. To understand that FISP/GRASS/FFE/SARGE (which can be gated) are a useful adjunct especially in those patients that have difficulty holding their breath.

Author Disclosure:

J.A. Guthrie: Speaker; Bayer Healthcare, Siemens AG.

A-692 14:29

Dilated pancreatic duct

R. Manfredi; *Verona/IT (riccardo.manfredi@univr.it)*

The prognosis of pancreatic adenocarcinoma is very poor, and little improvement has been reported in the past several decades. Only a low percentage of patients in whom pancreatic cancer is detected at an early stage without local infiltration have the potential for long-term survival after surgical resection. The earliest possible diagnosis may be the most effective way to improve the prognosis. Dilatation of the main pancreatic duct may represent a secondary sign of pancreatic adenocarcinoma. Therefore, the diagnosis of dilated main pancreatic duct may be a predictive sign of pancreatic adenocarcinoma; therefore, careful follow-up in people with such signs have been recommended and eventually prompt treatment. Pancreatic endocrine neoplasms are relatively rare, with an incidence rate of approximating five cases per one million person-years. Some pancreatic endocrine neoplasms release hormones into the blood stream that cause clinical syndromes, whereas others are non-syndromic and present as a mass lesion. At diagnostic imaging, pancreatic endocrine neoplasms typically produce hyperenhanced well-demarcated lesions that are best seen on arterial phase images. Pancreatic endocrine neoplasms may be responsible for pancreatic duct stenosis, even when they are small in size (<2 cm) and be responsible for marked dilatation of the main pancreatic duct and/or marked atrophy of upstream pancreas. Intraductal papillary mucinous neoplasm (IPMNs) originates from the ductal epithelium and overproduce mucin which is responsible for dilatation of the main pancreatic duct and/or the side branches. Diagnostic imaging is helpful in the diagnosis and follow-up of these patients.

Learning Objectives:

1. To learn how to diagnose and manage adenocarcinoma of the pancreas mimickers: autoimmune pancreatitis and paraduodenal pancreatitis.
2. To appraise how to manage incidental cystic lesions of the pancreas.
3. To learn how to diagnose and manage neuroendocrine neoplasms of the pancreas.

A-693 14:37

Liver biopsy

V. Vilgrain; *Clichy/FR (valerie.vilgrain@aphp.fr)*

Liver biopsy is the most common invasive procedure of the liver. Indications of biopsy in diffuse liver diseases have declined due to improvements in non-invasive assessment of fibrosis and steatosis. On the contrary, biopsy of liver tumours is still indicated mostly for diagnostic purpose and to a lesser extent for assessing the prognosis or the prediction of tumour response. Three keys are important: first, check the indication. There are very few contraindications (mostly related to coagulation disorders) and the most important is to ensure that there is a good indication for liver biopsy; second, use ultrasound guidance, which is faster, easier and more accurate than CT. It allows real-time control; third, if a primary tumour liver is considered, always perform a biopsy in the adjacent liver. This will help the pathologist for the diagnosis.

Learning Objectives:

1. To understand the risk/benefit of liver biopsy.
2. To know the absolute contraindications.
3. To be aware of the most important technical tricks.

A-694 14:45

Bowel ischaemia

A. Filippone; *Chieti/IT (a.filippone@rad.unich.it)*

Mesenteric ischaemia is associated with a high mortality rate, especially in the acute setting. A high index of suspicion is necessary to achieve early diagnosis. The main challenge is to differentiate acute mesenteric ischaemia from other more common causes of acute abdominal pain. Nonvascular CT findings including bowel wall appearance, mesenteric involvement, intestinal pneumatosis, and portal venous gas play a crucial role to reach a prompt diagnosis. Therefore, the radiologist has to be aware either of the meaning of all these signs in terms of diagnosis and prognosis or of their mimics to avoid an incorrect treatment. We will review the typical CT pattern of mesenteric pneumatosis which allows to distinguish it from the so-called “pseudopneumatosis”. Furthermore, we will discuss those conditions of mesenteric pneumatosis not associated with acute ischaemia. Since the bowel wall appearance plays a crucial role to understand the pathogenesis of mesenteric ischaemia and, therefore, its treatment planning, we will describe the different patterns to understand their meaning and the possible differential diagnosis. Then, we will review the value of peritoneal involvement to figure out its role in terms of diagnosis and prognosis.

Learning Objectives:

1. To understand the reliability of mesenteric pneumatosis.
2. To learn about the different faces of ischaemic bowel wall.
3. To understand the meaning of peritoneal fluid.

A-695 14:53

Colon polyp

F. Iafrate; *Rome/IT (francoiafrate@gmail.com)*

Colorectal cancer (CRC) is a major cause of morbidity and mortality in western societies. According to the adenoma-carcinoma sequence, the vast majority of CRC arise from benign polyps over a very long period of time so that screening based on polyp detection has been universally accepted. Among the available options, CT colonography (CTC) has shown an excellent accuracy for large polyps and carcinomas and it has been included among the recommended options for CRC screening in average-risk people. CT colonography (CTC) interpretation using a combined three-dimensional/two-dimensional (3D/2D) approach requires a specific set of diagnostic tools to facilitate this strategy. The software viewing platform should provide these tools to maximize the advantages of this interpretation algorithm. Recent advances in CTC software have given rise to a number of new features aimed to facilitate analysis and improve diagnostic accuracy. In this respect, endoluminal data can be analysed by virtual colon dissection, which virtually dissects and unfolds the colon to obtain a quick view of the entire colonic surface without requiring antegrade or retrograde fly-through. One of the key components of effective polyp detection at CT colonography (CTC) involves the bowel preparation for the study and up to now faecal tagging technique represents a crucial step and strong weapon in the hand of radiologists to obtain greatest accuracy in detecting large and small polyps. In addition, advanced post-processing tools such as electronic fluid cleansing or computer-aided detection (CAD) may help readers.

Learning Objectives:

1. To quickly review different morphological aspects and "weapons" in the hand of radiologist to detect colonic polyps with CT colonography with small focus on correct preparation and the use of CAD.
2. To define large, small and intermediate polyp size and to review polyp pathology including the risk of cancer and high grade dysplasia moreover in small and intermediate polyps.
3. To summarise the current debate with regard to intermediate polyps (conservative management vs polypectomy) and the rational for non-reporting of diminutive polyps.

A-696 15:01

Acute pancreatitis

W. Schima; *Vienna/AT (wolfgang.schima@khgh.at)*

For the diagnosis of acute pancreatitis, at least 2 of the 3 following criteria, (1) abdominal pain consistent with pancreatitis, (2) increase (≥threefold) in serum amylase or lipase levels and (3) imaging findings of acute pancreatitis, have to be fulfilled. According to the Revised Atlanta Classification, the disease is categorized as interstitial oedematous or necrotizing pancreatitis. Development of necrosis may take some time, so that CT imaging should not be performed earlier than 2-3 days after clinical onset. Imaging too early may lead to

underestimation of disease severity. Necrotizing pancreatitis may present with either combined pancreatic and peripancreatic necrosis (most common) or with pancreatic necrosis or with peripancreatic necrosis alone. These acute necrotic collections (ANC) in the early phase may evolve into walled-off necrosis (WON) in the late stage (≥ 4 weeks). A WON containing chunks of digested fat and parenchyma must not be confused with a pseudocyst containing enzymatic fluid. They may appear similarly hypoattenuating in CT imaging, but US or MRI will show the predominantly solid nature of a WON. Secondary infection of necrotizing pancreatitis usually occurs in the 3rd week after onset (or later). Diagnosis of infection is difficult based on imaging alone. Infection is more likely if collections have broad contact with bowel. Gas within a collection is not a sensitive sign, but quite specific. In case of infection percutaneous aspiration is sought, followed by drainage in positive cases. However, necrotic collections with large proportions of debris require a more aggressive approach for clearance.

Learning Objectives:

1. To learn about the proper timing of imaging studies in acute pancreatitis.
2. To learn about the imaging manifestations of necrotising pancreatitis.
3. To understand the different nature of fluid collections with regard to further therapy.

A-697 15:09

Crohn's disease

J. Rimola; *Barcelona/ES (jrimola@clinic.ub.es)*

Bowel imaging had experienced relevant clinical advances in the last decade and represents the first diagnostic tool for assessing bowel inflammation in patients with Crohn's disease (CD). There is growing evidence that cross-sectional imaging is able to accomplish main endpoints in the diagnosis of CD, including the detection of active disease, especially severe lesions, and the achievement of healing of inflammatory lesions. The identification of structuring and penetrating complications is also a key aspect that has implications in the therapeutic management as well as in the determination of bowel damage. The lecture will provide the key points to confidently diagnose activity and complications related to CD.

Learning Objectives:

1. To learn about useful signs indicating active Crohn's disease.
2. To understand the changes which occur after treatment of intestinal inflammation.
3. To become familiar with complications related to Crohn's disease.

Author Disclosure:

J. Rimola: Consultant; Robarts Clinical Trials.

A-698 15:17

Liver metastases follow-up

Y. Menu; *Paris/FR (yves.menu@sat.aphp.fr)*

Liver metastasis follow-up is dramatically important in patients with systemic chemotherapy. The first tip is to identify if the treatment is adjuvant, neo-adjuvant or palliative. The goals and evaluation methods will be completely different. For adjuvant therapy, the question is detection of new lesions. For neo-adjuvant therapy, the question is to select the optimal schedule for curative treatment if relevant, mostly surgery. For palliative treatment, the role of imaging is to evaluate treatment efficacy. The second tip is to understand if the treatment is cytotoxic, targeted or immune. Evaluation criteria and complications are different for each category. Knowledge of the treatment details is critical. The third tip is to apply the relevant evaluation standard for the tumour and for the treatment. RECIST, CHOIs, irRC, irRECIST may apply for liver metastases. The report should be structured according to these criteria.

Learning Objectives:

1. To learn how to quickly identify three most common systemic treatments of liver metastases (cytotoxic, targeted and immune), and to understand why knowledge of the regimen is essential for the radiological report.
2. To understand the rationale of international standards for the evaluation of response to treatment, and how to build accordingly a useful report.
3. To appraise the respective objectives of neoadjuvant and palliative chemotherapy, and to be able to explain the specific endpoints for each clinical situation.

14:00 - 15:30 **Room C**

E³ - ECR Master Class (Chest)

E³ 1526a

Large airway disease

Moderator:
M. Occhipinti; Florence/IT

A-699 14:00

A. Diseases of the trachea

P.A. Grenier; *Paris/FR (philippe.grenier@aphp.fr)*

Multidetector CT (MDCT) using thin collimation during a single breath hold has become the preferred imaging technique for assessing tracheal diseases. MDCT acquisition is performed from the larynx to the termination of the left main bronchus or beyond, at full suspended inspiration. Axial images are reconstructed with thin slice thickness and overlap (50% overlap is optimal). Additional acquisition at full continuous (dynamic) forced expiration using reduced dose technique is useful for assessing tracheobronchial collapsibility. Multiplanar reformations along the long axis of the trachea are helpful to display tracheal abnormalities. Minimum intensity projections can highlight diverticulas and fistulas. Volume rendering techniques can segment the airway lumen wall interface and can be useful to detect subtle changes in airway calibre and to facilitate understanding of complex tracheobronchial abnormalities. Virtual bronchoscopy provides an internal rendering of the tracheobronchial inner surface and can better depict subtle mucosal abnormalities such as neoplasia and granulomatous disease. The different CT patterns of tracheal disease include luminal filling defect, multinodular appearance of the inner surface of the airway, focal tracheal narrowing, diffuse tracheobronchial wall thickening, tracheal bronchial diverticula, fistulas and cysts, and tracheobronchial collapsibility. Dynamic expiratory MDCT can offer a feasible alternative to bronchoscopy in patients with suspected tracheobronchomalacia. It shows complete collapse or collapse of greater than 80% of the airway lumen.

Learning Objectives:

1. To appreciate standard and dynamic techniques in assessing large airways.
2. To learn what is normal and what is disease in adults.
3. To know how imaging can help clinicians in assessing tracheal disease.

A-700 14:30

B. Tracheobronchial instability

M.O. Wielpütz; *Heidelberg/DE (mark.wielpuetz@med.uni-heidelberg.de)*

Advanced-stage chronic obstructive pulmonary disease (COPD) is associated with severely altered respiratory dynamics. Progressive inflammation may lead to malacia of cartilaginous airways, resulting in a collapse during tidal breathing and exercise, which often remains undiagnosed when employing pulmonary function testing (PFT) only. The diagnosis of tracheobronchomalacia (TBM) is traditionally made by invasive flexible bronchoscopy, and TBM has been reported in up to 44% of patients with chronic bronchitis. TBM is differentiated from excessive dynamic airway collapse (EDAC), characterized mainly by a bowing of the posterior membranous part of the trachea. Bronchoscopic examination and severity estimation is not standardized and user dependent, and may also influence the visibility of a collapse due to stabilization of the airways. Thus, airway instability has subsequently been assessed by imaging techniques. 1) Paired inspiratory-expiratory computed tomography (CT) scans may detect airway instability, but is an inherently static technique and limited by patient cooperation. 2) Dynamic cine-CT (2D+t CT) is used to continuously monitor a pre-defined airway segment (single-slice acquisitions to stack of few slices) during shallow or forced breathing. These acquisitions are effective in detecting and quantifying airway instability, but are limited in z-axis direction. 3) Dynamic 4D-CT (3D+t), either using a large detector or as respiratory-gated CT of the whole chest, finally allows for the evaluation of airway instability by volumetric time-resolved datasets. These different techniques will be addressed and compared with respect to individual advantages and drawbacks for the safe and precise diagnosis of airway instability of the trachea and large conducting airways.

Learning Objectives:

1. To appreciate the possible causes of tracheobronchial instability and its differential diagnosis.
2. To learn how to assess airway instability with 4D-CT.
3. To understand how 4D-CT could help in treatment planning.

C. Quantitative analysis and imaging biomarkers of chronic obstructive pulmonary disease (COPD)

H.A. Gietema; *Enschede/NL (hester.gietema@gmail.com)*

Airflow limitation in COPD is a result of combination of small airway remodelling, emphysema and large airway disease. The presence and extent of emphysema can easily be assessed with CT by calculating the number of voxels with density below a certain threshold, usually -950HU, as percentage of the total number of voxels. This method has been shown to correlate well to the extent of emphysema in pathology specimens. The thresholding method can also be used to quantify airtrapping, an indirect marker of small airways disease. Furthermore, CT can be used to establish bronchial wall thickening as marker of chronic bronchitis. Presence of CT emphysema has been shown to correlate to COPD-related symptoms as cough, phlegm production and dyspnoea, independent of smoking history or lung function. COPD patients with emphysema show more exercise-induced oxygen desaturation than those with a chronic bronchitis (CB) phenotype. While spirometry is still the main tool to diagnose COPD, imaging has become more and more important to assess the relative contributions of emphysema and airway disease in COPD patients to predict patient response to therapeutic interventions. While patients with airway predominant disease may show better response to drugs, patients with emphysema predominant disease and a heterogeneous distribution may be eligible for endoscopic lung volume reduction (ELVR) therapy. CT markers as extent of emphysema, distribution and completeness of fissures are crucial in patient selection for ELVR.

Learning Objectives:

1. To consolidate knowledge of post-processing image tools and imaging biomarkers.
2. To understand how imaging biomarkers are related to clinical events and patient prognosis.
3. To discuss about the clinical relevance of phenotyping COPD and identifying COPD patients in a lung cancer screening setting.

14:00 - 15:30 **Room O**

Imaging in child abuse: an update

Moderator:
G.M. Magnano; Genoa/IT

A-702 14:00

A. Skeletal fractures

R.R. van Rijn; *Amsterdam/NL (r.r.vanrijn@amc.uva.nl)*

In childhood, fractures are a common cause for presentation in an emergency department. Estimates in the USA report that approximately 15% of all emergency department presentations in this population are related to fractures. Although the vast majority of all fractures are accidental they also represent the second most common finding in cases of physical child abuse. Radiologists may, therefore, be amongst the first caregivers to discover an indication of child abuse. To detect indicators of child abuse it is of importance to interpret all childhood fractures in relation to the provided clinical history and trauma mechanism. In this lecture, attention will be given to imaging techniques and the applicable protocols as well as fractures, frequently seen in child abuse, and their differential diagnosis. Finally, the need for collaboration with clinicians in the diagnosis of child abuse will be discussed, this as the diagnosis can never be solely based on radiological imaging but always on a combination of clinical, investigative and social findings.

Learning Objectives:

1. To understand the basic mechanisms.
2. To learn about fracture patterns suggestive of abuse and the evidence behind.
3. To become familiar with the most important differentials.

Author Disclosure:
R.R. van Rijn: Author; Royalties from Springer and Thieme.

A-703 14:30

B. Abusive head trauma

C. Adamsbaum; *Le Kremlin-Bicêtre/FR (c.adamsbaum@bct.aphp.fr)*

Radiologists play a key role in the early diagnosis of child abuse. Imaging must be performed and interpreted with rigour. The recommended guidelines for imaging in children younger than 2 years suspected of abuse include a highly detailed complete skeletal survey with centred views, and brain CT (or MRI if the child is free of neurological symptom). The use of abdominal imaging is debatable if the child has no symptoms. All siblings younger than 2 years should be assessed in the same way. To determine if the pattern may be of "age-different" lesions is a major point and must be assessed on robust criteria. This provides a strong argument for the diagnosis of abuse and also indicates repetitive violence which occurs in more than half of the cases. The differential diagnoses must be exhaustively discussed. However, they are usually easy to rule out. A changing or absent history of trauma in a non-ambulatory child is a key diagnostic sign for abuse. Radiologists must communicate clearly the suspicion of abuse and its degree of certainty to clinicians. The medical challenge is only to protect the child.

Learning Objectives:

1. To understand the basic mechanisms.
2. To learn about imaging findings suggestive of abuse.
3. To become familiar with the differentials and the controversies.

A-704 15:00

C. The medico-legal issues

A.C. Offiah; *Sheffield/UK (amaka.offiah@nhs.net)*

The presentation will be given in the context of suspected child physical abuse and will cover both the written report and court attendance. The various types of written report (clinical report, police statement, witness statement and expert report) will be covered, including what is expected from the individual who is providing the report or statement. The importance of the 3 Rs (retain, record, reveal) and 3 Is (independence, impartiality, integrity) will be emphasised and the manner in which witnesses should conduct themselves while giving oral evidence will be addressed. Common pitfalls in both written and oral evidence that should be avoided will be highlighted where relevant throughout the talk.

Learning Objectives:

1. To learn about the information required by any court, and how to structure the radiological report.
2. To recognise imaging markers suggestive for abuse and how to raise the suspicion.
3. To become familiar with the terms that should be used when highly specific imaging markers for abuse are identified in an otherwise normal infant.

A.C. Offiah: Consultant; Expert witness for Her Majesty's Courts, UK.

14:00 - 15:30 **Room N**

Cardiac

RC 1503

Imaging of cardiac function, perfusion and viability by MR

A-705 14:00

Chairman's introduction

M. Francone; *Rome/IT (marco.francone@uniroma1.it)*

Ischaemic cascade is usually triggered by the presence of a flow-limiting stenosis inducing a perfusion defect which is initially reversible and progressively evolves to tissue necrosis with a subendocardial to transmural expansion of necrotic frontwave. Cardiac MR is able to comprehensively assess the entire spectrum of events characterizing this complex process from the regional and global functional impairment occurring in the early phase of ischaemia usually combined with rest-stress perfusion, to the direct visualization of necrotic areas/scars in post-infarct imaging. This has been achieved already almost twenty years ago and was recently integrated with novel imaging techniques providing further insight into the pathophysiology of ischaemic heart disease. Present session will focus on this crucial indication of cardiac MR offering precious information regarding image quality optimization in this setting and imaging features for differentiation between ischaemic vs non-ischaemic heart disease. An overview about CMR application of tissue perfusion in congenital heart disease will also be presented and session will close with a discussion focusing on the real and clinical reliability of CMR "comprehensiveness" in this clinical scenario.

Author Disclosure:
M. Francone: Speaker; Bracco Medical Imaging Invited Speaker.

A-706 14:05

A. Getting the best image quality

B. Jankharia; *Mumbai/IN (bhavin@jankharia.com)*

Reading cardiac MRIs require high-quality scans to be available to the radiologist interpreting the scan. There are many issues to be considered to ensure optimal quality, signal-to-noise and artefact-free scans. Current advances are 1. 3T scanning: it has become easier to scan on 3.0T as compared to 1.5T scanners and the situation a few years ago. The differences

will be discussed along with current state-of-the art cine and perfusion sequences. 2. Parametric imaging and tissue characterization: T1 and T2 mapping, STIR images and late gadolinium enhancement help us assess myocardial oedema, inflammation, infiltration and fibrosis. These will be discussed. Pitfalls are 1. shim artefacts: these can create bad-looking scans. 2. Rhythm abnormalities: these affect the quality of the scans but can be taken care off, with a little understanding of cardiac physiology. 3. Artefactual enhancement: this occurs in some segments of the myocardium and can simulate disease. 4. Wall motion pitfalls: left bundle branch block can simulate septal hypokinesia. These and other such issues need to be understood. Integrated approach: different clinical questions need different protocols. A viability scan has a different protocol from a scan for suspected amyloidosis or arrhythmogenic right ventricular cardiomyopathy (ARVC). While some aspects of scanning (basic cine imaging) remain the same for all types of indications, there are many other differences that allow us to highlight the specific issue at hand.

Learning Objectives:

1. To become familiar with the latest technical and methodological advances in cardiac MRI.
2. To learn about important and typical pitfalls in cardiac MRI and how to avoid or overcome these.
3. To consolidate the knowledge about an optimised, integrated approach using cardiac MRI depending on the clinical question.

A-707 14:28

B. Differentiation of ischaemic and non-ischaemic cardiomyopathy

P. Croisille; *Saint-Etienne/FR*

"no abstract submitted"

Learning Objectives:

1. To correctly define various causes of cardiomyopathies and compare functional and structural changes occurring with ischaemic and non-ischaemic cardiomyopathies.
2. To recognise common and less common signal intensity abnormalities and late enhancement patterns to provide etiological differentiation of the various forms of cardiomyopathies.
3. To review the prognostic significance of various functional and tissue abnormalities observed by cardiac magnetic resonance in cardiomyopathies.

A-708 14:51

C. Best applications in congenital heart disease

J. Schäfer; *Tübingen/DE (juergen.schaefer@med.uni-tuebingen.de)*

Congenital heart disease (CHD) comprises a wide-ranging of specific anomalies of the heart and the pulmonary vessels. Detailed knowledge of embryology, anatomy, and pathophysiology is crucial for diagnosis by imaging. Additionally, patient's age ranges from newborn to adults with an increasing life expectancy due to advancing in treatment. Apart from cardiac ultrasound and catheterization, traditionally in the hand of the cardiologist, cardiac MRI and MDCT are integral parts of the diagnostic workup. In this context, radiologists should be familiarized with indications, imaging protocols and standardized reporting. Advances in imaging technology are resulting in higher temporal resolution with better assessment of disorders and patient's comfort. Furthermore, radiation exposure essentially decreases in the past decade. In the case of MRI, 4D-imaging of blood flow opens a new horizon for treatment planning. The applications are related to patient management and treatment options. The domain of MDCT is the detailed visualization of morphology whereas MRI is the reference standard for functional analysis. However, there is overlap for both modalities. Thus, very complex anatomy or emergency cases are suitable indications for MDCT, while MRI determines the time point of (re)intervention by assessment of cardiac function.

Learning Objectives:

1. To decide which modality (MDCT/MRI) is the most appropriate for which indication in CHD.
2. To learn about the role of various MR applications in the diagnosis and planning of therapy of CHD.
3. To be able to perform a morphological and functional assessment of the right and left ventricle in CHD.

15:14

Panel discussion: Has MRI matured to a one-stop shop in cardiac imaging?

14:00 - 15:30 **Studio 2017**

New Horizons Session

NH 15

Large cohorts: imaging biobanks

A-709 14:00

Chairmen's introduction

M.H. Fuchsjäger, M. Pasterk; *Graz/AT (michael.fuchsjaeger@medunigraz.at)*

This session will offer insights not only into why biobanks should include imaging data, but also into the technological basis required to integrate imaging data and on how to deal with potential incidental findings in these large cohorts. Furthermore, the potential future benefits - specifically for radiology and radiologists - of including imaging data in large biobanks will be discussed.

Session Objectives:

1. To understand why biobanks should include imaging data.
2. To learn about the relevance of incidental findings in large cohorts.
3. To consolidate knowledge on integration and analysis of imaging data in biobanks.

A-711 14:05

Why biobanks should include imaging data

R.L. Vanninen; *Kuopio/FI (ritva.vanninen@kuh.fi)*

Imaging e-infrastructure is based on radiomics, a new omic science which provides a comprehensive quantification of tissue phenotypes by extracting large number of quantitative image features to higher dimensional data and the subsequent mining of these data for improved decision support. Correlating imaging phenotype with genomic information (referred to as radiogenomics), to better understand genetic variability and the ability to predict prognosis or response to therapy, is a new field of research. It has been initiated mainly in oncology and neuroradiology studies, but it is applicable to other diseases and can be performed with several diagnostic imaging modalities.The overlap between image-based tumour phenotype features and genomic characteristics is not currently well established. Image features are extracted from regions or volumes of interest, which can be either entire tumours or defined sub-volumes within tumours, known as habitats. Recently, the interest is increased in clinical research. Radiomics is potentially useful in the diagnosis of many diseases and can be used in decision support of personalised medicine. Development of "omics" analyses in parallel with growing interests towards translational research has also created a need for quality-assured sample sets with available clinical, imaging, epidemiological and treatment data. Imaging biobanks can be defined as organised databases of medical images and associated imaging biomarkers (radiology and beyond) shared among multiple researchers, and linked to other biorepositories. European Society of Radiology contributes to develop imaging e-infrastructures combined with work on digital pathology.

Learning Objectives:

1. To understand why inclusion of imaging data is the logical next step of phenotypical characterisation in cohorts.
2. To learn about the importance of enriching clinical datasets in biobanks with imaging data.
3. To learn about biobanks in which imaging data have already been included.

A-712 14:30

Incidental findings in large cohorts (German national cohort)

S. Weckbach; *Heidelberg/DE (sabine.weckbach@med.uni-heidelberg.de)*

The German National Cohort (GNC) is a long-term, multi-centre population-based cohort study in Germany with the goal of investigating the development of common chronic diseases. 30.000 out of 200.000 participants are being examined by whole body MR imaging at 3 Tesla. Incidental findings (IF) are findings deemed beyond the aims of a study and an expected consequence of imaging studies with potential high impact. By the use of national and international ethical guidelines and the current literature, a system was developed within the GNC to classify and report incidental findings that might be detected on whole body MR imaging and possibly are of risk to the participant's health. This system focuses on guiding radiologists in the decision of reporting or not-reporting a finding in an attempt to balance the risk of over- and underreporting and to minimize false-positive and false-negative findings. In the centre of that process is a (constantly updated and online available) list of defined incidental findings separating them into reportable and not reportable - taking into account study-specific limitations and confounders. In the talk, the necessary steps to develop such a reporting system are explained, particular challenges and ethical dilemmas are summarized. Quality assurance

tools to guarantee high quality and consistency for incidental finding reporting in large multicentre studies are presented.
Learning Objectives:
1. To consolidate knowledge on the significance of incidental findings in large cohorts.
2. To learn about how incidental findings may be detected in large cohorts.
3. To understand the management of incidental findings in large cohorts.

A-713 14:55

Analysis of big imaging data (UK Biobank)
A. Jackson; *Manchester/UK (Alan.Jackson@manchester.ac.uk)*

Collection of large datasets, often with many thousands of subjects poses specific problems for data analysis. Although specific analyses might be used by individual investigators on selected subsets this does not make optimal use of the availability of datasets, characterised by extensive imaging and other data derived from soluble and tissue biomarkers and genomic analysis. The analysis of by biobank imaging data must be considered from the inception of the imaging protocols. Automated image analysis techniques must be applicable so that quality control of individual imaging datasets across the database is essential. Selection of acquisition protocols for MRI and other imaging techniques should be designed to facilitate automated analysis with generation of quantitative imaging biomarkers. To facilitate information extraction series of preselected quantitative imaging biomarkers should be identified. These might include relatively standard biomarkers such as regional grey matter volume and CSF volume cardiac ejection fraction. The important features of these analytical techniques is that they should produce a reliable and reproducible qualitative imaging biomarker that can be included in combined biomarker databases for analysis using data extraction and informatics methodologies.
Learning Objectives:
1. To consolidate knowledge on the technological basis necessary to enable analysis and interpretation of big data.
2. To learn about how imaging data can be integrated in large research databases.
3. To understand the importance of imaging on new biomarker development.

15:20
Panel discussion: What are the benefits of linking imaging and biobanks?

EIBIR Session

EIBIR 3

Innovative solutions for diagnosis and treatment concepts for GIST patients from the MITIGATE project

Moderator:
S.O. Schönberg; Mannheim/DE

A-714 14:00

Introduction to the state-of-the-art therapy in GIST
P. Hohenberger; *Mannheim/DE*
(peter.hohenberger@medma.uni-heidelberg.de)

GIST primarily affects the GI tract with the stomach being most frequently involved, followed by the small intestine, the rectum and the duodenum and oesophagus. This disease entity represents "the" role model for the efficacy of molecular-based targeted therapy, molecular imaging and minimally invasive treatment. The detection of the *KIT*-protooncogene in 1988 and the *KIT*-receptor antagonist TKI imatinib provided an effective treatment in the advanced stage of the disease. Unlike other tumours, no valid blood tumour markers exist for monitoring the course of the disease, rendering functional and molecular imaging-based approaches of high importance. Patients with completely resected primary tumour, but imatinib-resistant progressive oligometastatic disease are quite frequent. Tumour types as those with a platelet-derived growth factor receptor-alpha (PDGFRA)-D842V mutation or SDH mutant GIST, or so-called quadruple-negative GIST represents 10-15% of all GIST patients. They are insensitive to imatinib or other TKI drugs as are the huge group of patients who no longer respond to imatinib due to secondary mutations in the *KIT* protooncogene. Therefore, for a major group of patients with metastatic GIST no treatment alternatives currently exist as tumours are neither sensitive to large-field external irradiation nor cytotoxic chemotherapy. Thus, interventional techniques such as SIRT, RFA or radionuclide therapy such as ion is the clinical focus when treating patients who live for 10 to 15 years at very good QoL with a disease that has metastasized but is still to be controlled by various measures and interventions.
Learning Objectives:
1. To learn about current therapy options for GIST patients.
2. To understand specificity of GIST treatment.
Author Disclosure:
P. Hohenberger: Advisory Board; Novartis; Pfizer; Bayer;. Grant Recipient; Novartis;. Investigator; Novartis; Bayer; Infinity; AROG, Pfizer. Research/Grant Support; Novartis. Speaker; Novartis; Bayer; AROG; Pfizer.

A-715 14:10

Improving the diagnostic imaging approach in GIST patients
C. Decristoforo; *Innsbruck/AT (Clemens.Decristoforo@tirol-kliniken.at)*

Gastrointestinal stromal tumour (GIST) is a rare disease and can be treated with tyrosine kinase inhibitors (TK). Resistance to TK is a common problem limiting therapeutic options and life expectancy. The MITIGATE project aims to develop new approaches to diagnose and treat patients with metastatic GIST resistant to the standard TK treatment. PET/CT is a widely used molecular imaging tool in oncology, usually investigating glucose metabolism with FDG. More specifically targeted radiopharmaceuticals are sought to better identify and characterise tumour lesions. Within the MITIGATE project, a novel ^{68}Ga-labelled peptide, NeoBOMB1 was selected to be investigated in GIST patients within the MITIGATE clinical study. ^{68}Ga-NeoBOMB1 binds specifically to gastrin-releasing peptide (GRP) receptors highly overexpressed on GIST tumour cells. The combination of ^{68}Ga, an ultra-short-lived, generator-derived positron emitter, with a small bombesin peptide analogue with antagonistic receptor properties provides a unique basis for highly sensitive and specific imaging of GIST tumours. The MITIGATE study aims not only to assess safety and pharmacokinetics of this novel imaging approach, but also to provide a basis for better characterisation of GIST tumours by molecular imaging opening new therapeutic options in this rare disease. Preclinical development of ^{68}Ga-NeoBOMB1, clinical trial design and first clinical results of PET/CT imaging in GIST patients will be presented.
Learning Objectives:
1. To learn about the current imaging approach in GIST patients.
2. To discover the novel imaging approach applied in the MITIGATE clinical study.

A-716 14:35

Minimally invasive treatment of GIST patients in a compassionate use programme
S. Diehl; *Mannheim/DE (Steffen.Diehl@umm.de)*

Several minimal invasive treatments are currently available for GIST patients. In case of multiple liver metastases, radioembolization (RE) offers a safe and effective treatment for patients with GIST liver metastases who do not show a response to TKIs. In case of oligometastatic disease, percutaneous ablations such as microwave ablation (MWA) or irreversible electroporation (IRE) can be used in lung, liver and soft tissue metastases. Besides a brief description of the methods, the use within the MITIGATE compassionate use programme will be presented. The focus will be on the combination of several minimal invasive therapeutic options.
Learning Objectives:
1. To understand minimally invasive treatment options.
2. To learn about the MITIGATE compassionate use programme and its minimally invasive treatment options.

A-717 15:00

Impact of the MITIGATE project on European GIST patients
A. Bruno-Lindner; *Vienna/AT*

Learning Objectives:
1. To learn about the need of European GIST patients.
2. To discover how patients might benefit from the developments of the MITIGATE project.

15:25

14:00 - 15:30 **Room E1**

Special Focus Session

SF 15b

Breast cancer screening with tomosynthesis: the time is now

A-718 14:00

Chairman's introduction

P. Skaane; *Oslo/NO (PERSKA@ous-hf.no)*

A main limitation of conventional mammography (FFDM) is the poor sensitivity in women with dense breast parenchyma. During the last decade there has been much discussion how to improve the quality of breast cancer screening, especially for women at increased risk. Focusing on personalized (individualized) screening, ultrasound and MRI has been considered the most important adjuncts to mammography. It is important to distinguish between low-volume ("individualized") and high-volume ("population-based") screening regarding implementation of new techniques. An emerging mammographic technique that might significantly improve screening is digital breast tomosynthesis (DBT). Cancer visibility and conspicuity is increased using tomosynthesis, and DBT has significantly higher sensitivity (cancer detection rate) than FFDM. DBT has also a higher specificity (lower recall rates). Furthermore, DBT can replace conventional cone-mag views for evaluation of non-calcified indeterminate lesions, which also is an important contribution for reducing recalls in screening programs. Implementation of DBT with synthetic 2D reconstructed from the 3D data has several advantages compared with other modalities: Ultrasound is time-consuming and has a low specificity; MRI is expensive and availability is limited. Other modalities are still at a research level. DBT might easily be incorporated into existing programs, and transition from FFDM to DBT would be less challenging than the transition from screen-film to FFDM a decade ago. DBT might be the next improvement of population-based breast cancer screening. Cost-effectiveness studies and studies on outcomes including number and stage of interval cancers and subsequent round cancers are still to be desired.

Session Objectives:

1. To learn about the need for improving breast cancer screening.
2. To learn about alternative screening techniques.
3. To learn about the potential benefits of DBT as compared with other modalities.

Author Disclosure:

P. Skaane: Grant Recipient; Has previously received travel costs and fee for lectures from Hologic. Research/Grant Support; Financial and technical support for the Oslo Tomosynthesis Screening Trial was provided by Hologic.

A-719 14:05

Screening with digital breast tomosynthesis in the USA: performance indicators and breast density

E.A. Morris; *New York, NY/US*

Mammography is the best screening test for the early detection of breast cancer. Mammography had not changed for many years until the advent of digital imaging technology. Digital technology allowed the development of digital breast tomosynthesis (DBT), an advanced application, informally called 3D mammography (in contrast to conventional 2D DM). DBT has arrived on the world stage in time to address many of the limitations of mammography. Dense tissue has always been the challenge of mammography due to the masking effect. Trials have shown that cancer detection rate with DBT is improved as the cancers are "unmasked" as the issue of overlapping tissue or summation artefacts are eliminated. Additionally, recent criticism of mammography has centred false-positive examinations and overdiagnosis. In numerous trials, the call back rates are lower when DBT is used compared to standard DM. Fewer women are asked to return for summation shadows as DBT easily resolves these at interpretation. A recent multicentre study published in the Journal of the American Medical Association (JAMA) found that when tomosynthesis is used in addition to digital screening mammography, there is a 41% increase in invasive cancer detected, 15% decrease in unnecessary callbacks for false alarms and a 29% increase in the detection of all breast cancers. The conclusion is that DBT finds more of the invasive, harmful cancers and saves women the anxiety and cost of having additional screenings for what turns out to be a false alarm.

Learning Objectives:

1. To learn about recalls and cancer detection in the USA DBT screening studies.
2. To understand the false positive and the false negative interpretations in screening with tomosynthesis.
3. To understand the influence of breast density and age on the performance of DBT screening.

A-720 14:30

Screening with digital breast tomosynthesis in Europe: tumour characteristics and potential harms including overdiagnosis

F.J. Gilbert; *Cambridge/UK (fjg28@cam.ac.uk)*

The introduction of a new more expensive technique to breast screening requires careful analysis of the cost-benefit. DBT has been shown to increase the sensitivity and specificity of the detection of breast cancer especially in younger women, those with increased breast density (BIRADS C & D) and for those readers who are less experienced. However, it should not be assumed there will be a mortality benefit. One method is to use surrogate end points - tumour size and stage. However, information on tumour aggressiveness determines whether the additional cancers might have caused harm. There is increased sensitivity in cancers presenting as spiculate masses and also asymmetric density or distortion both of which tend to be associated with less aggressive cancers. In the prospective studies, there were relatively few additional DCIS cases being found and slightly more grade 1 cancers compared to grade 2 & 3 cancers. The three large prospective trials cannot report interval cancer rates as each case was read by all combinations but one small American series has reported a non-significant decrease in the number of interval cancers. Tumour size should decrease in incident rounds following the introduction of DBT. The potential harms of DBT are increased number of biopsies for benign lesions or even further excision. The radiation dose is small but can be avoided using synthetic 2D with DBT. The unknown harm is the increase in "overdiagnosis" (diagnosis of cancers that would not otherwise have been found in the woman's lifetime).

Learning Objectives:

1. To learn about the tumour characteristics of cancers detected with tomosynthesis.
2. To understand the potential influence of DBT screening on interval cancer rate and next round cancers.
3. To learn about the potential harms of tomosynthesis screening with special focus on so-called "overdiagnosis".

Author Disclosure:

F.J. Gilbert: Research/Grant Support; Hologic, GE Healthcare.

A-721 14:55

Which challenges should we consider prior to tomosynthesis screening implementation?

G. Gennaro; *Padua/IT (gisella.gennaro@ioveneto.it)*

Clinical benefits of digital breast tomosynthesis (DBT) in screening application have been demonstrated. However, there is concern about some technical aspects which should be analysed before implementing tomosynthesis in screening. The first concern regards radiation dose, which is supposed to be minimized when x-ray techniques are used to image healthy population. Dose differences depending on the tomosynthesis and the number of projections will be discussed, along with dose dependence from the clinical protocol (number of views, tomosynthesis alone or in combination with standard mammography), and the role of synthetic mammograms in this respect. The second negative aspect associated to the introduction of tomosynthesis is the increase of the interpretation time; learning curve is crucial, but also software developments like navigation tools or computer-aided detection (CAD) systems might help the reduction of the reading time. Appropriate hanging protocols should be defined to allow comparison with prior DBT examinations in subsequent screening rounds. Finally, the large amount of data produced by DBT versus standard mammography have a significant IT impact. IT infrastructure should be adapted to handle datasets that can be from 10 to 20 times the size of standard digital mammography images. The storage space needs to be increased, but also pre-fetching mechanism could be necessary to cope with the time necessary to retrieve DBT datasets from the PACS. Advantages of the implementation of the DICOM standard format for DBT images will be shortly discussed.

Learning Objectives:

1. To discuss radiation dose, number of DBT projections, and the need for conventional or synthetic 2D images in combination with DBT.
2. To learn about hanging protocols, reading time, and potential solutions for reducing the interpretation time.
3. To understand the "IT issues" in DBT screening implementation.

15:20

Panel discussion: Is tomosynthesis ready for replacing 2D mammography in organised breast cancer screening?

14:00 - 15:30 **Room E2**

Professional Challenges Session

PC 15a
Radiology at the core of interdisciplinary communication

A-722 14:00
Chairman's introduction
E.J. Adam; *London/UK (drjaneadam@gmail.com)*

The role of a radiologist is the same as any other doctor - to help patients. In diagnostic radiology, this is often done through written communication (report) to the referrer. The radiologist should understand the needs of the referrer and ensure that the radiological findings are clearly described and interpreted in the light of the clinical information. It should also be communicated in a timely manner to prevent patient harm. The means of communication should be secure and ensure that patient data are processed in line with data protection legislation.The challenges to effective communication can be significant, even when the radiologist and referrer are in the same institution, but are potentially magnified with offsite teleradiology. Direct verbal discussion in clinico-radiological meetings can add considerable value, and discussion directly with patients is recognised to be important for the future of radiology, but is increasingly 'squeezed out' by the volume of work.
Session Objectives:
1. To appreciate the importance of communicating in a timely and clear way.
2. To understand the particular issues related to communicating verbally or using written or electronic information.
3. To appreciate how the communication style and needs will be different for different groups of people.

A-723 14:05
Sharing information within the hospital
D. Regge; *Turin/IT (daniele.regge@ircc.it)*

Communication within hospital walls is a difficult process due to the multiple interconnections between individuals having different professional profiles. Furthermore, sharing information implies knowledge of management of sensitive information, including patient medical records. In this lecture, both the behavioural and technological aspects of knowledge sharing within the hospital will be explored, and tips will be provided to avoid miscommunication or misunderstanding. Effective communication through information sharing of electronic health records and the role of multidisciplinary team meetings on patient assessment, management and outcome will be reviewed.
Learning Objectives:
1. To identify who you will be communicating with within the hospital and who will be communicating with you.
2. To learn how to avoid miscommunication or misunderstanding.
3. To learn how to promote effective communication.
Author Disclosure:
D. Regge: Board Member; Springer. Speaker; GE Medical Systems.

A-724 14:30
Sharing information beyond the hospital
W.R. Jaschke; *Innsbruck/AT (werner.jaschke@i-med.ac.at)*

Communication between radiologists and referring physicians depends mainly on 4 columns: referral forms, radiology reports, individual consultations and clinical conferences. If radiologists and referring physicians are familiar with each other, communication is usually easy and efficient. Years of collaboration and "problem solving" generate a positive working environment supporting a trustworthy communication between equal partners. This positive attitude between radiologists and clinical partners supports a concise and team-oriented communication. Thus, the most important clinical information (previous/chronic illnesses, current complaints; risk factors for adverse events related to the planned procedure) is usually included in the referral forms. If this is not the case, direct consultation of the referring physician or of the electronic patient record is possible in an in-house setting. The same applies to questions regarding the indication for an radiological exam/procedure and the choice of exam/procedure. Communication beyond the hospital is sometimes hampered because of technical reasons and misunderstanding due to lack of appropriate information and a lack of knowledge regarding the requested radiological exam/procedure. Typical technical obstacles to efficient communication are lacking clinical information, ill-defined indications for exam/procedure and non-availability of the person you want to talk to in case of missing information. Triage of patients in case of workforce overload is another problem which cannot be easily dealt in case of an outside referral. Typical examples will be given which illustrate the above-mentioned scenarios. In addition, solutions how to avoid bad communication will be given.
Learning Objectives:
1. To identify the key routes of communication outside the hospital, including teleradiology.
2. To understand barriers to good communication.
3. To learn how to promote good communication.

A-725 14:55
Sharing information with the patient
E. Briers; *Hasselt/BE (erikbriers@telenet.be)*

The average patient is a statistical invention and does not attend the radiology department. Even the equipment used has a set of possibilities to adjust to the individual size of a patient. The same is true with the communication capabilities of the patients. This is caused by the differences is coping capacity and literacy. The information that a patient needs or wishes when he enters the radiology department is at different levels. The internal level of the department is really linked to what is done in the department, how it is done, etcetera. This should be known by the patient and can be provided on paper or any other means that are effective. But, as patients are so diverse this information should also be offered in a multi-layered system, and the radiologist should be available to answer questions or have someone available who can. The other level is the pathology, the reason why the patient is coming to the department. This can be quite simple a broken rib or wrist, questions on this can be answered in the department as the clinical data are rather clear. But complex pathologies require knowledge of the patient file, his past, family situation and more, only known by the clinician who did the referral. In these cases, the best option is the interdisciplinary consult with the clinician where the radiologist can transmit his feelings about the patient and findings. In these cases, the clinician would be the ideal person to speak with the patient.
Learning Objectives:
1. To understand what information patients require before they attend a radiology department.
2. To appreciate the communication needs of patients when they are undergoing investigations, and when they receive results.
3. To learn how to communicate effectively with patients.

15:20
Panel discussion: Conveying information clearly. Do we still need to 'speak' to each other?

14:00 - 15:30 **Room F1**

E³ - European Diploma Prep Sessions

Musculoskeletal

A-726 14:00
Chairman's introduction
F.M.H.M. Vanhoenacker; *Antwerp/BE (filip.vanhoenacker@telenet.be)*

Diagnosis of acute-onset musculoskeletal trauma is usually straightforward on plain radiographs. Despite its higher radiation dose than CR and the longer interpretation time, CBCT is a very valuable technique for evaluation of trauma of small bones and joints in patients with negative radiographs or doubtful fractures and a high clinical suspicion for fractures or when complex fractures are suspected. MRI is the imaging technique of choice for evaluation of chronic-onset trauma and stress fractures, particularly in sports-related injuries. If atypical fractures of the femoral shaft are encountered, one should think of underlying bisphosphonates treatment. Analysis of clinical features (age, location, concomitant diseases) is a prerequisite for characterization of bone tumours. For imaging characterization, plain films are the mainstay, as they accurately depict matrix, cortical permeation or disruption, and periosteal reaction. MRI has an additional role as most tumours have a low SI on T1-WI and a high SI on T2-WI. The major role of MRI consists of local tumour staging and monitoring of treatment. Whole body MRI and PET-(CT) may evaluate distant tumour spread. Meticulous analysis of distribution and morphology of imaging findings are the clues to distinguish inflammatory arthritides and degenerative joint disorders. Whereas ultrasound has an emerging role for grading of synovitis and early detection of erosions of peripheral joints in RA, MRI is the preferred technique for early diagnosis and detection of active inflammatory lesions by demonstrating bone marrow oedema in axial spondyloarthropathy. MRI is a powerful imaging modality for monitoring treatment response of inflammatory arthritis treatment.

Session Objectives:
1. To understand typical and atypical imaging features of traumatic disorders of the musculoskeletal system.
2. To learn typical imaging features of benign and malignant bone tumours.
3. To become familiar with the imaging appearance of degenerative and inflammatory disorders of the musculoskeletal system.

A-727 14:06

A. Traumatic disorders of the musculoskeletal system
M. Maas; *Amsterdam/NL (m.maas@amc.nl)*

Assessing post-traumatic situations is common practice in MSK radiology. It is often thought easy, already learned in first year of residency and most often topic of radiological education in medical school. Very often films are read by on call clinicians first, often without very much proper training, and radiology reading is done later. This brings important responsibilities to us as radiology community when dealing with trauma. We need to provide an everyday meeting with emergency room physicians and supervising trauma surgeon focused on quality and on teaching. We need to be experts in the field of trauma radiology, adding information to the discussion and providing advise concerning consequential imaging steps. We need to understand and talk the language of traumatology, we need to be aware of the consequences there are for the surgeon; when is conservative treatment first option, when will be decided for surgery. If we can provide all the answers to the questions that influence surgical planning, we are performing most optimally. This session will take two complex small joints as focus, ankle-foot and wrist-hand. We will discuss normal radiological anatomy, we will describe standards in positioning, and we will enhance present guidelines in a given clinical situation. We will stress the value of adding cross-sectional imaging early, and will emphasise which answers need to be provided. A special focus lies on sports-related injury of bone and soft tissue. This goes for high-performing athletes as well as the so-called weekend warriors.
Learning Objectives:
1. To understand the anatomy and normal variants of the musculoskeletal system.
2. To become familiar with common imaging presentations of acute and chronic trauma involving the skeleton and soft tissue.
3. To learn common pitfalls in trauma imaging of the musculoskeletal system.

A-728 14:34

B. Bone tumours
S.L.J. James; *Birmingham/UK (stevenjames@nhs.net)*

Diagnosis and characterisation of bone tumours still relies heavily on the radiographic features to reach a differential diagnosis. An approach to radiograph interpretation will be presented. The radiographic features that give an indication of rate of growth will be discussed along with illustrations of the common patterns of matrix mineralisation. This will allow a description of a potential bone tumour to be provided so that the so-called "don't touch" lesions can be assessed. In the latter part of the presentation, some common patterns of haematological malignancy will be discussed.
Learning Objectives:
1. To learn the typical imaging features of common bone tumours.
2. To understand the typical imaging features of "don't touch" ("leave-me-alone") lesions.
3. To become familiar with the imaging manifestations of haematological disorders.

A-729 15:02

C. Degenerative and inflammatory disorders of the musculoskeletal system
D. Spira; *Heidelberg/DE (daniel.spira@med.uni-heidelberg.de)*

In most cases, inflammatory arthritides can be contrasted from primarily degenerative disorders according to their distribution and morphology. A subset of patients, however, presents with overlap syndromes, e.g. erosive degenerative disorders such as erosive osteoarthritis, or florid stages of activated osteoarthritides. Radiography and magnetic resonance imaging both help the clinician in characterising inflammatory arthritides. Commonly, rheumatoid arthritis and seronegative spondyloarthropathies are differentiated by their characteristic distribution, imaging appearance and concomitant soft tissue and bone involvement. Metabolic diseases such as gout and connective tissue diseases such as lupus and scleroderma also involve joints and can present in a typical manner. Several anti-inflammatory drugs are used in the treatment of inflammatory and degenerative arthropathies. In this context, magnetic resonance imaging may complement the clinical course and further assist in therapy response monitoring.
Learning Objectives:
1. To understand the imaging presentation of degenerative disorders of the joints and to appreciate their clinical relevance.
2. To learn the imaging features and clinical features of degenerative disease of the spine, disc and facet joints.
3. To become familiar with the typical imaging manifestations of infection, inflammation and metabolic diseases of the musculoskeletal system.

14:00 - 15:30 **Room F2**

Emergency Imaging

RC 1517
The latest update in imaging of polytrauma patients

A-730 14:00

Chairman's introduction: the role of proper imaging and management in patients after severe trauma
M. Stajgis; *Poznan/PL (stajgis@gmail.com)*

The rationale of emergency procedures in severe trauma patients is based on time factor and adequate selection of imaging modalities. The “Golden Hour” concept describes the need for as-fast-as-possible management of these patients very well. The present-day diagnostic workup of polytrauma patients is mostly based on whole body CT (WBCT); however, this method is thought to be overused in some clinical scenarios. Therefore, we should very carefully look again at advantages and limitations of still evolving all modern diagnostic modalities such as ultrasound, CT and MR. All 3 lectures in this session are dedicated to effective imaging of polytrauma patients, management priorities in different clinical situations and suggested practical approach.
Session Objectives:
1. To understand the role of early and fast diagnostic imaging in patients after severe trauma.
2. To recognise the basic statistics in management of polytrauma patients, which have the impact on practical approach regarding selection of proper diagnostic modalities.
3. To be aware of the position and responsibilities of radiologist in "decision-making team".

A-731 14:05

A. Ultrasound: when, why and by whom?
P.-A. Poletti; *Geneva/CH (pierre-alexandre.poletti@hcuge.ch)*

"FAST" (Focused assessment with sonography for trauma), which is now part of the ATLS^{R} guidelines, refers to real-time sonographic scanning of four regions for depiction of intra-peritoneal, pericardial and pleural blood, without visualization of parenchymal injuries, during the primary survey of a polytrauma patient. Depiction of a large haemoperitoneum mandates urgent exploratory laparotomy, while a negative FAST directs a search toward extra-abdominal sources of haemorrhage. The adequate training schedule of non-radiologist FAST operators is subject to controversy; there is no consensus with regard to the number of proctored examinations necessary before an operator can be considered capable to perform a FAST examination. This number varies from 10 to 200 according to the different societies. Some recent reports advocate to extend FAST (E-FAST) to the screening of large pneumothoraces during the primary survey, while others also recommend to evaluate the efficiency of fluid resuscitation by assessing the inferior vena cava diameter. This raises further concerns about the training of the operators. In haemodynamically stable patients, ultrasound may be useful for the triage of mild trauma patients towards CT or clinical observation, when time constraint is no major issue and/or CT not immediately available. However, the absence of free intra-peritoneal fluid is not sufficient per se to rule out potentially life-threatening injuries and ultrasound achieves low sensitivity (40 to 55%) for the direct depiction of parenchymal injuries. Contrast-enhanced sonography can be useful to improve the detection of solid-organ lesions and for the detection of vascular injuries, such as delayed splenic pseudoaneurysms.
Learning Objectives:
1. To become familiar with the role of modern ultrasound in polytrauma patients.
2. To comprehend the rationale of using FAST protocol in selected patients.
3. To know the advantages and limitations of ultrasound imaging in emergency setting.

A-732 14:31

B. CT: is it always whole-body?

F.H. Berger; *Toronto, ON/CA (fhberger@gmail.com)*

In the western world, polytrauma is the major cause of mortality in people under 45 years of age. Furthermore, it is a major contributor to loss of quality of life and ability to work. The setting of polytrauma is almost always chaotic, not a favourable environment to come to timely diagnosis and treatment. To decrease morbidity and mortality, time is everything. It is our job as radiologist to contribute to the trauma team and help facilitate timely diagnosis - and in many cases, also timely treatment by interventional radiology. To reach the best treatment strategy for the patient as quick and accurate as safely possible, is the goal. In this update on imaging of polytrauma patients, I will focus on the role of CT to achieve this goal. With the progress in CT scanner development, different protocol options arise. Which CT protocols are being used and what factors do they depend upon? In addition, there is a widespread increase in use of whole body CT internationally, is this a good thing or should we be more selective? What is the current evidence to select patients for targeted CT examinations in polytrauma? A lot of these questions have not been definitively resolved. This lecture aims to provide an update of the current insights into the use of CT for trauma care, with the goal to choose wisely how to investigate the polytrauma patient in a timely and meaningful fashion.

Learning Objectives:

1. To be familiar with currently worldwide accepted protocols in polytrauma CT imaging.
2. To know clinical conditions requiring whole-body CT.
3. To comprehend the selection of trauma patients for targeted CT examinations.

A-733 14:57

C. Where is the proper place for MRI?

K. Katulska; *Poznan/PL (katarzyna_katulska@op.pl)*

A multimodality of imaging should be involved in the diagnosis and management of severely injured multi-trauma patients. The current role of magnetic resonance imaging (MRI) is confident in the spinal cord and brain injuries. MRI examination is the imaging method of choice in assessment of lesion morphology, extent and severity of trauma. In case of neurological symptom not completely explained in CT findings, an MRI must be performer. Among all post-traumatic intracranial pathologies, the diagnosis of diffuse axial injury remains more complex. In fact, about 30% of negative CTs are already positive on MRI. MRI is a powerful diagnostic tool that can detect signs of injury such as minute bleeding (microhaemorrhage), small areas of bruising (contusion) or scarring (gliosis), which are invisible to the CT scan. Newer, specialized types of MRI can assess brain structure at an even finer level or measure brain function to detect alterations in brain structure and function due to traumatic spinal cord and brain injury (TBI, SCI). Protocol for routine MRI of patients with TBI and SCI, which consists of SE and GRE sequences, is proposed. MRI techniques such as SWI, DWI and DTI are discussed, as a new standard protocol. In the acute setting, MRI can determine the presence and extent of injury and guide surgical planning and minimally invasive interventions. Neuroimaging also can be important in the chronic therapy of injury, identifying chronic sequel, determining prognosis and guiding rehabilitation.

Learning Objectives:

1. To learn which patients are the best candidates for post-traumatic MRI.
2. To be familiar with standard and short MRI examination protocols.
3. To understand the impact of MR findings on further management of polytrauma patients.

15:23

Panel discussion: Comprehensive guidelines how to qualify post-traumatic patients for the proper imaging modality - summary

E³ - ECR Master Class (Musculoskeletal)

E³ 1526c

MRI developments and techniques in musculoskeletal (MSK) radiology

Moderator:
C.W.A. Pfirrmann; Zurich/CH

A-734 14:00

A. Whole-body MRI (WBMRI) and diffusion-weighted imaging (DWI) in MSK: where is it (not) useful and how do I do it?

F.E. Lecouvet; *Brussels/BE (frederic.lecouvet@uclouvain.be)*

WB-MRI has growing indications in many oncologic and rheumatologic disorders, as a tool for early diagnosis, quantification of disease extent and assessment of treatment response. The technique is refining and efforts are made to decrease examination durations and to tailor sequences to the targeted disease. WB-MRI studies should at least include anatomical (morphological) sequences, most commonly T1, STIR, sometimes acquired in a 3D approach. These may be sufficient to assess multifocal inflammatory conditions affecting bones, joints, muscles. In oncology, diffusion-weighted imaging (DWI) sequences are very sensitive and have become mandatory, but should not be acquired without anatomic sequences, as some findings may be confusing. This lecture illustrates the protocols, imaging findings, strengths and pitfalls of WB-MRI in oncologic indications, including metastatic disease, lymphoma and myeloma, and in rheumatologic disorders. It also highlights how the technique extends the exploration of the body beyond the musculo-skeletal system.

Learning Objectives:

1. To know the indications for WBMRI in MSK imaging.
2. To understand the advantages and limitations of diffusion-weighted imaging of the MSK system.

A-735 14:30

B. MR neurography: how to optimise and interpret your images

G. Andreisek; *Münsterlingen/CH (gustav@andreisek.de)*

Evaluation of peripheral nerve disorders is an emerging field and may make up to 20% of the daily musculoskeletal magnetic resonance imaging studies in some centres, where MR neurography techniques are well established. Whereas nerve ultrasound is today mainly performed by neurologists in their clinics along with the clinical examination and the traditional electrodiagnostic studies such as electromyography and nerve conduction studies, dedicated clinical programs in MR neurography are currently available at relatively few centres around the world; however, interest in the techniques and clinical indications is spreading rapidly. The focus of this lecture will, therefore, be on the common clinical MR neurography techniques, which are particularly methods that use fairly basic MR pulse sequences for high-resolution cross-sectional imaging of nerves. Often mentioned advanced imaging techniques such as diffusion-weighted, diffusion tensor imaging and tractography will only be described briefly because to date, those techniques only play a limited role in the clinical routine. Even in specialized MR centres where nerve imaging is an established part of the daily clinical business, DWIT/DTI/tractography is only used as complementary to standard imaging techniques.

Learning Objectives:

1. To know the pathophysiology and grades of peripheral nerve lesions.
2. To understand the need for a MR neurography protocol.
3. To learn how to interpret MR neurography examinations.

Author Disclosure:

G. Andreisek: Advisory Board; Otsuka Pharmaceuticals.

A-736 15:00

C. 3D-spin echo (3D-SE) and radial imaging: uses and limitations

J. Fritz; *Tübingen/DE (jfritz9@jhmi.edu)*

Three-dimensional spin echo MRI has evolved into a powerful technique for the non-invasive assessment of joint, cartilage, ligament, tendon, muscle, and nerve abnormalities. In addition to interactive multi-planar imaging evaluation for the evaluation of fine detail, standard transverse, sagittal and coronal images can be created from a single isotropic 3D volume. The high spatial resolution of such isotropic data sets further allow for the creation of radial MR images as well as individualized curved and oblique planar image reconstructions, which improve the visualization of oblique ligaments and curved tendons. Recent advances in acceleration techniques have dramatically increased the speed of 3D spin echo data acquisition. With the use of optimized parallel imaging techniques and compressed sensing data sampling,

high-quality isotropic 3D spin echo sequences can now be acquired in under 5 minutes and further enable rapid high-resolution 3D MR imaging protocols of joints within an acquisition time of 10-15 min.
Learning Objectives:
1. To understand the MR imaging techniques used for 3D MR imaging of joints.
2. To know the strength and limitations for 3D MR imaging of joints.
3. To learn about new imaging acceleration techniques used for 3D MR imaging of joints.
Author Disclosure:

14:00 - 15:30 **Room G**

Physics in Medical Imaging

RC 1513
Dose reduction using iterative image reconstruction in CT

A-737 14:00
Chairman's introduction
V. Gershan; *Skopje/MK (vesna.gershan@pmf.ukim.mk)*

Filtered backprojection (FBP) was the primary method for reconstructing CT images for many years. Advancements in algorithm design and computer hardware have led to development of iterative reconstruction (IR) algorithms for CT images. Iterative algorithms can model many of the physical parameters that FBP cannot, such as the x-ray spectrum, the blurring of the focal, etc. The first type of IR algorithms goes through a series of iterations applied on first-pass FBP raw datasets. This technique results in longer reconstruction time, but also in substantially less image noise. Degree of the noise reduction can be taken as either improved image quality or as a reduction of patient dose, typically up to 40%. Recently, more complex IR algorithm called fully model based has become available. It uses both backward and forward projections datasets. By combining many more iterations, image noise can be reduced to a higher degree, enabling 80-90% patient dose reduction compared to FBP. The last developed IR algorithm is called partial model-based IR. It takes much less reconstruction time than fully model based, but results also in substantially greater noise reduction. The patient dose reduction is 50-60% compared to FBP. Images reconstructed by IR techniques have different appearance compared to FBP, mainly due to decrease in overall noise and different pattern of tissue depiction. Therefore, radiologists need a period of adaptation on the new image appearance. Over time, as they became accustomed to the look of images, the iterative strength level may be decreased and reduce the patient dose even further.
Session Objectives:
1. To learn about the origins of dose reduction using iterative image reconstruction in CT.
2. To understand dose reduction using iterative image reconstruction in CT.
3. To learn about solutions and workarounds.

A-738 14:05
A. Basics of iterative image reconstruction in CT
M. Kortesniemi; *Helsinki/FI (mika.kortesniemi@hus.fi)*

Computed tomography image reconstruction is a mathematical process where the raw data projections (sinogram data) acquired during rotational CT scan exposure are transformed into volumetric (3D) image data. As such, reconstruction is an inverse problem, with no direct analytical solution. Traditional algorithms (filtered back projection, FBP) approximate the true acquisition method and are prone to artefacts and noise. Iterative reconstruction methods approach the final solution gradually in steps and may take quantum statistics, physical properties and limitations of image acquisition more faithfully into account. Thus, a more accurate and correct outcome may be achieved. However, more detailed modelling of the actual CT acquisition system, physics, optics and object also increases the calculation time and related CPU requirements. Especially, the forward projection phase (calculation of simulated raw-data) on each iteration step is computationally intensive. More optimised reconstruction techniques with clinically acceptable reconstruction times are under active research. As the main diagnostic benefit, higher image quality in terms of lower noise and artefacts can be achieved using iterative methods, and/or a lower radiation dose. However, users should be aware that current iterative reconstructions potentially alter the image texture in different clinically relevant contrast and detail levels. Therefore, sufficient clinical image quality should be verified when applying iterative techniques on new exam indications and protocol optimization.
Learning Objectives:
1. To learn about the basic aspects of iterative reconstruction.
2. To learn about potential dose reduction via iterative reconstruction.
3. To compare iterative reconstruction with other techniques.

A-739 14:28
B. Iterative image reconstruction in clinical practice (dos and don'ts)
H. Alkadhi; *Zurich/CH (hatem.alkadhi@usz.ch)*

The increasing use of computed tomography (CT) for clinical imaging in patients has raised concerns about its potential risks, leading to the development of various strategies for optimizing and reducing the radiation dose associated with CT. Of those techniques, iterative reconstruction algorithms have gained wide acceptance as powerful tools for improving image quality on dose-optimized CT studies through image noise reduction. This presentation reviews the clinical challenge of applying iterative reconstruction techniques to computed tomography (CT) examinations, and especially to low radiation dose CT examinations. The various currently available techniques are discussed, and their potential for improving image quality and increasing the diagnostic accuracy are discussed. Practical aspects of the different iterative reconstruction techniques are emphasized, along with their benefits, pitfalls and potential clinical implementations.
Learning Objectives:
1. To understand the radiologist's requirements for image reconstruction.
2. To learn about current best practice in image reconstruction for clinical CT.
3. To learn about the potential benefits and pitfalls of using iterative reconstruction in clinical CT.

A-740 14:51
C. Image quality assessment of iterative reconstruction: pitfalls and future directions
C. Ghetti; *Parma/IT (CGhetti@ao.pr.it)*

The use of iterative reconstruction algorithms in computed tomography (CT) has become a crucial issue for dose reduction in CT examinations. The main advantage of iterative algorithms as opposed to filtered back projection (FBP) is the incorporation of physical models, which allow for CT studies at reduced doses with preserved image quality and low levels of image noise. The most common iterative reconstruction methods and the solutions introduced by CT manufacturers will be briefly presented. A simple phantom-based approach will be described to explore the features of iterative algorithms. Quantitative parameters that can be evaluated are image noise, impact of different reconstruction kernels on noise reduction, noise power spectrum (NPS), contrast-to-noise ratio (CNR), spatial resolution, and linearity and accuracy of CT numbers. The evaluation of noise properties of a CT image using standard deviation metric is not exhaustive because the image appearance depends also on the noise distribution in frequencies, described by noise power spectrum NPS. Usually the shape of NPS curves are different from FBP; peaks are shifted towards low frequencies and this effect is more marked if the iteration is applied with a greater strength. In iterative reconstruction, a blotchy image quality impression is commonly reported by radiologists, for this reason it is important to measure NPS to give at the radiologists a feedback on how to reach a good compromise between dose reduction and a familiar image appearance.
Learning Objectives:
1. To learn about basic image quality metrics employed in CT.
2. To understand why image quality assessment is difficult with iterative reconstruction.
3. To learn about up-and-coming methods for image quality assessment.

15:14
Panel discussion: How low can we go?

14:00 - 15:30 **Room K**

Professional Challenges Session

PC 15b

A team approach towards ensuring patient safety and care

A-741 14:00

Chairmen's introduction: A team approach - why is this necessary?

T. Owman[1], J. McNulty[2]; [1]*Lund/SE*, [2]*Dublin/IE (Titti.Owman@gmail.com)*

In this session, we will discuss and present different ways in which teamwork and cooperation can change and improve our daily work in medical imaging departments. Team-based solutions is a concept that is growing in a wide variety of professions and medical imaging is no exception. Due to an increasing awareness of value-based healthcare and rapidly rising healthcare costs it is of utmost importance that we take care of, and use, available competences and resources as well and efficiently as we possibly can. A well-functioning team constellation may be the future for an increasing number of medical imaging procedures as we continue to move from what used to be imaging-only modalities toward a more complex diagnostic reality where physiology, functional measurements and therapies are included in our daily work. We need persons on our medical imaging teams with unique skills, overlapping knowledge and different levels of expertise to optimise the results from our departments and clinics. The specialised team approach is also dependent on a good leadership, trust and a well-functioning information system. When this is done in a successful way we end up with better procedures, enhanced quality and improved safety for both patients and staff members. Well-functioning teamwork would also mean increased motivation and involvement among all personnel.

Session Objectives:

1. To explore the added value of a team approach to radiological procedures.
2. To understand the impact of radiographer reporting on clinical practice.
3. To explore the benefits provided by a team approach in interventional procedures.

A-742 14:06

A team-based approach to delivering safe practice

J. Damilakis; *Iraklion/GR (damilaki@med.uoc.gr)*

A considerable number of medical accidents, incidents and omissions can be attributed to lack of communication. Medical physicists, radiographers and radiologists should work collaboratively with colleagues and clinicians to develop effective radiation dose reduction strategies, increase patient safety and optimize the outcomes of patient care. Medical physics experts (MPEs) are involved in medical imaging departments to measure the radiation output to estimate the radiation dose, monitor doses using dose tracking methods, maintain patient doses within diagnostic reference levels, reduce doses while maintaining the image quality needed for diagnosis, establish appropriate acquisition techniques and train staff in radiation protection. These activities are of great importance for all modalities and especially for CT and interventional radiology, where radiation doses are high. A team approach is needed in medical radiation protection to ensure patient safety and care.

Learning Objectives:

1. To understand a team-based approach to ensuring patient safety during radiological procedures.
2. To consider how a joint approach may improve the culture of radiation safety within the clinical environment.
3. To highlight how a collaborative approach to practice leads to improved effectiveness and patient safety.

A-743 14:29

The radiographer and radiologist: joint responsibility for reporting

S. Rowe; *London/UK (Susan.Rowe@homerton.nhs.uk)*

Effective efficient utilisation of all staff within radiology departments has the potential to maintain and improve patient experience, minimising the impact of increasing demand for imaging services on a background of financial continued austerity and shortage of radiology consultants. Allied health professionals (AHPs) have provided both acquisition and reporting of radiology diagnostic examinations for many years in the UK, initially largely in ultrasound. Over the last 2 decades, reporting radiographers have been providing x-ray reports in many UK departments and more recently in specific areas of MR reporting. Due often to complex local factors utilisation of their skills has been highly variable between different hospitals leaving many UK hospitals paying potentially expensive independent sector providers to report examinations, often as part of backlog recovery programmes rather than real-time service. Apart from reporting, AHPs have successfully undertaken intervention work, including biopsies and therapeutic joint injections, supporting service provision traditionally undertaken by radiologists. Embracing a diverse workforce increases resilience during periods of acute workforce shortages or spikes in demand and potentially enables more extensive provision of 7-day services. In addition, it facilitates deployment of consultant radiologist skills to areas that require their different levels of expertise and more varied clinical experience and training. Ensuring appropriate development of the whole clinical team while working in a supportive integrated service enables decreased length of imaging pathway from request to report and the increased availability of consultants for more complex work/discussions centred around improving patient care.

Learning Objectives:

1. To discuss the concept of joint reporting and responsibility and how this system may be developed within clinical practice.
2. To highlight the benefit of reporting abnormality detection by radiographers.
3. To discuss future opportunities for radiographers and radiologists in this area.

A-744 14:52

A team approach in interventional procedures

C. McLaren; *London/UK (clare.mclaren@gosh.nhs.uk)*

A team approach in interventional procedures advanced practice is well established in the UK, in nursing and other allied health professions. At Great Ormond Street Hospital, we responded to poor staff retention and low morale by implementing advanced practice in interventional radiology. There was strong support for this from the medical director of the hospital and lead consultant interventional radiologist. The establishment of the role of consultant radiographer in the interventional radiology team has created a strong link between the radiologists and radiographers. The consultant radiographer provides a similar service to the radiologist by being an expert in specific areas of paediatric interventional radiology. This role incorporates clinical work, research and maintaining an expert knowledge of complex radiographic techniques, for example cone beam CT-guided procedures. The consultant radiographer is also heavily involved with multi-disciplinary team meetings, presenting imaging findings to referring teams. Incorporation of the WHO safety checklist into everyday practice has led to interaction with the whole team involved in the planning of procedures for the day. All team members are encouraged to voice their opinions and concerns at the team brief. National safety standards for invasive procedures were implemented in the UK in September 2016. These standards have been set to reduce never events, such as wrong site surgery, serious incidents and near misses. The standards promote multi-disciplinary team working in the operating department and interventional radiology.

Learning Objectives:

1. To familiarise attendees with the active role of the radiographer when performing interventional procedure.
2. To discuss the professional issues and responsibilities within such a team.
3. To emphasise the benefits for patient care and patient safety.

15:15

Panel discussion: Can a team-based approach ensure patient safety?

14:00 - 15:30 **Room M 4**

E³ - ECR Academies: Multiparametric Ultrasound (MPUS)

E³ 1520

Vascular multiparametric US

A-745 14:00

Chairman's introduction

P.S. Sidhu; *London/UK (paulsidhu@btinternet.com)*

A-746 14:05

A. Deep venous thrombosis and chronic venous insufficiency of the lower extremity

G. O'Sullivan; *Galway/IE (gerard.osullivan2@hse.ie)*

Ultrasound is the first modality for diagnosis of deep vein thrombosis (DVT). The purpose of this session is to familiarise attendees with the various ultrasound modalities, including compression, colour, Doppler, the use of respiratory and augmentation manoeuvres and their use. In addition, the limitations of US particularly above the groin will be stressed. Diagnosis of reflux is an important component of venous ultrasound and it is quite a specific technical skill. Ultrasound guidance for catheterisation of superficial and deep venous structures will be elaborated. Lastly, the place of intra-vascular

ultrasound (IVUS) will be discussed and its use will be illustrated with examples.
Learning Objectives:
1. To learn about the current role of MPUS to diagnose DVT.
2. To become familiar with the US examination technique: compression US and Doppler.
3. To learn how US is used to diagnose varicose veins and valve insufficiency.
Author Disclosure:
G. O'Sullivan: Advisory Board; Siemens Healthcare. Author; New Horizons in Venous Disease. Speaker; Cook Medical, Straub, Bard, BSCI, Marvao Medical.

A-747 14:33

B. Abdominal vascular emergencies: ruptures and occlusions
D.A. Clevert; *Munich/DE (Dirk.Clevert@med.uni-muenchen.de)*

Conventional ultrasound is the most widely used imaging modality in routine clinical practice worldwide. The limitations of conventional ultrasound in the detection of aortic lesions vs multi-slice computed tomography angiography (MS-CTA) are well known. Conventional unenhanced ultrasound is in direct comparison with contrast-enhanced CTA probably inappropriate given the fact that without contrast enhancement the performance of CT may well be equal or even inferior to that of ultrasound. Due to the introduction of microbubbles (MB), ultrasound contrast might be a way of bridging the gap between these modalities. In the last three years, recent articles have focused on the use of contrast-enhanced ultrasound (CEUS) for diagnosis of ruptured abdominal aortic aneurysm and other vascular disorders.
Learning Objectives:
1. To understand MPUS findings in arterial rupture (aneurysm, other).
2. To learn about Doppler techniques and CEUS to improve diagnosis of vascular occlusions and infarcts.
3. To understand the advantages and limitations of US techniques compared to CT.
Author Disclosure:
D.A. Clevert: Advisory Board; Samsung, Siemens, Philips, Bracco. Speaker; Samsung, Siemens, Philips, Bracco.

A-748 15:01

C. Upper and lower extremity arterial emergencies
B. Brkljačić; *Zagreb/HR (boris@brkljacic.com)*

B-mode ultrasound enables evaluation of arterial anatomy and of the vessel wall, it detects early atherosclerotic changes, allows detection of stenosis and occlusions, but tends to overestimate the degree of stenosis and should not be used for the stenosis grading. Colour duplex Doppler ultrasound (CDUS) enables fast visualization of vessel to be examined. It demonstrates haemodynamic changes, including velocity increase. Underestimation of disease is likely if only colour is used and the precise assessment of haemodynamic disturbances is impossible without the spectral analysis. In general, CDUS has high diagnostic accuracy, it is cheap, widely available, there is no exposure to ionizing radiation, and no contrast media injection. However, the examination is time consuming and requires high operator dependence. The thorough understanding of haemodynamics and physics is needed for adequate interpretation of Doppler findings. The factors influencing spectral morphology will be discussed in the lecture and different types of spectra presented. Waveform changes will be presented in stenosis and occlusion. The typical findings of pseudoaneurysms and arteriovenous fistulas will be presented. Findings in acute occlusion and collateral flow will be discussed, both for native arteries and for bypass grafts. The role of ultrasound in endovascular recanalizations will be discussed, both in planning and performing of the procedure and in the follow-up. The role of CEUS will be discussed. Several clinical examples will be presented.
Learning Objectives:
1. To understand the MPUS imaging techniques to diagnose arterial occlusion.
2. To learn how to improve diagnosis by Doppler techniques and CEUS.
3. To learn US limitations, challenges and pitfalls.
Author Disclosure:
B. Brkljačić: Speaker; Guerbet, Bayer.

E³ - ECR Academies: Neuroradiology: from Morphology to Function

E³ 1522

Functional MRI of the brain opens new horizons

A-749 14:00

Chairman's introduction
T.A. Yousry; *London/UK (t.yousry@ucl.ac.uk)*

Since their development about 25 years ago, functional MRI and diffusion-weighted imaging have been central in research and also in clinical patient management. This session will explore the latest developments in terms of techniques and postprocessing as well as their clinical applications. Consideration will be given to pitfalls, limitations and practical guidelines for quality control and analysis.
Author Disclosure:
T.A. Yousry: Advisory Board; Biogen Idec; Genzyme, Ixico. Board Member; Neuroradiology. Grant Recipient; Medical Research Council, MS Society of Great Britain and Northern Ireland, Stroke Association, British Heart Foundation, Wellcome Trust. Research/Grant Support; BRC. Speaker; Novartis.

A-750 14:06

A. No function without structure: challenges in diffusion MRI and fibre tractography for clinical research
C. Tax; *Cardiff/UK (taxc@cardiff.ac.uk)*

Diffusion MRI (dMRI) has the unique ability to characterise tissue microstructure in vivo, and has been widely used in clinical and biomedical research applications to infer valuable information about the brain's structural connectivity. dMRI is based on the fundamental principle that water molecules randomly move due to thermal energy, and that this motion is modulated by tissue structures. With diffusion tensor imaging (DTI) the anisotropic behaviour of diffusion can be characterised in a three-dimensional fashion. This allows for the virtual reconstruction of pathways - a process called fibre tractography. In the first part of this presentation, the basic principles of diffusion, dMRI, and tractography will be explained. Due to the growing interest in dMRI, the society has been continuously triggered to develop novel dMRI image processing approaches. Such approaches are necessary to 'prepare' the data for subsequent analysis. In the second part of this talk several preprocessing steps are highlighted, including data quality assessment and correction for artefacts. Subsequently, some analysis strategies will be summarised. With the overwhelming amount of processing and analysis strategies available and still being developed, it is unfortunately not always evident how dMRI can be optimally used in applications and which conclusions can and cannot reliably be drawn from dMRI data. In the final part, methodological challenges related to dMRI will be discussed.
Learning Objectives:
1. To present an introduction to the use of diffusion MRI and fiber tractography of the brain.
2. To illustrate how these techniques have provided new insights into functional neuroanatomy.
3. To raise awareness about methodological challenges and limitations for clinical applications.

A-751 14:34

B. Clinical utility of fMRI for preoperative brain mapping
H. Urbach; *Freiburg/DE (horst.urbach@uniklinik-freiburg.de)*

Subtle epileptogenic lesions (mainly focal cortical dysplasias) are often missed on standard MRI. To find them, a 3 Tesla 3D T1-weighted MPRAGE (for morphometric analysis), a FLAIR SPACE, and a coronal highly resolved T2-weighted TSE sequence in-plane resolution 0.45x0.45 mm (for visual inspection) are key sequences within a epilepsy-dedicated protocol. In further presurgical workup language, laterality (which is related to the verbal memory capacity of the ipsilateral anterior temporal lobe and hippocampus) and spatial relationship of lesions to eloquent cortex and white matter tracts must be evaluated. With clear left laterality language fMRI is sufficient, in atypical laterality electrical stimulation mapping rather than a Wada test is added. Primary motor cortex and corticospinal tract on one and visual cortex and optic radiation on the other side are displayed with fMRI and diffusion tensor tractography. For the corticospinal tract, a "global" tracking algorithm and for the optic radiation including Meyer's loop, which may be damaged in anterior temporal lobe resections, a probabilistic algorithm are best suited. However,

most neuronavigation systems only process white matter tracts calculated with the FACT algorithm.
Learning Objectives:
1. To reveal how morphometric analysis of 3D data sets can help to reveal the true extent of a cerebral lesion in the presurgical work-up.
2. To demonstrate how fMRI is useful for documenting the spatial relationship of brain lesions to the adjacent eloquent cerebral cortex.
3. To illustrate how diffusion tensor tractography can reveal important white matter tracts such as the corticospinal tract and optic radiation.
Author Disclosure:
H. Urbach: Board Member; Clinical Neuroradiology, Neuroradiology. Investigator; Stryker. Research/Grant Support; BMBF. Speaker; Bayer, Stryker, UCB.

A-752 15:02

C. Introduction to resting state fMRI and functional connectomics
M. Oldehinkel; *Nijmegen/NL (m.oldehinkel@donders.ru.nl)*

Our brain consists of networks formed by structurally as well as functionally connected brain areas. Functional communication between brain regions is assumed to play a key role in the various functions of the brain. This makes the investigation of 'functional connectivity' in the human brain of high importance as it provides insights into the basic organisation of the brain. Regions are said to be functionally connected if their activation patterns (as measured with a functional MRI (fMRI) scan) are highly correlated. An fMRI scan can be acquired while participants or patients are performing a specific cognitive task, but also at 'resting state' during which participants are instructed to relax and to not think of anything in particular. Various studies have reported that the functional architecture of brain networks is altered in neurological and psychiatric diseases. However, before resting-state fMRI (rfMRI) can be used for diagnosis and predicting disease outcome, the field needs to overcome several challenges. In this talk I will cover the basic concepts of rfMRI and functional connectivity, give some examples of innovative rfMRI applications for studying brain function in neurological and psychiatric disorders and discuss the current challenges in the field.
Learning Objectives:
1. To understand how spontaneous fluctuations in activity in different parts of the brain can be used to study functional brain networks.
2. To review how resting-state functional MRI (rfMRI) can be used to map the macroscopic functional connectome.
3. To highlight some upcoming challenges in functional connectomics, using high-quality rfMRI data being generated by the Human Connectome Project.

E³ - ECR Academies: Interactive Teaching Sessions for Young (and not so Young) Radiologists

E³ 1621
Imaging of the chest

A-753 16:00

A. Fibrosing lung diseases
F. Molinari; *Lille/FR (francescomolinari.dr@gmail.com)*

The diagnostic approach to patients with fibrosing interstitial lung disease (FILD) is often complicated even when clinical history and physical findings are correctly assessed at presentation. In fact, many disorders of known and unknown aetiology may result in lung fibrosis and have overlapping clinical and radiographic features. Surgical lung biopsy is a viable tool for establishing the diagnosis. However, the procedure is associated to morbidity and mortality risks. HRCT remains the most important noninvasive modality for the diagnosis and management of patients with FILD. HRCT findings such as parenchymal reticulation, ground-grass attenuation, traction bronchiectasis and bronchiolectasis, architectural distortion and honeycombing indicate the presence of FILD. Honeycombing also indicates that lung fibrosis is irreversible and potentially progressive. To differentiate the most commonly encountered FILDs, current guidelines recommend to consider the presence of subpleural and basilar reticulation associated with honeycombing, altogether as the "UIP pattern". In the absence of known causes of lung fibrosis, a "definite" UIP is consistent with a diagnosis of idiopathic pulmonary fibrosis and does not require lung biopsy. The forms of FILD that manifest at HRCT as "possible" UIP and for which an alternative diagnosis of NSIP exists require lung biopsy. Finally, if the FILD manifests with HRCT findings that are inconsistent with UIP, the potential diagnosis of chronic HP is considered and lung biopsy is usually not indicated. This clinical-HRCT interpretative algorithm facilitates the assessment of HRCT scans that show the presence of lung fibrosis and provides guidance in the management of patients with FILD.
Learning Objectives:
1. To become familiar with the differential diagnosis.
2. To identify the key imaging findings.

A-754 16:45

B. Pleural disease
C. Beigelman; *Lausanne/CH*

Diffuse or focal pleural disorders are commonly encountered in routine practice, including pleural effusions, pleural thickenings, calcified or not, pneumothoraces or masses. Differential diagnosis must be known. In particular, focal pleural thickening (PT) may be related not only to typical pleural plaques, but also to normal structures, previous tuberculosis, pleural metastasis, silicosis, or other rarer conditions. Furthermore, postero-basal PT in supine examination may be reversible on prone position. Any atypical shape, location or change of a PT should suggest a pleural metastasis in a context of malignancy. In all cases, a careful analysis of other CT findings, previous imaging studies and clinical history are determinant for the final diagnosis. Parenchymal bands or rounded atelectasis are helpful for the diagnosis of benign diffuse pleural thickening. Features suggestive of malignancy include circumferential pleural thickening, nodular pleural thickening, parietal pleural thickening greater than 1 cm, and mediastinal pleural involvement. Atypical aspects such as pleural effusion even without plaque and pleural irregularity may be observed in mesothelioma, and slight changes in the mediastinal or interlobar pleura should be considered as suspicious of this diagnosis. Mistakes may be related to the difficult recognition of features such as in case of pneumothorax in supine position or to atypical features such as loculated effusions or atypical presentations of malignant pleural involvement that may lead to a delayed diagnosis.
Learning Objectives:
1. To become familiar with the differential diagnosis.
2. To identify the key imaging findings.

16:00 - 17:30 **Room B**

Abdominal Viscera

RC 1601
Abdominal MRI: from standard to advanced protocols

A-755 16:00

Chairman's introduction
F. Caseiro-Alves; *Coimbra/PT (caseiroalves@gmail.com)*

Abdominal MR imaging is a continuously evolving technique where researchers, vendors and clinical users get together to push it to the next level of medical practice. Recent advances in the MR field include the development of dedicated DWI sequences, increased spatial resolution and functional imaging capabilities to name a few. Therefore, there is a clear-cut need to use and take advantage of the most recent and best suited protocols. In this session, we will deal with three important common clinical situations: a) the suspected pancreatic cancer where MR appears not only as a problem-solving tool but also as a competitive diagnostic modality compared with MDCT ranging from DWI to high-resolution MRCP and time-resolved dynamic imaging; b) inflammatory bowel disease that, as a chronic relapsing disease, is one of the cases where MR may contribute to drive patient management exquisitely monitoring the inflammatory activity of the disease; c) MRI of pelvic floor disorders that consists in the use of high-resolution morphological data together with functional information under straining conditions. Its diagnostic power and contribution to patient management is well acknowledged today but protocol optimisation and proper quantification assumes a vital importance. To enhance the educational value of this session an illustrative clinical case for each clinical problem will be presented exploring the benefits and/or MR limits.

A-756 16:05

A. Suspected pancreatic tumour
R. Manfredi; *Verona/IT (riccardo.manfredi@univr.it)*

Pancreatic cancer is the fourth leading cause of cancer-related death. Surgical resection is the sole curative treatment option; however, only 15%-20% of them are resectable at the time of diagnosis. Furthermore, the prognoses for patients with pancreatic cancer remains poor. Although the 5-year survival rate is up to 20% after complete resection, it is further improved to more than 75%, in patients with a diagnosis of stage 1 disease. Computed tomography (CT) remains the initial imaging modality of choice for pancreatic solid neoplasms, even because recent improvements in multidetector CT technology, including improved temporal and spatial resolution, have facilitated more precise timing

of multiphasic imaging and increased the accuracy of CT for the detection and staging of pancreatic adenocarcinoma. Recently magnetic resonance (MR) imaging has developed a role in the early diagnosis of adenocarcinoma, because of diffusion-weighted (DW) MR imaging. By means of DW imaging MRI is able to depict changes in water mobility caused by interactions with cell membranes, macromolecules and alterations to the tissue environment, and thus provides a tissue contrast that is different from that on conventional T1- and T2-weighted images. DW imaging plays a role in oncology for tumour detection in general. DW imaging allows detection of pancreatic adenocarcinomas with high sensitivity and specificity, because it appears hyperintense compared with the rest of the gland. DW-MR imaging is also useful in finding small functioning neuroendocrine neoplasm, responsible for a clinical syndrome, but difficult to diagnose because of their small size.

Learning Objectives:

1. To learn about the role of MRI in the assessment of a patient with suspected pancreatic tumour.
2. To become familiar with the optimal MRI protocols including the role of DWI and secretin in this group of patients.
3. To appreciate the advantages and limitations of MRI in comparison with other imaging techniques.

A-757 16:28

B. Inflammatory bowel disease

J. Rimola; *Barcelona/ES (jrimola@clinic.ub.es)*

Magnetic resonance enterography (MRE) examinations are increasingly used in bowel imaging in particular for Crohn's disease assessment. In this setting, MRE has an evolving role not only for detecting and grading inflammation and their complications, but also for monitoring the course of the disease. MRE has unique technical characteristics including the distension of the bowel and the scanning of large areas of the body. Knowledge about patient preparation (bowel distension, anti-peristaltic drugs, etc.), scan technique and sequence parameters optimization as well as being familiar with commonly encountered problems that can arise during scan acquisition is of paramount importance. In this session, we will outline the most common sequences employed in routine MRE and its application in clinical practice. The potentialities and limitations of new functional sequences such as diffusion-weighted imaging and motility will be also discussed.

Learning Objectives:

1. To learn about the role of MRI in patients with IBD.
2. To become familiar with the optimal MRI protocols including bowel distension in this group of patients.
3. To appreciate the role of functional imaging techniques for assessment of IBD.

Author Disclosure:

J. Rimola: Consultant; Robarts Clinical Trials.

A-758 16:51

C. Pelvic floor disorder

D. Weishaupt; *Zurich/CH (dominik.weishaupt@triemli.zuerich.ch)*

Imaging of the female pelvic floor is of rising interest due to an ageing population, harbouring an increasing incidence of pelvic floor disorders (PFD) and the rising need for comprehensive diagnosis and treatment. Magnetic resonance imaging (MRI) of the female pelvic floor combines high-resolution imaging with an excellent soft tissue contrast and provides the possibility to assess noninvasively and objectively a spectrum of possible disorders affecting the pelvic floor in one examination. There is general agreement that MRI of the pelvic floor should encompass static and dynamic MR images, whereas dynamic means imaging under maximum stress to the pelvic floor and MR defecography. Static MR images visualize pelvic floor anatomy and defects of the supporting structures, while dynamic MR images visualize pelvic organ mobility, pelvic floor weakness, pelvic organ prolapse (POP) and associated compartment defects. In this lecture, a standardized approach regarding indications, patient preparation, sequences acquisition, interpretation and reporting of MRI for diagnosis and grading of PFD is presented. Due to the different views of the clinical specialists involved in the treatment of PFD, adapting the MRI reporting scheme according to the speciality of the referring physician is discussed. Finally, the limitations of the technique are addressed.

Learning Objectives:

1. To learn about the clinical relevance of MRI in the management of patients with pelvic floor disorders.
2. To become familiar with the optimal patient preparation and MRI protocols in this group of patients.
3. To appreciate the advantages of MRI relative to other imaging modalities including conventional defecography.

State of the Art Symposium

SA 16

Detection and management of small renal masses

A-759 16:00

Chairman's introduction

H.C. Thoeny; *Berne/CH (harriet.thoeny@insel.ch)*

Small renal masses are often incidentally detected on cross-sectional imaging. Management of these focal renal lesions depends on the underlying histology, age and comorbidities of the patient. However, characterisation of these small renal masses is often a big challenge. Cystic real lesions are classified according to Bosniak. In recent years, differentiation of solid renal lesions has improved substantially mainly thanks to a multiparametric approach using MRI. In the past years, solid renal lesions were surgically resected in most centres; however, in recent years, active surveillance and imaging-guided minimally invasive treatment are increasingly used alternatives to partial nephrectomy depending on histology of the tumour and various patient factors. As a consequence treatment monitoring is not only based on change in size or macroscopic tumour recurrence, but needs more detailed knowledge of the performed treatment including normal and pathological findings and knowledge of functional imaging techniques to early evaluate treatment success or recurrence.

Session Objectives:

1. To understand the imaging features of small benign and malignant renal masses.
2. To learn about the treatment options using imaging-guided minimally invasive treatment.
3. To appreciate typical normal and abnormal imaging findings during treatment monitoring.

Author Disclosure:

H.C. Thoeny: Advisory Board; Guerbet SA.

A-760 16:05

Detection and characterisation of small renal masses

N. Grenier; *Bordeaux/FR (nicolas.grenier@chu-bordeaux.fr)*

Imaging is the main source of detection of small renal masses. Primary detection is based on US and CT. MRI may help in indeterminate cases, DWI playing a major role. Characterisation of solid component of a small renal mass is based on CT-contrast enhancement, but, when doubtful, DCE-MRI and CEUS are more sensitive. Considering cystic masses, Bosniak classification is required. Considering solid masses, characterisation of fat-rich angiomyolipomas is based on plain CT, but fat-poor AMLs can be distinguished from carcinomas by multiparametric MRI only. Multiparametric MRI includes chemical shift gradient echo (GRE) sequences, signal intensity on T2-weighted images, DCE sequences, diffusion-weighted sequences and late contrast-enhanced images. Using different combinations of two or several parameters, now makes it possible to clearly distinguish some renal tumours such as fat-poor AMLs, papillary carcinomas and clear cell carcinomas, the latter being difficult to separate from oncocytoma when a central scar is absent. A larger validation of all these combinations is still necessary to define those having a clinical significance for routine practice. Percutaneous biopsy remains mandatory before such a validation, as soon as pathological result is supposed to have an impact on tumour management.

Learning Objectives:

1. To understand the definition of small renal masses.
2. To understand the typical imaging findings of small renal masses on CT.
3. To become familiar with multiparametric MRI to characterise small renal masses.

Author Disclosure:

N. Grenier: Advisory Board; Supersonic Imagine.

A-761 16:30

Image-guided minimally invasive treatment

M. Krokidis; *Cambridge/UK (mkrokidis@hotmail.com)*

The clinical management of small renal masses generates significant controversy. The gold standard still remains surgical excision; nevertheless, nephron sparing minimal invasive percutaneous ablation appears to offer similar oncologic outcomes and less complication than surgery. Active surveillance is only reserved for patients that are not suitable for any kind of treatment. Percutaneous ablation (radiofrequency, cryo or microwave) may be performed under local or general anaesthesia with minimal hospital stay;

guidance may be performed under CT, MRI or US guidance and with the use of fusion and navigation systems. Long-term results and comparative data are now available. Psutka et al. [Eur Urol. 2013] report the results of 185 patients with Stage I renal tumour (median size 3 cm) treated with RFA and followed up for a median of 6.43 years (range: 5.3-7.7). Local recurrence occurred in 6.5% of the patients after a median time of 2.5 years; however, the 5-year recurrence-free survival was 96.1%. Olweny et al. [Eur Urol. 2012] identified no significant difference between RFA and open partial nephrectomy for the treatment of T1a RCC in terms of 5-year disease-free survival, metastasis-free survival and local recurrence-free survival. Furthermore, Thompson et al. [Eur Urol. 2015] recently published a retrospective single-centre comparison of ablation with partial nephrectomy for Stage I RCC of 1424 patients with no difference on recurrence-free survival and comparative oncologic results. Ablation is offering excellent long-term results for the management of small renal tumours and should be considered as a first-line therapy for T1a tumours.

Learning Objectives:

1. To become familiar with the clinical management of small renal lesions.
2. To understand the minimally invasive treatment options of small renal lesions.
3. To learn about the current evidence on the minimal invasive treatment of small renal tumours.

A-762 16:55

Treatment monitoring with imaging

G. Cardone; *Milan/IT (cardoneg@tin.it)*

Most frequent treatments for small renal masses (SRM) are partial nephrectomy, radiofrequency ablation, cryoablation and active surveillance. CT and MR are commonly used in the imaging follow-up of patients treated for SRM. Parenchymal changes after partial nephrectomy are the presence of postoperative granulomas, fat, scars or parenchymal defects at the excision site. Imaging patterns of recurrence are the presence of a mass with enhancement, increasing in size during the follow-up, at the excision site or perinephric space. Radiofrequency ablation and cryoablation are minimally invasive approach for the treatment of SRM. Both ablative treatments, performed with percutaneous approach under US or CT guidance, provide tissue necrosis. Since it is not possible to document histopathologically the complete tissue necrosis after renal ablation, an adequate radiological follow-up is mandatory. Recurrence patterns after ablative treatments are the presence of an enhancing nodule in the treated area, increasing in size during the follow-up. Active surveillance has emerged as an alternative to extirpative or ablative treatments for SRM, in elderly and comorbid patients. Serial abdominal imaging (CT/MR) is performed to monitorize tumour size, with delayed intervention reserved for those tumours that show clinical progression during follow-up. In treated kidneys imaging follow-up, the most effective imaging techniques were multiphasic acquisition (CT) and morphologic TSE T2w and dynamic ce-FS-GRE T1w sequences before and after digital subtraction technique (MR). MR diffusion-weighted imaging may also be helpful to identify foci of residual tumour when contrast enhancement is difficult to evaluate, or when contrast cannot be administered due to renal insufficiency.

Learning Objectives:

1. To become familiar with imaging techniques for patients under active surveillance.
2. To understand typical imaging findings after minimally invasive treatment.
3. To appreciate functional imaging techniques to assess early treatment response.

A-763 16:00

A. Imaging of abdominal masses at diagnosis: clues for benignity vs malignancy

Ø.E. Olsen; *London/UK (oystein.e.olsen@googlemail.com)*

Radiology is a probabilistic discipline since there is no test-diagnosis pair with perfect sensitivity and specificity. This also means that the definition of what distinguishes a likely benign vs. a likely malignant lesion must change depending on pre-test likelihoods. In most instances, the accuracy of imaging to make this distinction is low, hence the pretest likelihood is more important than the imaging findings themselves. So, for example, if you work in a general hospital you will very rarely see malignant tumours in children, so you are rarely wrong calling all lesions benign. The opposite is true in a specialised paediatric cancer centre. Similarly, it is possible to make decision rules based on clinical presentation, age, etc. There are, however, a few clues that often help shift these pre-test likelihoods, albeit none is absolute. Almost always benign: 1) origin splenic, hepatic in children <3 months of age, gastrointestinal, dermal. 2) Perfusion pattern similar to organ of origin. 3) Uptake of tissue-specific contrast agent. 4) Typical appearance of hamartoma. 5) Sharply demarcated lytic bone lesions. Almost always malignant: solid tissue with any pattern of growth. Most other characteristics must be interpreted with caution. Specifically, the following are NOT good predictors: 1) Doppler features (a vascular tumour is not always a haemangioma). 2) Heterogeneity (teratomas may contain malignant elements). 3) Containment (renal tumour are typically very large yet rarely breach the renal capsule). 4) Lack of enhancement (embryonal tumours often do not enhance much). 5) Apparent diffusion coefficient.

Learning Objectives:

1. To become familiar with clinical characteristics and imaging features of a mass suggesting benignity.
2. To emphasise clinical and imaging manifestations of abdominal malignancies.
3. To learn how to report according to international standards.

A-764 16:30

B. From whole-body MRI to MR/PET

W. Hirsch; *Leipzig/DE (wolfgang.hirsch@medizin.uni-leipzig.de)*

Whole body MR (WB-MR) and PET-MR are suitable methods to determine precisely the spread pattern of diseases. Whole body MRI is routinely used in paediatric oncology. It is very effective in the initial staging in multifocal oncological diseases. In restaging, the PET MRI has been shown to be more specific and sensitive in many diseases than the WB-MR. The new hybrid technique of whole body PET-MR leads, particularly in children, to significantly less radiation compared to whole body PET-CT. The radiation dose derives only from the PET part. The radiation exposure in PET-MR equals 3-4 mSv in 3D-mode. In contrast to this, a typical effective dose for a child on PET-CT is about 25 mSv. Therefore, it is likely that by establishing PET-MR 80% of radiation exposure can be prevented compared to PET-CT. A lot of radiotracers are used for PET imaging. For paediatric PET-MR mainly ^{18}F-fluorodeoxyglucose (^{18}F-FDG) and ^{11}C-methionine (^{11}C-MET) are used. However, other tracers are available, e.g. ^{68}Ga-DOTATOC for neuroendocrine tumours or meningioma. Using case studies, typical clinical indications and findings of hybrid imaging in children will be demonstrated, such as PET-MR for oncologic issues, or to locate biopsy areas for brain tumours (hotspot-biopsy). However, the diagnostic usefulness and impact on patient management (“diagnostic imaging efficacy”) must be weighed against the exposure of radiation and also the costs.

Learning Objectives:

1. To understand differences and pitfalls of whole-body MRI and MR/PET in children compared to adults.
2. To compare PET/MRI to PET/CT.
3. To discuss the impact of whole-body MRI and PET/MRI in paediatric oncology.

Coronary CT angiography: how to get it done?

Moderator:
K. Pagonidis; Iraklion/GR

A-766 16:00

A. Beautiful cases from clinical practice I

S. Feger; *Berlin/DE (sarah.feger@charite.de)*

Coronary computed tomography angiography (CTA) is a non-invasive diagnostic test with high diagnostic accuracy in detecting coronary artery disease (CAD). Due to its very high negative predictive value, it is especially suitable for ruling out CAD in patients with low to intermediate pretest probability. For stable chest pain patients in this pretest probability range, the current European guidelines already recommend the use of CTA. Additionally, in patients with unstable chest pain and a low CAD probability, CTA can be considered to detect relevant differential diagnoses. Different acquisition techniques are applied in clinical practice. Initially, retrospective ECG-gated

CTA was routinely used. While this approach is very robust, especially for high or irregular heart rates, radiation exposure is relatively high. Prospective axial scanning reduces radiation exposure, since data acquisition is only performed in predefined ranges within the RR interval with the tube current entirely being turned off outside the acquisition window. Further approaches to reduce radiation exposure are the adjustment of scanning parameters, ECG-gated tube current modulation, automatic tube potential selection and, recently, the introduction of iterative reconstructions.

Learning Objectives:

1. To learn about cardiac CT acquisition techniques, pitfalls, and dose reduction strategies.
2. To summarise current indications and clinical applications of CT coronary angiography.
3. To review the diagnostic performance of CT for the diagnosis of coronary artery disease.

A-767 16:35

B. Staff training and technical requirements

M. Francone; *Rome/IT (marco.francone@uniroma1.it)*

The complexity of cardio-thoracic motion combined with the need of scanning small and tortuous vessels like the coronary arteries pushes technical requirements for cardiac CT to the maximum level. Image quality is directly influenced by the spatial and temporal resolution of the scanners adopted, which are pivotal parameters to consider when selecting a machine to be used for setting up a cardiac CT programme. High temporal resolution is needed, in particular, to minimize cardiac-motion artefacts, and can be raised by increasing gantry rotation speed, or using multisegment reconstructions or by means of a dual-tube solutions. Different technical solutions have been adopted in last years to improve diagnostic performances. After an initial phase of “slice-wars” in which different vendors adopted the strategy of increasing number of slices, there has been a more articulated differentiation in technological proposals ranging from the diffusion of dual tube and dual energy scanners to the availability of “single heart-beat” machines characterized by full-volumetric z-coverage increase; scanner’s tubes have also been implemented to minimize noise and reduce patient’s dose. An additional focus regards the training of personnel, which highly varies geographically all over Europe and, mostly, between different specialities (radiology vs. cardiology) reflecting the still-existing deep differences in training and formation between various backgrounds. On completion of this lecture, participants will be provided an overview of updated technological proposals to implement a cardiac CT programme. Training requirements for radiologists will also be reviewed and compared between different scientific societies and specialities.

Learning Objectives:

1. To become familiar with technical prerequisites and post-processing tools for coronary CT angiography.
2. To discuss a necessary team setup and training modules for radiologists and technical staff.
3. To evaluate the role of coronary CT angiography and requirements for the radiological team in routine imaging and in emergencies.

Author Disclosure:

M. Francone: Speaker; Bracco Medical Imaging Invited Speaker.

A-768 16:55

C. Beautiful cases from clinical practice II

F. Plank; *Innsbruck/AT*

Content of this refresher course will be to illustrate a coronary CTA exam of patients with coronary stents and coronary artery bypass grafts, including step by step accomplishment of a CT exam and differences to usual coronary CTAs, technical and post-processing tools, anatomical configurations of different types of stents, advantages and limitations of CT to visualise stents, appearance of different types of CABG, case discussions, possible pit falls, strategies to improve visualisation and decrease false results.

Learning Objectives:

1. To outline the technical and contrast administration parameters and post-processing tools for the assessment of coronary stents and coronary artery bypass grafts (CABG).
2. To review anatomical configurations and CT appearance of different types of CABG.
3. To discuss current limitations and spectrum of artefacts produced by different types of stents and strategies to improve visualisation of stents.

16:00 - 17:30 **Studio 2017**

Special Focus Session

SF 16a
The male pelvis

A-769 16:00

Chairman's introduction

J.J. Fütterer; *Nijmegen/NL (jurgen.futterer@radboudumc.nl)*

Urogenital organs include the testes, epididymis, vas deferens, ejaculatory ducts, urethra, penis, prostate and seminal vesicles. The male reproductive system consists of those organs whose function is to accomplish reproduction. This consists of testes, which produce spermatozoa and hormones, a series of ducts that store and transport the sperm, seminal vesicles, the prostate and the penis. Imaging has given radiology a significant role in the characterization, diagnosis and staging of tumours in these organs.

Session Objective:

1. To provide an overview of indications, biopsy techniques and multiparametric MR imaging of the prostate.

A-770 16:05

Update on prostate MR

O. Rouvière; *Lyon/FR (olivier.rouviere@chu-lyon.fr)*

Typically, prostate multiparametric MRI (mpMRI) combines T2-weighted imaging (T2WI) with at least diffusion-weighted imaging (DWI) and dynamic contrast-enhanced imaging (DCEI). The use of spectroscopic imaging is optional, as is the use of an endorectal coil. Recent works suggest that the added value of DCE imaging is limited, especially in some settings (history of radiation therapy), but whether DCE can be systematically omitted in all patients remains controversial. Correlations to prostatectomy specimens showed that mpMRI could detect 88-92% of cancers with a volume ≥0.5cc and a Gleason score of 7, and more than 95% of cancers with a Gleason score ≥8. Although many benign conditions can mimic cancer, existing scoring systems can stratify the risk of malignancy and the aggressiveness of the tumours. The recent PIRADS V2 score introduced the concept of a dominant pulse sequence (DWI in the peripheral zone, T2WI in the transition zone), and should help standardizing mpMRI interpretation, even if further refinements of the PIRADS score are to be expected. Quantitative approaches have also shown promising results and will probably be increasingly used in the future.

Learning Objectives:

1. To become familiar with indications and technique.
2. To demonstrate new developments in prostate imaging.
3. To raise awareness about prostate imaging.

Author Disclosure:

O. Rouvière: Consultant; EDAP-TMS, Bracco.

A-771 16:23

Template biopsy vs TRUS/MR-fusion guided biopsy

T. Fischer; *Berlin/DE (thom.fischer@charite.de)*

Prostate cancer is the most common malignancy in men and its incidence is continuously increasing. As with other malignant tumours, early and adequate diagnosis improves the chances of cure. Patients who underwent organ-sparing treatment should be risk-stratified based on localisation, extent, and actual Gleason score of the cancer. Real-time magnetic resonance imaging/ultrasound (MRI/US)-fusion-guided biopsy detects more clinically significant prostate cancers than conventional transrectal ultrasound (TRUS) biopsy. The aim of this session is to discuss state-of-the-art ultrasound techniques for MRI/US-fusion-guided biopsy in daily practice in comparison with transperineal template biopsy, which has high sensitivity (>90%) in detecting aggressive prostate cancer but is also much more invasive. Both techniques are useful in planning organ-sparing approaches (active surveillance, focal therapy). In addition, we use ultrasound contrast agents to characterise focal prostate lesions and to monitor irreversible electroporation (IRE) as well as for molecular imaging.

Learning Objectives:

1. To become familiar with the different fusion techniques.
2. To review the pros and cons of each approach.
3. To show complications and outcome.

Author Disclosure:

T. Fischer: Advisory Board; Bracco, Toshiba. Consultant; Toshiba. Speaker; Toshiba, Siemens, Hitachi, Bracco.

A-772 16:41

Imaging after focal prostate therapy

C. Allen; *London/UK*

"no abstract submitted"

Learning Objectives:

1. To understand image findings of the post-treated gland.
2. To show imaging characteristics of local recurrent disease.
3. To highlight some challenges in the follow-up after focal therapy.

A-773 16:59

Biopsy strategy

A. Briganti; *Milan/IT*

"no abstract submitted"

Learning Objectives:

1. To become familiar with indications and technique.
2. To demonstrate different biopsy strategies.
3. To show complications and outcome.

17:17

Panel discussion: Is there a role for MR imaging to steer the biopsy?

16:00 - 17:30 **Room L 8**

ESR Patient Advisory Group (ESR-PAG)

ESR-PAG 2

Big data - data management, standardisation, access and protection: the way forward in developing personalised/precision medicine

A-774 16:00

Chairmen's introduction

B. Brkljačić[1], N. Bedlington[2]; [1]*Zagreb/HR*, [2]*Vienna/AT (boris@brkljacic.com)*

The session about the management of big data, standardisation, access and protection will include presentations of several perspectives. The perspective of European Society of Radiology will be provided, with presentation of current European situation and future developments. Then patient's perspective will be provided, demonstrating that patients are entitled to personal care and understand that sharing and access to images is needed for their proper precision care. Finally, the US perspective will be provided, where the lessons learnt so far in the top US institution will be highlighted, and US perspective as a whole will be presented.

Session Objectives:

1. To understand the importance of wider recognition for medical imaging and its role in personalised/precision medicine.
2. To understand the key issues of medical imaging in the development of personalised medicine.
3. To learn how patient involvement and education can facilitate the development of personalised medicine.

Author Disclosure:

B. Brkljačić: Speaker; Guerbet, Bayer.

A-775 16:10

European developments within data management, standardisation, access and protection

P. Mildenberger; *Mainz/DE (mildenbe@uni-mainz.de)*

Development in imaging strategies is clearly providing new and exciting opportunities in, e.g. functional or molecular imaging, image processing and many others. These techniques generate a lot of different data, which require more sophisticated workup than conventional x-ray or CT imaging. Therefore, for research or analysis, very often multi-site collaboration will be necessary. For individual treatment, patients will try to find the 2nd opinion outside their primary care-centre seeking for experts throughout their country or even on international level. The EU directive on cross-border healthcare supports this. Several countries have already regional or national eHealth strategies, which help to communicate information between different care providers or patients themselves. One internationally accepted way of standardised communication in healthcare is the application of IHE-profiles. Many of such profiles are already recommended for procurement by the EC. Building such networks could enable access for patients to experts, or pseudonomized/anonymized imaging data could be used to feed national or international registers for benchmarking quality parameters, e.g. for radiation exposure optimisation. Some more work has to be organised to build such registers and to have consensus on coding systems to be used in such environments.

Learning Objectives:

1. To define the current status of play from ESR leadership.
2. To advise on future developments.
3. To highlight advantages of improvements from patient perspective.

A-776 16:25

Patients' point of view (part I)

N. Bedlington; *Vienna/AT (nicola.bedlington@eu-patient.eu)*

The presentation will outline European patients' forum's work to date on big data and data management in the policy context, and describe key principles from the perspective of patients. The changing role of patients will be explored, as will concepts such as informed consent, patients' ownership of data, and transparency. Finally, the presentation will highlight EPF's work on precision medicine and our contribution to the policy debate, with particular emphasis on data management.

Learning Objectives:

1. To understand that patients are entitled to personal care (medicine) as this is to be seen as a minimal requirement.
2. To understand that patient wants precision medicine that their treatment is to be adjusted to the specific properties of their disease - genetic or otherwise.
3. To understand that, from a patients view, data sharing is a necessary instrument to improve the patient journey through her or his disease and that images are also data that need to be shared.

A-777 16:40

Patients' point of view (part II)

E. Briers; *Hasselt/BE (erikbriers@telenet.be)*

Patients are entitled to personal care, care that is tailored to the personal needs of the individual patient, taking into consideration not only the pathology to be taken care of but also the patients' needs and wishes, medical or otherwise, in as far as humanely possible. Precision medicine is tailored to the genetic characteristics of the disease, which will guide the treatment options. Precision medicine can prevent the application of new medicines that would not work or precisely identify a medicine that could be effective eventually from another cancer. To gather knowledge on personalized and precision medicine it is not enough to perform some clinical trials as the level of information is potentially too large. This kind of information can best be distilled from large data sets in which not only many patients are present but of these patients a lot of data. At the start you do not know which data will be relevant. Patients with life-threatening diseases that depend for their treatment on innovative new medicines know that these are the fruit of tenacious research over many years. Those who participate in the trial do so for their own benefit but also from an altruistic point of view for others. In the same reasoning patients know that the analysis of "good" data could allow better treatment options for other patients in the future. Therefore, patients are willing to share their data for their own benefit and the benefit of research but they want to be asked in advance.

Learning Objectives:

1. To understand that patients are entitled to personal care (medicine) as this is to be seen as a minimal requirement.
2. To understand that patient wants precision medicine that their treatment is to be adjusted to the specific properties of their disease - genetic or otherwise.
3. To understand that, from a patients view, data sharing is a necessary instrument to improve the patient journey through her or his disease and that images are also data that need to be shared.

A-778 16:55

Current US status pros and cons and issues

J.A. Brink; *Boston, MA/US (JABRINK@partners.org)*

To enable research in clinical data science, the radiology community must embrace a number of initiatives intended to establish several important standards. International image sharing networks with robust, clean image data sets are needed to serve as reference data sets of proven cases against which new artificial intelligence programs can be tested. Moreover, standardized imaging protocols are critical for subsequent analysis by new machine learning tools. Watermarking methods are needed to ensure the integrity of images in image sharing networks. Image data may be altered intentionally or inadvertently corrupted in transmission or storage, making it difficult to reproduce studies and conclusions in more than a single institution. Watermarks that have been altered will allow recognition of disruptions of data integrity.

Learning Objectives:

1. To discuss the US perspective.
2. To understand the issues from an US perspective.
3. To highlight the lessons learnt.

Author Disclosure:

J.A. Brink: Research/Grant Support; NVIDIA Corporation.

17:10

Panel discussion: Importance of data management in modern medicine - what are the main issues to be addressed?

16:00 - 17:30 **Room E1**

Multidisciplinary Session

MS 16

Virtual autopsy imaging in children: the role of pathologist vs radiologist, one big happy family?

A-779 16:00

Chairman's introduction

C. Owens; *London/UK (owensc@gosh.nhs.uk)*

In this session, we intend to present a multidisciplinary approach to state-of-the art virtopsy imaging in children. We have contributions from radiologists and pathologists, working in harmony to achieve the best possible outcome for bereaved parents, with a conjoint, highly accurate but sympathetic approach. Advances in postmortem imaging and tissue sampling techniques will be outlined to provide a comprehensive autopsy service in the most clinically appropriate setting, whilst respecting the bereaved parents' wishes.

Session Objectives:

1. To learn about the multidisciplinary nature of perinatal autopsy, with reference to the scientific contribution of radiology and pathology.
2. To learn about the limitations of both conventional autopsy, and conventional imaging techniques.
3. To appreciate the role that novel imaging and pathology techniques have to play in future service provision.

A-780 16:05

Minimally invasive autopsy: setting the scene - why, how and by whom?

N.J. Sebire; *London/UK (neil.sebire@gosh.nhs.uk)*

The approach to standard paediatric autopsy has changed little over many years, remaining predominantly based on external examination, dissection and subsequent organ examination and then histological evaluation. Minimally invasive autopsy is a new approach encompassing external examination, non-invasive comprehensive cross-sectional postmortem imaging, and limited tissue sampling to permit the most appropriate tissue sampling techniques necessary to reach a final diagnosis or cause of death which is more acceptable to parents and families.

Learning Objectives:

1. To learn about novel minimally invasive autopsy techniques.
2. To understand how imaging fits into a modern clinical autopsy service.

A-781 16:25

State-of-the-art post-mortem imaging: the way it works and how we do it

O.J. Arthurs; *London/UK (owen.arthurs@gosh.nhs.uk)*

Postmortem (PM) magnetic resonance imaging (MRI) has high diagnostic accuracy for the majority of perinatal and paediatric diagnoses, when accompanied by other non-invasive investigations, and compared to traditional autopsy. Comprehensive whole body imaging using PM MRI performs particularly well for cardiac, neurological and abdominal diagnoses, but less well for thoracic and skeletal abnormalities. PM MRI performs better than PM CT in the same individual, although ventilated PMCT and CT angiography have been proposed to increase PMCT diagnostic detection rates. However, both modalities become increasingly non-diagnostic with reducing foetal size, typically below 500g body weight or at early foetal gestations. Postmortem ultrasound is yet to be assessed in a comprehensive trial.

Learning Objectives:

1. To learn about the recent advances in cross-sectional imaging in a post-mortem setting.
2. To learn about the advantages and disadvantages of conventional PMCT and PMMR techniques.

A-782 16:45

Latest advances: the new kid on the block micro-CT - when and how?

J.C. Hutchinson; *London/UK (ciaran.Hutchinson@gosh.nhs.uk)*

Microfocus computed tomography has been proposed as an alternative to MR or CT in small specimen foetal imaging. Diagnostic accuracy is high for excised foetal hearts and kidneys, with appropriate tissue and image optimisation parameters. Whole body foetal autopsy may be possible with micro-CT in future. However, several issues remain to be addressed for widespread implementation of micro-CT scanning, including tissue colouration, distortion due to fixation, data storage of large files, and comprehensive reconstruction and post-processing.

Learning Objectives:

1. To learn how novel techniques like micro-CT can be used in the perinatal autopsy setting.
2. To appreciate how micro-CT works.
3. To learn what high resolution imaging can offer within a clinical setting.

17:05

Multidisciplinary case presentation and discussion

16:00 - 17:30 **Room E2**

Special Focus Session

SF 16b

Black and white spots in the brain

A-783 16:00

Chairman's introduction

H.R. Jäger; *London/UK*

Session Objectives:

1. To learn about the differential diagnosis of white matter lesions and cerebral microhaemorrhages (including small vessel disease, demyelination and trauma).
2. To understand clinical correlates including the prognostic and therapeutic impact of black spots and white spots.
3. To appreciate the best MR sequences used for detection of white and black spots and tools for quantitative analysis of disease burden.

A-784 16:05

White spots in the brain on T2 and FLAIR: what are they?

A. Rovira-Cañellas; *Barcelona/ES (alex.rovira@idi.gencat.cat)*

White matter hyperintensities (WMHs) are common findings on brain MRI, especially in middle-aged and elderly individuals, and are usually regarded as surrogates of small vessel disease. However, evaluation of WMHs in any age group is challenging because their cause may vary from infectious, inflammatory, or demyelinating findings to nonspecific findings related to ageing and other systemic conditions. Even in the absence of any clue in the clinical data, many WMHs are classified as 'vascular', particularly in elderly individuals, implying a presumed hypoxic-ischaemic pathogenesis and the expression of arteriolosclerotic disease. However, mechanisms other than arteriolosclerosis should also be considered, such as amyloid angiopathy, Wallerian degeneration due to cortical atrophy, or Alzheimer disease-related pathological changes. A more specific diagnosis within the group of hypoxic/ischaemic disorders may be suggested when certain MRI features are

present, such as haemorrhage (amyloid angiopathy), significant asymmetry of the WMHs (ipsilateral carotid disease), and involvement of the external capsule and temporal poles (CADASIL) or the central part of the corpus callosum (SUSAC). In young adults, presence of WMHs commonly suggests the diagnosis of multiple sclerosis, leading to an overdiagnosis of this disease. Therefore, in the absence of typical clinical and MRI features of multiple sclerosis, alternative conditions must always be considered such as migraine, systemic inflammatory diseases, or genetic-related vascular disorders, which are commonly associated with WMHs. In this presentation, we will review different disorders that may present with WMHs and the value of MRI in the diagnosis and management of them.

Learning Objectives:

1. To learn about the differential diagnosis of white spots.
2. To understand semi-quantitative and quantitative approaches for measuring the burden of white spots.
3. To appreciate the role of white spots as biomarkers for natural history and treatment of disease.

A-785 16:30

Black spots in the brain on SWI: differential diagnosis

M. Vernooij; *Rotterdam/NL (m.vernooij@erasmusmc.nl)*

Compounds which distort the local magnetic field may result in 'black spots' in the brain on MRI sequences that are susceptible to such paramagnetic effects, such as susceptible-weighted imaging (SWI). These black spots may result from various tissue changes, such as iron deposition, calcifications or microbleeds. In turn, these changes can reflect different underlying conditions, ranging from traumatic- or radiation-induced pathology, to amyloid angiopathy or hypertensive small vessel disease. Detection of these 'black spots' strongly depends on the MR pulse sequence and field strength used. Cerebral microbleeds in particular have been an important topic of research in (clinical) populations in the past decade, in view of their emergence of a marker of small vessel disease with links to both stroke (ischaemic as well as haemorrhagic) and dementia.

Learning Objectives:

1. To learn about the differential diagnosis of black spots.
2. To understand semi-quantitative and quantitative approaches for measuring the burden of black spots.
3. To appreciate the role of black spots as biomarkers for natural history and treatment of disease.

A-786 16:55

Advanced MR imaging and quantification techniques: do they help?

S. Haller; *Carouge/CH (Sven.Haller@affidea.ch)*

The third and final presentation of this special focus session discusses example applications of advanced imaging methods in the context of the diseases discussed before, notably traumatic brain injury and cerebral microbleeds. The first part will discuss diffusion tensor imaging (DTI) as an example of an advanced MR technique in the context of mild traumatic brain injury (MTBI). DTI may detect subtle trauma-related changes in the brain, which are not visible using standard MR imaging sequences. Given the recent public interest in sports-related MTBI and concussion, such as the movie "Concussion" featuring Will Smith, recent DTI brain imaging in American football and soccer players are critically discussed. The second part will critically discuss an example of quantitative MRI, notably automatic counting of cerebral microbleeds in cerebral amyloid angiopathy (CAA) as well as traumatic microbleeds/haemorrhagic diffuse axonal injuries (DAI).

Learning Objectives:

1. To understand how diffusion tensor imaging (DTI) might be helpful to detect subtle structural brain changes related to minor traumatic brain injury, which are not visible using standard structural MR sequences.
2. To understand the limitations of DTI for clinical applications and notably the need for strict standardisation of both data acquisition and data analysis.
3. To understand the principle potential of quantitative imaging analysis tools of brain MR imaging, based on the example of cerebral micro bleeds.

17:20

Panel discussion: How to image, quantify and report black and white spots in the brain?

16:00 - 17:30 **Room F1**

E³ - European Diploma Prep Sessions

E³ 1623

Breast

A-787 16:00

Chairman's introduction

F. Pediconi; *Rome/IT (federica.pediconi@uniroma1.it)*

Radiology is a medical speciality that involves all aspects of medical imaging. It provides information about the anatomy, physiology, and function of organs and systems of the human body in normal and abnormal status, allowing for imaging-based diagnosis, tissue sampling, and therapy. This is even more applicable to the breast radiology subspeciality where only appropriately trained physicians should carry out this duty. The fundamentals of undertaking and interpreting a wide range of imaging techniques and disease manifestations remain essential for breast radiologists. Mammography is the main investigation for breast cancer. It is used primarily to detect and diagnose breast cancer and to evaluate palpable masses and non-palpable breast lesions. So starting from the anatomical and pathological knowledge of the breast disease, the first step is to understand the principles of the mammography and how to apply them. This will be followed by all the other imaging modalities currently available to gain an appropriate diagnosis (US, MR, biopsy, etc.). What it is desirable for all the radiologist embracing the breast subspeciality is to interpret and report mammograms, breast ultrasound and breast MRI examinations using a standardized diagnostic categorization system such as the ACR Breast Imaging Reporting and Data System (BI-RADS®) and put the patient into a correct diagnostic pathway. It is important to have the appropriate breast imaging knowledge to choose the best suited method for evaluating the breast disorder in each patient. Finding breast cancers early greatly improves women's chance for successful treatment and it really affects their prognosis.

Session Objectives:

1. To understand the methodological principles of mammography.
2. To learn the mammographic appearance of benign and malignant lesions of the breast.
3. To become familiar with the imaging appearance of benign and malignant breast lesions.

A-788 16:06

A. Fundamentals of mammography

S. Barter; *Cambridge/UK (suebarter@btinternet.com)*

In this lecture anatomy, normal variants and common abnormalities of the female breast will be discussed, with particular emphasis on breast cancer detection. The importance of technical aspects of diagnostic mammography especially with regard to positioning, dose and image quality will be discussed. Quality can be lost at different points in the mammography process, positioning of the patient, the x-ray beam and dose, the detector and display. Viewing conditions must be optimised to ensure accurate detection of abnormalities. There is good evidence from two population-based screening programmes that poor image quality can reduce cancer detection on screening mammograms by 15% to 24%. Finally, the principles of current practice and risk/benefit analysis in breast cancer screening will be explained. Screening is the practice of mammograms performed regularly in asymptomatic women. The goal of screening is to ensure detection of breast cancer in the examined population at the earliest possible stage to reduce breast cancer mortality, and minimise potential side effects and unnecessary interventions in the screened population. Fundamental to a successful program is strict quality assurance.

Learning Objectives:

1. To understand the anatomy, normal variants and abnormalities of the female breast.
2. To become familiar with the technical aspects of diagnostic mammography, especially in regard to dose and image quality.
3. To become familiar with the principles of current practice and risk/benefit analysis in breast cancer screening.

Saturday

A-789 16:34

B. Breast cancer diagnosis and interventions

M. Müller-Schimpfle; *Frankfurt a. Main/DE (MMS@KlinikumFrankfurt.de)*

Mammography, ultrasound and MRI are the imaging modalities of choice for diagnosing breast diseases. The ability to detect lesions depends on density, glandular heterogeneity or background enhancement. The most important typical types of findings that can be differentiated are masses, non-mass lesions, architectural distortions, asymmetries and additional findings. Masses can be characterised by shape and margin, non-mass lesions by morphology and distribution, suggesting a category of suspicion for malignancy. Further elements such as density, echogenicity, contrast kinetics, pre-test probability or individual risk can modify a category of suspicion. Whenever a lesion shows a probability of malignancy >2% a needle biopsy should be considered. The modality of choice as well as the needle used depends on the detection method and lesion type. The same is true for pre-surgical localisations. Most masses will show a correlating finding in ultrasound which subsequently can guide a fine needle, a 14G needle biopsy or a wire, clip/coil marker online. Non-mass lesions such as microcalcifications or lesions in breast MRI will typically be biopsied by vacuum-assisted techniques to diminish sampling error.

Learning Objectives:

1. To learn the different presentation of normal breast patterns and the appearance of common benign diseases and of breast cancer at mammography, ultrasound, and MRI.
2. To understand principles and basic application of a standardised diagnostic categorisation systems such as the ACR breast imaging reporting and data system (BI-RADS®).
3. To become familiar with indications, contraindications and technical aspects of image-guided interventional breast procedures (fine needle aspiration, core needle biopsy, vacuum-assisted biopsy, presurgical localisation).

Author Disclosure:

M. Müller-Schimpfle: Equipment Support Recipient; Fujifilm, Tomosynthesis cooperation. Patent Holder; Cook Company: tumor marker coil.

A-790 17:02

C. Advanced imaging of the female breast

R.M. Mann; *Nijmegen/NL (r.mann@rad.umcn.nl)*

While mammography, ultrasound and MRI are the basis for current breast imaging, the field is rapidly evolving. Tomosynthesis is rapidly replacing mammography in the clinic and is in some countries already implemented in mass screening. Supplemental screening techniques for women with dense breasts are constantly under development. Automated breast ultrasound is already clinically available and in use for whole breast ultrasound evaluation, other modalities are tested in several trials. For lesion classification other techniques become important. Contrast-enhanced mammography may play an important role in the evaluation of women recalled from screening. Similarly, several add-ons for ultrasound have found their way to the clinic. Doppler is widely employed and also elastography is still gaining momentum, while opto-acoustic imaging as the next step is around the corner. Also in MRI many techniques help to classify lesions beyond what can be achieved with BIRADS evaluation alone, while simultaneously ultrafast techniques are under development to improve its value as a screening tool. In the evaluation of known cancers it becomes increasingly important to understand the biologic profile of a cancer. This is more and more determining the therapy given. Also translation of image findings to therapy is a major challenge. Multimodal evaluation and integration of imaging findings with clinical and histopathological parameters hence becomes a must. Advanced imaging techniques such as breast PET and spectroscopy might have an important role in this field in the near future.

Learning Objectives:

1. To understand the role of advanced imaging techniques in evaluation of the breast.
2. To use the added value of new techniques for lesion classification in mammography, ultrasound and MRI.
3. To recognise the major imaging issues for common indications of breast imaging.

Emergency Imaging

RC 1617

Abdominal trauma: things not to forget

Moderator:
G. Schueller; Opfikon/CH

A-791 16:00

A. Liver and spleen

M. Scaglione; *Castel Volturno/IT (scaglionefun@gmail.com)*

Abdominal injuries are a significant cause of death in the polytraumatised patients. Early recognition and communication of life-threatening hepatic and splenic injuries is crucial for an early and tailored management approach. The vast majority of the hepatic and splenic injuries are now treated non-operatively, independently from their volume, depth and location, thanks to the extensive use of MDCT technology in the emergency rooms. From a management viewpoint, size, depth or location of a contusion/laceration are relatively important if the patient is haemodynamically stable. However, using MDCT, the radiologists have to carefully scrutinise the images in the liver and spleen to look for vascular lesions, such as pseudoaneurysms, A-V fistula and active bleeding. Actually, the evidence of pseudoaneurysms, A-V fistula and/or active bleeding change injury grade and patients' management and outcome! This is our task, to look for such injuries within lacerations or haematomas in a pre-clinic stage, i.e. before the patents may develop haemodynamic instability. Thus, in this lecture, high-grade hepatic and splenic injuries will be illustrated, with special emphasis on vascular injuries as well as the value of post-processing techniques, protocols, pitfalls, tips and tricks. Furthermore, the importance of a rational and integrated imaging approach will be pointed out and, finally, the role of the radiologist in emergency room will be emphasised.

Learning Objectives:

1. To become familiar with traumatic injuries of the liver and spleen that can result in haemodynamic instability and other clinical complications.
2. To learn how to optimise scanning protocols to diagnose these injuries.
3. To understand the impact of these imaging findings on further management of patients and report accordingly.

A-792 16:30

B. Pancreas, bowel and mesentery

M.A. Patak; *Zurich/CH (Michael.Patak@hirslanden.ch)*

Imaging in abdominal trauma is crucial to get a fast overview of the situation and to plan treatment according to the different injuries. Injuries of the pancreas, the bowel and the mesenteries are a rather rare conditions and happens mostly to severely injured patients. It is important to actively rule out any possible injury to one of these organs. The presentation will show the typical aspects of traumatic injuries to pancreas, bowel and mesenteries. CT is the most often performed modality in acute trauma and will be discussed extensively. Treatment consequences according to imaging will be discussed.

Learning Objectives:

1. To become familiar with traumatic injuries of the pancreas, bowel and mesentery that can result in haemodynamic instability and other clinical complications.
2. To learn how to optimise scanning protocols to diagnose these injuries.
3. To understand the impact of these imaging findings on further management of patients and report accordingly.

A-793 17:00

C. Urogenital tract

R.H. Oyen; *Leuven/BE (Raymond.Oyen@uzleuven.be)*

Whatever cause (blunt, penetrating, iatrogenic), traumatic injury to the urogenital tract in the majority of cases requires dedicated multiphase scanning protocols (1) to assess the location and extent of lesions and (2) to tailor appropriate therapeutic strategies. With haemorrhagic complications optimised scan timing is essential to recognise active bleeding, and to evaluate whether interventional procedures are indicated to avoid invasive surgery. When urinary leakage is suspected, delayed scanning is essential to clearly demonstrate the site of the leakage. Retrograde opacification of the bladder can be useful to demonstrate subtle leakages and to gain time. Percutaneous procedures including nephrostomy, and antegrade or retrograde ureteral stenting may be therapeutic or supportive. Ultrasound with colour Doppler is the imaging modality of choice to assess penile and scrotal trauma. Detailed evaluation of penile and testicular integrity and vascularity are crucial to differentiate surgical from non-surgical cases. Urethral trauma deserves specific attention, with (conventional) imaging during retrograde and antegrade contrast opacification to assess the site and length of the urethral injury. For the evaluation of

iatrogenic injury it is essential to understand the surgical technique performed (organ sparing surgery, pouch constructions, bowel derivations, etc.). Some surgery is prone to more procedure-related complications as partial nephrectomy compared to total nephrectomy (9% versus 3%), including (active) bleeding and urinary leakage, and the reintervention rate is higher (2.5% versus 0.6%).

Learning Objectives:

1. To become familiar with traumatic injuries of the urogenital tract that can result in haemodynamic instability and other clinical complications.
2. To learn how to optimise scanning protocols to diagnose these injuries.
3. To understand the impact of these imaging findings on further management of patients and report accordingly.

16:00 - 17:30 **Room D**

Professional Challenges Session

PC 16
Ensuring the future role of radiologists

A-794 16:00

Chairman's introduction

J. Van Goethem; *Antwerp/BE (johan.vangoethem@uantwerpen.be)*

The role of radiologists has changed enormously in the past decades. With the advent of PACS most clinicians have gained direct and immediate access to radiology images. Many clinicians have at least the basic knowledge and capacities to interpret radiology studies and some clinicians are even highly skilled in interpreting studies in their specific field of expertise. Many radiologists on the other hand work disconnected from the 'patient flow' and report studies on their own pace. Together with the development of intelligent computer systems the traditional role of radiologists becomes less and less meaningful. We as radiologists will need to reinvent ourselves in we want our profession to stay relevant and meaningful in the future.

Session Objectives:

1. To understand what challenges lie ahead.
2. To learn how to deal with these challenges.
3. To learn what you can do as a radiologist.

A-795 16:05

SWOT analysis of the radiologic profession

J.-Y. Meuwly; *Lausanne/CH (jean-yves.meuwly@chuv.ch)*

Since decades, radiology has to face up to multiple challenges to survive as an independent medical speciality. Existential questions surge from everywhere, inside and outside the medical profession. At the same time, technology improvements in radiology open every day new horizons and expand the frontiers of radiological venture. How to find one's way in the extreme complexity of this perpetually evolving world? How to keep one's identity and propose the adequate answers to these multiple challenges? The SWOT analysis brings tools to identify the internal and external factors that are favourable or unfavourable to achieve the specific objectives of the radiological profession. In the SWOT analysis, the internal factors of the organization, as the strengths (S) and weaknesses (W), and the external factors, like opportunities (O) and threats (T) are analysed on the light of the defined objectives. Identification of SWOTs clarifies the challenges and helps in planning how to achieve the objectives.

Learning Objectives:

1. To understand our strengths and weaknesses within the medical world.
2. To recognise opportunities.
3. To identify threats lying ahead.

A-796 16:28

Turf battles: how to respond to the challenges

C. Loewe; *Vienna/AT (christian.loewe@meduniwien.ac.at)*

Different turf battles within or around radiology are challenging, and the way how radiologists deal with these challenges will decide about the future of radiology and radiologists. The "invasions" into our radiological world include not only activities by other medical specialities, but even from the technical evolution within radiology. With further improvement of post-processing, big-data handling and image-guided diagnostic tools, radiology will look completely different in 10 years. If radiologists are not able to adapt to this evolution, they might be replaced. The change from detection to communication, integration and interpretation, describing an evolution from classic "technical" speciality into an integrative clinical speciality is required. Radiology already represents the processor of the modern hospitals, and radiologists are the trigger for clinical decision-making. Beside these challenges from inside there are continuous invasions from outside. However, with view from a distance, it becomes obvious that radiology invades other specialities as well. With every newly implemented minimally invasive treatment offered by radiology, we are competing with other medical specialities and open a new border for turf battles. As more successful such new methods are higher the interest to overtake them will be. This moving target of invasion and being invaded produces many turf battles in many different fields. In this presentation, different "burning" turf battles such as cardiac imaging, stroke treatment as well as vascular IR will be addressed. Although there is no general clue to survive, some possible strategies to further strengthen radiology and to compete with the challenges around will be discussed.

Learning Objectives:

1. To identify possible future invasions in our radiological world.
2. To learn how to deal with turf battles.
3. To learn how to change battles in opportunities.

Author Disclosure:

C. Loewe: Speaker; GE Healthcare, BRACCO, Medtronic.

A-797 16:51

Always on the forefront: ensuring the future of radiology

G.P. Krestin; *Rotterdam/NL*

Imaging is the key diagnostic tool in many diseases and has an important role in monitoring treatment and predicting outcome. As the practice of medicine moves away from an intuitive, experience-based model to empirical, evidence-based and to personalized medicine, diagnostic precision becomes paramount to select the particular treatment that will best help each individual patient. "Precision imaging" requires objective quantitative and standardized assessment of all features available in digital images. This "deep image phenotyping" is at the basis of radiomics and radio-genomics and allows to use the big image data for prediction, diagnosis and monitoring of disease. Deep machine learning using neural networks on large image data repositories will allow computers to take over much of the repetitive interpretation work carried out by radiologists in today's practice. Is the profession in danger? The threat to radiology as a distinct speciality can be overcome only by adapting and embracing this change. Focusing on technological innovation and on high-level super-specialized consulting services and less on image interpretation activities will guarantee the future of the profession. Research into new applications of imaging and value-based imaging are some of the solutions for proving the added value of radiologists in daily practice.

Learning Objectives:

1. To become familiar with new emerging radiological techniques.
2. To learn how to be ahead.
3. To safeguard the future of our profession.

Author Disclosure:

G.P. Krestin: Advisory Board; Zebra Medical Vision, Technion Israel Institute of Technology. Consultant; Bracco Imaging. Research/Grant Support; Siemens AG, GEHC, Bayer AG. Other; Supervisory Board of Quantib BV..

17:14

Panel discussion: The real challenge for radiologists is "how to change ourselves"

16:00 - 17:30 **Room G**

Physics in Medical Imaging

RC 1613
MR: artefacts and devices

A-798 16:00

Chairman's introduction

M. Tosetti; *Pisa/IT (michela.tosetti@fsm.unipi.it)*

The course intends to describe causes and cures of a variety of artefacts encountered in MRI: the purpose is to promote understanding them, so they can be prevented or properly interpreted to optimise diagnostic effectiveness. First, we learn about the artefacts raised from the MRI chain (static magnetic field uniformity; eddy currents resulting from imperfect gradient pulses; nonuniformity of the transmit RF system; defects in the receive portion of the RF system) and from sampling strategies of the MR signals (unwanted signals and noise spikes as zipper or banding artefacts; aliasing effects). We follow up analysing what happens in the presence of metallic implants, which gives rise to important artefacts in the images of patients. Such artefacts impair the information contained in the image, namely near the metallic device. The extent of the artefact is dependent on the object's magnetic susceptibility, size, shape, position in the patient's body, the technique used for imaging and the processing method. Last, the advance MR techniques are particularly sensitive either to artefacts related to the MR system but also to those produced by different sources of physiological noise. Furthermore, it is also necessary to

look closely to the pitfalls in the analysis pipelines, which ultimately lead to the robustness of the advance MR studies. Recognise and understand artefacts encountered in MRI, together with the knowledge of the imaging and post-processing strategies to mitigate or treat them, will allow audience to obtain robust data to make sound interpretations and to do not lead to diagnostic errors.

Session Objectives:

1. To learn about MR image distortions.
2. To appreciate the appearance of metal-induced image distortions in MRI.
3. To appreciate image distortions in perfusion- and diffusion-weighted imaging.

A-799 16:05

A. Image artefacts in MRI and their mitigation

D.J. Lurie; *Aberdeen/UK (d.lurie@abdn.ac.uk)*

No imaging modality can reproduce the original object under study in a completely faithful manner because all imaging technology is susceptible to artefacts. It is very important that the sources of artefacts are understood so that the fidelity of images can be maximised. Artefacts in MRI can be discussed according to their primary source, under the following four categories. (a) Physics: artefacts include those arising from magnetic susceptibility differences, often around tissue/air interfaces, and chemical-shift artefacts, at fat/water boundaries. These effects can be mitigated by manipulation of gradient strengths and directions, and sampling bandwidths. (b) Hardware: examples include RF or gradient miscalibration or instability, leading to image shading and ghosting; RF interference, causing zipper artefacts; gradient nonlinearity, causing geometric distortion. These issues can be addressed by careful calibration and quality control procedures, and sometimes by post-processing. (c) Pulse sequence: this includes artefacts due to aliasing and slice-overlap shading (slice cross-talk); these can usually be reduced by careful setting of gradient directions and acquisition parameters. Other artefacts arising from pulse sequences are related to signal sampling and Fourier transformation, including Gibbs ringing artefacts at boundaries. (d) Physiological: artefacts can arise due to regular motion of the heart, or of abdominal organs during the breathing cycle. Mitigation is by gating, breath-holding and the use of rapid pulse sequences. Irregular, involuntary motion such as peristalsis in the gut can also lead to ghosting artefacts, which can be reduced by the administration of pre-scan medication and by ultra-rapid MR pulse sequences.

Learning Objectives:

1. To identify common types of artefacts in MR images.
2. To learn about the physical origins of artefacts in MRI.
3. To learn methods of minimising artefacts on MR images.

A-800 16:28

B. Imaging around metal implants: artefact reduction in MRI

C. McGrath[1], A. Fagan[2]; [1]*Belfast/IE,* [2]*Dublin/IE*

The presence of metallic implants within a patient distorts the main static magnetic field of an MRI scanner and can lead to very severe image artefacts that may render the resultant images non-diagnostic. The physics behind these artefacts is described. Acquisition parameter changes, such as matrix size, receive bandwidth and pulse sequence choice, are described that can reduce the impact of these artefacts and improve the diagnostic quality of these scans. Advanced metal artefact reduction techniques are also discussed.

Learning Objectives:

1. To review the origin of signal in MRI.
2. To understand the MRI physics of artefact reduction around metal implants.
3. To understand the parameters used in an optimised imaging protocol.

Author Disclosure:

C. McGrath: Speaker; GE: Invited speaker at 2 GE MRI symposia (honoraria recieved). Other; Bayer: Regional MRI education day sponsored (venue, catering and printing) by Bayer, twice and one upcoming, Bayer: assistance to attend ECR 2016.

A-801 16:51

C. Artefacts in perfusion and diffusion MRI

I. Tsougos; *Larissa/GR (tsougos@uth.gr)*

Accurate brain damage diagnosis plays an essential role in the selection of the optimum treatment strategy, as the nature of the damage and the definition of nature and grade defines the therapeutic approach. Advanced magnetic resonance imaging (MRI) techniques have added incremental diagnostic information regarding brain damage characterisation over conventional MRI alone. Particularly, diffusion-weighted imaging, diffusion tensor imaging and perfusion imaging provide, non-invasively, significant structural and functional information in a microscopic level, revealing aspects of the underlying pathophysiology. Although over the last 10 to 20 years, diffusion and perfusion MRI have become established techniques with a great impact on differential diagnosis, like any other MRI technique they remain subject to artefacts and pitfalls. Hence, it is evident that obtaining reliable data and drawing meaningful and robust inferences is of utmost importance. The current exhibit aims to: review the artefacts and pitfalls of diffusion MRI on a qualitative basis, especially in terms of eddy currents and sensitivity to motion; review and evaluate the possible issues that can affect the accuracy of measurements regarding dynamic susceptibility contrast (DSC)-MRI (measurements of cerebral blood flow (CBF), cerebral blood volume (CBV), and mean transit time (MTT)). Introduce possible strategies that have been developed to mitigate or overcome these artefacts and pitfalls.

Learning Objectives:

1. To review the artefacts and pitfalls of diffusion MRI on a qualitative basis, especially in terms of eddy currents and sensitivity to motion.
2. To review and evaluate the possible issues that can affect the accuracy of measurements regarding dynamic susceptibility contrast (DSC)-MRI (measurements of cerebral blood flow (CBF), cerebral blood volume (CBV), and mean transit time (MTT)).
3. To introduce possible strategies that have been developed to mitigate or overcome these artefacts and pitfalls.

17:14

Panel discussion: Clinically applicable tools/strategies for minimising/avoiding MR imaging artefacts

16:00 - 17:30 **Room K**

EFRS Workshop

EFRS authorship and reviewer workshop

A-802 16:00

Chairman's introduction: Establishing the evidence base in radiology and radiography

G. Paulo; *Coimbra/PT (graciano@estescoimbra.pt)*

A profession is defined by the Australian Council of Professions as a disciplined group of individuals who adhere to high ethical standards and uphold themselves to, and are accepted by, the public as possessing special knowledge and skills in a widely recognised, organised body of learning derived from education and training at a high level, and who are prepared to exercise this knowledge and these skills in the interest of others. Radiography profession adheres to all the principals expressed in the definition. However, it is important to understand that the development of the radiographer specific field of knowledge is only possible through research and that research is only accepted and adopted by the peers, if published: “It doesn’t exist if it isn’t written down”. The invited speakers for this session will give an overview about the reasons why we should publish; on how to select the most adequate journal; the ethical principles of publication; an explanation about the reviewer process and finally some tips on how to increase the success of acceptance. At the end of this session, an interaction is expected with the audience to discuss the solutions to increase the research and publications in the field of medical imaging and radiotherapy.

Session Objectives:

1. To consider why publishing is important for the development of radiology and radiography.
2. To highlight the value of collaboration in medical imaging research.

A-803 16:05

Why publish your work?

F. Zarb; *Msida/MT (francis.zarb@um.edu.mt)*

Research is the contribution to the body of knowledge in a particular area/expertise. Any research finding, if contributing to this body of knowledge, should be shared and made available to fellow professionals. One of the ways of sharing this body of knowledge is through publication. Publication is the process of producing written material and making it available to others. The aim of this presentation is to highlight the importance of publishing for both the individual researcher/practitioner and to the clinical/academic departments they represent. The publication process may not always seem easy and straightforward, requiring a commitment and perseverance in the work it entails. However, the benefits and satisfaction associated with getting work accepted for publication outweigh the hard work involved.

Learning Objectives:

1. To explore the importance of publishing for individual researchers and practitioners.
2. To explore the importance of publishing for clinical and academic departments.

A-804 16:20

Journal selection: aims and scope, audience and metrics

J.M. Nightingale; *Salford/UK (j.nightingale@salford.ac.uk)*

A wide selection of professional peer-reviewed journals are available to radiography and radiology authors and researchers. Selecting the most appropriate journal for a particular article will depend upon many factors, the most important being the aims of the journal and the size and scope of the readership. A high-quality article will be of little value if it is never read by people who can potentially use it to develop knowledge or effect change. Journal selection may also be influenced by a number of metrics which can be used to indicate the impact or influence of a journal on the professional field. This presentation will explore the strengths and limitations of a range of traditional and contemporary citation-based metrics that are often used for journal comparisons.

Learning Objectives:

1. To highlight the classifications of journals available to radiography and radiology authors (generalist, specialist and methodological).
2. To consider the benefits and limitations of publishing in different journal formats.
3. To explore the role of traditional (Impact Factor) and contemporary journal metrics in demonstrating impact, speed and reach of a journal.

A-805 16:35

Ethics of publishing

J. McNulty; *Dublin/IE (jonathan.mcnulty@ucd.ie)*

The publication of our research in peer-reviewed journals is a fundamental step in contributing to the body of professional knowledge which may then contribute to evidence-based professional practice. When submitting an article to a journal for consideration for publication the authors have a number of responsibilities in terms of publishing ethics. These considerations go beyond the ethical considerations within the research itself and associated ethical approvals or exemptions. For the purpose of this presentation the topics of authorship, originality and plagiarism, data access and retention, multiple or concurrent publication, disclosures and conflicts of interest, and acknowledgements (of sources, limitations and errors) will be briefly explored. Plagiarism, often due to inappropriate citation, can vary significantly in severity and is readily detected by journals. What constitutes a potential conflict of interest must also be considered by authors in the name of transparency and objectivity. It is important that all authors are aware of these ethical issues and novice authors should make sure that they are fully informed by following guidelines and through good mentorship by senior colleagues and co-authors. It is also important to note that the editor and reviewers handling a particular submission must also adhere to guidelines on publication ethics.

Learning Objectives:

1. To understand the ethical implications of article authorship.
2. To consider the nature of plagiarism in publishing and how it can be avoided.
3. To highlight potential conflicts of interest and how these should be managed and declared.

Author Disclosure:

J. McNulty: Board Member; Associate Editor, Radiography journal (Elsevier).

A-806 16:50

Things to consider: the reviewer's perspective

A. England; *Salford/UK (A.England@salford.ac.uk)*

Undertaking a review of a journal article is a serious but rewarding task. There are many personal benefits but a high-quality review is also a valuable contribution to the profession and of importance to the authors. From a personal perspective, undertaking a review can help generate understanding of what the requirements of a journal article are. It allows the reviewer to develop an understanding of the art of journal manuscript writing. For the author, the reviewer provides an important role in giving feedback on both the good and bad elements of the manuscript but ultimately how it can be improved. If this is via a recommendation to accept the paper, then the role of the reviewer is to provide feedback and and a list of tasks which allow the manuscript to reach its full potential. If the decision is to reject, then it is down to the reviewer to provide some justification and direct the authors appropriately for any future submissions. This may include details of any changes needed in the research design and manuscript structure. Ultimately, it is a balance of aiming for high-quality manuscripts whilst providing the readership with new information which is likely to positively influence the profession and clinical practice. Reviewing a journal article is a skill and with experience this can develop into a significant contribution for developing authors and support the publication of high-quality research papers.

Learning Objectives:

1. To identify the purpose of peer review.
2. To explain the steps within the peer review process.
3. To understand the qualities of a good reviewer.

A-807 17:05

Editor's ten top tips for publishing success

J.M. Nightingale; *Salford/UK (j.nightingale@salford.ac.uk)*

The peer review process is a well-established method of improving the quality of articles published within a journal. Very few articles will be accepted at first submission; the majority will require either minor or major revision to bring them to the standard required of the journal. This will often require more work for the authors and will delay the publication of the article, but the published article will be of better quality than the original submission. However, for some papers the editor makes a decision to reject the manuscript before sending it for peer review, or they reject it following peer review because the revisions required are significant. This presentation explores the most common reasons why a paper may be rejected before and after peer review, and offers some simple guidelines to help authors to avoid the common errors and pitfalls. The presentation concludes with a reminder of the author's responsibilities in ensuring that their published article is promoted widely.

Learning Objectives:

1. To discuss reasons why a manuscript may be rejected.
2. To emphasise how common manuscript errors can be avoided.
3. To highlight the author's responsibilities in promoting their article.

17:15

Panel discussion: What are the barriers to publishing your research or becoming a reviewer and how can they be overcome?

16:00 - 17:30 **Room M 2**

Computer Applications

RC 1605

Will the good old PACS disappear?

A-808 16:00

Chairman's introduction

D. Regge; *Turin/IT (daniele.regge@ircc.it)*

Picture Archiving Communication Systems (PACS) have originally been conceived as local archives of medical images originating from different modalities interconnecting using DICOM, a universal format for image storage and transfer. This course will approach the changing world of PACS pragmatically, by providing helpful information and tips on when and how to implement a new PACS system and how to perform data migration safely even in complex environmental conditions. The course will include an overview of different cloud healthcare solutions and on how to improve interconnectivity by the implementation of vendor-neutral archiving systems. PACS has paved the way to the filmless department, but a paperless department is still a long way off. Advantages and challenges of a truly paperless infrastructure will be discussed in this course.

Session Objectives:

1. To explain when and how to replace PACS.
2. To provide insight on how to improve interconnectivity and information sharing in medicine.
3. To envisage the role of off-site archiving solutions in radiology.

Author Disclosure:

D. Regge: Author; Springer. Speaker; GE Medical Systems, GE Medical Systems.

A-809 16:05

A. It's time for PACS replacement: how-to guide, recommendations and pitfalls

S. Morozov; *Moscow/RU (npcmr@zdrav.mos.ru)*

PACS has made a great progress from a pure storage and a radiologist's tool to a platform for interdisciplinary collaboration and big data analysis. It has allowed transition from analogue to digital workflow and further in the direction of decentralized enterprise clinical imaging. Major drivers for PACS development are expansion of imaging into clinical areas, EHR integration, and radiological practices consolidation on regional and international levels. The major trends of PACS development are the following: cross-functionality, cross-integration, patient-centric solutions and analytic tools development. Any PACS with a lack of standardization, workflow optimization and comprehensive viewing tools limits interoperability and efficiency of a radiology practice. PACS should enable communications, feedback, collaboration, second opinion, report

interpretation, clinical integration, tumour board applications, reports dispersal to patients, and tracking of outcomes. It should be affordable, faster, integrated with voice recognition, EMR and prior studies. The typical lifetime of a PACS is 7-10 years. New PACS selection process considers in-house or cloud-based solutions, VNA, modular approach, division of storage/diagnostics functionality. Capital costs for a new PACS purchase should be justified in terms of productivity increase and return of investment. New PACS adoption includes resource, workflow and cut-over planning, risk assessment, test version installation, integration, implementation, data migration and changeover. Major pre-requisites for a successful PACS installation are planning, standardization, team involvement, iterative testing, over-communication, feedback analysis and correction.

Learning Objectives:

1. To explain why and when PACS should be replaced.
2. To provide recommendations for PACS replacement and risk assessment analysis including image migration issues.
3. To give a practical example of how PACS is replaced in a large health facility or region.

Author Disclosure:

S. Morozov: Advisory Board; Philips. CEO; Radiology research and practice center, Moscow.

A-810 16:28

B. The paperless radiology department

C. Heilmaier; *Zurich/CH (christina.heilmaier@triemli.zuerich.ch)*

Within the last 30 years, radiology underwent tremendous changes. The implementation of radiology information systems (RIS), picture archiving and communication systems (PACS), and electronic health records (EHR) has considerably altered the workflow and cleared the way for an (almost) paperless radiology department. The next step within the electronic environment is to further improve the interoperability of one system with another to achieve a seamless communication, data exchange and interactivity (e.g. dose information from dose management software is automatically added to image report, which is automatically sent to EHR). At the same time, the electronic environment enables the formation of imaging portals, so that patients can access their health data. This might motivate them to fully participate in their healthcare and might increase their satisfaction, medical knowledge and self-care. However, as shown by recent experience, not only transition from hard-copy practice to a paperless department but also improving the interoperability of different systems comes along with many challenges. To name just a few, it needs to be assured that all modalities are digital-ready, that the department has the required infrastructure and that the management of the electronic environment is clearly structured to address issues such as data correction and user support. The major problem in establishing data exchange between different systems (and also between different radiology departments) is that standards are often not uniform. While, for example, for PACS the DICOM 3 standard is nowadays broadly accepted, sometimes multiple standards are available to accomplish a given task, which considerably impairs interoperability.

Learning Objectives:

1. To provide reasons to give patient direct access to their medical imaging data.
2. To describe the challenges and infrastructure needed to implement an imaging portal.
3. To discuss first experiences and lessons learned.

A-811 16:51

C. Does PACS into the cloud means PACS evaporates?

J. Schillebeeckx; *Knokke/BE (jan@schillebeeckx.com)*

Cloud computing is a model for enabling ubiquitous on-demand network access to a shared pool of computing resources that can be rapidly provisioned with minimal management effort or service provider interaction. This cloud model is composed of five essential characteristics, three service models, and four deployment models. Service models are provision models of applications, hardware, software, data, operation systems, telecom, etc. managed by external parties in the cloud. The three types of service models are Software as a Service (SaaS), Platform as a Service (PaaS) and Infrastructure as a Service (IaaS). Deployment models mean different environments (clouds) where different service models are located. The characteristics of those four types of environment are the private cloud, the community cloud, the public cloud and as a combination, the hybrid cloud. PACS in the cloud has several advantages and weaknesses. Clear advantages are less upfront costs, access to on-demand capacity, reliable back-up and recovery, easier management of IT staff and better financial planning. Weaknesses are performance, data migration and portability of data. Most likely PACS will not evaporate but become a game player in the enterprise imaging model.

Learning Objectives:

1. To explain the concept of cloud archiving and its advantages.
2. To address limitations and risks of cloud PACS solutions.
3. To give insight on future developments of cloud technology.

Author Disclosure:

J. Schillebeeckx: Advisory Board; NDSC Europe. Consultant; Agfa Healthcare. Shareholder; Qaelum NV.

17:14

Panel discussion: How will increased interconnection affect radiologists' day-to-day life?

16:00 - 17:30 **Room M 3**

E³ - ECR Master Class (Molecular Imaging)

E³ 1626

Molecular imaging in oncology

A-812 16:00

Chairman's introduction

K. Nikolaou; *Tübingen/DE (Konstantin.Nikolaou@med.uni-tuebingen.de)*

Today, radiology is playing a central role in the set-up of multidisciplinary cancer centres and in the comprehensive work-up of oncologic patients, integrating an ever increasing amount of qualitative and quantitative diagnostic information. Still, radiology is facing significant challenges, as “precision medicine” develops and matures. Integrating functional and molecular information in a quantitative fashion and adding complementary multimodality information is crucial. In detail, molecular imaging is regarded as the direct or indirect non-invasive monitoring and recording of the spatial and temporal distribution of in vivo molecular, genetic, and/or cellular processes for biochemical, biological, diagnostic, or therapeutic applications. Molecular images that indicate the presence of malignancy can be acquired using an abundance of modalities, including optical, ultrasonic, radiologic, radionuclide, and magnetic resonance techniques. In this session, molecular and functional imaging of oncologic processes are reviewed with respect to their physical basics and imaging characteristics, including attributes of hypoxia, proliferation, and metabolism. Also, the role, development and standardisation of prognostic, predictive and therapy response oncologic imaging biomarkers will be discussed, and current and future clinical applications in oncologic diagnosis will be reviewed.

Session Objectives:

1. To understand the basics of molecular imaging.
2. To appreciate the unmet needs of oncological imaging.
3. To learn the role of molecular imaging in oncology.

A-813 16:05

A. Imaging of hypoxia

V.J. Goh; *London/UK (vicky.goh@kcl.ac.uk)*

Tumour hypoxia is present in up to 60% of locally advanced solid tumours. Tumour hypoxia is a significant challenge to successful therapy, contributing to treatment resistance and a poor prognosis. Intra-tumoural hypoxia may be assessed by molecular markers including hypoxia inducible factor 1 (HIF-1) and carbonic anhydrase isoenzyme IX (CA-IX). However, hypoxia is a dynamic process and alters depending on perfusion and oxygenation status. Non-invasive imaging of intra-tumoral hypoxia provides an opportunity to better stratify patients to improve local control. Tumour hypoxia may be assessed in vivo by direct and indirect imaging techniques. Positron emission tomography (PET) imaging targets hypoxic cells with tracers including18F-fluoromisonidazole (18F-MISO), 18F-fluoroazomycin arabinofuranoside (18F-FAZA) and 64Cu-diacetyl-bis(N4-methylthiosemicarbazone (64Cu-ATSM). Hypoxia imaging may also be undertaken by magnetic resonance imaging (MRI) with techniques such as blood oxygenation level-dependent (BOLD) MRI and oxygen enhanced MRI measuring R2* and R1 changes, respectively. This lecture will review the biological basis and fundamentals of hypoxia imaging and potential clinical applications including radiotherapy.

Learning Objectives:

1. To review the fundamentals of hypoxia imaging.
2. To review the advantages and disadvantages of hypoxia imaging and its relation to perfusion.
3. To learn about hypoxia imaging in radiation treatment.

B. Imaging of proliferation

A. Kjaer; *Copenhagen/DK*

"No abstract submitted."

Learning Objectives:

1. To understand basic principles of proliferation imaging.
2. To become familiar with imaging of proliferation.
3. To learn about difficulties in liver proliferation imaging.

A-815 16:41

C. Imaging of metabolism

C. Nanni; *Bologna/IT (cristina.nanni@aosp.bo.it)*

18F-FDG PET/CT is an imaging technique that is aimed to evaluate glucose metabolism of tissues and organs. PET/CT scanners consist of a combination of a PET scanner and a CT scanner providing both morphological and functional images. The procedure is standard and includes several steps. Patients are not allowed to consume any food or sugar for at least 6 h prior to the start of the PET study. Injection should be fully intravenous. Optimal uptake time is 60 minutes. In general, for a 3D system and 3 MBq/Kg of FDG, 2 min/bed position is enough, leading to an average overall acquisition time of 14 minutes. Low-dose CT (120 kV, 80 mA) is necessary both for attenuation correction and for image interpretation. Once reconstructed, images must be interpreted on a dedicated workstation. SUV max based on body weight is the standard semi-quantitative index. FDG PET/CT was proved to be accurate for several malignancies for the definition of TNM at staging and in the suspect of relapse. Furthermore, changing in SUV max are related to the response to systemic therapies, both during and after treatment. This parameter is considered a non-invasive surrogate for therapy assessment. Some particular kinds of malignant tumours are not detectable by FDG PET. In particular, mucinous cancers, transitional cell cancers, clear cell cancers, indolent HCC and some adenocarcinomas fail to significantly concentrate FDG. Low accuracy can also be found in some particular areas of the body where FDG is physiologically concentrated such the brain and the urinary tract.

Learning Objectives:

1. To learn the clinical indications for FDG imaging.
2. To become familiar with imaging protocol.
3. To learn about difficulties in FDG imaging.

A-816 16:59

D. Biomarker imaging with MR

M.E. Mayerhöfer; *Vienna/AT (marius.mayerhoefer@meduniwien.ac.at)*

Originally regarded as a morphological imaging technique with excellent soft-tissue contrast, MRI today is recognised as a technique that can also provide functional biomarkers through different approaches. For treatment response assessment, diffusion-weighted imaging (DWI), which indirectly provides information on cell density in tumours, is quite well-established. In lymphoma, for instance, it is even considered as an alternative to [18F]FDG-PET after treatment with chemo- or immunochemotherapy. Nevertheless, limitations for DWI include artefacts and standardisation of apparent diffusion coefficients between different DWI pulse sequences, and between MR scanners of different vendors. Perfusion-weighted imaging (PWI) is another technique that is increasingly being used in the response evaluation of hypervascular tumours, such as hepatocellular carcinoma. In the body, PWI is most commonly performed on the basis of dynamic contrast-enhanced sequences (relying on T1 shortening), with k-trans, a measure of capillary permeability, as one of several quantitative parameters. Alternatively, PWI may be performed using arterial spin labelling, without contrast media. MR spectroscopy (MRS), which today is most frequently based on protons, is another technique that can be used to assess biomarkers in the form of metabolites, such as lactate and choline. While several studies reported encouraging data, for instance in breast cancer and prostate cancer, limitations such as long acquisition times and difficulties in terms of standardisation and quantification have prevented MRS from being introduced into routine clinical imaging. Cutting-edge techniques, such as chemical exchange saturation transfer (CEST) imaging, may overcome the limitations of MRS.

Learning Objectives:

1. To learn the clinical indications for biomarker imaging.
2. To become familiar with quantification.
3. To learn about difficulties in quantification.

Multiparametric US in musculoskeletal applications

A-817 16:00

Chairman's introduction

P. Peetrons; *Brussels/BE*

A-818 16:05

A. Sports-related lower extremity injuries

P.J. O'Connor; *Leeds/UK*

"No abstract submitted."

Learning Objectives:

1. To learn about muscle and tendon injuries in athletes.
2. To know how to perform MPUS in this setting and how to interpret findings.
3. To understand the advantages and limitations of US compared to MRI.

A-819 16:33

B. Entrapment neuropathies of extremity nerves

H. Gruber; *Innsbruck/AT (hannes.gruber@i-med.ac.at)*

Entrapment neuropathies are rather frequent issues: the “standard” neuropathies in this field are clinically fast forward and “standard” measures are to be taken to solve the typical clinical problem. So why do we need imaging and why should one modality be superior in comparison to another (e.g. sonography vs. MRI)? What are features of interest or features relevant for further therapy and prognosis? In this rather wide field, however, tricky features and constellations can be depicted sometimes using, e.g. a functional access to a pretended “banal” problem (“Do the right thing at the right time”): I will try to present the banal and the special imaging to provide a more profound knowledge and understanding of radiologic options and relevance of imaging entrapment neuropathies.

Learning Objectives:

1. To learn imaging anatomy of entrapment neuropathies.
2. To become familiar with the specific US techniques and US findings in this setting.
3. To know the advantages and limitations of US compared to MRI.

A-820 17:01

C. Inflammatory joint disease

A. Klauser; *Innsbruck/AT*

The standard for diagnosing and differentiating arthritis is based on clinical examination, laboratory exams, and imaging findings. B-mode ultrasound (US) and PDUS are established imaging modalities for early detection, characterisation and follow-up of various forms of inflammatory arthritis. They allow for detection and characterisation of synovial thickening, synovial proliferation, destructive pannus, effusion, erosions and enthesitis. PDUS allows a further assessment of synovitis and erosions by classifying them into active versus nonactive, what has implication for therapy. CEUS (contrast-enhanced US) with and without the use of quantification, such as parametric mapping of contrast uptake is an emerging sensitive tool for assessing vascularization and disease activity at the angiogenetic level with the possibility of quantitative assessment performed at the region of interest level. Beside intraarticular inflammatory changes also periarticular and extraarticular inflammation in terms of tenosynovitis and enthesitis assessment are of importance. SEL (sonoelastography) has a proven role in tendon assessment and might give new insights into enthesitis. A summary and analysis of the current evidence on the role of multiparametric ultrasound in the assessment of inflammatory joint disease will be presented.

Learning Objectives:

1. To learn how to apply various US techniques in inflammatory joint disease.
2. To understand the indications, contraindications, challenges and limitations US in the specific clinical setting.
3. To know the advantages and disadvantages of US compared to XR, CT and MRI.

E³ - ECR Academies: Neuroradiology: from Morphology to Function

E³ 1622
Functional imaging of the spine

A-821 16:00
Chairman's introduction
D. Balériaux; *Brussels/BE (dbaleri@me.com)*

When considering "spine" for functional imaging very different areas may be studied: the spinal cord proper, well protected in a bony canal, surrounded by CSF and the spinal column. Imaging the spinal cord has been very challenging and the functional aspects remain even more challenging. Still, recently, diffusion-based imaging provides a new in vivo inside information of the spinal cord. MRI and its sensitivity to flow allows better information about CSF flow. Finally, the spinal bony structures are continuously solicitated to enable movement of the human whilst assuring protection of the nervous structures. Dynamic MRI helps in analysing spinal movements in an unmatched noninvasive manner. In this session those different aspects will be discussed. A tricky though simple case of a conus medullaris lesion associated with a lumbar fracture will be discussed emphasizing the necessity to know the clinical history of the patient as always to achieve the right diagnosis.

A-822 16:06
A. Measuring CSF flow: technique and clinical usefulness
B. Ertl-Wagner; *Munich/DE (Birgit.Ertl-Wagner@med.uni-muenchen.de)*

The cardiac cycle is the motor of cerebrospinal fluid (CSF) flow. During systole, there is an inflow of volume into the cranial vault. As the skull is nearly rigid, a compensatory downward flow of CSF ensues. During diastole, there is an upward flow of CSF from the spinal canal into the cranial vault with a nearly simultaneous venous outflow. Using MR phase contrast sequences, it is possible to quantify and assess the direction of CSF flow and the arterial inflow and venous outflow. When measuring flow, it is important to acquire the imaging planes perpendicular to the main axis of flow. Branching vessels or vascular loops should be avoided. Moreover, the velocity encoding (VENC) needs to be carefully chosen to ascertain a reliable quantification of flow and to avoid aliasing. To measure aqueductal flow, the measurement plane should be positioned perpendicular to the aqueduct. This also enables the quantification of the aqueductal net flow and an estimation of the CSF production rate. To quantify the cerebrospinal CSF volume shift, the imaging plane should be positioned at the level of C2 above the most cranial pair of exiting nerve roots. When combining the measurements of arterial inflow and venous outflow to and from the cranial vault as well as the craniospinal volume shift, the intracranial pressure can be estimated. Chiari malformations can lead to an impaired craniospinal CSF flow. The assessment of CSF flow parameters can be combined with the evaluation of morphological parameters to enhance diagnostic decision making.
Learning Objectives:
1. To review the physiology of CSF flow during the cardiac cycle.
2. To evaluate the reliability of the quantification of CSF flow rates by use of phase contrast MRI.
3. To show examples where alterations of CSF flow in the craniocervical junction can influence clinical management (e.g. in patients with Chiari Malformation Type I).

A-823 16:34
B. Diffusion tensor imaging of the spinal cord in the assessment of intramedullary changes
M. Sasiadek; *Wroclaw/PL (marek.sasiadek@umed.wroc.pl)*

Conventional MRI sequences provide limited information of the spinal cord pathology. Diffusion tensor imaging (DTI), including tractography (DTT), might improve qualitative and quantitative assessment of the spinal cord lesions. DTI is based on anisotropic, one-direction diffusion, which theoretically is ideally suited to imaging of the spinal cord. However, due to the small size of the spinal cord and many artefacts, obtaining a good quality spinal cord DTI is a challenge. Fortunately, technical improvements (e.g. parallel imaging, decrease of slice thickness, increased number of diffusion directions, use of 3T MR) have improved the quality of DTI images. The main clinical applications of the spinal cord DTI include degenerative myelopathy, intraspinal tumours, spine trauma, demyelinating and inflammatory diseases of the spinal cord. In degenerative disease of the spine DTI can detect, on the base of fractional anisotropy (FA), mean diffusivity (MD) or average diffusion coefficient (ADC) metrics, myelopathic changes, not visible on plain MRI and correlated with the degree of spinal canal stenosis and spinal cord compression. In traumatic spinal cord injury DTI can evidence changes in the spinal cord at and away the site of trauma. In intraspinal tumours DTI and DTT are helpful in differentiation compression from infiltration of the spinal cord adjacent to tumour. In multiple sclerosis and other demyelinating diseases DTI metrics might detect changes in normal appearing spinal cord. The advantages of spinal cord DTI described above should increase the role of this technique in diagnosis, prognosis and follow-up of the spinal cord diseases.
Learning Objectives:
1.To review the technique of diffusion tensor imaging (DTI) in the assessment of the spinal cord.
2.To document the usefulness of DTI in the detection of cervical spinal cord integrity alterations in different stages of degenerative spine disease.
3.To discuss the value of DTI in other diseases of the spinal cord.

A-824 17:02
C. Dynamic MR lumbar evaluation in degenerative spine disease
M. Muto; *Naples/IT (mutomar2@gmail.com)*

Thanks to its peculiarity in recognizing soft tissues pathologies entailing articular structures and nerve roots, great interest emerged in the last two decades on new MR scanners able to perform dynamic acquisitions in upright. Dynamic MR allows a correct evaluation of structures involved in lumbar back pain due to radicular conflict and spondylolisthesis; in supine position relevant factors can be underestimated or hidden and become evident only patient standing upright. Lumbar lordotic angle, flavum ligament thickness, herniated discs, spinal canal area, spinal canal and dural sac antero-posterior diameters and spinal alignment can be measured and compared in both supine and upright positions. The standard protocols include supine standing: sagittal T1- and T2-weighted turbo spin echo, sagittal short tau inversion recovery and axial T2-weighted turbo spin echo; upright standing: sagittal turbo spin echo T2-weighted and axial turbo spin echo T2-weighted turbo spin echo. This technique entails some limitations: low-field magnet, long scanning time, difficulty in evaluating the most lateral areas of the spine. This presentation aims to discuss technical aspects, advantages and disadvantages of dynamic MRI, supported by illustrative case studies.
Learning Objectives:
1. To provide technical information on how to perform dynamic MRI of the lumbar spine.
2. To discuss the advantages and disadvantages of dynamic MRI, as compared with static MRI.
3. To document the added value of dynamic MRI of the lumbar spine in selected, illustrative case studies.

E³ 1721
Brain tumours

A-825 08:30
A. Paediatric brain tumours
M.I. Argyropoulou; *Ioannina/GR (margyrop@cc.uoi.gr)*

Primary brain tumours in childhood are the second most common malignancy after leukaemia. The presenting symptoms depend on age with macrocephaly and failure to thrive in infants and headache, morning vomiting, diplopia, ataxia motor and sensory deficits, seizures endocrinological symptoms in older children. Brain tumours may be of glial origin (astrocytomas, ependymomas), neuronal or neuroglial (gangliogliomas, gangliocytomas, DNET), embryonal (PNET, ATRT) and from germ cells (germinomas, teratomas). Tumours arising in the sellar and parasellar region (craniopharyngiomas, hypothalamic hamartomas and pituitary adenomas) may also occur. Neurinomas and meningiomas are rare in children arising mainly in the context of neurofibromatosis type II. Secondary brain tumours arise mainly from CSF seeding while haematogenous metastases are rare. MRI is the modality of choice to for the diagnostic workup of brain tumours. Imaging protocols may include T2W, T1W plain and contrast-enhanced images, diffusion tensor imaging, dynamic susceptibility-weighted contrast-enhanced perfusion imaging (DSC), functional MRI (fMRI) and MR spectroscopy (MRS). Brain tumours may be heterogeneous with cystic and solid components. The latter appears with low signal on T1W and high signal on T2W images. A low signal intensity on T2W images associated with restricted diffusion and increased perfusion indexes on DSC may be suggestive of a more aggressive tumour. Increased choline and lactate and decreased N-acetyl aspartate in MRS is also suggestive of malignant tumours. Tractography and f-MRI are useful for preoperative evaluation to assess major white matter tracts and eloquent areas of the brain related with the tumour.

Learning Objectives:
1. To become familiar with different paediatric brain tumours.
2. To learn the imaging criteria for differentiation.

A-826 09:15
B. Adult brain tumours
P.C. Maly Sundgren; *Lund/SE (Pia.Sundgren@med.lu.se)*

Glioblastomas are the most common malignant neoplasms and together with metastatic tumours comprise half of all malignant tumours in the adult population. The latest WHO classification is from 2016 and several changes has occurred with respect to classification of brain tumours. The grading of tumours presumes biological behaviour or phenotype of a lesion and is of high importance clinically by guiding therapy selection: adjuvant radiation, chemotherapy, surgical or palliative treatment of brain tumours. MRI is considered the standard modality for diagnosis and prognosis of brain tumours, based primarily on gadolinium (Gd) enhancement. However, this concept has become more and more challenging due to the fact that not all high-grade gliomas demonstrate Gd enhancement while low-grade tumours might enhance in up to 30% of the cases. This lecture will review the more common primary and secondary brain tumours in adults, their imaging characteristics on CT and MRI. The use of advanced imaging for diagnosis and treatment follow-up will be discussed.

Learning Objectives:
1. To become familiar with the different types of brain tumours.
2. To learn the imaging criteria for differentiation.

08:30 - 10:00 **Room B**

Abdominal Viscera

RC 1701
IgG4-related disease: what is it and what do I need to know?

A-827 08:30
Chairman's introduction
S.A. Jackson; *Plymouth/UK (simon.jackson1@nhs.net)*

IgG4-related disease represents a systemic fibro-inflammatory condition, which includes autoimmune pancreatitis. The condition was first reported in 2003 by Kamisawa and colleagues and during the same year autoimmune pancreatitis was also sub-classified into two histologically separate sub-types, with the “classical” type 1 form comprising part of the IgG4-related disease spectrum. Multiple modality imaging plays a central role in the diagnosis of both pancreatic and extra-pancreatic disease involvement which can affect multiple organs. This session will review the systemic manifestations of IgG4-related disease, including both pancreatic and hepatobiliary findings. In particular, various tips and tricks will be presented, to aid a confident imaging diagnosis in patients with IgG4-related disease.

A-828 08:35
A. Pancreatic manifestations
R. Pozzi-Mucelli; *Verona/IT (roberto.pozzimucelli@univr.it)*

The pancreatic manifestation of IgG4-related disease is autoimmune pancreatitis (AIP) which represents a distinct form of chronic pancreatitis. Histologically, AIP is characterised by a dense lymphoplasmacytic infiltrate of mainly CD4+ T lymphocytes and immunoglobulin G4 plasma cells, located around the pancreatic ducts with mass-forming regions of fibrosis. AIP has been classified into focal or diffuse forms. The differential diagnosis between focal AIP and pancreatic adenocarcinoma represents a medical need, since AIP responds to steroid therapy and surgery should be avoided. CT and MRI findings of AIP are characterised by an enlargement of the gland, either focal or diffuse. In CT, the affected areas are isodense before contrast enhancement, hypodense (due to hypovascularity) in the arterial phase with progressive increase in density in the venous and late phases following contrast administration. The involved areas appear hypointense on T1-weighted MR images, mild hyperintense on T2-weighted images with reduced diffusion at DWI. The lesion appears hypovascular during the arterial phase, with progressive enhancement and delayed retention of contrast in the venous and late phases. MRCP is able to assess the involvement of the pancreatic duct system and these features are important in the differential diagnosis with the pancreatic adenocarcinoma in which the main pancreatic duct is characterised by single short stenosis, with marked dilation of the upstream ductal system. In cases in which AIP involves the head of the pancreas, dilatation of the common bile ducts and the intrahepatic ducts can be seen.

Learning Objectives:
1. To describe clinical and biological presentation of IgG4-related pancreatitis.
2. To describe morphological and functional (DWI, PET/CT, etc.) imaging features of IgG4-related pancreatitis.
3. To identify imaging findings for the differential diagnosis with other solid pancreatic lesions, i.e. pancreatic cancer, and to avoid unnecessary invasive therapeutic procedures.

A-829 08:58
B. Hepatobiliary manifestations
M. Ronot; *Clichy/FR (maxime.ronot@bjn.aphp.fr)*

IgG4-related cholangitis is frequent in patient with IgG4-related disease. IgG4-RC should be carefully diagnosed based on a combination of clinical, serological, morphological, and histopathological features. Asian Diagnostic Criteria (Japan-Korea Consensus) and Mayo Clinic Diagnostic Criteria (The HISORt Criteria) have been commonly accepted. On imaging, the affected segments demonstrate irregular stenosis, focal, or diffuse circumferential thickening of the wall with contrast enhancement. The most commonly involved segment are the intrapancreatic segment of the common bile duct showing tapering with upstream biliary dilatation and the biliary convergence. It remains difficult to distinguish IgG4-RC from primary sclerosing cholangitis (PSC) or bile duct malignancy based on imaging features alone. The presence of other organs' involvement, especially pancreatic abnormalities, and elevated serum IgG4 level favour a diagnosis of IgG4-RC. The presence of an inflammatory bowel disease is more frequent in PSC. Biopsy should be used in all patients with a suspicion of malignancy. Although some patients may respond to biliary drainage or surgical resection, IgG4-RC displays a good response to steroid

therapy, as is the case for pancreatic lesions. Thus, early introduction of steroid therapy is recommended, especially for patients with obstructive jaundice.

Learning Objectives:

1. To describe clinical, biological presentation and morphological and functional imaging findings for the diagnosis of IgG4-related cholangitis.
2. To discuss the role of imaging to avoid unnecessary invasive diagnostic and/or therapeutic procedures.
3. To discuss the diagnostic criteria to differentiate IgG4-related cholangitis from other causes of cholangitis and biliary cancer.

A-830 09:21

C. Systemic manifestations

G. Morana; *Treviso/IT (gmorana@ulss.tv.it)*

IgG4 related diseases include swelling of involved organs, a lymphoplasmacytic infiltrate with IgG4-positive plasma cells and a variable degree of fibrosis. Elevated serum concentrations of IgG4 are found in 60-70 percent of patients. IgG4-RD often affects more than one organ. Immunoglobulin G4-related disease (IgG4-RD) generally occurs most commonly in middle-aged and older men, although disease extent and severity appear to be similar in men and women. IgG4-RD-associated disorders - other than Type 1 AIP and IgG4-related sclerosing cholangitis - include: aalivary and lachrymal gland involvement: dacryoadenitis/sialadenitis and sclerosing sialadenitis: about 40 percent of patients with AIP also have salivary or lachrymal gland involvement (despite marked lachrymal and salivary gland enlargement, these patients experience relatively mild dryness of the eyes and of the mouth than patients with Sjogren's syndrome); inflammatory orbital pseudotumour: account for 25 to 50 percent of all orbital pseudotumours; idiopathic retroperitoneal fibrosis and mesenteritis, chronic sclerosing aortitis and periaortitis: it involves the infrarenal aorta and simultaneously affect the iliac arteries (chronic inflammatory and fibrotic change can involve regional tissues, such as the ureters, leading to obstructive uropathy); Riedel's thyroiditis; interstitial pneumonitis and pulmonary inflammatory pseudotumours, which may mimic sarcoidosis; tubulointerstitial nephritis and membranous glomerulonephritis, in most cases with involvement of other organs. The likelihood of IgG4-RD is significantly increased if high serum levels of IgG4, allergic symptoms, and/or other fibrotic processes are also present. Because of the systemic nature of the disease, imaging workup of IgG4-RD should always include whole body examinations to detect multiorgan involvement.

Learning Objectives:

1. To describe extra-pancreatic and extra-biliary manifestation of IgG4-related disease.
2. To describe the imaging findings of the most common extra-pancreatic and extra-biliary organ involvement.
3. To discuss the role of "whole-body" imaging modality for the diagnosis and the follow-up of IgG4-related systemic disease.

Novelties in lung cancer imaging

Moderator:
B. Feragalli; Chieti/IT

A-831 08:30

A. New approaches to the management of pulmonary nodules

A. Nair; *London/UK (arjun7764@gmail.com)*

Small pulmonary nodules are an increasingly common incidental finding, as the indications for thoracic CT widen while the threshold for performing the investigation is lowered. Although the majority are benign, the difficulty in histologically verifying such nodules inevitably means that CT follow-up using pragmatic algorithms is mandated. Such algorithms aim to minimise over-investigation while detecting potentially malignant nodules early. Most recommendations have been extrapolated from lessons learnt from lung cancer screening trials, and have relied on measuring diameter to prove stability. In 2015, the British Thoracic Society (BTS) published novel guidelines combining the use of semi-automated volumetric measurement (where possible) and malignancy risk calculation using the Brock model to guide nodule management. Volumetric measurements are more repeatable and reproducible than diameter measurements, but the radiologist should be aware of patient, technical and vendor factors that influence this reliability. With the sanctioning of low-dose CT screening in the USA, the American College of Radiology released Lung-RADS version 1.0 in 2014, a standardised reporting system for nodules found at baseline and incidence rounds of lung cancer screening stratified by diameter. As with the BTS guidelines, Lung-RADS recommends using the Brock model to estimate malignancy for more suspicious nodules, but also allows the radiologist to use their judgement to move a nodule into a more suspicious category. In this lecture, we review the categories, similarities and differences between BTS and the most recent version of Lung-RADS, and discuss how both BTS and Lung-RADS can affect the management of incidental- and screening-detected nodules, respectively.

Learning Objectives:

1. To learn about strengths and limitations of the recent British Thoracic Society guidelines in managing pulmonary nodules.
2. To become familiar with LungRads classification and reporting system in pulmonary nodule assessment.
3. To understand how LungRads may affect results in a lung cancer screening programme.

A-832 09:00

B. CT phenotypes of lung adenocarcinoma

M. Lederlin; *Rennes/FR (Mathieu.LEDERLIN@chu-rennes.fr)*

Adenocarcinoma, the most prevalent type of lung cancer, represents a heterogeneous group of tumour with a large spectrum of genetics, histologic subtype, CT appearance, clinical behaviour and prognosis. The IASLC/ATS/ERS histopathological classification of lung adenocarcinoma defines a wide range of subtypes showing interesting correlations with CT findings. These correlations are particularly strong for pre-invasive lesions (i.e. atypical adenomatous hyperplasia, adenocarcinoma in situ and minimally invasive adenocarcinoma), appearing as sub-solid nodules at CT. AAH and AIS typically exhibit no ground-glass opacity, while MIA has a tiny solid component within ground glass opacity. The growth rate of the solid component may be critically informative for the prognosis and the management of these lesions. Invasive adenocarcinomas usually display suggestive CT features such as peripheral location, lobulated margins, or pleural tags. Intra-tumoural mixed attenuation with ground-glass opacity and internal bronchogram suggest the presence of lepidic pattern, a subtype defined by preserved alveolar architecture, which conveys a less aggressive behaviour. Furthermore, some CT findings might be associated with genomic alterations such as EGFR and KRAS mutations, as well as ALK rearrangements. Invasive mucinous adenocarcinoma is a rare separate entity characterised by areas of ground-glass opacity or consolidation with a tendency to spread along the airways and lung parenchyma. Beyond visual analysis, radiomics is a new trend which aims to capture information of the tumour phenotype by extracting a large number of quantitative descriptors from medical images. In lung adenocarcinomas, some radiomics features have been shown to be significantly associated with prognosis and survival.

Learning Objectives:

1. To become familiar with CT assessment of lung adenocarcinoma phenotypes.
2. To learn how CT-based radiomic features can capture information on phenotypes.
3. To understand if non-invasive evaluation of phenotypes can predict patient prognosis.

A-833 09:30

C. Imaging of immune-related response criteria (irRC)

O.L. Sedlaczek; *Heidelberg/DE (sedlaczek@web.de)*

Imaging of immune-related response criteria (irRC) cancer immunotherapy is a broad field of approach employing the immune system to treat cancer. They can be divided into active priming of the endogenous immune system and the passive delivery of compounds that may use immune system as an effector (monoclonal antibodies/adoptive cell transfer). In contrast to cytotoxic agent anti-tumour response, immunotherapy may take longer and in the initial phase the response to immune therapies can manifest in a morphologic "progressive disease", therefore, called "pseudoprogression". In this situation a early discontinuation of the treatment would not be appropriate, unless PD is confirmed. On the contrary to standard RECIST criteria, initially "clinically insignificant" PD including even the detection of new lesions can be called "stable disease" and may in the long run result in an long-term tumour control reflecting the ongoing antitumour activity. Checkpoint inhibitors will play a major role in the first-line treatment of lung-cancer and, therefore, the broad use of adjusted response criteria a major need. Morphologic patterns of cancer-specific immunologic mechanisms and those of cytotoxic agents will be shown and examples of the evaluation of immune therapies using irRC compared to the conventional ones will be given.

Learning Objectives:
1. To become familiar with mechanisms of inducing lung cancer-specific immune response.
2. To learn about the response imaging patterns beyond those of cytotoxic agents.
3. To understand the clinical benefits from immune therapies using irRC compared to the conventional ones.

08:30 - 10:00 **Room O**

Special Focus Session

SF 17a

Paediatric parenchymal lung disease: what imaging technique to choose?

A-834 08:30

Chairman's introduction

H. Ducou le Pointe; *Paris/FR (hubert.ducou-le-pointe@aphp.fr)*

Chest x-ray should be performed prior to considering advanced imaging. It is an useful procedure for evaluating the airways, lungs and others chest components. Ultrasound is a well-known technique to explore to investigate the pleura and the mediastinum. It could be also a tool to explore the lung. To perform this exam, one must know the physical basis of the ultrasonographic method because images of the lung are based on artefacts. Chest CT is the method of choice to explore lung disease. Multidetector CT is now widely available and is characterized by high, almost isotropic resolution. Despite this fact, the main disadvantage of CT is the radiation exposure. Low HRCT protocols are mandatory to explore lung disease in children. MRI combines structural and functional information. MRI could be an effective tool to explore lung diseases because most lung diseases are accompanied by an increase in the quantity of tissue, cells, or blood within the lungs. Recent technical advances have helped MRI to become an effective tool to explore lung diseases.

Session Objectives:
1. To be familiar with paediatric parenchymal lung disease.
2. To learn the advantages and drawbacks of each imaging modalities.
3. To understand the optimal use of the different imaging modalities.

A-835 08:35

Chest x-ray

P. Tomà; *Rome/IT (paolo.toma@opbg.net)*

Parenchyma refers to the gas-exchanging part of the lung, consisting of the alveoli and their capillaries. The parameters for a normal lung size are: less than one third of the heart is below the hemi-diaphragm, the diaphragm is not flattened and the sixth anterior rib crosses the diaphragm. Complete increase of transparency of the thorax in association with low flattened diaphragms is commonly associated to air trapping as in asthma, bronchiolitis, cystic fibrosis, etc. In a child with asymmetric lung transparency, usually the lung with less vascularity is the abnormal one. Air bronchogram is the radiological sign of alveolar space involvement. It stands for air in patent airways surrounded by high-density alveolar spaces. This sign is frequent in consolidations and in atelectasis. Consolidation relates to a product of disease that substitutes alveolar air, solidifying the lung (as in infective pneumonia). In atelectasis reduced volume is seen, accompanied by increased opacity. About the aetiologies of pneumonia in infants and young children (<5 years), the majority of infections are viral: respiratory syncytial virus, metapneumovirus and adenovirus. In older children (5-18 years), main causes are viruses and atypical bacteria. Imaging studies have limited value in the differentiation between viral and bacterial respiratory tract infections. Probably, type of pattern is related to age and not to aetiologic agent.

Learning Objectives:
1. To learn about the aetiologies of paediatric parenchymal lung diseases.
2. To understand the differential diagnosis based on clinical and imaging findings.
3. To discuss the radiographic appearances of paediatric parenchymal lung diseases.

A-836 08:55

US

S.P. Deftereos; *Alexandroupolis/GR (sdefter@med.duth.gr)*

According to the basics of lung ultrasound (LUS), from the physics point of view (physical acoustic phenomena that produces special signs: sliding sign, A-lines, B-lines, etc.) the resulting images from LUS do not represent a clear image. Actually images are artefacts that are (or may) combined with disease-specific profiles with the assumption that the disease patterns correlate with the amount of fluid in the lung. Based on the presence or absence of those artefacts and with the estimation of the amount of B-lines, “imaging models” or lung ultrasound (LUS) findings have described both for the lung diseases of new-born (respiratory distress syndrome, transient tachypnoea of the new-born, bronchopulmonary dysplasia, etc.) and for lung diseases of infant and child, e.g. bronchiolitis, community acquired pneumonia etc. Of course, specific LUS findings are present in conditions such as pneumothorax, pleural effusion, opacification, etc. The use of LUS is advantageous in terms of radiation protection but there are a lot of limitations with the inability to have an overview of the entire thorax being the first (but not the only) weakness of the LUS. Furthermore, the acoustic phenomena are not always satisfactory corresponding to the pathology and thus the idea of routinely replacing chest radiography with LUS is unenforceable. The LUS has no ground to replace conventional chest radiology, but when appropriately applied, can save time to achieve a critical diagnosis especially in neonatal intensive care unit and also is a very useful follow-up tool (easy/safe/cheap/without radiation but of course operator dependent).

Learning Objectives:
1. To learn about the role of ultrasonography (US) in paediatric parenchymal lung diseases.
2. To discuss the ultrasonographic appearances of parenchymal lung pathology in children.
3. To understand pitfalls and limitations of US of the chest/lung.

A-837 09:15

CT

P. Ciet; *Rotterdam/NL (p.ciet@erasmusmc.nl)*

Despite chest radiograph (CR) being the most used technique for paediatric thoracic imaging, chest computed tomography (Chest-CT) remains the gold standard imaging modality to characterize parenchymal lung diseases. Chest-CT enables high-quality images both in non-collaborative and collaborative children. In non-collaborative children, fast acquisition CT protocols can be used to avoid sedation or anaesthesia without compromising image quality. Conversely, collaborative children can be trained prior to the CT scan to perform specific inspiratory and expiratory manoeuvres using a spirometer. The use of the spirometer improves protocol standardization and image quality. Nonetheless, the main limitation of chest-CT remains radiation exposure, which always conveys a risk of developing cancer related to its stochastic nature. However, dose reduction measures have been introduced to minimize this risk and nowadays chest-CT can be performed at the same radiation dose of a CR. Further radiation dose reduction might be achieved through chest-CT protocol standardization across vendors, which is still lacking. Finally, chest-CT has enabled to shift from qualitative to quantitative radiology. Newly developed imaging analysis techniques allows today to extract numbers from CT images that can be used to assess treatment’s efficacy or to determine patient’s prognosis. In this presentation will be shown a series of clinical examples where the combination of clinical, laboratory and CT imaging data allowed to obtain an integrated report jointly written by radiologist and clinician.

Learning Objectives:
1. To learn about the role of CT in paediatric parenchymal lung diseases.
2. To discuss the technique and protocols of CT of the lung parenchyma in children.
3. To learn about the differential diagnosis based on clinical and imaging findings.

A-838 09:35

MRI

M.O. Wielpütz; *Heidelberg/DE (mark.wielpuetz@med.uni-heidelberg.de)*

Using magnetic resonance imaging (MRI) for the management of paediatric patients with lung disease has obvious advantages: comprehensive structural and functional imaging without ionizing radiation. Functional imaging with MRI comprises measurements of perfusion, blood flow, ventilation, gas exchange as well as respiratory motion and mechanics. However, MRI of the lung is challenging for three reasons: 1) low tissue density containing few protons to generate signal; 2) multiple air-tissue interfaces causing susceptibility artefacts and fast signal decay; 3) respiratory, vascular, and cardiac motions requiring fast imaging or triggering and gating techniques. Most lung diseases are associated with an increase in tissue per volume (“plus pathology”), due to the interstitial, alveolar, bronchial or pleural accumulation of cells, extracellular matrix or fluid, displacing air content inside a voxel. Subsequently, proton MRI signal is enhanced. On the other hand, lung diseases may present with tissue loss or loss of blood volume attributable to hypoxic vasoconstriction (“minus pathology”), posing additional challenges to MRI. Still, lung MRI has benefited much from recent research in obstructive lung diseases such as cystic fibrosis, propelling its introduction in clinical routine and broadening experience with lung MRI in paediatric population. Nowadays, lung MRI provides robust

protocols for paediatric oncology, inflammatory lung diseases (especially pneumonia) and airways disease, which will be discussed in the talk.
Learning Objectives:
1. To learn about the (potential) role of MRI in paediatric parenchymal lung diseases.
2. To discuss the technique and protocols of MRI of the lung parenchyma in children.
3. To learn about the differential diagnosis based on clinical and imaging findings.

Functional imaging in head and neck radiology: beyond morphology

Moderator:
M.M. Lemmerling; Ghent/BE

A-839 08:30
A. Diffusion-weighted MRI: apparent diffusion coefficient (ADC) and beyond
A.D. King; *Hong Kong/HK (king2015@cuhk.edu.hk)*

The apparent diffusion coefficient (ADC), obtained from DWI images, measures diffusion of water molecules in head and neck tumours. Many factors influence the ADC but in general malignant tumours show greater impairment of diffusion and lower ADC values compared to benign lesions. When used in the correct clinical context ADC aids MRI lesion characterisation. Lower ADCs are reported in metastatic compared to benign /reactive nodes; malignant salivary gland tumours compared to pleomorphic adenomas; malignancy compared to infection/ inflammation; lymphoma compared to squamous cell carcinoma (SCC); poorly compared to well differentiated SCC. However, ADC thresholds overlap and low ADC values occur in benign processes. The ADC of SCC shows associations with chemoradiotherapy response, an unfavourable outcome reported for tumours with high ADC pre-treatment, smaller %ADC rise early intra-treatment and low ADC post-treatment. ADC is obtained usually from a monoexponential model using b-values from 0 to 800/1000 sec/mm^2, but the choice of b-values influences ADC values and provides diffusion parameters beyond ADC. Intravoxel incoherent motion (IVIM) uses lower b-values (~0-200 sec/mm^2) to measure pseudodiffusion related to the microcirculation (D* and f) and higher b-values (~400-1000 sec/mm^2) to measure pure diffusion (D). Diffusion kurtosis imaging extends the range to even higher b-values (>1000 sec/mm^2) and takes into account non-Gaussian diffusion to obtain a diffusion parameter (Dapp) and also a kurtosis parameter (Kapp) which is believed to better reflect tumour heterogeneity and cell complexity. Methods of analysing the diffusion maps also are evolving to take into account tumour heterogeneity.
Learning Objectives:
1. To understand the concept of diffusion in oncology.
2. To learn how to evaluate diffusion images and numeric values.
3. To understand new trends and restrictions of the method.

A-840 09:00
B. Perfusion imaging in head and neck: what is new?
R. Maroldi; *Brescia/IT (roberto.maroldi@unibs.it)*

As chemo-radiation therapy is increasingly applied to head and neck cancer, there is a growing need to develop non-invasive surrogate-biomarkers to predict and assess the response to a non-surgical treatment. Therefore, imaging techniques exploring tumour properties other than CT density, T2-T1 weighting or the single-phase "static" enhancement pattern have been devised. These "functional techniques" aim at targeting tumour micro-architecture, perfusion and heterogeneity (texture analysis). In particular, CT and MR perfusion techniques have been developed to investigate the changes induced by neo-angiogenesis in the microcirculation of tumour. This has been accomplished by analysis of the kinetics of the passage through the tissues of a bolus of contrast agent (DCE-CT, DCE-MR) or of an endogenous bolus (blood, ASL-MR perfusion). These kinetics can be explored with different strategies to obtain visual information, semi-quantitative or quantitative parameters. Though quantitative parameters should reproduce tissue microvascular physiology more precisely than semi-quantitative parameters, they are less simple to calculate. Presently, most of the medical literature on perfusion analysis encompasses pilot studies only. In addition, these studies share several limitations, not only linked to the complexity of the physiological model used to extract quantitative parameters but also correlated to the variety of the acquisition techniques, outcome measures as well calculation procedures. These limitations deter the reproducibility of results. Nevertheless, one emerging finding is that neoplasms showing great heterogeneity of a parameter like Ktrans are associated with a poorer prognosis; probably related to the presence of areas capable of surviving in conditions of hypoxia.
Learning Objectives:
1. To review the clinical usefulness of perfusion imaging in head and neck.
2. To understand advantages and disadvantages of perfusion.
3. To become familiar with the value of perfusion imaging in monitoring the early effects of non-surgical treatment.

A-841 09:30
C. MR/PET: the way to go
M. Becker; *Geneva/CH*

This lecture focuses on clinical applications of MR/PET in head and neck tumours with special emphasis on squamous cell carcinoma. First, principles of MR/PET are discussed and the current evidence regarding clinical feasibility, image quality, optimized imaging protocols and quantification with MRI-based attenuation algorithms in the head and neck are reviewed. Typical tumour manifestations are presented and the recent literature on the diagnostic performance of MR/PET in head and neck cancer is reviewed. The appearance of primary and recurrent squamous cell cancers, lymph node metastases and distant metastases on MR/PET is summarized and the appearance of benign lesions mimicking malignant tumours, such as scar tissue, granulation tissue, soft tissue necrosis and osteonecrosis is addressed. We present illustrative cases of multiparametric evaluations of malignant and benign lesions with MRI, diffusion-weighted imaging, perfusion and PET and we discuss the dilemma how to deal with discrepant multiparametric data.
Learning Objectives:
1. To become familiar with the technique of MR/PET.
2. To discuss the value of MR/PET in head and neck oncology.
3. To be aware of the possible pitfalls.

Pitfalls in gynaecologic oncologic imaging: how to avoid them and minimise risks

A-842 08:30
Chairman's introduction
A. Sahdev; *London/UK (anju.sahdev@bartshealth.nhs.uk)*

The increasing use of pelvic MRI for staging and assessing treatment response in gynaecological cancers opens a new world of pathology and pitfalls in pelvic imaging. These pitfalls are commonly encountered and may be due to poor acquisition, incorrect technical parameters, mimicking pathology or pitfalls in interpretation of the MR image. Functional imaging with diffusion-weighted imaging and dynamic contrast enhancement in particular, confer unique challenges at acquisition and image interpretation. This session will highlight pitfalls in common gynaecological MRI practice and relate these pitfalls to their consequences on patient management. The panel will also provide handy tips and solutions, where possible, to avoid and minimise the pitfalls.
Session Objectives:
1. To provide an overview of pitfalls and errors in interpretation of gynaecologic cancers.
2. To become familiar with strategies for avoiding pitfalls.

A-843 08:35
A. Mistakes in assessment of cervical cancer
M.M. Otero-García; *Santiago de Compostela/ES (milagros.otero.garcia@sergas.es)*

Cervical cancer (CC) continues to be staged at clinical examination but the International Federation of Gynaecology and Obstetrics (FIGO) staging system and different guidelines acknowledge the benefits of MRI staging. MRI is the best single imaging method for determining prognostic factors such as lymphatic involvement, tumour size, and depth of stromal invasion. High-resolution T2 images are a mainstay for tumour detection. Oblique axial T2W

images perpendicular to the cervical long axis provide more accurate assessment of stromal involvement and parametrial invasion. Diffusion-weighted imaging (DWI) and dynamic multiphase contrast (Gd)-enhanced T1 sequence are useful complementary sequences. Possible pitfalls in assessing CC staging and follow-up are as follows: overstaging when a wrong oblique axial acquisition is performed, or cervical oedema secondary to post-biopsy changes or large tumours is present; difficult tumour delimitation (e.g. early CC, isointense tumours in young women, cervical versus endometrial in adenocarcinoma); nearby structures invasion misinterpretation (e.g. bladder bullous oedema as direct invasion); misdiagnosis in unusual appearance of CC; benign conditions are mistaken as tumour (e.g. "burned out'' endometriosis, polypoid adenomyoma, vaginal vault nodularity after hysterectomy, etc.); post-chemoradiation changes produce soft tissue stranding in the cervix and parametria simulating recurrent tumour. To avoid pitfalls it is very important to plan MRI exploration correctly and to review all the sequences together including DWI and dynamic multiphase contrast (Gd)-enhanced T1 sequences. PET/CT can help in evaluating equivocal findings in post-treatment setting.

Learning Objectives:

1. To become familiar with pitfalls in staging of cervical cancer and in monitoring treatment response.
2. To learn how to differentiate mimics of cervical cancer.
3. To understand the central role of MRI in treatment planning.

A-844 08:58

B. Mistakes in assessment of endometrial cancer

T.M. Cunha, M. Horta; *Lisbon/PT (tmargarida@gmail.com)*

Endometrial carcinoma represents 4.8% of all cancers in women worldwide with approximately 75% of cancers diagnosed at an early stage. Although magnetic resonance imaging is not considered in the International Federation of Obstetrics (FIGO) 2009 staging classification, it plays an important role in the diagnosis and pre-operative staging of endometrial carcinoma; thus being a crucial tool for defining the surgical and therapeutic approach of these tumours. To help preventing diagnostic errors and to guide appropriate therapeutic management, radiologists should be aware of common magnetic resonance imaging mistakes in assessment of endometrial carcinoma. Pitfalls that may mask or simulate endometrial carcinoma include: a cervical adenocarcinoma misinterpreted as an endometrial adenocarcinoma; benign endometrial pathology misinterpreted as malignant pathology; specific tumoural locations and uncommon cancer enhancing patterns. Several common mistakes in staging endometrial carcinoma will also be outlined. Knowledge of the existence of these diagnostic pitfalls should help prevent misinterpretation of a pelvic magnetic resonance for assessment of endometrial carcinoma.

Learning Objectives:

1. To become familiar with pitfalls in local tumour spread in endometrial cancer.
2. To learn how to differentiate benign and malignant mimics.
3. To appreciate the complementary value of functional MRI techniques.
4. To understand the potential clinical impact of these mistakes in treatment planning.

A-845 09:21

C. Mistakes in assessment of ovarian masses

I. Thomassin-Naggara; *Paris/FR*

Pelvic MR imaging allows to avoid most of the mistakes in the assessment of ovarian masses made using transvaginal ultrasonography or CT scan. However, even using pelvic MR imaging, there are some pathologies that may mimic primitive ovarian cancer including pelvic inflammatory disease, uterine myoma, digestive tumour or ovarian metastases. Preoperative diagnosis of these pathologies is crucial because the therapeutic strategy is completely different and the absence of a diagnosis may impact the prognosis. Thus, this lecture will present three clinical situations where the radiologist needs to accurately analyse MR images to not misdiagnose a wide variety of pelvic pathologies as ovarian cancer.

Learning Objectives:

1. To become familiar with benign masses mimicking ovarian cancer.
2. To demonstrate benign and malignant diseases mimicking peritoneal carcinomatosis.
3. To learn about imaging strategies for avoiding these pitfalls.

E³ - ECR Master Class (Breast)

E³ 1726b

Taking clinical breast MRI to the next level

A-846 08:30

Chairman's introduction

J. Camps Herrero; *Valencia/ES (juliacamps@gmail.com)*

This masterclass will tackle three issues that are currently at the forefront of the breast MRI debate: imaging biomarkers, preoperative staging and so-called "overdiagnosis". Breast MRI should have already passed the phase of diagnostic validation and must now head towards the definition of imaging biomarkers that are capable of sampling the whole cancer in its entire heterogeneity as well as allowing serial measures in response evaluation. Imaging biomarkers must be solid, reproducible and standardised. This lecture will define common imaging biomarkers in the clinical setting as well as set the path for their further development in the future. Preoperative breast MRI is still being questioned as a valid indication and the MIPA study has been designed to answer the questions raised by published evidence on the contrary (excess mastectomies, no significant difference in mastectomy rates, etc) tainted by methodological biases which will be highlighted during this session. The number of high-risk (B3) lesions has increased after the use of breast MRI, being considered traditionally false-positive diagnoses, when in fact they have underlying prognostic implications. This lecture outlines these implications and lets us see breast MRI under a different light, when pathology correlates are considered.

Session Objectives:

1. To understand the concept of breast MR imaging biomarker and its role in the standardisation of the MRI technique.
2. To know how the results of the MIPA trial might influence the general approach to staging with breast MRI.
3. To understand the close relationship between pathology and MRI in the characterisation of high-risk lesions.

Author Disclosure:

J. Camps Herrero: Advisory Board; Bayer.

A-847 08:35

A. Breast MRI biomarkers for the clinical setting

E.A. Morris; *New York, NY/US*

Enhancement of the existing underlying fibroglandular tissue has been termed background parenchymal enhancement (BPE). As BPE is related to vascular flow, it has been proposed that this may represent an imaging biomarker of the underlying proliferation of fibroglandular tissue. Investigations have shown that there is an extremely strong association between BPE and risk of breast cancer, at least a strong as the association between mammographic density and breast cancer. BPE is also affected by treatment changes and hormonal manipulation. Tamoxifen and aromatase inhibitors decrease BPE, demonstrating an imaging treatment response. Radiation therapy to the breast causes a permanent reduction in BPE. Rim enhancement: MRI phenotypic features can predict aggressiveness of breast cancer. For example, we know that spiculation on MRI is associated with a lower histologic grade and lower ki67 expression and is more commonly seen in ER+ cancer. Rim enhancement has been shown to be associated with cancers that are higher in grade and ER-. Rim enhancement is associate with a worse distant metastatic survival. It has been shown that triple-negative tumours without rim enhancement are associated with tumour infiltrating lymphocytes. High TIL levels are associated with pCR following NAC and improved survival in TNBC. Peritumoural oedema: peritumoural oedema is caused by increased vascular permeability and release of cytokines. It is seen in <10% of breast cancer and is associated with early distant metastases (<2.5 y). In TNBC, peritumoural oedema was a significant independent predictor of worse recurrence-free survival.

Learning Objectives:

1. To explain which are the most common MRI biomarkers for breast cancer.
2. To understand the value of biomarkers in clinical practice.
3. To know the new possibilities for the future.

Author Disclosure:

E.A. Morris: Advisory Board; Delphinus, Devicor. Board Member; Avon. Consultant; Grail. Research/Grant Support; Hologic.

A-848 09:00

B. Preoperative MRI: which changes to expect after the MIPA trial?

F. Sardanelli; *San Donato Milanese/IT (f.sardanelli@grupposandonato.it)*

Preoperative MRI (pMRI) is highly debated. Context: established breast conserving surgery (BCS), with 10-40% positive margins rate; low ipsilateral recurrence rate after BCS plus radiation therapy (9% at 20 years); 0.5-1% annual risk of contralateral breast cancer (BC). Of 4 published RCTs, 2 against, 2 in favor; meta-analyses found 11-12% of wider ipsilateral surgery (8% mastectomies), 3-4% of contralateral surgery for true-positive pMRI; all observational studies have an intrinsic selection bias. An overdiagnosis/overtreatment risk by pMRI exists: some ipsilateral/contralateral cancers are cured by radiation therapy and/or adjuvant therapy. Guidelines by EUSOBI and ACR included pMRI indication for contralateral screening; the former also suggested ipsilateral MRI for dense breasts and invasive lobular cancer (ILC), the latter for tumour extent, additional cancers, invasion deep to fascia; both societies noted the lack of evidence for a pMRI effect on patient outcome. A multidisciplinary EUSOMA working group agreed on four indications: 1) ILC; 2) high risk; 3) mammography/US size discrepancy >1 cm; 4) selection for partial breast irradiation. Other indications: Paget; multifocal/multicentric/bilateral BC at conventional imaging; skin-/nipple-sparing mastectomy; positive margins after BCS. The ongoing multicentre MIPA study is enrolling two concurrent series of first-BC patients, not candidate to neoadjuvant therapy, receiving or not receiving pMRI. First results on 2,500 patients (50%/50% MRI/no-MRI): 40% of pMRIs are requested by surgeons; 20% of MRI-group had mastectomy already planned before pMRI; only 1% of mastectomies prompted by pMRI; after pMRI, more extensive BCS (14.2%) compensated by less extensive BCS (12.7%); re-operation rate 8.3% (MRI-group), 13.4% (no-MRI group).

Learning Objectives:

1. To understand which methodological issues of evidence-based medicine are implied in preoperative breast MRI (PB-MRI).
2. To become aware of the intrinsic bias of observational studies reporting only series of breast cancer patients who had PB-MRI.
3. To become aware of the first results of the MIPA study showing from the real clinical world that: a) surgeons are largely involved in requesting PB-MRI; b) PB-MRI is often requested as a confirmation tool for an already planned mastectomy; c) the additional rate of mastectomies really induced by PB-MRI is very low; d) PB-MRI allows for tailoring the breast conservative treatment balancing more and less extensive surgery.

Author Disclosure:

F. Sardanelli: Advisory Board; Bracco, General Electric. Research/Grant Support; Bracco, Bayer. Speaker; Bracco, Bayer.

A-849 09:25

C. Is breast MRI increasing the number of high-risk lesions?

C.K. Kuhl; *Aachen/DE*

"No abstract submitted."

Learning Objectives:

1. To describe MR imaging findings of DCIS, ADH/ALH, FEA.
2. To list common pathophysiological correlates of false positive diagnoses made by MRI vs conventional imaging.
3. To describe the different prognostic implications of false positive diagnoses made by MRI vs conventional imaging.

09:50

Panel discussion: Breast MRI: what more evidence do we need?

Imaging of traumatic brain injury

Moderator:

M. Karlovic-Vidakovic; Mostar/BA

A-850 08:30

A. New MRI techniques in the diagnosis of patients with traumatic brain injury

D. Galanaud; *Paris/FR (galanaud@gmail.com)*

Traumatic brain injury (TBI) is a major cause of disability among younger patients. MRI is emerging as the leading method to evaluate the extent of brain damage in this setting, especially using advanced sequences such as diffusion tensor imaging (DTI), MR spectroscopy and functional imaging. Each of these sequences has its own promises and challenges. DTI allows a precise and direct evaluation of the extent of white matter damage, which is the leading lesional mechanism in TBI. It is currently the most widely used and promising sequence for TBI evaluation. Its main limitation is significant inter-machine variability, still difficult to correct with controls or phantoms. MR spectroscopy, performed on the brain stem and the thalamus has shown promising results but suffers from a limited acceptance and availability. Functional MRI may show brain reorganisation following TBI and has shown promising results in evaluating the level of consciousness in vegetative/minimally conscious subjects. However, it is much less reliable in the acute setting due to the confounding effects of sedations. Large-scale studies are currently under way to standardise the acquisition procedures and determine the best approach to perform a reliable assessment of TBI severity based on MRI data.

Learning Objectives:

1. To learn about different types of traumatic brain injuries.
2. To understand how to use advanced MR techniques in brain injury.
3. To enhance the value of DTI in traumatic brain injury.

A-851 09:00

B. Computer-aided diagnosis in trauma imaging: status and developments and the role of deep learning

R. Manniesing; *Nijmegen/NL (rashindra.manniesing@radboudumc.nl)*

Computed tomography (CT) is the first-line imaging technique in the acute situation of traumatic brain injuries (TBI) and has high sensitivity for visualising haemorrhages and bone fractures. MR has superior soft tissue contrast and is capable of visualising diffuse axonal injuries including cerebral microbleeds, which may have long-term prognostic value and which are frequently present in all severities of TBI. However, detecting, quantifying, and characterising these lesions are time-consuming tasks and subject to observer variability. Furthermore, imaging data from trauma patients have additional complexity because of the typical heterogeneity of the patient group and the variability inherent to the image acquisition protocols. Computer-aided diagnosis (CAD), therefore, has an important role. For example, CAD systems can be developed to detect and measure the volume of intracerebral haemorrhages in CT, or to count and determine the laterality of cerebral microbleeds in MR. In this talk I give an overview of the current status of computer-aided diagnosis in trauma imaging. I identify the areas of interest which has a high potential and need for automation. As an example, a recently developed CAD system for cerebral microbleed detection is described. Finally, future developments and the potential role of deep learning in trauma imaging are discussed.

Learning Objectives:

1. To learn how automated image analysis can aid diagnosis and prognosis in traumatic brain injury.
2. To demonstrate the potential of computer-aided detection of cerebral microbleeds.
3. To discuss future developments of computer-aided diagnosis in trauma imaging.

Author Disclosure:

R. Manniesing: Research/Grant Support; Toshiba Medical Systems Corporation, Japan.

A-852 09:30

C. Structured reporting of traumatic brain injury lesions: introducing common data elements

T. Vande Vyvere; *Antwerp/BE (thijs.vandevyvere@icometrix.com)*

Conventional interpretation of radiologic findings in brain-injured patients is prone to error and highly variable between observers. It is believed that the visual, qualitative and subjective nature of interpretation, combined with a narrative form of reporting, are the root causes of these differences in evaluation. Agreement is especially low in cases with multiple coexistent lesion types. Reporting skills are commonly transmitted through the master-apprentice model, but unfortunately, agreement is low, even between experts. Novel up-and-coming structured scoring systems show a lot of promise to standardize the way traumatic brain injuries are interpreted and reported. The National Institute of Neurological Disorders and Stroke (NINDS) Common Data Elements (CDEs) were specifically designed to minimize inter- and intra-reader variability. Using specific operational definitions to describe each type of lesion, and by providing a framework of structured templates, the narrative report can be replaced by a more reliable and mineable structured report. Drop-down menus can be completed for each lesion using tiers of progressive complexity. Studies have shown high inter-reader reliability for reporting primary and secondary lesions when using this structured scoring system. However, significant variability is still found in some tiers with higher complexity where subclassification is required. Reported features which still show high variability when using structured reporting could be tackled by including more quantitative techniques. A combination of human-computer interpretation could, therefore, not only significantly increase the reliability of imaging-outcome research, it can also pave the way towards new hybrid reporting initiatives in radiology training and practice.

Learning Objectives:
1. To demonstrate the different patterns of primary and secondary extra-axial and intra-axial traumatic brain lesions.
2. To understand assessment of intracranial hypertension and cerebral herniation.
3. To discuss the issue of paediatric brain trauma and stress the importance of MRI in non-accidental injury.

T. Vande Vyvere: Employee; icometrix NV, Leuven, Belgium.

08:30 - 10:00 **Room F1**

Special Focus Session

SF 17b
Errors in emergency radiology

A-853 08:30
Chairman's introduction: Why do radiological errors occur?
A. Brady; *Cork/IE (abrady@muh.ie)*

Errors and discrepancies in radiology practice are uncomfortably common, with an estimated day-to-day rate of 3-5% of studies reported, and much higher rates reported in many targeted studies. Nonetheless, the meaning of the terms “error” and “discrepancy”, and the relationship to medical negligence are frequently misunderstood. This session will outline the incidence of these events, the ways they can be categorised to aid understanding and potential contributing causes, personal and system based. Possible strategies to minimise error and means of dealing with perceived underperformance when it is identified will be considered. The inevitability of imperfection will be explained, while the importance of striving to minimise such imperfection will be emphasised.

Session Objectives:
1. To learn about the frequency of errors in radiology practice.
2. To understand some of the contributing factors.
3. To prepare for a discussion later in the session of possible strategies to minimise errors.
4. To understand the frequency of and reasons for errors in radiological interpretation.
5. To learn about common errors in trauma radiology and non-traumatic abdominal emergency imaging.
6. To learn about the physical and human factors that can influence radiology error rates, and strategies that can influence the frequency of such errors.
7. To appreciate the personal and environmental influences that can contribute to a radiologist’s error rate, and how to optimise conditions to keep error to a minimum.

A-854 08:40
Imaging in multiple trauma
U. Linsenmaier; *Munich/DE (Ulrich.Linsenmaier@helios-kliniken.de)*

Multiple injury due to penetrating or blunt trauma is common and associated with significant morbidity and mortality and many of these injuries are or can become critical. They have to be characterized fully by diagnostic imaging in an early clinical phase. With the introduction of fast MDCT an established emergent diagnostic modality is now available for imaging multiple trauma that allows the detection and characterization of a large variety of parenchymal, vascular and skeletal injuries. Beside ultrasound (US) and conventional radiography (CR) it allows now in the emergency setting a thorough morphologic characterization of injuries and its potential bleeding dynamics. This presentation reviews the role of MDCT and spectrum of blunt and penetrating injuries as well as the imaging algorithm commonly used in the acute trauma setting. The diagnostic process is complex and difficult; possible sources of error are: A. technical errors: availability and proper use of the CT scanner and monitoring and life support equipment; B. logistic errors: availability and proper use of transportation equipment and organization and staffing of the trauma team; C. management errors: availability and proper use of a shock room algorithm based on ATLS, organization of diagnostic and therapeutic procedures; D. diagnostic errors: availability and proper use of a whole body CT protocol, individual errors, impact of delayed lesions in CT; E. current controversies.

Learning Objectives:
1. To learn about possible sources of error in imaging of multiple trauma.
2. To appreciate guidelines and algorithms in use in the imaging of multiple trauma.
3. To become familiar with current controversies in imaging of multiple trauma.
4. To understand state-of-the-art of imaging in multiple trauma.

A-855 09:00
Non-traumatic abdominal emergencies
A. Pinto; *Naples/IT (antopin1968@libero.it)*

Non-traumatic abdominal emergencies include a large spectrum of medical and surgical conditions. The clinical outcome depends on different factors based on the diagnosis, severity of the disease, and management. Imaging plays a major role in diagnosing these conditions, as well as in identifying associated complications. The imaging workup of patients with abdominal pain often starts with radiographs including supine and upright abdominal radiographs, and upright chest radiograph. The main cause of diagnostic error in the emergency department is the failure to correctly interpret chest and abdominal radiographs. Leading factors contributing to missed diagnosis on radiographs are lack of relevant clinical information, inappropriate or insufficient radiographs performed, failure of perception, lack of knowledge and error in interpretation. Ultrasonography (US) is an inexpensive and widely available imaging modality for evaluation of abdominal pain in the emergency department. Causes of error in emergency US are multifactorial, frequently exist in combination as in other diagnostic imaging techniques and include lack of attention to the clinical history, lack of communication with the patient, lack of knowledge of the technical equipment, failure of perception, lack of knowledge of the possible differential diagnoses, failure to suggest further ultrasound examinations or other imaging techniques. The utility of multidetector row computed tomography in the diagnosis and management of non-traumatic abdominal emergencies is well established. Technical factors, lack of knowledge, error in interpretation, satisfaction of search, error due to multitasking and increased workload may all play an important role in missed diagnosis on MDCT performed in patient with abdominal pain.

Learning Objectives:
1. To review the spectrum of diagnostic errors related to radiographs and CT performed in patient with non-traumatic abdominal pain.
2. To understand the leading factors contributing to missed diagnosis on radiographs and CT.
3. To learn how to reduce errors in radiographic and CT evaluation of patient with non-traumatic abdominal pain.

A-856 09:20
How not to fail in emergency radiology
P. McCoubrie; *Bristol/UK (paul.mccoubrie@nbt.nhs.uk)*

Most concepts of error in radiology concentrate on the technical expertise of the individual. In emergency radiology, a radiologist needs to work quickly and their decisions are increasing central in the management of the critically ill patients. However, many mistakes that happen in radiology are often little to do with the individual and their radiological prowess. The error is precipitated as the individual radiologist has been ‘set up to fail’. Even the best technically skilled radiologists will make the worst mistakes when working in a challenging environment and when they lack certain non-technical skills. First, the radiologist may be attempting in an unsuitable physical environment. Any number of factors may interfere with productive and effective reporting, including room temperature, lighting, background noise. Second, the workflow of the whole radiology department is crucial. Without the department being well organised (e.g. efficient teamwork, adequate staffing, adequate rest, a manageable workload and minimal interruptions) radiologists will make more mistakes. Third, technical skill is not all a radiologist needs. A radiologist needs a number of non-technical skills to prevent errors inadvertently entering their work. Primarily, they need to be a consummate communicator, both written and verbal. They also need excellent consultation skills to effectively help clinicians. A radiologist also needs the ability to make decisions safely and effectively, often under considerable pressure and stress. Only by concentrating on these topics will radiologists be truly ‘set up to succeed’.

Learning Objectives:
1. To list the key factors in improving a physical layout of a radiologist’s working environment that optimise performance.
2. To explain the non-technical, non-interpretative skills necessary for a radiologist to reduce error.
3. To enumerate the key concepts behind successful working with other healthcare professions to reduce the risk of errors.

Diffusion-weighted imaging (DWI) in oncology: how I do it

A-857 08:30

Chairman's introduction

D.-M. Koh; *Sutton/UK*

Diffusion-weighted MRI (DWI) is now widely used for the routine management of patients in clinical practice both at 1.5T and 3.0T. There is significant interest in going beyond simple ADC calculations for disease assessment. Such non-monoexponential models (e.g. intravoxel incoherent motion, diffusion kurtosis and stretched exponential) can provide additional information about underlying tissue characteristics. However, knowledge of the strengths and limitations of such approaches are important for their wider application. There is also increasing interest in using whole body DWI for disease assessment, particularly for the evaluation of bone marrow disease.

Session Objectives:

1. To understand the technical principles on DWI and to understand DWI-tailored protocols in function of the clinical questions to be answered.
2. To learn about calculation of true diffusion and perfusion fraction using DWI.
3. To learn about whole-body MRI vs DWI dedicated to one organ: strengths and weaknesses of both approaches.

A-858 08:35

A. DWI: how to optimise protocols

N. Papanikolaou; *Lisbon/PT (npapan@npapan.com)*

Diffusion-weighted imaging (DWI) is a modality that can be used to study microscopic motion of water molecules. Therefore, the presence of macroscopic physiological motion, like respiration or peristalsis affecting abdominal organs, poses certain challenges. Several methods have been proposed including breath holding, respiratory triggering or free breathing to overcome respiratory-related image degradation. Additionally, ultrafast pulse sequences, like single-shot echo planar imaging, are preferable for diffusion applications due to their capability to freeze macroscopic motion; however, they are sensitive to susceptibility artefacts. Efficient fat suppression is a prerequisite for adequate image quality. Different approaches including spectral fat sat pulses or inversion recovery methods (DWIBS) have been proposed. Geometrical distortions represent another potential problem, since it may hamper diagnostic efficacy of DWI images. To minimise the latter effects, strong gradients need to be recruited to achieve short echo times and furthermore, make the right selection of the phase encoding direction. In the context of a reliable and accurate analysis of the DWI data, the choice of a sufficient number of b-values and an optimal distribution is mandatory and still under discussion. Literally, signal attenuation due to capillary blood flow (perfusion) is most apparent at low b-values with their range varying depending on the tissue of interest. On the other hand, diffusivity is highlighted in higher b-values. Therefore, choosing the optimum number and group of b-values can substantially minimise the overall measurement error of the diffusion metrics that lead to better quantitative and qualitative results.

Learning Objectives:

1. To learn about examination protocols and techniques.
2. To understand the different models describing diffusion in various organs and diseases.
3. To become familiar with basic and advanced post-processing aspects.

A-859 08:58

B. DWI in abdominal oncology: ready for clinical practice?

D.M. Lambregts; *Amsterdam/NL (doenja.lambregts@gmail.com)*

Diffusion-weighted MRI plays a central role nowadays in oncologic MR imaging. In the abdomen, important applications of DWI include lesion detection (for example, in the prostate and liver), lesion characterisation, response monitoring (for example, in rectal cancer), response prediction and prognostication. The strengths and weaknesses for these different applications of DWI within the abdomen will be discussed. Moreover, important pitfalls of using DWI in the abdomen will be addressed with specific emphasis on how to avoid them.

Learning Objectives:

1. To learn about the different ways diffusion imaging protocols can be used for qualitative and quantitative evaluation of malignant tumours in the abdomen.
2. To understand the pitfalls of using DWI in abdominal oncology.
3. To become familiar with the current clinical applications for DWI in abdominal oncology.

A-860 09:21

C. DWI: whole-body imaging

V. Vandecaveye; *Leuven/BE (vincent.vandecaveye@uzleuven.be)*

Diffusion-weighted imaging (DWI) uses differential tissue microstructural properties for tumour detection, staging and response assessment. Technical developments have enabled clinically efficient whole body DWI (WB-DWI) and is warranted in oncology due to the increasing need for assessment of multifocal disease. WB-DWI brings a number of challenges in terms of correct selection of indications, optimisation of sequences and qualitative and quantitative interpretation protocol. WB-DWI is best applied in indications where metabolic imaging has lower diagnostic yield due to inflammatory background such as in the post-treatment setting, in case of expected small volume disease such as in peritoneal carcinomatosis in ovarian or colorectal cancer or in case of cancer with low metabolic profile such as lobular breast cancer or gastric cancer. The DWI sequence is the core of the imaging protocol but requires anatomical sequences for correlation and exact interpretation. The types of applied anatomical sequences vary depending on the indication but with contrast-enhanced sequences being indispensable in abdominal cancer and non-enhanced T1 sequences being mandatory for assessing skeletal metastases. WB-DWI benefits most from the application of the short tau inversion recovery (STIR) prepulse as it is robust to inhomogeneity-induced fat suppression and susceptibility artefacts and facilitates the detection of small tumoural lesions. Image interpretation should be qualitative as much as possible for clinical efficiency and to enhance communication with referring clinicians. Quantitative image evaluation in case of response assessment of nodal staging requires development of computer-aided imaging interpretation tools. This presentation outlines indications, optimised imaging and interpretation protocols for WB-DWI.

Learning Objectives:

1. To learn about the most common indications of whole-body diffusion imaging in cancer staging and treatment planning.
2. To become familiar with normal anatomy and physiological signal at whole-body diffusion imaging.
3. To understand how to integrate qualitative and quantitative interpretation criteria into a structured report to optimise communication with the referring clinician.

09:44

Panel discussion: How to optimise DWI for clinical practice?

Musculoskeletal

RC 1710

MRI of articular cartilage and bone: areas of imaging confusion and practical solutions

Moderator:

O. Papakonstantinou; Athens/GR

A-861 08:30

A. Bone oedema syndromes and avascular necrosis

B. Vande Berg; *Brussels/BE (bruno.vandeberg@uclouvain.be)*

The bone marrow oedema (BME) pattern is defined as an ill-delimited marrow area of homogeneous decrease in signal intensity on T1-weighted SE images and of intermediate to high signal intensity on fluid-sensitive sequences.The BME pattern is non-specific and can be observed in epiphyseal marrow in association with numerous bone or joint disorders. We will emphasize the significance of BME in association with systemic osteonecrosis. We will also review specific imaging features that enable distinction between the three most common causes of non-traumatic epiphyseal fractures, i.e. systemic osteonecrosis, insufficiency stress fractures and osteoarthritis.

Learning Objectives:

1. To understand the aetiologies of bone marrow oedema syndromes.
2. To learn about the imaging characteristics of avascular necrosis of bone.

A-862 09:00

B. Osteochondral injury, subchondral fractures and traumatic bone oedema: what is important and how do I describe it

F.W. Roemer; *Erlangen/DE (frank.roemer@uk-erlangen.de)*

Bone marrow contusions are frequently identified on MRI after an injury to the musculoskeletal system. These osseous injuries may result from a direct blow to the bone, from compressive forces of adjacent bones impacting one another, or from traction that occurs during an avulsion injury. Commonly these injuries resolve without long-term sequelae. However, they may also involve the cartilaginous surface with or without an associated fracture line defining these as osteochondral injuries, which may have a different prognostic relevance. Subchondral fractures have been implicated in the genesis of some destructive articular conditions whose cause was previously undetermined, such as rapidly progressive osteoarthritis or spontaneous osteonecrosis of the knee. Subchondral fractures may ultimately lead to bone collapse, secondary osteonecrosis and severe articular damage. It should be suspected in the appropriate clinical setting, as in early stages it is usually indistinct on initial plain radiographs and MRI is required for a definitive diagnosis. The fracture line usually appears as a band of low signal intensity in the subchondral bone plate, adjacent to the articular surface, most often surrounded by bone marrow oedema. As these injuries may be occult on radiographs, the differentiation of bone contusions from osteochondral injuries or subchondral fractures is possible only with MRI including fat-suppressed and non-fat suppressed sequences. While purely subchondral lesions may have a good prognosis if diagnosed early, disruption of the articular surface may lead to early degenerative alterations including focal cartilage loss and other features of osteoarthritis.

Learning Objectives:

1. To understand the pathomechanisms of osteochondral injury and subchondral fractures.
2. To learn about the imaging techniques and prognostic values.

Author Disclosure:

F.W. Roemer: Shareholder; Boston Imaging Core Lab (BICL), LLC.

A-863 09:30

C. Is this osteomyelitis? If not what else could it be?

A.B. Rosskopf; *Zurich/CH (andrea.rosskopf@balgrist.ch)*

This talk will cover the most important key points for radiologists to diagnose osteomyelitis and to successfully distinguish other mimicking diseases, such as bone and soft tissue tumours, Charcot arthropathy and Langerhans cell histiocytosis. Diagnosis of osteomyelitis may require the combination of different imaging techniques depending on disease stage (acute, subacute, or chronic). Plain radiographs have low sensitivity and specificity for bone infection, but should be the primary imaging modality to start with. Magnetic resonance imaging (MRI) is the most sensitive and specific modality for detection of osteomyelitis: pattern and location of a signal drop on unenhanced T1-weighted sequences can distinguish between osteomyelitis and reactive bone marrow oedema. The so-called “penumbra sign” helps to differentiate subacute osteomyelitis from bone tumour lesions, and a positive “ghost-sign” can be helpful in patients with a diabetic foot. Ultrasound plays a key role for surrounding soft tissue abnormalities and periosteal involvement in children. In chronic osteomyelitis, computed tomography provides valuable information regarding the presence of involucrum, sequestrum, or cloaca formation.

Learning Objectives:

1. To understand the imaging characteristics of osteomyelitis.
2. To learn the value of different imaging modalities for the diagnosis of osteomyelitis.

08:30 - 10:00 **Room G**

Physics in Medical Imaging

RC 1713

Artefacts and pitfalls in tomography

A-864 08:30

Chairman's introduction

V. Tsapaki; *Athens/GR (virginia@otenet.gr)*

A number of imaging techniques are currently present to facilitate clinical diagnosis. More specifically, CT, PET/CT and MR/PET are excellent imaging modalities for evaluation of a wide variety of pathologies, due to either their spatial resolution and/or tissue contrast. Furthermore, hybrid imaging can provide clinicians with tools for making an accurate diagnosis prior to making treatment recommendations. Their use, however, is occasionally restricted by a variety of associated artefacts. Artefacts degrade image quality leading in some cases in diagnostically useless images. In some cases, they also appear due to the inevitable consequence of natural properties of the human body. There are many different types of artefacts such as noise, beam hardening, scatter, pseudoenhancement, motion, cone beam, helical, ring or metal artefacts. Understanding the technical basics of hybrid imaging is vital to avoid misinterpreting artefacts as pathological findings. In addition, a deeper understanding of the origins and imaging characteristics of artefacts will reduce the likelihood of misdiagnosis and optimise the image. As accurate CT, PET/CT and MR/PET imaging is a question of knowledge, the particular refresher course intends to refresh the participants’ knowledge of the physical origins of artefacts. The course will present different methods for minimising artefacts, how to image regions of the body close to metal implants, as well as solutions to frequent image distortion.

Session Objectives:

1. To learn about the origins of image artefacts in tomographic imaging.
2. To understand image distortions in hybrid imaging.
3. To learn about solutions and workarounds.

A-865 08:35

A. CT

J. Kuntz; *Heidelberg/DE (j.kuntz@dkfz.de)*

Although CT is the most quantitative diagnostic tomographic imaging modality, its images still suffer from several kinds of artefacts. Among the CT artefacts the most prominent, severe, and well known one in diagnostic CT is the metal artefact, mainly because larger metal implants are almost opaque to the x-ray radiation and thus x-rays that are scattered from the surrounding tissue into the metal shadow cause a very high scatter-to-primary ratio. In addition, there are many less dominating sources of artefacts. Among those are beam hardening and scatter causing dark streaks between dense objects such as bones, motion causing motion blurring and partial cycloid artefacts, very large patients causing truncation artefacts, sampling issues causing aliasing artefacts, as well as the finite detector size which causes linear and non-linear partial volume artefacts. Last but not least, there are artefacts that are known mainly to experts in CT physics because the manufacturers typically correct for them: defect detector pixel artefacts, detector afterglow artefacts, and geometric misalignment artefacts. The lecture discusses the source of artefacts and gives, wherever applicable, examples and points towards approaches of how to reduce such artefacts.

Learning Objectives:

1. To understand the source of artefacts in clinical CT.
2. To understand the most important correction methods.
3. To find out what artefact correction techniques are actually provided by the CT vendors in their systems.

A-866 08:58

B. PET/CT

T. Beyer, I. Rausch; *Vienna/AT (ivo.rausch@meduniwien.ac.at)*

A proposal to combine PET with CT was made in the early 1990s by Townsend, Nutt et al. In addition to the intrinsic alignment of complementary images, the anticipated benefit of PET/CT was to use the CT images to derive the mandatory attenuation maps for the PET data. In short, CT-based attenuation correction (CT-AC) is based on the assumption that CT image can be segmented into bone and non-bone tissues; voxels in each tissue class are then scaled with corresponding scale factors. CT-AC is prone to several errors arising from the methodological shortcomings of the segmentation-scaling method in light of CT-transmission measurements in clinical conditions. These include: truncation artefacts, artefacts from high-density implants and positive contrast agents and others. More frequently, errors from patient motion during the examination propagate through CT-AC into the final emission images and lead to distortions/bias of the reconstructed data. In addition, artefacts and biases may occur from involuntary mistakes made during the set-up/conduct of the imaging procedure. During this presentation, we will rehearse the principles of CT-AC in PET/CT and point to source of artefacts arising from the methodology of CT-AC and from specific imaging workflow scenarios not optimized for routine PET/CT.

Learning Objectives:

1. To understand image distortions, artefacts and bias from methodological pitfalls.
2. To appreciate and understand solutions to frequent image distortions.
3. To understand the methodological limitations of PET/CT.

Author Disclosure:

T. Beyer: Research/Grant Support; Siemens Healthcare. Other; Manging Director cmi-experts GmbH. **I. Rausch:** None.

A-867 09:21

C. MR/PET

H.H. Quick; *Essen/DE (Harald.Quick@uni-due.de)*

Each new imaging modality and technical system introduces new types of artefacts and in MR/PET hybrid imaging the potential for new artefacts is even higher than just considering two independent systems. Artefacts in MR/PET might affect the visual impression of either MR or PET data and, furthermore, may also have an effect on quantification in MR and even stronger on PET being a quantitative method. Artefacts in integrated MR/PET may result from technical crosstalk between the MR and the PET components. Both imaging centres might not be co-aligned correctly. Differences in the data acquisition speed between MR and PET might lead to local misalignments due to patient motion. MR-based attenuation correction (AC) is still a new concept to support PET data quantification in the best possible way. All deviations from the real physical gamma quanta attenuation will ultimately lead to false values in PET quantification following AC. Administration of contrast agents before application of MR-based AC due to changes in tissue contrast potentially may lead to errors in tissue segmentation. The MR field-of-view is limited which may lead to truncation of patient tissues exceeding the constraints of the field-of-view. Consequently, the arms are not fully considered in AC leading to false PET quantification. Metal implants might introduce signal voids or local distortions in MR-AC that exceed the physical implant volume. Such signal voids might then be assigned with the low linear attenuation coefficients of air in image segmentation. Typical artefacts, pitfalls, and their avoidance will be presented.

Learning Objectives:

1. To identify common artefacts.
2. To understand the physical origin of and methods to resolve artefacts.
3. To understand the interrelation of MR artefacts and bias in PET quantification.

Special Focus Session

SF 17c

How do radiographers enhance paediatric imaging?

A-868/A-869 08:30

Chairmen's introduction: The role of the radiographer when imaging a paediatric patient

L.J.O.C. Lança; *Lisbon/PT (luis.lanca@estesl.ipl.pt)*
E. Sorantin; *Graz/AT (erich.sorantin@medunigraz.at)*

The radiographer knowledge, skills and competences regarding the paediatric patient-centred care needs to be highlighted to pursue the enhancement of paediatric imaging. In the paediatric radiology department, radiographers and radiologists, among other healthcare professionals, develop their work that may be involved in child care. The associated risks information and the justified procedures to be undertaken for any radiological examination need to be appropriately and confidently communicated to child carers. Informed consent procedures would encourage radiographers and radiologists to be more attentive to consistently provide patients with adequate benefit-risk information relating to imaging examinations. Therefore, it is important that radiographers are aware on how to confidently communicate to paediatric patients and their families, as well as to other health professionals that may be involved in their care. Promoting a paediatric patient radiation safety culture for radiographers assumes a major relevance in paediatric imaging as the biological effects and lifetime risks of ionising radiation are higher in children than in adults. Identifying the types of traits that radiographers working with children have identified as being important to their practice emphasises how emotional intelligence impacts on their ability to gain the cooperation of paediatric patient and parents or carers, producing a high-quality clinically justified diagnostic examination. This special focus session will provide an opportunity for radiographers, radiologists and other healthcare professionals to share their experiences and their views about how to enhance paediatric imaging in a paediatric patient-centred care environment.

Session Objectives:

1. To learn about informed consent in paediatric imaging.
2. To emphasise the need of dose reduction practices in paediatric imaging.
3. To discuss emotional intelligence in paediatric imaging as a requirement for practice.

A-870 08:35

Informed consent: is this possible in paediatric imaging?

J. Portelli; *Msida/MT (jonathan.portelli@um.edu.mt)*

Concerns about the possible development of cancer as a result of the use of ionising radiation during medical imaging examinations are increasing. Consequently in a era driven towards patient-centred care, it has been argued that it is time for imaging departments to adopt informed consent procedures for imaging examinations that are considered to pose higher risks to patients, such as those performed in paediatric patients and those involving higher radiation doses. Such recommendations have been made on the presumption that an informed consent procedure would encourage referring physicians, radiographers and radiologists to be more attentive to consistently provide patients with adequate benefit-risk information relating to imaging examinations, unlike current practice whereby it appears that such information is not always disclosed. Subsequently, adequately informed patients and parents would be empowered to take a more active role in shared decisions concerning what would be best for them or their child. It is in this context that this lecture will seek to analyse and discuss the issue of informed consent in paediatric imaging, as well as highlight potential challenges radiographers face when imaging paediatric patients. Subsequently this lecture will seek to emphasise the importance of radiographers being knowledgeable and skilled on how to confidently communicate benefit-risk information to paediatric patients and their families, as well as to other health professionals that may be involved in their care.

Learning Objectives:

1. To discuss informed consent in paediatric imaging.
2. To highlight the challenges for radiographers in paediatric imaging.
3. To focus on risk communication as part of informed consent during paediatric imaging.

A-871 08:58

Dose reduction in paediatric imaging

G. Paulo; *Coimbra/PT (graciano@estescoimbra.pt)*

It is interesting to observe that over 120 years after the revolution triggered by Roentgen's discovery, there are still persisting problems, similar to those described in 1910 by Eddy German, one of the pioneers of the radiographer profession in the United States: "It was difficult to find two operators who were anywhere near in accord regarding technical procedure. Some would advise certain procedures and others entirely different programs". Despite the scientific knowledge and the technological development in the last decades, the reality described by Eddy German in 1910 still applies to today's practice of medical imaging. The reasons are manifold: (a) the lack of harmonisation of professional practice at all levels; (b) a communication gap between science and professional practice; (c) a delay in integrating the new technology concepts of medical imaging into curricular programmes of health professions; (d) a barrier between manufactures/equipment developers and clinical practice. Current research evidence shows that by developing applied research in radiography, involving clinical and academic radiographers, a significant dose reduction without compromising diagnostic image quality is achieved. The link between radiographers, radiologists and hospital management in the process of developing and translating research evidence into clinical practice, is the key for success in promoting a radiation safety culture, contributing to the development of best practice. The implementation of a radiation safety culture assumes particular relevance in the field of paediatric imaging due to the fact that the biological effects and lifetime risks of ionising radiation are higher in children than in adults.

Learning Objectives:

1. To discuss the current research findings and their implications for paediatric imaging.
2. To illustrate essential practical approaches to minimising doses.
3. To highlight the importance of radiation safety culture in paediatric imaging.

A-872 09:21

Personality traits: a way of maximising cooperation during paediatric imaging

S.J. MacKay; *Liverpool/UK (S.Mackay@liverpool.ac.uk)*

This paper will begin by defining and explaining trait, ability and tripartite models of emotional intelligence. It will then focus on the trait model and identify the types of traits that paediatric radiographers have identified as being important to their practice. It will then give examples from current clinical practice at a specialist paediatric hospital in the UK of how emotional intelligence impacts on their ability to gain the cooperation of patients and parents and produce a high-quality diagnostic image. Finally, it will give some examples of how radiographers can improve their emotional intelligence in paediatric radiography.

Learning Objectives:
1. To define and explain the different models of emotional intelligence (EI).
2. To discuss aspects of paediatric practice that require EI in order to deliver a quality paediatric radiography service for the patient and parent/guardian.
3. To discuss methods of improving emotional intelligence in radiographers.

Dementia and movement disorders

A-873 10:30
A. MR contribution to diagnosis and differential diagnosis in dementia
M. Sasiadek; *Wroclaw/PL (marek.sasiadek@umed.wroc.pl)*

Imaging methods play an increasing role in diagnosing, differentiating, prognosis and follow-up of dementia. The most important imaging methods are: CT, MR, SPECT and PET. Among them MR, including MR spectroscopy (MRS), perfusion MR (PWI), diffusion tensor imaging (DTI) or functional MRI (fMRI), appears to be the most valuable modality. Plain MR might provide valuable contribution to the diagnostics of dementia. The distribution of the brain atrophy indicates the specific dementia disease, e.g. hippocampal atrophy is highly suggestive for Alzheimer disease and frontotemporal atrophy for frontotemporal dementia. There are also specific MR patterns of progressive supranuclear palsy (mesencephalic atrophy) or multiple system atrophy (cerebellar/brainstem or putaminal atrophies). Vascular dementia changes (e.g. small vessel disease, CADASIL, amyloid angiopathy) could be reliably diagnosed with MR, including MR angiography and susceptibility weighted sequences. There are also typical MR patterns of many other diseases, which may be accompanied by dementia, e.g. normal pressure hydrocephalus, multiple sclerosis, Wilson disease, Fahr disease, Creutzfeldt-Jakob disease, etc. Advanced MR techniques provide further contribution to diagnosing dementia by adding quantitative data. MRS could reveal increase of myoinositol level in degenerative diseases or of choline in multiple sclerosis. PWI shows decrease of perfusion in vascular dementia, but also in Alzheimer disease. DTI detects decrease of fractional anisotropy in white matter tracts affected by degenerative or inflammatory process. fMRI provides assessment of the impairment of cognitive functions in dementia disorders. MR, due to the advantages described above, should be a part of routine diagnostic protocol in patients with dementia.
Learning Objectives:
1. To become familiar with imaging in different types of dementia.
2. To learn the imaging criteria for differentiation.

A-874 11:15
B. Imaging in Parkinsonism and other extrapyramidal disorders
T. Stosic-Opincal; *Belgrade/RS (stosic.tanja@yahoo.com)*

Extrapyramidal disorders can be classified as pathologies that affect basal ganglia (*caudate*, *putamen*, and *globus pallidus*), subthalamic nucleus and structures that are functionally connected with them (substantia nigra). On histological level, affected tissues exhibit high level of deposits of paramagnetic ions (presumably iron and copper) and loss of neural tissue. This is manifested in loss of volume of brain structures and dysfunction of specific neural tracts. Parkinsonism refers to any condition that causes a combination of the movement abnormalities such as tremors, slow movement, impaired speech or muscle stiffness. Besides idiopathic Parkinson's disease, a several conditions fulfil definition, such as progressive supranuclear palsy, multisystem atrophy and corticobasal degeneration. Role of imaging techniques is assessment of structural and physiological changes caused by EPD. Magnetic resonance imaging is the primary choice since it provides morphological, structural and physiological insight into changes caused by extrapyramidal disorders. Positron emission tomography gives additional information about physiological changes by using neurotransmitters labelled with positron emitters. Computerized tomography has limited possibilities which are restricted to assessment of morphological changes.
Learning Objectives:
1. To become familiar with the different imaging modalities.
2. To learn the imaging criteria.

10:30 - 12:00 **Room B**

ESR meets Peru

EM 3
Peru in the radiological world

Presiding
J.L. Guerrero Gil; Lima/PE
P.M. Parizel; Antwerp/BE

A-875 10:30
Introduction: Peruvian radiology: how is it going?
J.L. Guerrero Gil; *Lima/PE (jguerrero@auna.pe)*

Peru is a South American country. We are about 30 million people. Our geography is very difficult and our cities have different conditions of life. That is why we have few modern cities specially at seaside with good level of health and education facilities and many other cities in the mountains and jungle regions with not so good level. The best hospitals, clinics and universities are in the main cities. There are 25 universities in Peru, 15 of them have medical schools. There is only one national program of residency and a 3-year training of radiology is included. Approximately 10 universities in different hospitals and clinics are able to train 30 or 40 radiologists a year and most of those are in Lima. There are about 500 radiologists in Peru and almost a half of them live and work in Lima, and are not yet members of the radiology society. We do not have official programs of fellows yet, but this is not bad at all because a Peruvian radiologist usually has to resolve a lot of problems in US, CT, MRI, x-ray in thorax, abdomen, etc. in different patients such as children, adults or old patients every day and that makes them very good general radiologists. We have a few modern hospitals and clinics with modern equipment such as PET CT, MRI, CT scans and digital mammography. They are distributed in the seaside cities specially in Lima; digital mammography, ultrasounds, digital radiography are spread out in almost all the cities of the country.
Session Objectives:
1. To become familiar with the Peruvian situation in the radiological world.
2. To show some radiological tools and their distribution over the country.
3. To give some information about radiological training in Peru.

A-876 10:35
MRI findings in CNS tuberculosis
R. Marquina Diaz; *Lima/PE (rmarquina@cinternacional.com.pe)*

In Peru, tuberculosis is a major cause of morbidity in the group of young adults, 82% of TB cases reported in 2013 and 2014 primarily affected the lungs. 77% of cases were diagnosed with pulmonary TB smear positive and nearly 40% with smear with a high bacillary load (2-3 crosses). Almost 18% of cases of extra pulmonary tuberculosis and pleural location had the highest percentage (54%), lymph nodes (11.1%) and meningeal/nervous system (9%) was reported. Magnetic resonance (MR) imaging has been shown to be superior to CT in evaluating patients with suspected meningitis and its associated complications. Complications of meningitis include hydrocephalus, vasculitis, cranial nerve involvement, and associated multiple tuberculomas. Tuberculomas are among the most common intracranial mass lesions and the most common manifestation of parenchymal TB and less than 2 to 3 cm in size. Tuberculous abscess are generally larger. In tuberculous spondylodiscitis, MR imaging is currently the imaging modality of choice, given its superior ability in the detection of soft tissue and bone marrow changes. Finally, numerous conditions can mimic tuberculomas on conventional imaging. Other imaging techniques such as diffusion imaging, perfusion and MR spectroscopy may help in differentiating these conditions.
Learning Objectives:
1. To give information about the characteristics of the MRI signs of the CNS tuberculosis in Peruvian patients.
2. To understand the accuracy of the MRI signs in CNS tuberculosis.
3. To show MRI images of CNS tuberculosis simulating other pathologies.

A-877 10:55
Interlude: From Peruvian mummies to bones: use of x-rays in Peruvian archaeology (part 1)
J.L. Guerrero Gil; *Lima/PE (jguerrero@auna.pe)*

X-rays are not only useful in medicine but are also particularly useful in other studies like archaeology. We are going to show you some of those applications in the study of mummies in Paracas a Pre Inca civilization types of mummifications, some results about the uses of conventional x-ray and CT scans and differences between dry and freezing mummifications.

A-878 11:00

MRI findings in non-tuberculosis infectious diseases in the CNS

P. Tapia Puente Arnao; *Lima/PE (tapiapedro@hotmail.com)*

CNS infectious diseases in Peru are still one of the leading causes of morbidity and mortality. We still have socioeconomic barriers that have limited the physicians from offering the best diagnostic method for the patient. MRI and CT reveal structural abnormalities and play a critical role in the initial diagnosis of new onset of neurologic symptoms in general. Nowadays due to techniques like diffusion, perfusion and spectroscopy associated with clinical and laboratory tests a more detailed analysis can be made that may significantly improve the sensitivity and specificity of MRI. The role of radiology in the diagnosis of infectious diseases is enormous. We need to identify the extension of the disease, the geographic region, and evaluate response of the diseases to different treatments. There are many infectious pathogens known to cause CNS infection, including broad categories of bacteria, viruses, fungi, mycobacteria, and parasites. In most cases, it is impossible for the radiologist with certainty to identify a specific organism as the cause of an observed radiographic abnormality in the CNS. In Peru, we can see cases of infection such as *Balamuthia mandrillaris* amoeba and co-infection of rhinocerebral mucormicosis and sinonasal aspergillosis. Geographical information, exposures, and clinical information supplied in the medical record can significantly aid in developing a more specific differential diagnosis. Different areas of Peru are well known for specific infectious pathology; for example, the leading cause of late-onset seizures and epilepsy in the north of Peru is neurocysticercosis.

Learning Objectives:

1. To learn about some infectious illness of the CNS in Peru and their MRI signs.
2. To give information about the accuracy of MRI signs in infection diseases.
3. To show MRI images of CNS infections simulating other pathologies.

Interlude: From Peruvian mummies to bones: use of x-rays in Peruvian archaeology (part 2)

J.L. Guerrero Gil; *Lima/PE (jguerrero@auna.pe)*

X-rays are not only useful in medicine but are also particularly useful in other studies such as archaeology. We are going to show you some of those applications in the study of mummies in Paracas a Pre Inca civilization types of mummifications, some results about the uses of conventional x-ray and CT scans and differences between dry and freezing mummifications.

A-880 11:25

Non-diagnosed spondyloarthritis in MRI of the spine for lower back pain

J. Carpio; *Lima/PE (jeremy.carpio@resocentro.com)*

Spondyloarthropathies (SpA) include a group of long-term (chronic) diseases of joints as well as the spine and sacroiliac joints. It is divided into axial spondyloarthritis axSpA (ankylosing spondylitis AS) and peripheral spondyloarthritis. They share clinical and radiologic manifestations as well as familial aggregation and a strong association with HLA B27 antigen. Inflammatory back pain is the leading symptom of the SpA. ASAS criteria to diagnose axial SpA include MRI of sacroiliac joints to find bone marrow oedema (BME). However, MRI-identified structural lesions are not included (contradictory due to the fact that it is criteria in simple x-ray) as neither are spinal lesions. 23% to 50% of patients with ankylosing spondylitis (with disease clinically active) or “non-radiographic’’ axial SpA can have acute spinal inflammatory lesions without evidence of acute sacroiliitis by MRI. Chronic back pain is often investigated by nonrheumatologists and SI joint scanning may be excluded. On the other hand, ASAS criteria only evaluate sacroiliac joints leaving spine without evaluation. Are current criteria sufficiently capable of including all those patients with potential diagnosis of spondyloarthropathies? In any case, what can modify to achieve a greater range of sensitivity in our studies?

Learning Objectives:

1. To demonstrate that routine spine MRI for lower back pain is not sufficient for finding osteitis in spondyloarthritis.
2. To understand the MRI signs in lumbosacral spondyloarthritis.

Principles of imaging and radiation protection

A-881 10:30

Chairman's introduction

P. Vock; *Spiegel/CH (peter.vock@med.unibe.ch)*

This short introduction to the session will point out the importance of the three basic subjects covered in every radiologist's professional life. While it will not be possible to cover the full body of knowledge in each area, the speakers will discuss important principles and their application in the daily clinical work.

Session Objectives:

1. To understand the technical and methodological principles of computed tomography.
2. To understand the technical and methodological principles of magnetic resonance tomography.
3. To learn the principles of radiation biology and radiation protection.

A-882 10:36

A. Principles of computed tomography

W.A. Kalender; *Erlangen/DE (willi.kalender@imp.uni-erlangen.de)*

The introduction of x-ray computed tomography (CT) in 1972 meant the transition from conventional 2D projection imaging to superposition-free slice imaging. To understand the basic principles of CT to a certain degree, the data acquisition and the image reconstruction process will be explained in a general form. The resulting CT images do not only provide morphology but also give quantitative CT values according to the Hounsfield scale which will be explained in detail. There is an impressively broad spectrum of technical solutions and CT scanner types. It all started with single-slice imaging, was developed further into true 3D imaging by the introduction of spiral scanning approaches, and was augmented significantly by the introduction of multi-row detectors. Multi-slice imaging is today’s standard. In addition to the typical clinical scanner design, a variety of scanner types such as dual source CT and C-arm CT have to be mentioned; small dedicated peripheral CT scanners also gain increasing acceptance in clinical practice. Aspects of image quality and dose efficiency are of great importance. High spatial resolution and low image noise are contradictory goals and both may imply elevated radiation dose levels. Many innovative technical means for dose reduction are available today and are used to reduce dose at unimpaired image quality. Some important options, such as the use of optimized spectra, will be explained. Modern CT allows imaging at very high quality with effective dose values in the low mSv or even sub-mSv range.

Learning Objectives:

1. To understand the physical basis of image formation of computed tomography and of the physics of helical, multidetector and dual-source CT.
2. To learn the scale of Hounsfield units and the principle of window centre and width.
3. To become familiar with modern CT technology.
4. To understand the principles of optimising CT protocols with a focus on patient dose reduction.

A-883 11:04

B. Principles of magnetic resonance imaging

T. Metens; *Brussels/BE (tmetens@ulb.ac.be)*

Magnetic resonance imaging (MRI) is based on proton nuclear magnetic resonance (liquid NMR) inside a strong magnetic field (1.5T/3T). The tissue NMR signal is a Faraday induction in coils consecutive to radiofrequency pulse sequences. Magnetic field gradients are furthermore used in MRI to provide signal spatial encoding. The MRI signal provides an excellent soft tissue contrast. Indeed the signal intensity depends on NMR relaxation times T1 and T2 (spin-echo sequences) or T2* (magnetic susceptibility-dependent gradient-echo sequences) and soft tissue contrast occurs because relaxation times are tissue dependent. The sequence structure controls the image contrast: T1-weighted or T2-weighted (or T2*-weighted) images are commonly used for diagnostic purpose. When an inversion radiofrequency pulse precedes the main sequence by a time delay TI, a T1-based selective tissue suppression can be achieved (fat suppression in STIR, fluid suppression in FLAIR sequences). The presence of a paramagnetic agent inside a tissue shortens

the tissue T1 relaxation time and contributes to lesion detection or characterisation. The agent can be intrinsic (like methemoglobin after haemorrhage) or exogenous (intravenous injection of a gadolinium chelate). The MRI signal can be made sensitive to blood flow: flow-void in spin-echo or inflow hyper-intensity in gradient-echo sequences. Angiography is also obtained with Gd-enhanced gradient-echo sequences. Sequence structure, operator choices and tissue characteristics influence image quality, including signal-to-noise ratio and artefacts. MRI contraindications and staff or patient safety issues are mostly related to the strong magnetic field, to RF and gradient pulses or to contrast agent use.

Learning Objectives:

1. To become familiar with the physical basis of image formation in MRI including the principles of pulse sequences and relaxation times.
2. To understand the principles and main diagnostic applications for the most commonly used sequences in MRI, including T2-weighted sequences, T1-weighted sequences, STIR sequences, FLAIR sequences, other inversion recovery sequences, T2*- / susceptibility-weighted sequences and MR angiography sequences.
3. To learn typical artefacts on MR imaging and to discuss their respective causes.
4. To understand absolute or relative contraindications against MR imaging and safety issues in the MR environment with regard to patients and staff.

A-884 11:32

C. Radiation protection

M. Mahesh; *Baltimore, MD/US (mmahesh@jhmi.edu)*

The number of medical imaging procedures is growing exponentially across the globe. The overall benefit from medical imaging procedures far outweighs any associated risks. However, increasingly patients and families undergoing medical imaging are enquiring about radiation dose and risks. Hence, it is upon us as providers (radiologists, cardiologists, and any other physicians) of medical imaging studies to ensure the studies are justified and optimally performed with the focus of keeping any associated risks to a minimum. This lecture will focus on the biological effects of radiation and fundamental concepts of radiation protection applicable to both patients and staff alike. Three pillars of radiation protection, namely time, distance and shielding will be discussed with illustrations. Since there is an increasing demand from patients to know more about their radiation doses and risks, this lecture will also describe various radiation dose descriptors in CT, fluoroscopy and radiography. Finally, the lecture will summarize key radiation protection strategies for all those working in a radiation environment.

Learning Objectives:

1. To understand the phenomena of x-ray interaction with matter and the consequences for image generation, image quality and radiation exposure.
2. To become familiar with the types and magnitudes of radiation exposure from natural and artificial sources and the concepts of dose determination and dose measurement for patients, occupationally exposed personnel and the public.
3. To learn the types and magnitudes of radiation risk from radiation exposure in medicine.
4. To understand the basic principles of radiation protection, as outlined by the ICRP (International Commission on Radiological Protection).
5. To become familiar with the concepts and tools for dose management in radiology with regard to adult and paediatric patients.

E³ 25E

Still tricky after all these years

Moderator:
N. Howarth; Chêne-Bougeries/CH

A-885 12:30

A. The hila

B. Ghaye; *Brussels/BE (benoit.ghaye@uclouvain.be)*

Anatomy of the hila on plain films is generally considered as a difficult matter. Some simple anatomical landmarks are important to know to make easier interpretation of chest plain films, including the hilar angle, the infrahilar window and the normal anisomerism of both hila. Right upper lobe bronchus is eparterial and the left one is hyparterial. The left hilum is higher than the right in 97% while opacity and dimension of both hila are equivalent in about 90%. On lateral view, the right hilum and the left upper pulmonary vein are located in front of and the left hilum behind the tracheobronchial lumen. Knowing those simple findings makes easier the recognition of pathologies such as discrete lobar volume loss, small hilar lymphadenopathies or substantial congenital abnormalities that would be otherwise overlooked, including isomerism or persistent ductus arteriosus. On the other hand, knowledge of hilar and pulmonary vessels anatomy will avoid wrong diagnosis of pulmonary nodule or tumour due the 2D-projection of normal vascular structures. During this presentation, the side-by-side analysis of chest plain films and CT will present a comprehensive review of the most important anatomical and pathological findings in the hila and the proximal pulmonary vessels.

Learning Objectives:

1. To review the anatomy of the hila.
2. To learn how to identify hilar lesions.
3. To know the limitations of plain radiographic signs.

A-886 13:00

B. The mediastinum

M. Occhipinti; *Florence/IT (mariaelena.occhipinti@gmail.com)*

Hilar mass or pulmonary mass? Middle mediastinum or posterior mediastinum? Vessel or not? Normal or abnormal? CT or MRI? Many questions can arise during daily clinical practice on evaluating the complex anatomical region called mediastinum. Whether clinicians or radiologists bring up the question, the patient awaits an accurate answer. This answer is essential to address patient diagnostic workup and management. Chest radiography, CT and MRI are invaluable tools to study the mediastinum with a non-invasive approach. However, knowledge of the most appropriate technique to use in each context as well as knowledge of specific imaging signs and features are needed to narrow the differential diagnosis and to address the majority of the questions that have arisen when a mediastinal mass is either seen or suspected.

Learning Objectives:

1. To review the mediastinal anatomy according to old and new classifications.
2. To learn how characteristic features can be helpful in the differential diagnosis.
3. To know how to choose the most appropriate imaging modality according to the diagnostic question.

Infective/inflammatory disorders

F.M.H.M. Vanhoenacker; *Antwerp/BE (filip.vanhoenacker@telenet.be)*

Osteomyelitis is divided into acute, subacute and chronic osteomyelitis. Pathophysiological factors that determine imaging are patient's age, route of contamination, virulence of the causative micro-organism and the immune status of the patient. In haematogenous spread, the site and extent of the infection depends primarily on the vascularisation. The metaphysis is the common site for haematogenous osteomyelitis in children over 18 months, due to stasis of slow-flowing blood. In infants and adults, the presence of transphyseal vessels may cause spread of the infection to the epiphysis. Imaging plays a pivotal role in confirming the diagnosis of musculoskeletal infection, determining the disease extent and guiding early treatment. Plain radiography is not very sensitive for early diagnosis. Ultrasound is a reliable tool to detect subperiosteal spread in children, but its use in adults is restricted to evaluation of soft tissue infection and for aspiration of infected joints. In adults, MRI is the preferred modality, although CT may detect sequestrum formation in chronic osteomyelitis. SpA consists of a spectrum of chronic inflammatory disorders that are distinct from RA. Ultrasound is useful for grading of synovitis and early detection of erosions of peripheral joints in RA. SpA has a predilection for the axial skeleton. MRI is the preferred technique for early diagnosis and detection of active inflammatory lesions by demonstrating bone marrow oedema at the sacro-iliac joints. Two or more areas of BME or one focus of BME on at least two consecutive 3 mm slices is needed to reliably diagnose axial SpA.

Learning Objectives:
1. To learn about the pathomechanisms involved in inflammatory and infections disorders.
2. To understand the imaging appearances and their differential diagnosis in the acute, sub-acute and chronic phases of infection.
3. To become familiar with the spectrum of imaging features of inflammatory disorders in the axial and peripheral skeleton.

Chairman's introduction
C. Manelfe; *Toulouse/FR*

Session Objectives:
1. To learn relevant imaging and interventional algorithms and important imaging features of neurovascular disorders of the brain and spine.
2. To understand imaging features and prognostic implications of tumours of the brain and spine.
3. To become familiar with the role of different imaging modalities including hybrid imaging in diagnosing disorders of the central nervous system.

A-895 14:06
A. Congenital and white matter disorders of the brain
A. Rossi; *Genoa/IT (andrearossi@gaslini.org)*

Understanding of normal maturational steps and myelination is crucial for interpreting MR imaging scans of the brain in infants and children correctly. Planning of sequence parameters tailored to the water-rich brain environment of small children is also crucial for image quality. Among the several pitfalls, pineal gland cysts are extremely common in children and their significance will be highlighted. The principal features of the commonest brain malformations (corpus callosum, cortical, and cerebellar) and neurocutaneous syndromes (NF1, NF2, tuberous sclerosis, and Von Hippel-Lindau) will be discussed. Finally, a road map for differentiating congenital from acquired white matter disorders will be presented.
Learning Objectives:
1. To understand the development, normal anatomy and normal variants of the brain.
2. To become familiar with common congenital disorders of the brain and neurocutaneous syndromes.
3. To learn imaging features and differential diagnoses of white matter disease, inflammation and neurodegeneration.
Author Disclosure:

B. Neurovascular disorders and trauma of the brain
M. Forsting; *Essen/DE*

"No abstract submitted."
Learning Objectives:
1. To become familiar with the normal anatomy and normal variants of the craniocervical arterial and venous system and its relevance to interventional neuroradiology.
2. To learn the causes and imaging features of stroke, haemorrhage and other common vascular lesions of the brain.
3. To understand the imaging features of traumatic injury to the brain and spine.

A-897 15:02
C. Tumours of the brain and spine
M.M. Thurnher; *Vienna/AT (majda.thurnher@meduniwien.ac.at)*

Standardised MR brain tumour protocol is crucial for the preoperative evaluation and interpretation of postoperative changes. Brain tumour imaging objectives include: the diagnosis of brain tumour and the ability to distinguish it from non-tumoural lesions, assessment of histological grade of the tumour, delineation of the tumour borders and extension, differentiation between tumour and peritumoural oedema, and finally the evaluation of possible recurrence and therapy induced phenomena. In this lecture, the following issues will be discussed: how to distinguish between benign and malignant brain tumours; the value of different conventional and advanced MRI techniques in evaluation of CNS tumours; most common spine tumours not to miss.
Learning Objectives:
1. To understand the normal anatomy and normal variants of the spine, spinal cord and nerve roots.
2. To learn imaging features of benign and malignant tumours of the neurocranium.
3. To become familiar with the imaging features of benign and malignant tumours of the spine.

Hepatocellular carcinoma (HCC): detection, characterisation and therapeutic response

Moderators:
D. Ippolito; Monza/IT
N.N.

B-0001 10:30

Feasibility of 10-min delayed hepatocyte phase imaging using a 30° flip angle in Gd-EOB-DTPA-enhanced liver MRI for the detection of hepatocellular carcinoma in patients with cirrhosis

J. Choi, E.-S. Cho, J. Kim, Y. Choi; *Seoul/KR (justice-cjm@yuhs.ac)*

Purpose: To compare 10-min delayed hepatocyte phase imaging (HPI) using a 30° flip angle (FA) (10m-FA30) and 20-min delayed HPI using a 10° FA (20m-FA10) or 30° FA (20m-FA30) in Gd-EOB-DTPA-enhanced MRI in patients with chronic hepatitis or cirrhosis, in terms of contrast-to-noise ratio (CNR) for hepatocellular carcinoma (HCC) and detection sensitivity for focal hepatic lesions (FHLs).
Methods and Materials: 104 patients with 168 HCCs and 55 benign FHLs who underwent Gd-EOB-DTPA-enhanced MRI with 10m-FA30, 20m-FA10, and 20m-FA30 were enrolled. Patients were divided into two groups according to the Child-Pugh classification: group A with Child-Pugh A cirrhosis and group B with Child-Pugh B or C cirrhosis. CNR for HCCs and the detection sensitivity for FHLs were compared between 10m-FA30 and 20m-FA10 or 20m-FA30.
Results: In group A, the CNR for HCCs on 10m-FA30 (165.8±99.7) was significantly higher than that on 20m-FA10 (113.4±71.4) and lower than that of 20m-FA30 (210.2±129.3). However, there was no significant difference in the detection sensitivity between 10m-FA30 (95.0%) and 20m-FA10 (94.7%) or 20m-FA30 (94.7%). In group B, the CNR (54.0±36.4) for HCCs and the detection sensitivity (94.2%) for 10m-FA30 were significantly higher than those for 20m-FA10 (41.8±36.4 and 80.8%, respectively) and were not different from those for 20m-FA30 (62.7±44.4 and 93.3%, respectively).
Conclusion: The diagnostic performance of 10m-FA30 was similar to or higher than 20m-FA10 or 20m-FA30 in both groups A and B. This finding indicates that 10m-FA30 could replace 20-min delayed HPIs regardless of patient's liver function and reduce the delay time by 10 minutes.

B-0002 10:38

Assessment of gadoxetic acid-enhanced MRI phases for LI-RADS categorisation and non-invasive grading of hepatocellular carcinoma

M. Wutschke, U. Teichgräber, T. Lehmann, K. Katenkamp, T. Franiel; *Jena/DE (martin.wutschke@web.de)*

Purpose: This retrospective study evaluated the impact of transitional and hepatobiliary phase on LI-RADS classification and non-invasive grading in patients with hepatocellular carcinoma (HCC).
Methods and Materials: 61 patients with 61 histologically confirmed HCCs underwent MRI with gadoxetic acid. In all phases (arterial [AP], portal venous [PVP], transitional [TP], hepatobiliary [HP]) signal intensities (SI) of HCC and adjacent liver parenchyma were measured. For quantitative assessment ratio between SI of HCC and SI of normal liver were calculated. LI-RADS classification (LR-1 to LR-5) were done in A) LI-RADS major criterions with assessment of washout criterion only in PVP, B) same as A + ancillary feature "transitional phase hypointensity" and C) same as B + ancillary feature "hepatobiliary phase hypointensity". Histopathological HCC grading results were correlated with the SI HCC ratio (= SI mass HP / SI mass AP).
Results: None HCC was graded as LR-1 or LR-2. The inclusion of the feature "transitional phase hypointensity" led to a non-significant upgrading of 5/9 HCC from LR-3 to LR-4 (p = 0.062). The addition of the feature "hepatobiliary phase hypointensity" led to a statistical significant upgrading of 8/9 HCC from LR-3 to LR-4 (p = 0.008). None HCC with initial LR-4 was upgraded. None lesions were downgraded. The HCC SI ratios between G1 vs. G2/G3 tumours were statistically significant different (p = 0.008).
Conclusion: The addition of transitional and hepatobiliary gadoxetic acid-enhanced MRI phases improves LI-RADS categorisation. Quantitative assessment of HCC SI ratio enables non-invasive grading.

B-0003 10:46

Comparison between acoustic radiation force impulse quantification data and perfusion-CT parameters in hepatocellular carcinoma

M. Esser, S. Schneeweiß, M. Kolb, M. Kurucay, C. Ruff, K. Nikolaou, M. Horger; *Tübingen/DE (michael.esser@med.uni-tuebingen.de)*

Purpose: To find out, if ultrasound elastography of hepatocellular carcinoma (HCC) can predict patterns of tumour perfusion in volume perfusion computed tomography (VPCT).
Methods and Materials: 25 consecutive patients (mean age, 68.9; range, 51 - 85 years) with liver cirrhosis suspected of HCC underwent VPCT and acoustic radiation force impulse (ARFI) elastography the same day. Quantitative elasticity values were registered, while blood flow (BF), blood volume (BV) and hepatic perfusion index (HPI) of the HCC lesions were calculate. Additionally, we identified histologic WHO grading, lesion size and localisation. The Siemens Acuson S 3000 HELX-System with Virtual Touch™-Software and Siemens Somatom Definition Flash with Syngo® software were used.
Results: A total of 43 HCC lesions were assessed. Mean shear wave velocity was 2.6 m/s (range, 1.1 - 4.3 m/s). There was no significant linear correlation between the elasticity values and BF (p=0.751), BV (p=0.426) and HPI (p=0.437). However, elasticity values were higher, the larger the tumour was (p=0.008). Shear wave velocity declined with increasing distance of the HCC to the skin surface (p=0.028) and depending on liver segment. In addition, elasticity values were higher in less differentiated HCCs. This trend was not statistically significant (p=0.842).
Conclusion: Tissue elasticity in HCC does not correlate with the degree of tumour vascularisation, but calculated values are influenced both by the tumour size and localization inside the liver.

B-0004 10:54

Evolution of indeterminate hepatocellular nodules at initial Gd-EOB-DPTA-enhanced MRI in cirrhotic patients

F. Agnello, M. Galia, G. Sparacia, M. Miroddi, F. Midiri, G. Brancatelli; *Palermo/IT (fra.agnello@libero.it)*

Purpose: To retrospectively evaluate the evolution of indeterminate hepatic nodules at initial Gd-EOB-DPTA-enhanced MRI in cirrhotic patients.
Methods and Materials: 33 cirrhotic patients (24 males; mean age 64.9 years) with 69 indeterminate nodules (mean diameter 1.1 cm; range 0.5-2) at initial Gd-EOB-DPTA-enhanced MRI and a Gd-EOB-DPTA-enhanced MRI follow-up of at least 2 years (mean 805 days; range 745-2440) were evaluated. Indeterminate hepatocellular nodules were defined as nodules that cannot be diagnosed as HCC according to ASSLD 2010 criteria. Based on signal intensity at initial MRI, each nodule was classified into 6 groups: A) hyperintense on precontrast T1 phase (12/69); B) hyperintense on precontrast T1 and hepatobiliary phase (4/69); C) hyperintense on hepatobiliary phase (23/69); D) hypointense on hepatobiliary phase (9/69); E) hypointense on transitional and hepatobiliary phase (20/69); F) hypointense on portal-venous, transitional and hepatobiliary phase (1/69). Changes in size (disappearance, regression, no change, growth) and rate of progression to HCC were compared among groups using Chi-square test. Diagnosis of HCC was done by pathology and ASSLD 2010 criteria.
Results: 5/69 (7%) nodules (3 Group E; 2 group D) become HCC. There was no statistically significant difference in progression to HCC among groups. There was no statistically significant difference in rate of nodule disappearance (6%; 8/69); regression (4%; 7/69), no change (55%; 38/69) and growth (23%; 16/69) among groups.
Conclusion: Indeterminate hepatic nodules at Gd-EOB-DPTA-enhanced MRI in cirrhotic patients rarely progress to HCC.

B-0005 11:02

Fate of subcentimeter arterially enhancing and hepatobiliary hypointense lesions seen on gadoxetate-enhanced MRI in patients at risk of HCC

C. Park, C. An, J.-Y. Choi, M.-J. Kim; *Seoul/KR (CHANSIKAN@yuhs.ac)*

Purpose: To investigate the significance of subcentimeter (≤1 cm) arterially enhancing and hepatobiliary hypointense lesions (SAELs) found on gadoxetate-enhanced MRI in patients at risk of hepatocellular carcinoma (HCC).
Methods and Materials: Two radiologists jointly reviewed gadoxetate-enhanced MRI obtained from September 2008 to March 2013 in 2,311 patients at high risk of HCC, and found 52 SAELs that were confirmed histologically or followed by imaging over 12 months: 17 isolated SAELS in patients without accompanying HCC and 35 in patients with early-stage HCC (solitary or up to 3 nodules ≤ 5cm in size without vascular invasion). SAELs found in patients at beyond early stages were excluded. The imaging findings were compared between the malignant and benign SAELs.
Results: Of total 52 SAELs (in 46 patients), 30 (57.7%) were finally diagnosed as HCCs: 10 (58.8%) among 17 isolated SAELs and 20 (57.1%) among 35 SAELs accompanying early-stage HCCs. All HCCs were resectable with

curative intention at the time of diagnosis. Diagnostic accuracy of HCC based on imaging findings of arterial enhancement and venous-phase washout yielded the sensitivity, specificity, and positive predictive values of 83.3%, 50%, and 69.4%, respectively. Venous-phase washout was more frequently observed in the malignant SAELs than in the benign SAELs (57.7% vs. 30.6%; $P = 0.01$).
Conclusion: SAELs found on gadoxetate-enhanced MRI in patients at risk of HCC have a high malignant potential. Close observation can be an appropriate strategy for isolated SAELs. Venous-phase washout may be helpful to predict malignant SAELs.

B-0006 11:10

Hypovascular hypointense nodules on hepatobiliary phase without T2 hyperintensity on gadoxetic acid-enhanced MRI: long-term outcomes and risk factors of hypervascularisation

H. Yang, J. Song, E. Choi, E. Park; *Jeonju-si/KR (yphot@naver.com)*

Purpose: To evaluate the long-term outcome and risk factors associated with hypervascularisation in hypovascular hypointense nodules on hepatobiliary phase (HBP) without T2 hyperintensity on gadoxetic acid-enhanced magnetic resonance (MR) images in patients with chronic liver disease.
Methods and Materials: The institutional review board-approved retrospective analysis included 97 chronic liver disease patients with 222 hypovascular hypointense nodules on HBP without T2 hyperintensity on gadoxetic acid-enhanced MRI. The following MR features were analysed: nodule size, presence of fat, degree of hypointensity on HBP, degree of signal intensity on diffusion-weighted images (DWI) and T1-weighted images (T1WI). Baseline clinical characteristics were also obtained. Univariate and multivariate analysis with a Cox proportional hazard regression model was used for statistical analysis.
Results: The mean follow-up interval was 997 days (range, 137-1804 days). Of them, 41 nodules (18.5 %) became hypervascular hepatocellular carcinoma (HCC). Both univariate and multivariate Cox analysis identified that previous history of HCC, follow-up nodule size, degree of hyperintensity on T1WI and DWI were significant risk factors for hypervascularisation ($P<0.05$). The mean growth rate of hypervascularised nodule was 2.89×10^{-3}/days and 0.68×10^{-3}/days for non-hypervascularised nodule. The cumulative incidence of hypervascularisation was 3.7 % at 1 year, 12.9 % at 2 years, 21.3 % at 3 years.
Conclusion: The previous history of HCC, follow-up nodule size, degree of hyperintensity at T1WI and DWI were associated with progression to hypervascular HCC.

B-0007 11:18

Is CT perfusion a useful tool to predict response early after transarterial chemoembolisation?

D. Tamandl, F. Waneck, S. Unterhumer, A. Ba-Ssalamah, C. Loewe; *Vienna/AT (dietmar.tamandl@meduniwien.ac.at)*

Purpose: To determine the value of CT perfusion (CTP) to predict complete response early after transarterial chemoembolisation (TACE).
Methods and Materials: This prospective study was approved by the institutional review board, written informed consent was obtained from all patients. CTP was performed before and one day (interquartile range[IQR]: 1-2 days) after TACE in 18 patients. 46 lesions (41 hepatocellular carcinoma [HCC] and 5 hypervascular cholangiocarcinoma [CCC]) were amenable for analysis. Blood flow (BF), Blood volume (BV), time to start (TTS), arterial liver perfusion (ALP), portal liver perfusion (PVP) and hepatic perfusion index (HPI) were measured in all lesions, and values before and after TACE, as well as relative change was compared to clinical response on biphasic CT using mRECIST criteria 6 weeks after the procedure. Optimal cut-off values for detecting response were calculated using area under the ROC curves (AUROC). Long-term outcome was assessed using Kaplan-Meier estimates.
Results: CTP parameters were all significantly reduced after TACE in responding patients (PR, CR) while no difference was observed in non-responders. ALP_{post} was superior in prediction of CR compared to BF_{post} and BV_{post} ($AUROC_{ALP}$ 0.953 vs. $AUROC_{BF}$ 0.859 and $AUROC_{BV}$ 0.831, $p<0.001$) with a sensitivity, specificity, PPV, NPV and accuracy of 91%, 92%, 91%, 92% and 91%. Only 4/22 lesions with CR recurred with a median progression local-recurrence free survival of 22.7 months.
Conclusion: CT Perfusion is a feasible tool for early response assessment after transarterial chemoembolisation and can reliably detect lesions with complete response.

B-0008 11:26

HCC showing complete response according to mRECIST on CT after a first session of TACE: is lipiodol deposition a good predictor of local recurrence?

M. Dioguardi Burgio, M. Ronot, M. Lagadec, C. Garcia-Alba, M. Zappa, A. Sibert, V. Vilgrain; *Clichy/FR (marco_dioguardi@hotmail.it)*

Purpose: To evaluate if the lipiodol deposition pattern can predict local recurrence in hepatocellular carcinoma (HCC) nodules with complete response (CR) according to mRECIST on CT after a first session of conventional chemoembolisation (cTACE).
Methods and Materials: From January 2012 to May 2014 all consecutive patients undergoing a first cTACE for HCC were identified. Inclusion criteria were presence of ≤3 HCCs and available pre- and post-cTACE CECT. Each treated tumour response was classified according to mRECIST. The analysis focused on tumours showing CR. For them, the lipiodol deposition pattern was classified as complete (C-Lip, covering the entire tumour volume), or incomplete (I-Lip). Local recurrence was defined as the reappearance of enhancing areas on arterial phase showing washout on portal/delayed phase within 2 cm from treated tumours on follow-up CT.
Results: Final population included 50 patients (mean age 62+/-12 y; 45 male (90%)) with 82 HCCs (mean 26.8+/-14.2 mm). A total of 46 (52%) HCCs were classified as CR, including 16 (35% - mean 22.9+/-8 mm) with incomplete, and 30 (65% - mean 22.8+/-10 mm) with complete lipiodol deposition. After a median follow-up of 14 months (range 3.2-35.9 months), 15/16 (94%) and 10/30 (30%) of I-Lip and C-Lip HCCs showed local recurrence on CT ($p<0.001$). No statistical difference regarding delay of recurrence was noted between I-Lip and C-Lip HCCs (mean 334 vs 401 days $p=0.519$).
Conclusion: Despite showing CR according to mRECIST, HCCs with incomplete lipiodol deposition have a high risk of recurrence and should be considered as incompletely treated.

B-0009 11:34

Role of IVIM in the verification of response to locoregional therapy in HCC

W.R.A. Abdel Hamid, R. Salah Eldein, Y. Abbas; *Cairo/EG (w.gforever@yahoo.com)*

Purpose: Liver cirrhosis and HCC constitute an important cause of morbidity and mortality in Egypt. Our work aimed at evaluating the role of intravoxel incoherent motion (IVIM) as a non-contrast imaging biomarker in follow-up of HCC after locoregional therapy to reduce study cost.
Methods and Materials: Our study included 20 patients with liver cirrhosis accommodating 100 HFLs. They were assessed using 3T MR scanner with addition of IVIM both initially and in the follow-up after loco-regional therapy. Post-processing analysis was performed to measure IVIM parameters including D, D*, fp & ADC. fp was compared to the % of arterial enhancement of hepatic focal lesions in both initial and follow-up studies using Pearson correlation test. Moreover, we assessed the correlation between D and ADC initially and on follow-up using t test.
Results: Moderate correlation between fp and % of arterial enhancement of hepatic focal lesions ($r= 0.686$). Significant difference between fp initially and in follow-up with $P<0.01$. Better performance of D compared to ADC in follow-up studies regarding differentiating viable malignant tissue from non-malignant entities with $P=0.03$ and 0.04, respectively.
Conclusion: fp shows moderate correlation with % of arterial enhancement in differentiating well-treated lesions from residual malignancy. D value is better in assessing residual component compared to ADC. Thus, fp and D values can be considered reliable non-contrast MR tools in the verification of response to therapy.

Role of DW-MRI in the evaluation of HCC response to DEB TACE: correlation with DCE MRI

M.M.H. Faheem[1], M.I. Youssef[1], M.M. Reffat[1], I.M. Hamed[2]; [1]*Banha/EG*, [2]*Cairo/EG (dr.mohamed.yousef@fmed.bu.edu.eg)*

Purpose: Aim of study is to evaluate accuracy of DW-MRI in evaluating HCC response post-DEB TACE and compare results with DCE MRI.
Methods and Materials: 42 patients with 59 lesions underwent conventional precontrast abdominal MR, DWI, ADC map with ADC value measurement and DCE MR. According to DCE MR, the lesions have been classified into 4 groups (complete response, heterogeneous enhancement, partial nodular enhancement, diffuse enhancement groups). Qualitative DWIs and ADC values were correlated to the DCE MR findings.
Results: Upon comparing qualitative DWI findings to DCE MRI in the evaluation of HCC response to DEB TACE, it showed sensitivity of 83.9%, a specificity of 64.3%, a positive predictive value of 72.2%, and a negative predictive value of 78.3% and overall accuracy of 74.5%. The measured ADC values showed significant difference (P value <0.05) between ADC values

measured in active tumoural areas and those measured in necrotic areas with no significant difference between areas of active tumoural enhancement in the different groups. ROC analysis was performed for ADC values showing area under curve 0.7 and maximum combined sensitivity and specificity of 79% and 69.6%, respectively, at cutoff ADC value of 1.395mm²/sec.
Conclusion: DW-MRI is a useful highly sensitive technique in the evaluation of HCC response to DEB TACE, yet it has low specificity related to high number of false-positive results preventing using it solely. In addition, DWI is a reliable method in differentiation between active tumour residue/recurrence and benign perilesional enhancement.

Liver stiffness measured by 2D shear-wave elastography: prognostic values after radiofrequency ablation for hepatocellular carcinoma
D. Lee; *Seoul/KR (dhlee.rad@gmail.com)*

Purpose: Liver stiffness (LS) measured by supersonic shear-wave elastography (SWE) can estimate the degree of liver fibrosis. We prospectively evaluated the prognostic value of LS measured using SWE in patients with hepatocellular carcinoma (HCC) treated by radiofrequency ablation (RFA).
Methods and Materials: We prospectively enrolled a total of 145 patients with up to three HCCs≤5cm treated by RFA and who underwent pre-procedural 2D-SWE from January 2012 to December 2013. LS values were measured using real-time SWE (Aixplorer; Supersonic Imagine, France). After a mean follow-up of 32.2±11.5 months, we analysed overall survival (OS) after RFA using the Kaplan-Meier method and Cox proportional hazard regression model. The optimal cut-off LS value to predict OS was determined by the minimal P-value approach.
Results: During the follow-up period, 22 patients died and 11 patients underwent liver transplantation. The estimated 1- and 3-year OS was 96.4% and 85.8%, respectively. The LS value measured by 2D-SWE was a significant predictive factor for OS after RFA for HCC, as was the presence of extrahepatic metastases. The optimal cut-off LS value to predict OS was set at 13.3 kilopascal (kPa). Seventy-nine patients had an LS value ≥13.3kPa, and the estimated 3-year OS was 77.5%, compared to 96.4% in 66 patients with an LS value <13.3kPa. This difference was statistically significant (hazard ratio=5.27 [1.35-20.5]; P=0.017).
Conclusion: The LS value ≥3.3kPa measured by 2D-SWE is a significant predictive factor for OS after RFA for HCC.

Performance of high-resolution MRI in predicting tumoural response to neoadjuvant chemoradiotherapy in patients with rectal cancer
D.S. Feier, A. Cote, A. Lebovici, C. Caraiani, D. Florian, F. Epure, C. Iancu, S.M. Dudea; *Cluj-Napoca/RO (diana.feier@gmail.com)*

Purpose: To determine the performance of high-resolution MRI parameters in predicting complete tumoural response in patients with locally advanced rectal cancer treated with neoadjuvant chemoradiotherapy (CRT).
Methods and Materials: Population consisted of 52 patients with rectal cancer, who underwent pre-treatment 1.5-T MRI. Tumour ADC (DWI) measurements (10^{-3} mm^2/s), lesion site, tumour longitudinal extent, distance between lesion and puborectalis muscle, levator ani muscles infiltration, depth of extramural spread and lymph nodes involvement were appreciated. After CRT, all patients underwent complete surgical resection and the surgical specimen served as gold standard. Area under receiver operating characteristic curve (AUROC) analysis was performed to assess the discriminatory power of MRI parameters to predict complete response.
Results: Pathological complete response, partial response and no response were found in 6, 22 and 23 patients, respectively. Among analysed parameters mean ADC values, depth of extramural spread and lymph nodes involvement were independent predictors of pathological complete response (p<0.0001). Independently, pathological complete response can be predicted by mean ADC values (AUROC=0.90, Se=93.8%, Sp=73.3%), depth of extramural spread (AUROC=0.72, Se=36.73%, Sp=97.78%) and absence of lymph nodes involvement (AUROC=0.87, Se=80.82%, Sp=93.33%), respectively. Together, the three parameters can accurately assess pathological complete response with an AUROC of 0.92 (Se=79.59%, Sp=93.33%).
Conclusion: Baseline high-resolution MRI parameters have the potential to act as imaging biomarkers of tumoural response to neoadjuvant chemoradiotherapy.

B-0013 10:38

DWI predictive value of response to CRT in local advanced rectal cancer
A. Palmisano, A. Di Chiara, A. Esposito, P. Passoni, L. Albarello, A. Del Maschio, F. De Cobelli; *Milan/IT (palmisano.anna@hsr.it)*

Purpose: A complete response to CRT may candidate patients with local advanced rectal cancer (LARC) to a conservative management. Hence, the non invasive prediction of response to CRT is of pivotal importance. Aim was to assess the value of DWI in the prediction of pathological response to CRT in LARC.
Methods and Materials: 29 pts with LARC underwent 1.5T MRI before the beginning of CRT (preMRI), after 6 week of CRT (midMRI), and at the end of CRT (postMRI). High-resolution axial-T2w sequences on the three planes and DWI sequences (b:0-200-600-1000) were acquired. Cancer volume was segmented on T2w (V_{T2}) and b:1000 (V_{b1000}) images, and the percentages of modification over time (ΔV) were evaluated. V_{T2} was coregistered on ADC map, and a volumetric histogram-analysis of ADC performed. After surgery patients were classified according to Tumour Regression Grade (TRG) in Non-Responder (NR) when TRG=0-2, Partial Responder (PR) when TRG=3, and Complete Responder (CR) when TRG=4.
Results: At histopathology 8 patients were CR, 13 PR, 8 NR. A good correlation between V_{T2} and V_{b1000} was observed at each time point (p<0.01), with lower V_{b1000} values than V_{T2} (p<0.01). At multivariate analysis ΔV_{T2} >81.5% at midMRI, V_{b1000}<3 cc at postMRI and mean ADC>1,4 at preMRI resulted able to predict CR with an accuracy of 86%, 89% and 76%, respectively. At preMRI ADC was higher in CR as well as ADC skewness (p<0.01).
Conclusion: DWI may improve the MRI capability to predict the LARC response to CRT; in particular, V_{b1000} at postMRI increases its accuracy.

B-0014 10:46

The value of ADC measurements for assesing treatment response of neoadjuvant chemoradiotherapy in patients with localy advanced rectal cancer
A. Lebovici, A. Cote, D.S. Feier, C. Caraiani, D. Florian, F. Graur, C. Iancu, S. Dudea; *Cluj-Napoca/RO (andrei1079@yahoo.com)*

Purpose: To evaluate the diagnosis performance of ADC measurements in assessing treatment response to neoadjuvant chemoradiation therapy (CRT) in patients with locally advanced rectal cancer.
Methods and Materials: Forty-eight consecutive patients with pathologically confirmed rectal adenocarcinoma, who had undergone pretreatment MRI (1.5T; T2TSE/DWI) were retrospectively collected. ADC measurements based on variable b-value (50,400,800 x 10^{-3} mm^2/s) were performed using a variable ROI size and six diagnostic measurement tools were computed: min ADC, max ADC, mean ADC and their corresponding ratio with ADC values of normal rectal wall. Patients were classified as responders and non-responders according to rectal cancer regression grade. Univariate and multivariate logistic regression models were performed to predict complete response to treatment and the diagnostic performance was assessed using the area under the receiver operating characteristic curve analysis (AUROC).
Results: Mean ADC values presented significantly lower values in patients with complete response compared to those with partial or no response (692.16±43.7 vs 835.17±88.38, p<0.001) and had the best diagnostic performance (AUROC=0.91, Se=100%, Sp=82.50%, cut-off 0.758 × 10(-3) mm(2)/s) in predicting complete response after CRT.
Conclusion: Mean ADC values perform best in predicting complete response after CRT in patients with locally advanced rectal cancer.

B-0015 10:54

Locally advanced rectal cancer: predicting response to neoadjuvant chemoradiotherapy using apparent diffusion coefficient textures
L. Liu, Z. Wang, Z. Yang, E. Jin; *Beijing/CN (llh9821@163.com)*

Purpose: To evaluate whether ADC textures could predict patient with locally advanced rectal cancer (LARC) who would not response to neoadjuvant chemoradiotherapy (NCRT).
Methods and Materials: Thirty-two patients who underwent MRI including diffusion-weighted imaging at a 3.0 T system before NCRT were enrolled. Texture analysis of pre-therapy ADC mapping was performed, and a total of 135 ADC textures as well as routine mean ADC value of the primary tumour were extracted for each patient. Texture parameters and mean ADC value were compared between responsive group and non-responsive group. Receiver operating characteristic (ROC) curves were performed to evaluate the predictive performance of each significant parameter.

Results: Among the texture parameters, skewness, energy, Gabor-43, high-intensity emphasis, and low-intensity small area emphasis significantly differed between responsive and non-responsive groups (0.72 vs 0.30, p = 0.020; 0.11 vs 0.08, p = 0.045; 3.34 vs 2.19, p = 0.028; 65.67 vs 98.06, p = 0.045; 21.49 vs 8.06, p = 0.038). Further, skewness, high-intensity emphasis and low-intensity small area emphasis were identified as independent predictors for non-responders to NCRT, with areas under the ROC curves (AUC) of 0.754, 0.729, and 0.739, respectively.
Conclusion: Several texture features derived from pre-therapy ADC image could potentially be helpful to predict patients with LARC who would not response to NCRT.

DCE-MRI shows slower flow and more homogeneous vascularity in responding tumours after CRT for rectal cancer
R.A.P. Dijkhoff[1], M. Maas[1], G. Shakirin[2], D.M.J. Lambregts[1], J. van Griethuysen[1], M. Weibrecht[2], M. Perkuhn[2], M. de Boer[1], R.G.H. Beets-Tan[1]; [1]*Amsterdam/NL*, [2]*Aachen/DE* *(rebeccadijkhoff@hotmail.com)*

Purpose: To evaluate whether pre-chemoradiation(CRT) DCE-MRI can predict response to CRT in rectal cancer.
Methods and Materials: 20 patients with locally advanced rectal cancer underwent DCE-MRI with the contrast agent gadofosveset-trisodium before CRT. DCE-MRI was processed with the Intellispace Discovery research platform(Philips Healthcare). One reader delineated whole-tumour volumes on DWI. Semiquantitative DCE-parameters based on the enhancement curve(AUC(60), (AUC of)time to peak(TTP), maximum enhancement, bolus arrival time(BAT), initial signal excess (ISE), mean transit time(MTT), wash-in- and wash-out-parameters) were compared between patients with complete(CR;ypT0) or good response(GR;ypT0-2) and non-responders. Additionally, heterogeneity of DCE parameters (measured by coefficient of variance(CoV:sd/mean)) was compared.
Results: 8/20(40%) had CR. Almost all DCE-parameters were lower in CR and GR (p>0.05). MTT and BAT were higher in CR, with BAT significantly higher(p=0.015). In good responders the BAT was also significantly higher(p=0.028). Heterogeneity was higher in CR for almost all DCE-parameters, except for BAT and wash-out, that had somewhat lower heterogeneity (p>0.05). The higher heterogeneity of AUCTTP, wash-in and AUC60 in CR showed a trend towards statistical significance (p=0.062-0.099). In good responders AUC60 and TTP were significantly more heterogeneous than in poor responders(p=0.024-0.041). Washout slope(>0.05) and BAT (p=0.012) were less heterogeneous in good responders.
Conclusion: Bolus arrival time is longer and less heterogeneous in CR and GR after CRT, potentially reflecting slower but more homogeneous inflow of the contrast bolus. This could represent prolonged and more homogeneous exposure to chemotherapy and reduced hypoxia, leading to more response. Most other DCE parameters were lower and more heterogeneous in responders.

A modified 3-point MRI-predicted tumour regression grade incorporating diffusion-weighted image: locally advanced rectal cancer
B. Park, S. Cho, M. Lee; *Taegu/KR (redzon7543@gmail.com)*

Purpose: To evaluate the prognostic relevance of a modified 3-point MRI-predicted tumour regression grade (mrTRG) incorporating diffusion-weighted image (DWI) in patients with locally advanced rectal cancer (LARC) after preoperative chemoradiotherapy (PCRT).
Methods and Materials: Between March 2012 and September 2013, 118 consecutive patients with mid/lower LARC, who underwent PCRT followed by surgery, were enrolled in this retrospective study. Two radiologists in consensus assessed the mrTRG based on T2-weighted images and high b-value DWIs (0, 1000 s/mm2) using the following grade: Grade 0, good regression (no obvious tumour); Grade 1, intermediate regression (dominant fibrosis; regression > 50%); Grade 2, poor regression (dominant tumour; regression ≤ 50%). A multivariate Cox proportional-hazard regression was performed to evaluate the association of the modified mrTRG with the 3-year disease-free survival (DFS). A Kaplan-Meier analysis with a log-rank test was used to compare the DFS rate between responder (Grade 0 and 1) and non-responder (Grade 2) groups.
Results: The modified mrTRG (adjusted HR, 2.505; 95% CI 1.231 - 5.100) was independently associated with the 3-year DFS (P = 0.011). Additionally, there was a significant difference in the 3-year DFS rate between responder (73.8%; 95% CI 64.2 - 81.3%) and non-responder (41.7%; 95% CI 10.9 - 70.8%) groups (P = 0.028).
Conclusion: In patients with mid/lower LARC, the modified 3-point mrTRG incorporating DWI was independently associated with the 3-year DFS after PCRT followed by surgery. The grading scale may be used as a surrogate for expected prognosis to PCRT prior to surgery. Further prospective trials are warranted.

B-0018 11:18

Validity of MRI tumour volumetry as a biomarker in rectal cancer
E. Qasem; *Swansea/UK (eyasqasem@doctors.org.uk)*

Purpose: MRI tumour volumetry (TV) is a recently described imaging concept that may have advantages over radiological TNM staging of rectal cancer in assessing tumour response to chemoradiotherapy. This study aims to investigate the performance of TV against traditional radiological and pathological staging modalities, and introduces the novel concept of tumour volumetry to mesorectal volume ratio (TMVR).
Methods and Materials: Patients with histologically proven rectal cancer treated at a single cancer institute by surgery alone were selected from a prospective database. Axial MRI images for T2 to T4 disease were selected and transferred to an offline workstation (Prosoma ®). A single investigator delineated each axial slice for the rectal tumour and mesorectum defining the tumour (TV) and mesorectal volumes. The ratio of tumour volume to mesorectal volume (TMVR) was calculated. Correlations between the tumour volume, TMRV and tumour length were compared with MRI and pathological T staging
Results: 35 patients with rectal cancer treated without neoadjuvant therapy were analysed. A distinct correlation was observed between increasing TV and advancing ordinal T stage (p=0.027 , Logistic regression). TV correlated better with pathological T stage than radiological T stage. In particular there was improved prediction of pathological T3 subset (a-d) with volumetric over MR-T stage. Correction of TV with mesorectal volume did not improve accuracy.
Conclusion: Tumour volumetry is a promising predictor of final pathological T stage. This reflects that volumetry is a scale which potentially smooths out differences between discrete T staging categories.

Accuracy of MRI for predicting anterior peritoneal reflection involvement for locally advanced rectal cancer: prospective comparison with operation findings
K. Sim, B. Park, M. Kim, D. Sung, N. Han, S. Cho; *Seoul/KR (ha2sky@hanmail.net)*

Purpose: To assess the diagnostic accuracy of preoperative rectal MRI for rectal cancer involvement through anterior peritoneal reflection (PR) in comparison with operation findings.
Methods and Materials: This prospective study was approved by Institutional review board; informed consent was waived. Eighty-three consecutive patients (Group 1: direct surgery, n=56; Group 2: neoadjuvant CCRT and surgery, n=27) with locally advanced rectal cancer were enrolled in this prospective study. All patients underwent rectal MR imaging using 3T systems. The identification of anterior PR was assessed using a 5-point scale. The possibility of anterior PR involvement was designated as positive or negative and all radiologic assessment were obtained in independent review by two radiologists. Diagnostic accuracy of MRI was obtained by operation findings and surgical record.
Results: More than 90% patients showed relatively good anterior PR identification regardless of neoadjuvant CCRT (Chi square test, P = .580) and there was no statistical difference in two reviewers (McNemar test, P = .443). The fifteen patients (15 of 83 patients, 18.1%) were clinically suspected anterior PR involvement during surgery. The sensitivity, specificity, positive predictive value, and negative predictive value of anterior PR involvement in the preoperative MRI were 69.2%, 78.3%, 47.4%, and 90%, respectively. The diagnostic accuracy of MRI for predicting for anterior peritoneal reflection involvement was 76.3%.
Conclusion: MR assessment of tumour involvement through anterior peritoneal reflection has relatively low sensitivity and positive predictive value, although preoperative rectal MR provides accurate anatomical information regarding anterior PR with high conspicuity.

B-0020 11:34

MRI can accurately predict sphincter preservation after chemoradiation

J. Krdzalic[1], M. Maas[2], S. Engelen[3], J.J.M. Van Griethuysen[2], D.M.J. Lambregts[2], M.J. Lahaye[2], G.L. Beets[2], R.G.H. Beets-Tan[2]; [1]*Heerlen/NL*, [2]*Amsterdam/NL*, [3]*Maastricht/NL (jasenkokrdzalic@hotmail.com)*

Purpose: It is believed that chemoradiation for low rectal cancer increases sphincter preservation. Aim was to evaluate with MRI whether sphincter preservation is increased by chemoradiation and whether MRI can predict sphincter preservation after chemoradiation.
Methods and Materials: A radiologist independently evaluated the T2-weighted MRIs (in 3 directions) in 47 patients before and after CRT with tumours <5 cm from the anorectal junction (ARJ) and measured distance of the lower tumour pole to the ARJ. Also, a confidence level score for feasibility of sphincter preservation was scored (CL=0 definitely no sphincter preservation, CL4=sphincter preservation definitely possible). Likelihood for sphincter preservation before and after CRT was compared and receiver operator characteristics(ROC) curves with area under the curve (AUC) were calculated.
Results: Mean distance from ARJ increased significantly during CRT from 21±16mm pre-CRT to and 31±18mm post-CRT (P<0.001). In 42% sphincter preservation was deemed not feasible pre-CRT, which decreased to 23% after CRT. AUC for sphincter preservation based on confidence level score was 0.84(0.72-0.96), with sensitivity of 100% and specificity of 44%. Based on post-CRT height measurement AUC was 0.87(0.76-0.98), with optimal size cut-off at 26 mm (sens: 86%, spec: 71%).
Conclusion: This is the first study to show that CRT increases the distance to the ARJ and thus leads to a higher rate of sphincter preservation. MRI can accurately predict sphincter preservation after CRT.

B-0021 11:42

Organ preservation for clinical complete responders after chemoradiation for rectal cancer, does timing of selection matter?

M. Maas[1], B. Hupkens[2], M. Martens[3], M. van der Sande[1], J. Melenhorst[2], D. Lambregts[1], G. Beets[1], R.G.H. Beets-Tan[1]; [1]*Amsterdam/NL*, [2]*Maastricht/NL*, [3]*Sittard/NL (d.lambregts@nki.nl)*

Purpose: Wait-and-see policy could be offered to clinical complete responders(cCR) after neoadjuvant chemoradiation(CRT). In patients with near cCR a second restaging can be considered to evaluate whether response becomes complete. Aim was to evaluate whether timing of inclusion influences outcome, by comparing patients included for wait-and-see at initial assessment with patients who were included after a second assessment 3 months later.
Methods and Materials: (Near) CRs underwent endoscopy+MRI+DWI ±8 weeks post-CRT. 103 had typical cCR and were selected for wait-and-see (W&S-1). The other 67 patients had near cCR, 19 underwent TEM and the 48 had a second assessment after 3 months, after which 43 were included for wait-and-see (W&S-2); 5 had TME. 3-6 monthly follow-up (MRI+DWI+endoscopy) was performed. 2-year local regrowth (LR), disease-free survival (DFS) and overall survival (OS) were compared between W&S-1 and W&S2. Multivariable Cox regression analyses were performed to assess whether inclusion timing was predictive for higher LR.
Results: 2-year LR in W&S-1 was 18% and 23% in W&S-2. 2-year DFS was 82% in W&S-1 and 78% in W&S-2. 2-year OS was 99% in W&S-1 and 98% in W&S-2 (all: p>0.05). The timing of inclusion was not predictive of more local regrowth or lower DFS. All LRs were detected early, so that they could be easily salvaged with standard TME.
Conclusion: A second response assessment 3 months after the first post-CRT staging can offer wait-and-see to more patients, who would otherwise be referred for TME. However, the 2-year LR is slightly higher in the late inclusion group, but this does not affect OS.

B-0022 11:50

Air artefacts on diffusion-weighted MRI of the rectum: effect of applying a rectal micro-enema

J.J.M. van Griethuysen, E.M. Bus, M. Hauptmann, L. Molenaar, A. Kint, M.J. Lahaye, M. Maas, G.L. Beets, R.G.H. Beets-Tan, D.M.J. Lambregts; *Amsterdam/NL (j.v.griethuysen@nki.nl)*

Purpose: Diffusion-weighted imaging (DWI) is increasingly included in standard rectal MRI-protocols. Single-shot echo planar imaging (EPI) is the most commonly used DWI-method. DWI-EPI is prone to susceptibility artefacts, mainly caused by air in the rectal lumen. Aim was to assess whether application of a micro-enema can reduce these artefacts.
Methods and Materials: 50 patients were included who underwent sequential DWI-MRIs (1.5T; highest b-value b1000) during follow-up as part of a wait-and-see approach after chemoradiotherapy. Until March 2014 DWI-MRIs were acquired without bowel preparation, thereafter a micro-enema (Microlax®;5 ml) was routinely given ±15 minutes prior to the DWI-MRI. The presence/severity of air artefacts was scored by 2 readers in consensus on each b1000 DWI-scan with a confidence level, ranging from 0 (no artefact) to 5 (severe artefact). A score >= 3 (moderate-severe) was considered significant. The presence/severity of artefacts was compared between DWI-scans with/without a micro-enema. Potential confounding factors (age, gender, DWI acquisition parameters, MRI-scanner, endoscopy prior to MRI) were taken into account.
Results: In total 335 DWI-MRIs were assessed. Significant air artefacts were seen in 24.3% (no micro-enema) vs 3.7% (with micro-enema). Using binary logistic regression with samples clustered by patient, the odds ratio between the use of a micro-enema and presence of significant artifacts was 0.12 (95% CI 0.04-0.40), p=0.0005. None of the parameters assessed for possible confounding significantly altered this effect.
Conclusion: The use of a micro-enema prior to rectal EPI-DWI examinations significantly reduces the amount and severity of air artefacts, compared to examinations without bowel preparation.

Experimental ex-vivo flow studies in pig kidneys by multimodal angiography using DSA, MRA, and magnetic particle imaging

M.G. Kaul, I. Molwitz, J. Salamon, C. Jung, T. Knopp, G. Adam, H. Ittrich; *Hamburg/DE*

Purpose: Magnetic particle imaging (MPI) is a new imaging modality providing a high temporal resolution scanning magnetic particle distributions in 3D. To evaluate MPI for vessel imaging and perfusion studies a flow phantom is mandatory. To mimic in-vivo applications we established an experimental set-up and a work flow for multimodal evaluation of flow and perfusion in ex-vivo pig kidneys.
Methods and Materials: Kidneys of sacrificed pigs were perfused with heparin and saline. The main blood vessels and the ureter were connected to tubes allowing in and out flow of fluids. Flow was generated by a perfusion pump.
To minimize dislocations, kidneys were placed on a couch compatible with digital subtraction angiography (DSA), magnetic resonance imaging (MRI), and MPI. Measurements were performed in a clinical DSA (Allura, Philips), a preclinical high field MRI scanner (7T ClinScan, Bruker) and preclinical MPI scanner (Bruker/Philips). With each modality a dynamic sequence was performed and a dedicated DSA/MRI contrast agent (Imeron 300, Bracco) / (Ominscan, Ge Healthcare) and MPI tracer (Resovist, Bayer-Schering) was standardized injected by the pump.
Results: It was feasible to detect in and out flowing contrast agents/tracer and to produce angiograms with all three systems. Because flow can be steered temporal resolution can be traded for spatial resolution in MRI. Perfusion experiments for diffusion weighted intra voxel incoherent motion analysis are feasible as well.
Conclusion: Flow phantoms are essential when evaluating imaging and image analysis techniques. An experimental flow phantom was successfully established and will serve in future for detailed analysis procedures.

B-0024 10:38

The application of fat-water single-echo Dixon acquisition to time-resolved contrast-enhanced MRA

S. Riederer, E. Stinson, J. Glockner, J. Trzasko, P. Young; *Rochester, MN/US (riederer@mayo.edu)*

Purpose: Describe how fat-water decomposition using single-echo Dixon acquisition can be applied to time-resolved contrast-enhanced MR angiography (CE-MRA) for fat suppression.
Methods and Materials: The Dixon technique of fat-water decomposition has recently been applied to CE-MRA to eliminate background signal from fat and reduce the motion-induced misregistration artifacts. The first of these matches the performance of standard subtraction of pre- from post-contrast time frames ("time subtraction") while the second is an advantage over time subtraction methods. Such Dixon imaging has previously been performed using two echoes. Compared to time subtraction this requires double the amount of data and can also prolong the repetition time, TR. In this work we describe how the Dixon technique using a single echo can be applied to CE-MRA. The echo time is intentionally chosen so that water and fat are out of phase by 90 degrees. Corrections for other effects such as B_0 inhomogeneity are made using a pre-contrast calibration which also includes determination of coil sensitivities. The method was studied analytically and implemented experimentally.

Results: Results in phantoms demonstrate the feasibility of the technique. Results acquired in vivo in the lower extremity with 10 sec frame times show the ability of the method to reliably provide fat suppression over a large field of view. The increased intrinsic signal-to-noise ratio (SNR) of single-echo Dixon vs. that of time subtraction is shown in improved portrayal of small, enhancing vessels.
Conclusion: Fat suppression can be performed in time-resolved CE-MRA using the Dixon technique with a single echo.

B-0025 10:46

Getting rid of the grind: automated analysis of large quantity data and intraindividual stability on MRI aortic blood flow measurements for vascular age assessment

A. Knorr[1], T. Re[1], B. Stieltjes[1], D. Yates[2], R. Schmieder[3], J. Bremerich[1], T. Heye[1]; [1]*Basle/CH*, [2]*Cambridge, MA/US*, [3]*Erlangen/DE (alexander.knorr@usb.ch)*

Purpose: Aortic blood flow (ABF) characteristics are useful indicators for structural and functional vascular changes. We assessed the capabilities of an in-house developed algorithm to automatically analyze ABF curves obtained from MRI and to evaluate intraindividual curve stability over time.
Methods and Materials: 101 patients (70 male, age 60±11yrs.) were included from a multicenter trial on antihypertensive treatment. All patients underwent 3 standardized cardiovascular 3T MRI scans (0, 12, 52wks.). ABF in ascending and descending aorta was measured using semi-automatic analysis software on axial phase-contrast scans. Flow measurements were evaluated for all 303 examinations for 40 curve-defining characteristics using a sophisticated algorithm. Intraindividual ABF variability over time was characterized by full width half maximum (FWHM), peak acceleration and systolic area under the curve (AUC) coefficient of variation (COV). Observer-results-dependence was assessed by five observers for 45 patients.
Results: The automated analysis tool was able to process ABF curves for 303 examinations with speed and accuracy. Calculation of the entire data took 2.6s for 40 curve parameters in each data set including various time periods, functional ratios and AUCs. Median FWHM, peak acceleration and systolic AUC COV in the ascending aorta were 8.44%, 7.13% and 7.57% (range 0-31.96%, 0-24.80% and 0.63-28.06%). Median intra- and inter-observer COV was 0.67% (range 0.48-1.20%) and 1.54%.
Conclusion: Fully automated curve analysis facilitates evaluation of ABF data, enabling scalable and fast analysis thus shifting radiologist's time and focus from time-intensive manual evaluation to data interpretation. ABF characteristics show clear stability over time independent of the observer.

B-0026 10:54

Is there more to aortic flow curves than meets the eye? - MRI blood flow analysis of large quantity data as a substitute marker for vascular age assessment

A. Knorr[1], T. Re[1], B. Stieltjes[1], D. Yates[2], R. Schmieder[3], J. Bremerich[1], T. Heye[1]; [1]*Basle/CH*, [2]*Cambridge, MA/US*, [3]*Erlangen/DE (alexander.knorr@usb.ch)*

Purpose: Aortic blood flow (ABF) characteristics are useful indicators for structural and functional vascular changes. In this study we assessed ABF curve parameters of a large number of magnetic resonance imaging (MRI) measurements to assess their potential as substitute markers for aortic stiffness.
Methods and Materials: A subset of 101 adult patients (70 male, age 60±11 yrs) with essential arterial hypertension were included from a multicenter trial (3 sites, 140 patients total) on antihypertensive treatment. All patients underwent cardiovascular 3T MRI with a standardised imaging protocol at 3 different time points (0, 12, 52 wks). ABF in the ascending and descending aorta was measured by one reader using semi-automatic analysis software on axial phase-contrast scans (100 frames/RR-interval). Aortic stiffness was estimated via aortic strain calculations on maximum/minimum area measurements on cine gradient-echo scans. The flow measurements were then evaluated for all 303 examinations simultaneously for several curve-defining characteristics using a sophisticated Python algorithm. Pearson's product moment correlations and clustering between variables was done in RStudio.
Results: Peak acceleration, systolic, acceleration and deceleration time, as well as areas under the curve before and after peak flow of the ascending aorta emerged as significantly correlated to strain in the proximal descending aorta (r=0.44, -0.40, -0.37, -0.19, -0.27 and -0.23; p<0.001).
Conclusion: ABF measurements are a simple, reproducible and fast technique compared with other approaches to obtain aortic strain or stiffness and shows promise as a substitute marker for vascular age/aortic stiffness thus facilitating long-term prediction of vascular health.

B-0027 11:02

Dual-energy CT angiography in peripheral arterial stents: an investigation of optimal scanning protocols with regard to image quality and radiation dose

A.M. Almutairi[1], Z. Sun[2], Z. Al Safran[1], S.A. Al Zaabi[1]; [1]*Dammam/SA*, [2]*Perth/AU (aa1ss@hotmail.com)*

Purpose: To determine optimal scanning protocols of dual-energy computed tomography angiography (DECTA) in terms of radiation dose and image quality at different keV levels compared with conventional computed tomography angiography (CTA) in patients treated with peripheral artery stents.
Methods and Materials: Twenty-nine patients with prior stent placement in peripheral arteries were evaluated with DECTA. Images were reconstructed with virtual monochromatic spectral imaging (VMS) at 65, 68, 70 and 72 keV and adaptive statistical iterative reconstruction (ASIR) at 50% compared with CTA. Image quality comprising image noise, SNR and CNR were assessed and radiation dose were compared.
Results: A total of 56 identified stents, which were located in the main formal peripheral arteries were evaluated. At subject's level, the results show that DECTA (VMS) had less noise than the CTA for CIA, EIA and SFA stents, with lowest noise at 72 keV. In addition, the VMS set had greater SNR than the CTA for the EIA stents (P< 0.05); and that the VMS set had greater CNR than the CTA for CIA, EIA and SFA stents (P< 0.001). Also, with respect to CT attenuation, VMS continued to outperform CTA, but to a lesser extent. At between subjects level, average VMS noise varied significantly with the type of stent (P=0.025) for CIA stents. Radiation dose was highly significant between DECTA and CTA scans (P< 0.0001).
Conclusion: An optimal scanning protocol consisting of 72keV and 50% ASIR leads to better image quality for DECTA in peripheral arterial stenting when compared to CTA.

B-0028 11:10

High pitch sub-second chest CT angiography using third-generation dual-source CT scanner: intra-patient comparison with standard acquisition

F. Sodagari, H. Savas, R. Agrawal, A. Arslanoglu, V. Yaghmai; *Chicago, IL/US (Rishi.Agrawal@nm.org)*

Purpose: To evaluate image quality and contrast attenuation in chest CT angiography (CTA) on a third-generation dual-source CT scanner using high-pitch mode.
Methods and Materials: Fifty-four patients underwent chest CTA for pulmonary emboli evaluation. Previous chest CTA studies of the same patients on standard-pitch were used for comparison. Main pulmonary artery attenuation, overall image quality, vascular opacification, noise, CNR, and DLP were compared.
Results: Of 54 scans with standard-pitch, 42 scans (77.8%) had been performed with 100kV and 12 scans (22.2%) with 120kV. On high-pitch protocol, patients had been scanned with lower kV (30/54, 56%), same kV (12/54, 22%), or higher kV (12/54, 22%), compared to the standard-pitch protocol. Acquisition time was less than a second for all high-pitch CTAs (mean, 0.48±0.06s). The overall mean percentage radiation reduction on high-pitch for lower, same, and higher kVs was 64.7±10.8%, 57.5±13.7%, and 19.5±20.2%, respectively. In 12 patients with similar kVs at both scans, high- and standard-pitch scans had comparable attenuation (327.5±146.6 vs 298.5±95.8HU; P=0.35) and noise (22.3±6.4 vs 22.7 ±7.2; P=0.86). Vascular opacification score on high-pitch (4.1) was significantly higher than standard-pitch (3.5) (P=0.002). Overall image quality was acceptable for both high- and standard-pitch scans (3.8 vs 3.9; P=0.67). Mean CNR on high-pitch (12.0±6.4) and standard-pitch (13.4±5.9) was comparable (P=0.41). Mean DLP on high-pitch (219.0±116.2 mGy-cm) was significantly lower than the standard-pitch (555.5±282.4) (P=0.001).
Conclusion: High-pitch chest CTA with third-generation dual-source CT scanner provides excellent pulmonary artery visualisation at lower radiation dose with short acquisition times and without compromising the image quality.

4D flow can visualise and quantitatively analyse the characteristic reflection flow in infrarenal aorta and suction flow in renal arteries during diastole

M. Sugiyama[1], Y. Takehara[2], M. Alley[3], T. Wakayama[4], H. Nasu[1], S. Yamashita[1], A. Nozaki[4], H. Kabasawa[4], H. Sakahara[1]; [1]*Hamamatsu/JP*, [2]*Nagoya/JP*, [3]*Stanford, CA/US*, [4]*Hino/JP (m-sugi@hama-med.ac.jp)*

Purpose: Fusiform aneurysm is more commonly seen in infrarenal abdominal aorta (AAA), but hardly seen in descending thoracic aorta. We hypothesize that this is due to the characteristic flow dynamics in this specific portion affected by

the reflection flow from the common iliac arteries (CIAs) and suction by renal arteries (RAs) at diastole. Since inconsistent flow dynamics create fluctuated wall shear stress, the endothelium eventually stimulates atherosclerotic drive (J Biomech28(12):1515,1995). The purpose of our study is to quantitatively and visually analyse this characteristic blood flow dynamics that makes this area prone to atherogenic AAA using 3D cine PC MR imaging (4D-Flow).
Methods and Materials: 15 patients (40-84 y.o.) underwent 3.0T MRI including 4D flow and Gd-3DMRA. The maximum and minimal blood flow volume was measured at sections in supra and infrarenal abdominal aorta, celiac artery, superior mesenteric artery, RAs and CIAs. Streamlines within the supra and infrarenal aorta was visually assessed.
Results: The average minimal diastolic blood flow within suprarenal aorta was antegrade (11.93 +/- 6.74ml/sec), whereas that of infrarenal aorta was retrograde (-6.33 +/- 7.17ml/sec). The average minimal diastolic blood flow within RAs and other mesenteric arteries were antegrade. The average minimal diastolic blood flow of CIAs was negative, reflecting the reflection wave. Streamlines of infrarenal aorta depicted more turbulent flow than that of suprarenal aorta during diastole.
Conclusion: The retrograde flow due to RA suction and the reflection wave from the CIAs may be responsible for inconsistent flow within the infrarenal aorta, which may develop atherogenic AAA.

Differences in MRI and tonometry measured pulse wave velocity: effect of arterial composition, arterial length or technique bias?
J. Weir-McCall, A. Thakur, D. Cassidy, F. Khan, S. Matthew, H. Colhoun, J. Belch, G. Houston; *Dundee/UK (jweirmccall@doctors.net.uk)*

Purpose: Carotid-femoral pulse wave velocity (cf-PWV) and MRI-PWV show good correlation, but with a significant bias of 2m/s difference between the techniques across studies. The aim of the current study was to evaluate whether the differences between cf-PWV and MRI-PWV can be accounted for by inaccuracies of currently used distance measurements.
Methods and Materials: 109 study participants underwent cf-PWV and whole body MR angiography (WBMRA). 80 participants also underwent MRI-PWV. cf-PWV_{EXT} was performed using tonometric measures at the carotid and femoral arteries. WBMRA was performed on a 3T scanner using a dual bolus contrast injection of gadoteric acid and a 4-station acquisition protocol. From this, a true intra-arterial pathlength from the bifurcation of the common carotid to the aortic arch was measured. This MRA derived distance was then used to recalculate the cf-PWV_{EXT} to give a cf-PWV_{MRA}.
Results: MRI-PWV was significantly lower than cf-PWV_{EXT} (MRI-PWV= 8.8±3.4 vs. cf-PWV_{EXT} =10.77±2.67ms^{-1}, p<0.001). When cf-PWV was recalculated using the inter-arterial distance from WBMRA, this difference was lost (MRI-PWV=8.41±3.43ms^{-1} vs. cf-PWV_{MRA} 8.96±2.15 ms^{-1}, p=0.14). Recalculation of the cf-PWV using this MRA arterial distance also improved the correlation of PWV with age (cf-$PWV_{EXT:}$ r=0.49, p=<0.001; cf-PWV_{MRA}: r=0.59, p=<0.001) and global atheroma burden as measured on WBMRA (cf-$PWV_{EXT:}$ r=0.39, p=<0.001; cf-PWV_{MRA}: r=0.42, p=<0.001).
Conclusion: Differences in cf-PWV and MRI-PWV can be predominantly explained by inaccuracies introduced by the use of simple surface measurements to represent the convoluted arterial path between the carotid and femoral arteries. Correction of this also improves the association between cf-PWV and age and arterial atheroma burden.

B-0031 11:34

Optimising contrast media injection protocols in CT angiography at different tube voltages: evaluation in a circulation phantom using third generation dual-source CT
D. De Santis[1], U.J. Schoepf[1], D. Caruso[2], M. Eid[1], M.H. Albrecht[1], A. Varga Szemes[1], V.W. Lesslie[1], C.N. De Cecco[1]; [1]*Charleston, SC/US*, [2]*Latina/IT (domenico.desantis@hotmail.it)*

Purpose: To investigate the minimum iodine delivery rate and contrast media volume required for diagnostic contrast enhancement of 350 HU in the ascending aorta at different kV settings.
Methods and Materials: Dynamic CT acquisitions from 70 to 150 kV were performed in a circulation phantom. First, injections with iodine delivery rate ranging from 0.1 grams of Iodine/second (gI/s) to 2.0 gI/s were tested for each kV. In the second part, the iodine delivery rate was held constant with the contrast media volume reduced from 50 to 10 mL. Diagnostic aortic peak enhancement for each kV was compared using the Kruskal-Wallis test. A $p<0.05$ was considered statistically significant.
Results: The mean aortic peak enhancement for all diagnostic iodine delivery rates was 368.7±11.1 HU. Diagnostic iodine delivery rates returned similar aortic peak enhancement values for all protocols (all $p \geq 0.18$). For the second part of the study, a diagnostic enhancement was yielded by using a minimum of 30 mL of contrast media for 110 kV, 25 mL for 100 kV and 90 kV, 15 mL for 80 and 70 kV.
Conclusion: Our study suggests that a differentiated approach reducing the contrast media volume for tube voltages <120 kV and increasing the iodine delivery rate for higher kV settings seems the most effective approach.

U.J. Schoepf: Consultant; Guerbet. Research/Grant Support; Astellas, Bayer, Bracco, GE, Medrad, Siemens. **A. Varga Szemes:** Consultant; Guerbet. **C.N. De Cecco:** Consultant; Guerbet. Research/Grant Support; Siemens.

B-0032 11:42

Radiologic and biochemical correlates of arterial stiffness in patients with peripheral artery disease and in clinically healthy subjects
M. Zagura, J. Kals, M. Serg, P. Kampus, M. Zilmer, M. Jakobson, E. Unt, J. Eha; *Tartu/EE (Maksim.Zagura@kliinikum.ee)*

Purpose: Arterial stiffness is an independent predictor of cardiovascular outcome in patients with atherosclerosis. Angiographic score (ASc) reflects severity of atherosclerosis in patients with peripheral artery disease (PAD). Osteopontin (OPN) and oxidized LDL (oxLDL) are involved in the pathogenesis of atherosclerosis. The aim of the present study was to evaluate the association between arterial stiffness, ASc, serum OPN, and oxLDL in patients with symptomatic PAD and in clinically healthy subjects.
Methods and Materials: We studied 79 men with symptomatic PAD (mean age 64±7 years) and 84 healthy men (mean age 63±8 years). Calculation of the ASc was based on severity and location of atherosclerotic lesions in the arteries of the lower extremities. Aortic pulse wave velocity (aPWV) was evaluated by applanation tonometry using the Sphygmocor device. Serum OPN and oxLDL levels were determined by ELISA.
Results: The aPWV (10±2.4 vs. 8.4±1.7 (m/s); p<0.001), OPN (75 (62.3-85.8) vs. 54.8 (47.7-67.9) (ng/ml); p<0.001), and oxLDL (67 (52.5-93.5) vs. 47.5 (37-65.5); p<0.001) were different for the patients and for the controls. In multiple regression models, aPWV was independently determined by ASc, log-OPN, log-oxLDL, and eGFR in the patients (R^2=0.44; p<0.001) and with log-OPN, log-oxLDL, age, and heart rate in the controls (R^2=0.38; p<0.001).
Conclusion: The independent relationship of aPWV with ASc and serum levels of OPN and oxLDL in the patients with PAD indicates that radiologic severity of atherosclerosis as well as OPN and oxLDL might influence arterial stiffening in patients with atherosclerosis.

B-0033 11:50

Investigation basis for the resistive factors in blood circulation by MRI and CT
G. Beraia, M. Beraia; *Tbilisi/GE (beraiaguram@gmail.com)*

Purpose: Purpose of the study is, to identify the reason for the formation of the restrictive factors in blood flow: inertial flow in aorta and vena cava, high turbulence and resistivity associated with the pulsatile blood flow at the branching, extraction of the lymph from the blood, with the increasing erythrocyte aggregation in the venous blood flow.
Methods and Materials: Blood flow velocity measurements were made in the ascending, thoracic aorta and inferior vena cava of 35 adult normal subjects (15 men, 20 women, age 21-49 years) with the use of Magnetic Resonance Angiography. Blood mean density (HU) was measured by the CT scanner at the same levels. Blood flow pulsatility index and density were carried out.
Results: Pulsatility index for the ascending aorta - 6.0±0.3, thoracic aorta - 4.3±0.2, inferior vena cava - 1.2±0.1. (P<0.01). Blood density (HU) ascending aorta - 57.3±3.5, thoracic aorta - 35.7±3.1, inferior vena cava -59.3±3.3 (P<0.05).
Conclusion: Heart energy is stored in the elastic deformation of the blood cells and large vessel walls, in kinetic energy of the blood flow. Elasticity of the structure is associated with the inertiality. Inertial blood flow due to oscillation in the large arteries, transforms to the flow with high fluidity in capillaries - entropy of the system increases and changes Gibbs free energy, enabling chemical reaction to proceed spontaneously. In the venous blood flow, low oscillation with the reduced amount of the plasma and increased erythrocyte aggregation, decreases entropy of the system.

Transarterial bland embolisation for HCC using cyano-acrylate glue and 40-100µm microspheres
E. Lanza, V. Pedicini, D. Poretti, M. Tramarin, R. Ceriani, F. Procopio, D. Del Fabbro, M. Donadon, G. Torzilli; *Rozzano/IT (vittorio.pedicini@humanitas.it)*

Purpose: To present a modified technique of TAE for HCC, using both microspheres and cyano-acrylate glue. To report on its feasibility and effects on disease progression and tumour devascularisation.
Methods and Materials: Inclusion criteria were: a) HCC according to the AASLD criteria, b) unsuitable for surgery and c) multidisciplinary consensus on performing TAE. Exclusion criteria were: 1) Child-Pugh C, 2) GI bleeding, 3) encephalopathy and 4) portal thrombosis. All patient underwent preoperative MDCT or CE-MRI. TAE was performed entering the artery feeding the tumour, sparing the most healthy liver. Cone-beam CT was used for confirmation. After full embolisation with 40 or 100µm microspheres, a mixture of averagely 0.3mL cyano-acrylate/Lipiodol in a 1:10 ratio was injected. Follow-up was at 30days, 3months and every 6months. Response rates were assessed with mRECIST criteria.
Results: Between 2013 and 2016, 64 patients and 78 HCCs were treated. Overall survival was 93%; 54 patients at one year follow-up resulted in 24 complete responses (44%), 20 partial responses (37%), 4 stable disease (7%) and 16 progressive disease (30%). Forty-six tumours were completely devascularised at 1 year control (71%), 17 had a residual supply (26%), two did not show any devascularisation (3%). One case was complicated by a late-onset abscess of the treated lesion; another patient had postoperative pancreatitis. Both complications were treated conservatively.
Conclusion: TAE with microspheres and cyano-acrylate glue for HCC is safe and feasible, offering desirable rates of one-year disease control and tumour devascularisation. These appear in line and in some cases better to those reported in the current literature for standard TAE.

B-0035 10:47
Tumour response and survival outcomes of very small drug eluting beads used in trans-arterial chemoembolisation for unresectable hepatocellular carcinoma
A.M.K. Abdel Aal, S. Moawad, M. Hanaoka, S. Tatum, B. Jackson, C. Baalmann, N. Ertel, A. Abouarab, S. Saddekni; *Birmingham, AL/US (akamel@uabmc.edu)*

Purpose: The purpose of the study is to evaluate the tumour response rate and survival outcomes of a transarterial chemoembolisation (TACE) of unresectable hepatocellular carcinoma (HCC) using 75 microns Oncozene (Boston Scientific, MA, USA) drug-eluting beads (DEB).
Methods and Materials: We retrospectively reviewed the medical records and radiologic studies of 109 patients who had their first TACE for HCC between November 2013 and August 2016 using 75 microns Oncozene DEB. The primary endpoint of the study was tumour response rate which was categorised according to mRECIST and the toxicity profile using Common Terminology Criteria for Adverse Events (CTCAE) version 4.0. The secondary endpoint was patient survival.
Results: The study included 89 (81.7%) males with a mean age of 64.1 years. Overall tumour response was 23% complete response (CR), 66% objective response (OR) and 90% disease control (DC). CR, OR and DC were 27%, 64%, and 89% respectively in Child-Pugh A patients, and 27%, 72% and 92% respectively in BCLC stages A and B patients. CR, OR and DC were 15%, 71% and 91% respectively in Child-Pugh B and C patients, and 16%, 55% and 87% respectively in BCLC stages C and D patients. Grades 3 toxicity was seen in 10% of the patients and only 1 with grade 4. The 6, 12 and 18-month survival were 97%, 84%, and 72% respectively.
Conclusion: The present study shows very good tumour response rate and survival outcomes for TACE using 75 microns Oncozene DEB, with very low toxicity profile.

Evaluation of a newly developed biodegradable embolic agent for transcatheter arterial embolisation in a rabbit renal model
H. Wittgenstein, M. Stechele, J. Breinl, J. Schnorr, B. Rudolph, C. Schmidt, B. Hamm, R. Günther, F. Streitparth; *Berlin/DE (h.wittgenstein@gmx.de)*

Purpose: Evaluation of embolic effect, biocompatibility and biodegradability of a novel temporary embolic agent
Methods and Materials: Superselective embolization of the lower kidney pole was performed with bland (n=15) and SPIO-loaded (n=9) polydioxanone microspheres (90-500 µm) in 24 New Zealand White rabbits (female; 2,5-3,5 kg; 12-16 weeks) under fluoroscopy. Embolization effect was evaluated on DSA and MRI (T1-TSE pre/post-contrast, T2-TSE, T2*-GRE). 4 animals were sacrificed immediately after embolization. 20 animals underwent control angiograms and MRI 1 (n=3), 4 (n=3), 8 (n=3), 12 (n=8) and 16 weeks (n=3) post embolization. Final angiograms were compared with post-embolization angiograms for evaluation of embolization success and arterial reperfusion. Kidneys were harvested for histopathological analysis of embolic effect, biocompatibility and biodegradability.
Results: Evaluation of imaging modalities showed successful target embolization in 18/20 animals. In 2/20 animals the whole kidney was affected due to reflux. T2*-GRE images demonstrated the distributon of SPIO-loaded microspheres. Comparison of angiograms showed evidence of partial and complete reperfusion in 93 %. Macro- and microscopic pathological analysis revealed cell necrosis/infarct in the embolized areas. A mild acute inflammatory reaction was detected throughout and a foreign body reaction at advanced time intervals. The microspheres were increasingly degraded at sixteen weeks (Ø degradation score: 2,92/3).
Conclusion: Novel bioresorbable microspheres led to an effective occlusion of target vessels while simultaneously demonstrating good biocompatibility. The agent appeared extensively reabsorbed at sixteen weeks, thus offering advantages as a temporary embolic agent. SPIO-loaded microspheres allowed a non-invasive visualization of the microsphere distribution in MRI.

Evaluation of the effectiveness of transpulmonary chemoembolisation (TPCE) and intraarterial chemoperfusion (TACP) in treatment of colorectal lung metastases
A.I. Mekkawy[1], A. Hassan[1], M. El-Sharkaway[1], H.M. Kamel[1], D.B. Thabet[1], N.E. Nour-Eldin[2], N.N.N. Naguib[2], T.J. Vogl[2]; [1]*Assiut/EG*, [2]*Frankfurt a. Main/DE (time_dr@yahoo.com)*

Purpose: To assess the response, mean time to progression and mean survival time for patients with colorectal lung metastasis after palliative TPCE and TACP.
Methods and Materials: This study included 45 patients (mean age 57.3 ±13 years; 21 females, 24 males) with unresectable colorectal lung metastases, who failed or refused systemic chemotherapy, and underwent either repetitive TPCE (Group1; n= 16), TACP (Group2; n= 9) or both techniques (Group3; n= 20), between 2006 and 2015. Bilateral lung involvement was seen in 95.6% of patients and the median number of lung nodules was 14. Patients who underwent subsequent ablation were excluded. Chemotherapeutic agents were applied either through the pulmonary artery followed by embolisation (TPCE) or by means of intra-aortic chemoperfusion (TACP). The response according to Response Evaluation Criteria in Solid Tumours (RECIST 1.1) was evaluated and survival parameters were statistically analysed.
Results: After evaluation of the tumour response; partial response (PR) was 4.5% (n=2), stable disease (SD) 62.2% (n=28) and progressive disease (PD) 33.3% (n=15). The estimated mean survival time and mean time to progression were 21 months (±2.7 SE) and 5.5 ± 0.5 months, respectively. The mean survival time was significantly ($P < 0.05$) higher in Group3 with mixed treatment (27.8 ± 7 months) than the other two groups; Group1 and Group2 (18.9 ± 4.2 months and 14.2 ± 4.7 months, respectively).
Conclusion: TPCE and TACP could be a promising palliative treatment with acceptable survival for patients with colorectal lung metastases who failed or are not eligible for other treatment options.

B-0038 11:11

Effectiveness of intra-arterial steroid administration (IASA) for the treatment of steroid-refractory acute gastrointestinal GvHD

V. Bérczi, A. Tóth, J. Fábián, P. Reményi, T. Masszi; *Budapest/HU (Berczi@hotmail.com)*

Purpose: The aim of this study was to retrospectively assess clinical effectiveness of intra-arterial steroid-administration (IASA) treatment in adult patients, non-responsive to systemic corticosteroids, with grade III or IV GI-aGvHD.
Methods and Materials: Clinical data of 10 adult patients (age range, 19-61 years; mean age, 42 years) with GI-aGvHD (≥grade III) non-responsive to intravenous methylprednisolone (at least 2 mg/kg/day) and received IASA into the superior and/or inferior mesenteric artery between March 2015 and January 2016 were collected. The severity of acute GvHD was determined according to the Glucksberg grading system before, 12±3 [SD], 27±4 and 54±6 days after IASA. Long-term outcomes were also recorded in 4 cases (range, 87-370 days; median, 246 days).
Results: Seven patients had grade IV and 3 patients had grade III aGvHD prior to IASA treatment, with 4 patients having stage II, 2 patients having stage III, and 4 patients having stage IV gastrointestinal involvement. After IASA treatment 6 patients at 12 days, 7 patients at 27 days, 5 patients at 54 days had gastrointestinal response. Among them, 1 patient at 12 days, 4 patients at 27 days and the same 4 patients at 54 days showed complete remission of GI-aGVHD. Seven patients were alive 54 days after treatment. At follow-up evaluation time, 5 patients were alive. Among the 4 patients who were discharged from the hospital, 3 had no gastrointestinal symptoms, 1 patient had complains about occasional symptoms.
Conclusion: IASA treatment seems to be an effective second-line treatment in adult patients suffering from steroid-refractory GI-aGvHD.

B-0039 11:19

Adjuvant stereotactic body radiotherapy following transarterial chemoembolisation using small diameter drug eluting beads in patients with unresectable hepatocellular carcinoma

A.M.K. Abdel Aal, S. Moawad, M. Hanaoka, A. Abouarab, S. Tatum, K. Mahmoud, R. Jacob, B. Jackson, S. Saddekni; *Birmingham, AL/US (akamel@uabmc.edu)*

Purpose: The purpose of this study is to assess tumour response and locoregional control in patients with unresectable intermediate-stage hepatocellular carcinoma (HCC) treated with transarterial chemoembolisation using small diameter drug-eluting beads (DEB-TACE) compared to DEB-TACE followed by adjuvant stereotactic body radiotherapy (DEB-TACE-SBRT).
Methods and Materials: We retrospectively reviewed the medical records of patients with HCC and tumour size ≥3cm between November 2013 and June 2016 who underwent DEB-TACE using 75µm Oncozene beads (Boston Scientific) (n=56) or DEB-TACE-SBRT using 45Gy over 3 fractions (n=12). Tumours response was assessed using m-RECIST criteria.
Results: There were no significant baseline differences between the two groups. The number of lesions was not statistically significant between the 2 group (p=0.771). However, the diameter of the largest lesion as well as the total tumour diameter was larger in the DEB-TACE group (p=0.025 and 0.006 respectively). The tumour response according to mRECIST criteria did not show any significant difference between the 2 groups (p=0.251). After censoring for liver transplantation, the DEB-TACE-SBRT group showed better progression free survival (PFS) of 18 months compared to 9 months in the DEB-TACE group (p=0.006).
Conclusion: The study suggests that in patients with HCC of ≥3cm, treatment with DEB-TACE-SBRT provides better locoregional control with longer PFS, compared to DEB-TACE. Further prospective randomised controlled trial with larger number of patients is required to validate these results and to determine if there is an overall survival advantage.

Extended liver venous deprivation: the most powerful interventional radiology technique for liver preparation before major hepatectomy?

B. Guiu, L. Escal, L. Piron, M.-A. Pierredon, E. Deshayes; *Montpellier/FR (b-guiu@chu-montpellier.fr)*

Purpose: Relatively high rates of post-hepatectomy liver failure (PHLF) have been reported after portal vein embolization (PVE) or ALPPS despite adequate future remnant liver (FRL) volume. FRL function is probably a better endpoint than FRL volume to decide for resection and can be calculated by ^{99m}Tc-mebrofenin hepatobiliary scintigraphy (HBS). The aim of this study was to assess safety and efficacy of extended liver venous deprivation (eLVD), i.e. combination of right PVE and right and middle hepatic vein embolization before major hepatectomy for FRL functional increase.
Methods and Materials: eLVD was performed in non-cirrhotic patients referred for major hepatectomy in a context of small FRL (baseline FRL<25% of the total liver volume or FRL function <2.69%/min/m^2). All patients underwent ^{99m}Tc-mebrofenin HBS and computed tomographic evaluations.
Results: Ten consecutive patients underwent eLVD before surgery for liver metastases (n=8), Klatskin tumour (n=1) and gallbladder carcinoma (n=1). FRL function increased by 64.3% (range=28.1-107.5%) at day 21. In patients with serial measurements, FRL function was maximum at day 7 (+65.7±16%). The FRL volume increased by +53.4% at 7 days (+25±8 cc/day). Thirty-one days (range=22-45 days) after eLVD, 9/10 patients were resected. No PHLF ("50-50" criteria or peak bilirubin >7 mg/dL) was reported. Two grade II and one grade III complications (Dindo-Clavien classification) occurred. No patient died within 90 days following surgery.
Conclusion: eLVD is safe and provides marked and very rapid increase in liver function, unprecedented for an interventional radiology procedure. If these results are confirmed prospectively, this technique could replace PVE and challenge ALPPS.

B-0041 11:35

Prototype metal artifact reduction algorithm in flat panel CT: performance in patients with intraarterial angiography during hepatic selective internal radiotherapy

Q.M. Hamie[1], A. Kobe[1], L. Mietzsch[1], M. Manhart[2], T. Pfammatter[1], R. Guggenberger[1]; [1]*Zurich/CH*, [2]*Forchheim/DE (mustafa.hamie@usz.ch)*

Purpose: To retrospectively compare the effect of a prototype metal artifact reduction (MAR) algorithm in flat panel (FP)-CT on quantitative and qualitative image parameters in patients undergoing intraarterial (ia)-angiography during selective internal radiotherapy (SIRT) of hepatic masses.
Methods and Materials: After ia-catheter placement in celiac trunk application of 36ml contrast-agent (Ultravist®300 18ml + 18ml NaCl 0.9%) a FP-CT was acquired (Artis zeego, Siemens Healthineers) using a 8s rotation protocol (200 degrees rotation, 397 projections) in 29 patients (11 female), including 16 patients with arterial metallic coils. Image reconstructions with and without MAR were evaluated quantitatively by region-of-interest (ROI) measurements of attenuation in most pronounced streak-artifacts and qualitatively assessing visibility of hepatic parenchyma and vessels in near (2cm) and far field (5cm) of artifact sources (catheter curvature and coils). Paired Wilcoxon sign rank and Student t-test were used to compare quantitative measurements and qualitative scores of corrected and uncorrected images.
Results: Quantitative evaluation showed significant reduction of near field streak-artifacts with MAR (p<0.001), while remaining stable in far field and unaffected organs (all p>0.05). Qualitative image scores in near field were significantly improved after MAR (all p<0.005). Standard deviation of attenuation values in the near field decreased significantly after MAR (p<0.05). There was no significant difference in the amount of artifact reduction between catheter curvature and metallic coils (p<0.01).
Conclusion: MAR quantitatively and qualitatively improves image quality for visibility of hepatic parenchyma and vessels in near field of artifact sources in patients undergoing FP-CT ia-angiography for SIRT.

Locoregional treatments for HCC in patients with high risk for intraprocedural bleeding: is single-step combined therapy safe and feasible?

A. Posa, R. Iezzi, F. Carchesio, A. Gasbarrini, C. Colosimo, L. Bonomo; *Rome/IT (alessandro.posa@gmail.com)*

Purpose: To assess feasibility, safety, and efficacy of single-step combined therapy with radiofrequency ablation and drug-eluting beads transarterial chemoembolisation (RFA+TACE) in patients with HCC and low platelet count. Primary endpoints were major and minor complications, and death rates during and after the procedure.
Methods and Materials: Our single-centre retrospective study involved 115 cirrhotic patients (Child-Pugh A5-B7) with HCC, who underwent combined treatment between 2010 and 2015. Patients were divided into 3 groups by platelet count (>150.000/mm^3, low risk; >50.000/mm^3-<150.000/mm^3, average risk; <50.000/mm^3, high risk). Single-step combined treatment was performed with RFA during balloon occlusion of the tumour-feeding artery followed by selective TACE. Feasibility, safety, and efficacy were evaluated in terms of technical success, peri-procedural mortality and morbidity rates, laboratory values variations, blood transfusion needing, and 1-month TC follow-up.
Results: Technical success was obtained in all patients. There were no major complications. There was a significant increase of minor complications rate in group C after RFA only, all successfully treated with the subsequent TACE. No

patient required blood transfusion, nor post-procedural surgical treatment. The 3 groups did not significantly differ in terms of platelet count, INR and haemoglobin before and after the procedure, nor in terms of complete response rates at 1-month CT-follow-up.
Conclusion: Single-step combined treatment with RFA+TACE seems to be a safe, feasible, and effective treatment in patients with HCC at high risk for intraprocedural bleeding due to low platelet count, broadening the range of curative treatment. Chemoembolisation after radiofrequency ablation helps preventing iatrogenic hepatic bleeding.

Prospective randomised FAST II trial: evaluation of the response after regional chemoembolisation (TACE) of hepatocellular carcinoma (HCC) with two different protocols

T.J. Vogl, M. Langenbach, R. Hammerstingl, T. Gruber-Rouh;
Frankfurt a. Main/DE (t.vogl@em.uni-frankfurt.de)

Purpose: To compare two different embolisation protocols for transarterial chemoembolisation (TACE) regarding tumour volume, RECIST/mRECIST criteria and apparent diffusion coefficient (ADC) in a double-blinded randomised study.
Methods and Materials: In total 49 patients (32 men; 17 women; mean 70 years; range 43-84) with hepatocellular carcinoma (HCC) were included. The treatment protocol included three TACE sessions in 4-week intervals with MRI prior to TACE and four weeks after the last TACE. Two treatment groups were determined using a randomisation sheet: in group 1 TACE was performed using Lipiodol only, in group 2 using Lipiodol combined with EmboCept®S. Tumour volume, RECIST and mRECIST were evaluated for every scan, ADC only for first and last MRI.
Results: An average tumour volume reduction of 2.15% was documented in group 1 vs 1.39% in group 2 (p=0.3849), diameter reduction was 11.8% (group 1) vs 18.32% (group 2; p=0.72). Regarding the RECIST/mRECIST criteria group 1 showed stable disease (SD) in 18 cases, progressive disease (PD) in 4 cases and partial response (PR) in 1 case. Group 2 showed PR in 4 cases, SD in 20 cases and PD in 2 cases. During treatment the ADC coefficient raised on average 878.46mm^2/s in group 1 vs 578.91mm^2/s in group 2 (p=0.4336).
Conclusion: No significant benefit in local tumour-control was documented in group 1 vs group 2. A correlation of the decrease of tumour volume after TACE and an increase in the ADC was observed. This indicates that the ADC might be an individual predictor for success of TACE.

Comparison of the capability for differentiating malignant from benign nodules among quantitatively assessed dynamic perfusion ADCT and MR indexes and FDG-PET/CT

W. Tani[1], Y. Ohno[1], Y. Kishida[1], S. Seki[1], T. Yoshikawa[1], Y. Fujisawa[2], M. Yui[2], S. Ohyu[2], N. Sugihara[2]; [1]*Kobe/JP*, [2]*Otawara/JP (yosirad@kobe-u.ac.jp)*

Purpose: To compare the capability for differentiating malignant from benign nodules among quantitatively assessed dynamic first-pass contrast-enhanced (CE-) perfusion area-detector CT (ADCT) and magnetic resonance imaging (MRI) indexes and FDG-PET/CT.
Methods and Materials: 57 consecutive patients (38 male, 29 female; mean age 73 years) with 71 nodules underwent dynamic CE-perfusion ADCT and MRI at 3T, PET/CT, and microbacterial and/or pathological examinations. 71 nodules were classified into malignant (n=45) and benign nodules (n=26). In each patient, total nodule perfusion (TNP) and nodule perfusions from pulmonary (NP_P) and systemic (NP_S) circulations calculated by dual-input maximum slope method from on dynamic ADCT and MRI data and SUV_{max} on PET/CT were assessed by ROI measurements. On each index, ROC analysis was performed, and feasible threshold value was determined. Finally, sensitivity, specificity and accuracy were compared each other by using McNemar's test.
Results: Area under the curves (Azs) of TNPs of dynamic ADCT (Az=0.89) and MRI (Az=0.88) were significantly larger than that of NP_Ss on both methods (ADCT: Az=0.75, p<0.05; MRI: Az=0.81, p<0.05). When feasible threshold values adopted, accuracy of TNP on dynamic ADCT (87.3 [62/71] %) and MRI (87.3 [62/71] %) was significantly higher than that of NP_Ss (ADCT: 77.5 [55/71] %, p=0.008; MRI: 77.5 [55/71] %, p=0.008) and SUV_{max} (78.9 [56/71] %, p=0.02).
Conclusion: Quantitatively assessed dynamic first-pass CE-perfusion ADCT and MRI indexes have better potential than PET/CT for differentiating malignant from benign nodules. In addition, both quantitative perfusion methods were considered as having same potential in this setting.

Comparison of capability for differentiation of malignant from benign pulmonary lesions among CEST imaging, DWI and FDG-PET/CT

Y. Ohno[1], M. Yui[2], Y. Kishida[1], S. Seki[1], T. Yoshikawa[1], M. Miyazaki[3], K. Kyotani[1], K. Sugimura[1]; [1]*Kobe/JP*, [2]*Otawara/JP*, [3]*Vernon Hills, IL/US (yosirad@kobe-u.ac.jp)*

Purpose: To directly and prospectively compare the capability for differentiation of malignant from benign pulmonary nodules and/or masses among chemical exchange saturation transfer (CEST) imaging targeted to amide (-NH)groups, diffusion-weighted MR imaging (DWI) and FDG-PET/CT.
Methods and Materials: 88 consecutive patients with pulmonary nodules and/or masses underwent CEST imaging and DWI at a 3T MR system, FDG-PET/CT and pathological and/or follow-up examinations. According to final diagnoses, all lesions were divided into malignant (n=49) and benign (n=39) groups. On CEST imaging, magnetisation transfer ratio asymmetry (MTR_{asym}) was calculated from z-spectra at 3.5ppm in each pixel, and MTR_{asym} map was computationally generated. To evaluate the capability for differentiation between two groups at each lesion, MTR_{asym}, apparent diffusion coefficient (ADC) and SUV_{max} were assessed by ROI measurements. To compare each index between two groups, Student's t-test was performed. Then, ROC analysis was performed to determine each feasible threshold value for differentiation of two groups. Finally, sensitivity, specificity and accuracy were compared each other by McNemar's test.
Results: Mean MTR_{asym}, ADC and $SUV_{max}$of malignant group had significant difference with those of benign group (p<0.05). Results of ROC analysis showed that there were no significant differences of area under the curve (Az) among all indexes (p>0.05). When applied each feasible threshold value, there were no significant differences of diagnostic performance among all indexes (p>0.05).
Conclusion: CEST imaging is considered at least as valuable as DWI and FDG-PET/CT for differentiation of malignant from benign pulmonary lesions.

The role of diffusion weighted MR imaging for the characterisation of mediastinal lymphnodes

M.K. Garg, E. Ramamoorthy, P. Singh, A.N. Aggarwal, N. Gupta;
Chandigarh/IN (gargmandeep@hotmail.com)

Purpose: To assess the diagnostic performance and additional value of diffusion-weighted (DW) magnetic resonance imaging (MRI) in the characterisation of mediastinal lymphadenopathy.
Methods and Materials: This prospective study was approved by the institutional review board, and written informed consent was obtained from all patients. A total of 43 patients [23 males and 20 females with mean age of 49 years] with mediastinal lymphadenopathy underwent DW and T2 weighted MRI and pathological examination in the period of January 2015 to June 2016. Diffusion restriction pattern, apparent diffusion coefficient (ADC) mean value, size and T2 heterogeneous signal intensity of the nodes were evaluated. Receiver operating characteristic curve analysis was used to determine ADC mean threshold values. The best predicting combinations of these four parameters were selected by means of stepwise logistic regression analysis.
Results: ADC mean value of malignant lymphadenopathy (0.873±0.109×10−3 mm2/s) was significantly different from that of benign lymphadenopathy (1.663±0.311×10−3 mm2/s) (P<0.001). When an ADC mean value of 1.0955×10^{-3} mm^2/s was used as a threshold value for differentiating malignant from benign nodes, the best results were obtained with a sensitivity of 94%, a specificity of 96% and area under the curve of 0.996. The three other predictor

variables didn't add anything statistically significant to the regression equation with ADC mean.
Conclusion: ADC mean value of malignant mediastinal lymphadenopathy was significantly different from the benign lymphadenopathy. The ADC mean value was the strongest independent predictor of malignancy.

B-0047 10:54

Whole body MRI with diffusion-weighted imaging (DWI) for preoperative assessment of lymph node involvement in NSCLC patients: ADC value of primary tumour as prognostic factor

L. Calandriello, M. Ciliberto, G. Sica, D. Coviello, A. Larici, L. Bonomo;
Rome/IT

Purpose: To determine whether ADC (apparent diffusion coefficient) values of the primary tumour are a predictor of lymph node involvement in NSCLC patients and to compare its diagnostic capability with qualitative assessment of DWI images.
Methods and Materials: Twenty-eight patients with NSCLC underwent preoperative whole body MRI with DWI (b value: 0-1000mm^2/sec). A qualitative analysis of lymph node involvement was performed analysing DWI images and defining patients as N+ or N- (presence or absence of lymph node metastasis). Afterwards ADCmean and ADCmin of primary tumours were calculated for a quantitative analysis. Pathology reports served as the reference standard. Diagnostic accuracy of qualitative and quantitative analysis was calculated with receiver operating characteristic (ROC) curve analysis. Student's t test was used to compare ADC values of N+ and N- patients.
Results: Pathology reports showed 12 N+ patients and 16 N- patients. Qualitative analysis showed fair diagnostic accuracy with an AUC (area under the curve) of 0.75. ADCmin of the primary tumour showed a good diagnostic accuracy with an AUC value of 0.81. The cutoff ADCmin value to discriminate between N+ and N- patients was set as 0.77x10^{-3}mm^2/s with sensitivity, specificity, PPV and NPV of 83%, 75%, 71% and 85%. ADCmin differed significantly (p=0.007) between N+ and N- patients (ADCmin 0.63x10^{-3}mm^2/s vs ADCmin 0.86x10^{-3}mm^2/s). No statistically significant result was obtained with regards to ADCmean.
Conclusion: ADCmin of primary tumour can be used as a predictor of lymph node involvement in NSCLC with a better diagnostic accuracy compared to qualitative analysis of DWI images.

B-0048 11:02

Lung cancer: short-term reproducibility of diffusion-weighted magnetic resonance imaging and intravoxel incoherent motion parameters at 3.0T

J. Jiang[1], L. Cui[1], J. Yin[1], X. Gu[2], S. Gong[1]; [1]*Nantong/CN*, [2]*Suzhou/CN (1021809719@qq.com)*

Purpose: To prospectively evaluate the short-term test-retest reproducibility of Diffusion-weighted imaging (DWI) and Intravoxel Incoherent Motion (IVIM) parameters in lung cancer, and to investigate the influence of lung cancer type, size and location.
Methods and Materials: 38 lung cancer patients underwent free breathing DWI (b=0, 800s/mm^2) and IVIM (10 b-values, 0-1000s/mm^2) scans twice (0.5-1 h interval). Regions of interests were drawn on apparent diffusion coefficient (ADC) maps, DWI (b=800s/mm^2) and IVIM images to derive ADCs, LSR_{800}(lesion-to-spinal cord ratio) and IVIM parameters D, D*, f . All parameters were compared between repeated measurements , readers, and scans. Intra- and inter-observer, test-retest reproducibility and variability was assessed with interclass correlation coefficient (ICC), within coefficient of variation (WCV), and Bland-Altman analysis. Effects of lung cancer type, size and location on the short-term reproducibility were compared by WCVs.
Results: There were no significant differences between repeated measurements , readers, and scans (P> 0.05). All parameters showed good intra- and inter-observer agreement (ICC 0.845-0.986). The test-retest reproducibility of D was best (WCV 8.91%), ADC and LSR_{800} were good to moderate (WCV 12.12%, 21.84%), while D* and f was poor (WCV 54.83% ,33.87%). The test-retest WCVs of D and ADC were greater for central lung cancer or lesions smaller than 2cm or in the lower field. While f and LSR800 was less reproducible in larger lesions,and LSR800 was less reproducible in the upper field. D* was greatly influenced by lung cancer type, size, and location.
Conclusion: If the change of D, D*, f , ADC, LSR_{800} is less than 8.91%, 54.83%, 33.87% 12.12%, 21.84% respectively, it may be caused by measurement error. The type, size and location of lung cancer are the potential influencing factors.

B-0049 11:10

A comparative analysis of dual-phase dual-energy CT and FDG-PET/CT for the prediction of histopathological invasiveness of non-small-cell lung cancer

R. Ito, S. Iwano, H. Shimamoto, H. Umakoshi, S. Ito, K. Kato, S. Naganawa;
Aichi/JP (rintaro-ito@med.nagoya-u.ac.jp)

Purpose: To compare dual-phase dual-energy CT (DE-CT) with FDG-PET/CT for predicting histopathological locoregional invasiveness of non-small-cell lung cancers (NSCLCs).
Methods and Materials: We selected 57 consecutive patients with NSCLC lesions (34 males, 23 females; age range, 44-85 years; mean age, 69 years) who were evaluated preoperatively by both DE-CT and PET/CT. Postoperative microscopic invasiveness (lymphatic permeation, vascular invasion, or pleural involvement) was reviewed, and we defined locoregional invasive tumours as tumours that had at least one positive finding of microscopic invasiveness. DE-CT scanning in the arterial and delayed phases was performed after injection of iodinated contrast media using 140kVp and 80kVp tube voltages. Three-dimensional iodine-related attenuation of primary tumours in the arterial and delayed phases was quantified automatically using application software, and the ratio of arterial phase to delayed phase enhancement (A/D ratio) was calculated. The A/D ratio and SUVmax on PET/CT were evaluated with respect to postoperative invasiveness by univariate logistic regression analysis.
Results: The A/D ratio was significantly correlated with lymphatic permeation, vascular invasion and pleural involvement (p=0.017, p=0.024, and p=0.035, respectively). On the other hand, the SUVmax was significantly correlated with pleural involvement (p=0.012) but not with lymphatic permeation or vascular invasion (p=0.179 and p=0.303, respectively). In the subgroup of patients with lesion diameters ≤2cm, the A/D ratio was significantly correlated with locoregional invasiveness (p=0.048), while the SUVmax was not (p=0.160).
Conclusion: For the prediction of microscopic invasiveness of NSCLCs, the diagnostic performaof dual-phase DE-CT may be comparable to that of FDG-PET/CT.

B-0051 11:18

Comparison of capability for therapeutic outcome prediction among dynamic perfusion MRI, dynamic ADCT and FDG-PET/CT: in NSCLC patients with chemoradiotherapy

W. Tani[1], Y. Ohno[1], Y. Kishida[1], S. Seki[1], T. Yoshikawa[1], Y. Fujisawa[2], M. Yui[2], S. Ohyu[2], N. Sugihara[2]; [1]*Kobe/JP*, [2]*Otawara/JP (yosirad@kobe-u.ac.jp)*

Purpose: To directly compare the capability for therapeutic outcome prediction between dynamic first-pass CE-perfusion area-detector CT (ADCT) and MRI assessed by same mathematical method and FDG-PET/CT in non-small cell lung cancer (NSCLC) patients treated with chemoradiotherapy.
Methods and Materials: 43 consecutive Stage IIIB NSCLC patients underwent PET/CT, dynamic CE-perfusion ADCT and MRI, chemoradiotherapy, and follow-up examination. Then, all patients were divided into two groups according to the RECIST guidelines as follows: 1) CR+PR (n=23) and 2) SD+PD (n=20) groups. In each patient, total perfusion (TP) and tumour perfusions from pulmonary (TP_P) and systemic (TP_S) circulations calculated by dual-input maximum slope method from ADCT and MRI data and SUV_{max} on PET/CT were assessed. To compare the capability for distinguishing two groups, ROC analyses were performed. Then, disease free and overall survivals between responders and non-responders assessed by each index were compared by Kaplan-Meier method followed by log-rank test.
Results: Area under the curves (Azs) of TP (MRI: Az=0.90, ADCT: Az=0.87) and TP_S (MRI: Az=0.84, ADCT: Az=0.84) were significantly larger than that of TP_P (MRI: Az=0.72, p<0.05; ADCT: Az=0.72, p<0.05). Disease free survivals of responder were significantly longer than that of non-responder by TP (p<0.05) and TP_S (p<0.05). Overall survivals of responder were also significantly longer than that of non-responder by TP (p<0.05), TP_P (ADCT: p=0.008), TP_S (p<0.05) and SUV_{max} (p=0.04).
Conclusion: Dynamic first-pass CE-perfusion ADCT and MRI has equal to or better potential to predict therapeutic outcome than PET/CT in NSCLC patients treated with chemoradiotherapy.

Radiomics features provide reliable measurements from manual contouring of tumours in lung cancer

A. Eilaghi, M.A. Haider, Y. Zhang, A. Oikonomou, L. Jimenez-Juan, F. Khalvati; *Toronto, ON/CA (armin.eilaghi@utoronto.ca)*

Purpose: The purpose of this study was to quantify the inter-rater reliability of a set of grey level co-occurrence matrix features in a cohort of non-small-cell lung cancer patients who underwent stereotactic body radiotherapy.
Methods and Materials: 159 patients with overall 183 tumours, mean age (range) =71(52-92), were included in the study. Manual contouring of the tumours was performed on PET and CT images of staging PET/CT studies by two radiologists independently using ProCanVAS. Radiomics features were extracted using an in-house developed prototype for each slice and averaged across slices. Cohen's Kappa test was used to assess inter-rater agreement in 3 dimensions between two contouring sets. Intra-class correlation (ICC) was used to measure the reliability between the two contoured datasets. ICC>0.8 is equivalent to high reliability. Statistical analysis was performed using R Statistical Software.
Results: For CT images, 1608 slices were assessed. Tumours appeared in 1304 and 1399 slices according to radiologist 1 and 2, respectively. For CT images, the inter-rater agreement in tumour appearance, Cohen's kappa was 0.56 and the average ICC for image features was 0.899. For PET images, 899 slices were assessed. Tumours appeared in 558 and 582 slices according to radiologist 1 and 2, respectively. The agreement in tumour co-appearance was 0.893 and average ICC for PET image features was 0.835. No significant difference was found between ICC from PET and CT images (p=0.09).
Conclusion: Studied radiomics features showed high reliability in CT and PET images and moderate agreement in tumour appearance between radiological contours.

B-0053 11:34

CT texture analysis in metastatic lung adenocarcinoma treated with tyrosine kinase inhibitors: prediction of survival

J. Cardinale, V. Bettoni, G. Agazzi, M. Ravanelli, E. Roca, D. Farina, A. Berruti, R. Maroldi; *Brescia/IT (marcoravanelli@hotmail.it)*

Purpose: To assess the predictive and prognostic value of pre-treatment CT texture features in lung adenocarcinoma treated with tyrosine kinase inhibitors (TKI).
Methods and Materials: Texture analysis was performed with a commercially available software (TexRAD Ltd, UK) on pre-treatment contrast-enhanced CT studies of 27 patients with metastatic lung adenocarcinoma treated by TKI. Texture features were quantified on a 5-mm thick central slice of the primary tumour and were correlated with progression-free and overall survival (PFS and OS) using uni- and multi-variable analysis.
Results: Mean PFS and OS were 77.4±71 and 110±87 weeks, respectively. At multivariable analysis, kurtosis of 3-mm texture was independently correlated with PFS, tumours with high kurtosis (>0.98) had a 11.4 relative risk of progression compared with tumours with low kurtosis (p<0.0001); kurtosis on unfiltered images was correlated with OS, tumours with high kurtosis (>1.74) had a 10.3 relative risk of death compared with tumours with low kurtosis (p 0.0006). Among clinical variables, only age<60 years correlated with shorter PFS (relative risk 4.1, p0.02).
Conclusion: Texture features, in particular kurtosis, are strongly associated with PFS and OS in lung adenocarcinoma treated with TKI.

B-0054 11:42

Early lung adenocarcinomas appearing as subsolid nodules: is systematic nodal dissection always essential?

S. Jeon, C. Park, J. Goo; *Seoul/KR (sunkyung417@gmail.com)*

Purpose: To assess whether nodule size or solid portion size of early lung adenocarcinomas appearing as subsolid nodules can predict lymph node (LN) metastasis at preoperative CT.
Methods and Materials: For training set for model build up, 473 patients (pure ground-glass nodules (GGNs)=116; part-solid GGNs=357) who underwent surgery for clinical stage I adenocarcinomas were included. In addition to training set, another independent patients group (N=242) with same inclusion criteria except period when the patients underwent surgery were included for the test set. Presence of LN metastasis was confirmed through LN dissections (n=413) or 1-year follow-up (n=60). Maximal diameters of whole lesions including ground-glass opacities (D_{whole}) and solid components only (D_{solid}) were measured. Solid proportion [D_{solid}/D_{whole} x100(%)] was also calculated.
Results: Among 473 patients, 11 (2.33%) patients had LN metastasis (pN+). All patients with pure GGNs did not demonstrate LN metastasis (pN0)(n=116). All patients with D_{whole}≤15mm (n=214) or D_{solid}≤5mm (n=229) were pN0. Nodal metastases only occurred in 11 among 194 patients with D_{whole}>15mm and D_{solid}>5mm (*P*<0.001 versus the other 279cases). When we made diagnostic algorithm using pure GGN, D_{solid}≤5mm, and D_{whole}≤15mm, sensitivity of 59.1% and specificity of 100% were achieved. In addition, when we apply this diagnostic algorithm in the test set, sensitivity of 41.5% and specificity of 100% in prediction of LN metastasis were achieved.
Conclusion: Pure GGN, nodule size≤15mm or solid portion size≤5mm may be reliable predictors of the absence of lymph node involvement in early-stage clinically N0 lung cancers, making it possible to avoid unnecessary nodal dissections.

Do clinicians follow imaging recommendations on renal artery duplex ultrasound reports?

A.H. Rajaram; *Bangalore/IN (akashrajaram@gmail.com)*

Purpose: To characterise the use of renal artery duplex ultrasound (RADUS) in assessing renal artery stenosis (RAS) as well as the rate of provider compliance with follow-up with CT or MR angiogram.
Methods and Materials: RADUS examinations conducted from 2009 to 2016 were retrospectively reviewed by one radiologist. Patients with sonographic features of RAS were identified. Recommendations for additional imaging were recorded. Subsequent CTA or MRA examinations were identified, and the reports were reviewed for concordance with RADUS findings as well as incidental findings that required further workup. We used an unpaired t-test to assess the differences in basic demographics between patients who underwent CTA or MRA versus those who were not imaged.
Results: 103 patients (mean age ± SD, 67.9 ± 15.7 years; range, 12-92 years; 53 men, 50 women) with sonographic findings of RAS were included. All patients had been recommended for CTA or MRA. Only 24 patients underwent further imaging with CTA (n=10) or MRA (n=14). Of the 24 patients undergoing additional CTA or MRA, 11 were had unilateral or bilateral RAS. However, 13 patients who were suspected to have RAS were found to have widely patent bilateral renal arteries on CTA or MRA. Incidental findings on CTA or MRA triggering additional work-up was found in only two patients, one with hydronephrosis and another with a pulmonary nodule.
Conclusion: Our study suggests that referring clinicians do not always follow recommendations on RADUS reports, even in the presence of sonographically suspected renal artery stenosis.

B-0056 10:38

Evaluation of image quality and radiation dose for low kilovoltage peak (kVp) with an adaptive statistical iterative reconstruction algorithm in computed tomography urography

L. Zheng, Z. Zhou; *Shanghai/CN (zhenglinfeng04@aliyun.com)*

Purpose: To evaluate the image quality and radiation dose in CTU images acquired with a low kVp in combination with an ASiR algorithm.
Methods and Materials: A total of 45 subjects who underwent CTU with kV assist software for automatic selection of the optimal kVp were included and divided into groups A and B based on kVp and the image reconstruction algorithm: group A consisted of a 80-100 kVp and image reconstruction with 50% ASiR algorithm (n=32); group B consisted of a 120 kVp and image reconstruction with the FBP algorithm(n=13). The images were reconstructed with VR and MIP, respectively. Image quality was evaluated using image score, CT attenuation, image noise, CNR and SNR. Radiation dose was assessed using volume CT dose index (CTDIvol), dose length product (DLP) and effective dose(ED).
Results: No significant difference was found (p>.05) between the two group's image scores for either the volume rendering (VR) or maximum intensity projection (MIP) reconstruction images. The mean attenuation of the bilateral renal pelvis in group A was significantly higher than that in group B (p<.05), whereas the image noise in group A was significantly lower than that in group B (p<.05). The CNR and SNR in group A were both significantly higher than in group B (p<.05). The CTDIvol, DLP and ED in group A were significantly lower than in group B (p<.05).
Conclusion: The low kVp CTU images with 50% ASiR reconstruction exhibit sufficient image quality and facilitate up to a 44% radiation dose reduction.

B-0057 10:46

Split-bolus vs single-bolus MDCT urography: comparison of urinary tract opacification and radiation dose exposure

C. Valle[1], P.A. Bonaffini[1], F. Invernizzi[1], A. Barletta[1], S. Faenza[1], A.S. Casiraghi[2], A. Pappini[1], S. Sironi[3]; [1]*Desio/IT*, [2]*Monza/IT*, [3]*Bergamo/IT (clarissa.valle1987@icloud.com)*

Purpose: To evaluate the urinary tract opacification and the radiation dose exposure of split-bolus MDCT urography (CTU) as compared to standard single-bolus protocol.
Methods and Materials: Forty-eight patients (18-83 years), undergone a CTU study on a 64-row scanner (Aquilion, Toshiba) after i.v. administration of 90-110mL of iodinated contrast medium (350mg/mL), were retrospectively analysed: 24 were studied using a split-bolus protocol, including mainly a combined nephrographic-pyelographic phase (study group), 24 a single-bolus CTU (control group). Quantitative analysis of opacification in pyelographic phase (HU) was achieved by placing ROIs within the lumen of renal pelvis, ureters and bladder. Two radiologists (1-consultant, 2-resident) also qualitatively evaluated the opacification by using a 4-point scale. The radiation dose exposure was calculated as dose-length product (DLP, mGy*cm) and CTDIvol (mGy). All data were statistically analysed.
Results: The split-bolus protocol demonstrated a mean urinary attenuation significantly lower than the standard CTU (left pelvis 909 vs 1326HU, right pelvis 877 vs 1253HU, left ureter 810 vs 1114HU, right ureter 655 vs 1127HU, respectively) but no differences between the two groups were observed concerning the qualitative evaluation of urinary opacification. Mean split-bolus DLP was significantly lower (1869 mGy*cm; p=0.045) as compared to the single-bolus protocol (3002 mGy*cm), with a dose exposure reduction of 37%; no significant differences were achieved for CTDIvol.
Conclusion: The urinary tract opacification, even if quantitatively lower, was qualitatively comparable between the two protocols; moreover, the split-bolus DLP was significantly lower, with an overall dose reduction of 37%.

B-0058 10:54

Rescanning in prone position in CT urography: is it really necessary for the evaluation of an incompletely opacified bladder?

P. Martingano, M. Muca, M.F. Cavallaro, M. Iannelli, M.A. Cova; *Trieste/IT (pmartingano@sirm.org)*

Purpose: To assess diagnostic confidence in bladder malignancy detection of CT urography (CTU) performed with split bolus technique in case of incomplete bladder opacification due to urine retention.
Methods and Materials: From January 2014 to February 2015, 100 consecutive patients who underwent both CTU and cystoscopy were retrospectively identified. One investigator with 10 year genitourinary imaging experience evaluated bladder wall in the supine position and then, when available, in the prone position to detect bladder malignancy. Cystoscopy was considered as reference standard to calculate receiver operating characteristic (ROC) curves of diagnostic confidence.
Results: 62 out of 100 CTU exams met inclusion criteria (38 were rule out for absence of unopacified urine or presence of artifacts due to hip prosthesis), and 35/62 were performed in both supine and prone position. In these 35 exams there were not statistically significant difference between the evaluation of the supine scan alone and both scans. In the 62 exams the overall accuracy of the supine scans was 94.6%, with a 94.7% sensitivity and a 94.4% specificity (ROC Area: 0.985).
Conclusion: The split-bolus technique, with a single scan in a nephro-excretory phase, allows a good evaluation of bladder wall also in patients with distended but not entirely opacified bladder. Its high diagnostic confidence spare in most cases rescanning in prone position, with consequent radiation exposure reduction and time saving.

B-0059 11:02

Role of diffusion-weighted magnetic resonance imaging in predicting renal dysfunction in chronic kidney disease patients

M.S. Shaaban, M. Sakr, A. Fathy, G. Kortam; *Alexandria/EG (mohamed.shaban@gmail.com)*

Purpose: To assess the relationship between ADC of renal parenchyma and serum markers of renal function and stage of chronic kidney disease (CKD), and to establish cut-off ADC values to identify CKD.
Methods and Materials: This is a prospective study conducted from December 2013 to April 2016. Subjects divided into 2 groups: Group I included 15 CKD patients at different stages and aetiologies, Group II included 15 individuals control group who have normal renal function indicated for MRI for other aetiologies. Both groups underwent DWI. ADC values were determined for renal parenchyma and compared. ROC curves were drawn to establish cut-off ADC values. Pearson's correlation coefficient (R) was calculated between ADC and renal function parameters.
Results: ADC values in patients with renal dysfunction were significantly lower than in patients with normal renal function. There was significant inverse correlation between ADC and serum creatinine, and significant linear correlation with eGFR. ADC values showed a statistically significant decreasing trend with increasing stage of CKD. ROC curve for average ADC of both kidneys revealed ADC cut-off value ≤1.866 with 86.67% sensitivity and 78.57% specificity.
Conclusion: ADC values may serve as an additional marker for the presence and degree of renal dysfunction.

B-0060 11:10

Observational study on the incidence of nephrogenic systemic fibrosis in patients with renal impairment following gadoteric acid administration

A.I.B. De Backer; *Ghent/BE (adelard.debacker@azstlucas.be)*

Purpose: To determine the incidence of Nephrogenic Systemic Fibrosis (NSF) in patients with renal impairment after gadoteric acid (DOTAREM, Guerbet, France) administration.
Methods and Materials: Worldwide post-marketing study including 540 patients with at least moderate renal impairment scheduled to undergo a routine contrast-enhanced Magnetic Resonance Imaging (MRI) using gadoteric acid. Medical history, MRI indication(s) and Adverse Events (AEs) were recorded for each patient. Patients were followed up over 2 years with 3 visits separated by at least 3 months in order to detect any signs of NSF.
Results: Among the 540 patients (mean age: 69.6 years [min-max: 21-95]; men: 58.5%), renal impairment was evaluated as moderate for 69.3% of patients, severe for 16.1% and end-stage for 12.0%; 2.6% of patients had undergone a previous kidney transplant. Mean eGFR was 37.6 ± 15.7 ml/min/1.73 m2 [4.0-74.2]. Main MRI indication was to assess suspected abnormalities of the central nervous system (34.6%). As of 1st September 2016, 97.3% of patients attended the first follow-up visit, 76.9% attended the second and 55.4% attended the third. Neither AE considered to be related to the administration of gadoteric acid, nor NSF suspicion were reported.
Conclusion: Intermediate data of the NSsaFe study show no cases of NSF after gadoteric acid administration, confirming its good safety profile in patients with renal impairment.
Author Disclosures:
A.I.B. De Backer: Investigator; Dr De Backer is a study investigator with no other financial relationship with Guerbet. The NSsaFe Study is a Guerbet-sponsored study. The investigators who participated in the study, including Dr, received funding from Guerbet for participating in the study. Dr De Backer is not a party to a consulting agreement with Guerbet..

B-0061 11:18

Perfusion MRI in early detection of renal fibrosis in patient with ADPKD: a preliminary study

A. Di Gaeta, E.L. Indino, S. Lai, D. Mastroluca, C. Catalano, V. Panebianco; *Rome/IT (alessandro.digaeta@hotmail.it)*

Purpose: The aim of our study is the evaluation through perfusional MRI (PMR) of Total Kidney Volume (TKV), Total perfusional volume (TPV) and the Total Fibrotic Volume (TFV) correlating to clinical data in patient with Autosomal Dominant Polycystic Kidney Disease (ADPKD).
Methods and Materials: Twenty-five ADPKD patient (mean age 39 years), thirteen of them ADPKD-hypertensive, with eGFR > 50 ml/min and blood aldosterone levels measurement. All patient enrolled underwent perfusional MRI (MRP) with Magnet 3T (Discovery MR 750, 3T, GE Healthcare) and 32-channels surface coil. PMR protocol included morphological sequences T2-W single shot (SSFS), and T1-W Gradient Echo (GRE). During MRP were used ultrafast T1-W 3D-GRE sequences high time resolution repeated for 8 minutes. Perfusion was evaluated with qualitative and quantitative approaches. The former based on two colour maps (showing functional parenchyma and the late parenchymal enhancement); the latter obtained by using a post-processing 3D-Volume Rendering software to quantify TPV and TFV. Mean follow-up period of 15±2 months, in which MRP was repeated.
Results: All correlations were obtained with Spearman's rho coefficient and was considered significant $p<0.05$. Time 1 eGFR negatively correlates with TKV ($r = -0.059$, $p<0.02$), with TFV ($r= -0.61$, $p<0.04$) and TPV/TKV(%) ($r= -0.59$, $p<0.02$). TFV positively correlates with aldosterone blood levels ($r= 0.50$, $p<0.05$).
Conclusion: PMR is a useful tool in monitoring progression of the disease and to evaluate early ADPKD, highlighting early changes in terms of fibrotic evolution in renal parenchyma even when renal function is preserved.

B-0062 11:26

DW-MRI as an alternative to biopsy in renal allograft patients with deteriorating renal function: a preliminary study

S. Barbieri, P. Steiger, A. Kruse, M. Ith, H.C. Thoeny; *Berne/CH (sebastiano.barbieri@insel.ch)*

Purpose: To assess the accuracy of diffusion-weighted MRI (DW-MRI) used to classify renal allograft patients with deteriorating renal function into two groups: the "biopsy-mild" group consisting of patients with normal or mild grade I interstitial fibrosis and tubular atrophy and the "biopsy-severe" group with grade II-III interstitial fibrosis and tubular atrophy, rejection, or other pathologies not due to rejection. At our institution, "biopsy-severe" patients are associated with a change in clinical management.
Methods and Materials: Forty kidney transplant patients underwent DW-MRI (1.5T, 10 b-values) and biopsy (the reference standard) within 10 days. Patients were classified in two subsequent steps: at first patients with allografts appearing heterogeneous on b=900 sec/mm^2 images were assigned to the "biopsy-severe" group; the remaining patients were classified by applying a threshold to the average or minimal ADC or intravoxel incoherent motion parameters (pseudodiffusion D*, diffusion D, perfusion fraction f) measured within the upper, middle, and lower pole of the allograft.
Results: According to histopathology 15 patients were in the "biopsy-mild" group and 25 in the "biopsy-severe" group. Classification based on minimal ADC or minimal f led to the highest accuracy of 80% (sensitivity 84.0% and 92.0%; specificity 73.3% and 60.0%, respectively). Patients were considered "biopsy-severe" if the allografts appeared heterogeneous or the minimal ADC was less than $179.5 \cdot 10^{-5}$ mm^2/sec or the minimal f was less than 14%.
Conclusion: DW-MRI is a promising technique to predict the severity of histopathologic findings in renal allograft patients and might, in the future, reduce the number of biopsies.

B-0063 11:34

Usefulness of transplanted kidney evaluation by multiparametric ultrasonography: including two different types of ultrasound elastography

M. Yoo, D. Jung, Y. Oh, S. Park, K. Han; *Seoul/KR (placeborain@yuhs.ac)*

Purpose: The purpose of this study was to investigate the association between microscopic abnormalities of transplanted kidney and ultrasonography based imaging biomarkers including elasticity, venous impedance index, arterial resistive index and renal size.
Methods and Materials: Between 2011 and 2015, ultrasonography was performed in 159 recipients who would be planned to undergo transplanted kidney biopsy. Maximal longitudinal length on greyscale images, arterial resistive index, and venous impedance index on Doppler images, and shear wave velocity on Acoustic Radiation Force Impulse imaging or Young's modulus on Supersonic Shear Imaging were measured before biopsy. Ultrasonography parameters and clinical variables were analysed with individual and sum of Banff scores derived from the tissue samples.
Results: On Spearman's rank correlation coefficient and ordinal logistic regression, no ultrasonography parameters were associated with sum of Banff scores. Only the duration between kidney transplantation and biopsy was significantly associated with sum of Banff scores (r=0.588, B=0.018, p<0.05). On univariate logistic regression analysis with individual Banff scores, mm were associated with arterial resistive index; t, cg, mm with venous impedance index; and t, cg, ct, ci, mm, ah with duration between transplantation and biopsy (p<0.05). Shear wave velocity or Young's modulus were not associated with any individual Banff scores.
Conclusion: Both types of elastography were not significantly associated with any histopathologic change of the transplanted kidney. Although arterial resistive index and venous impedance index were related to a few individual Banff scores, time after transplantation showed stronger correlation with renal allograft deterioration than imaging biomarkers.

B-0064 11:42

Diffusion-weighted imaging and diffusion tensor imaging in the evaluation of transplanted kidneys before and after furosemide

D.C. Caltabiano, L. Mammino, V. Costanzo, P. Foti, P. Milone, L. Mauro, N. Sinagra, M. Veroux, S. Palmucci; *Catania/IT (daniele.788@gmail.com)*

Purpose: To evaluate renal function in a population of kidney transplant recipients using diffusion-weighed imaging (DWI) and diffusion tensor imaging (DTI) before and after furosemide administration.
Methods and Materials: 29 patients with transplanted kidneys were studied using 1.5 Tesla MRI; DWI and DTI sequences were performed before and after intravenous administration of furosemide. Patients were divided into 2 groups according to their creatinine clearance values: group A, including patients with normal clearance value (≥60 ml/min), and group B, including patients with low clearance value (<60 ml/min). Apparent diffusion coefficient (ADC) and fractional anisotropy (FA) were calculated placing region of interests both in renal cortex and medulla; their values - before and after furosemide administration - were compared among groups using Mann-Whitney U test.
Results: Cortical ADC values were statistically different between groups before furosemide, with p=0.01; after furosemide administration, a higher statistical difference was observed between groups A and B, with p=0.007. No statistical differences were found for cortical FA before and after furosemide stimulation, with p values, respectively, of 0.329 and 0.723. Medullar ADC and FA values were statistically different between groups, showing respectively p values of 0.001 and 0.041 before functional furosemide administration; after diuretic stimulation bolus, p values of 0.017 and 0.023 were observed comparing, respectively, ADC and FA among groups.
Conclusion: In functional MRI with DTI, furosemide improves differentiation between normal and abnormal transplanted kidneys; however, a certain degree of overlap remains between groups. Medullar FA is a reliable parameter for renal function evaluation.

B-0065 11:50

CT diagnosis and follow-up of urolithiasis using ultra-low dose hybrid and pure iterative reconstruction algorithms based on size

V. Vardhanabhuti[1], S. Tenant[2], C.-L. Pang[2], P. Dissanayake[2], C. Gutteridge[2], C.J. Hyde[3], C.A. Roobottom[2]; [1]*Hong Kong/HK*, [2]*Plymouth/UK*, [3]*Exeter/UK*

Purpose: The aim of this study was to evaluate the accuracy of scans for the primary investigation and follow up of urolithiasis, comparing MBIR with as low a dose as possible with a standard ASIR reconstruction algorithm.
Methods and Materials: A single-centre IRB-approved prospective study recruited 125 patients with written consent. Standard-dose (SD) and low-dose (LD) were performed. Scans were reconstructed with adaptive statistical iterative reconstruction (ASIR) and model-based iterative reconstruction algorithms (MBIR). Accuracy of detection of urolithiasis were analysed. Dose was recorded.
Results: Mead doses were as follows: SD: $CTDI_{vol}$ 4.7 mGy, DLP 223.6 mGy.cm, SSDE 5.3 mGy; LD: $CTDI_{vol}$ 2.2 mGy, DLP 102.6 mGy.cm, SSDE 2.3 mGy. Primary end-point (the presence of obstructive uropathy), for each reader, review of the reduced-dose MBIR scan was found to concur perfectly with that reader's review of the standard-dose scan. In all cases the obstructing calculus was correctly observed. By contrast, the reduced-dose scans reconstructed using ASIR were of reduced accuracy, with a sensitivity of only 0.81 and 0.86 for readers 1 and 2 respectively. MBIR had excellent sensitivity for stones of 3mm (95.7% identified) and performed perfectly for stones above this size. Accuracy dropped off between 2mm and 1mm, where sensitivity fell from 90% to 67.5%.
Conclusion: Significantly reduced-dose CT KUB scans can be performed with the use of model-based iterative reconstruction without any loss in diagnostic accuracy for obstructing calculi and whilst maintaining very high accuracy for renal calculi of 3mm and above.

US localisation of abnormal findings in neck PETCT or scintiscan: a preliminary experience with 3D and 2D virtual navigation (VN) and bodymap technology (BMT) vs cognitive approach

G. Bizzarri, A. Bianchini, D. Valle, L. Velari, S. De Nuntis, A. Dell'Era, L. Di Vito, L. Forzoni, E. Papini; *Albano Laziale/IT (bizzarrigiancarlo@libero.it)*

Purpose: US is the modality of choice for neck examination and for image guided neck biopsies. However scintiscan and PETCT can provides specific functional information which are useful for detecting pathologies. Cognitive correlation between US findings and functional findings can be challenging. We report a preliminary experience using 3D VN and 2D navigation with BMT.
Methods and Materials: MyLabTwice ultrasound scanner equipped with 2D navigation with BodyMark and 3D VN was used (Esaote S.p.A., Italy). 20 patients with different findings (abnormal uptake in thyroid nodules, residual uptake after thyroidectomy, lymph nodes pathologic uptake, parathyroid pathologic uptake) at Scintiscan and PETCT were enrolled. Functional images were loaded on the equipment before performing US examination. After a standard US scan, US was co-registered with scintiscan or PETCT using anatomical landmarks (linear probe LA533, 5-13 MHz with magnetic sensor

support CIVCO, USA). Each patients was examined by 3 operators that were asked about the confidence in localization with cognitive versus VN or BMT technology. The time necessary for cognitive and VN or BMT were recorded.
Results: Operators reported that VN and BMT increased the confidence in localization of pathologic uptake in 76% of cases. The mean time necessary for cognitive, VN and BMT was 4, 2 and 5 minutes respectively.
Conclusion: 3D VN and 2D Navigation with BMT increase the confidence in US localization of abnormal or pathologic functional findings on scintiscan and PETCT compared to cognitive approach. Furthermore the navigation techniques are not time consuming.

B-0067 10:38

TSE or SPACE for high-resolution dental-MRI?
T. Hilgenfeld, M. Prager, S. Schwindling, A. Heil, S. Kuchenbecker, P. Rammelsberg, M. Bendszus, S. Heiland; *Heidelberg/DE (tim.hilgenfeld@med.uni-heidelberg.de)*

Purpose: Dental MRI is a new, radiation free diagnostic tool. Unfortunately, the application is often limited due to poor resolution and artefacts due to metallic dental-materials. Here, we for the first time systematically evaluated whether the turbo spin echo (TSE) or sampling perfection with application optimized contrasts using different flip angle evolution (SPACE) sequence is advantageous for the demanding requirements of Dental MRI.
Methods and Materials: Sequences were optimized on a 3T MRI for maximal resolution and artefact suppression. Normalised signal-to-noise ratio (nSNR), artefact volume and image quality were assessed in vitro in T1- and T2-weighted images. Image quality was assessed by two blinded reader's on a five-point scale. Four titanium and one zirconia dental implants provided with different single crowns were studied: porcelain-fused-to-metal precious-alloy (GP-T), porcelain-fused-to-metal non-precious-alloy (CCT-T), porcelain-fused-to-zirconia (ZC-T) and monolithic-zirconia (Z-T, Z-Z).
Results: Amount of artifact volume depended on used sequence and material composition. Smaller artefacts were always observed for the optimised TSE sequence beside the Z-Z sample (mean reduction over all samples 73.9±12.9%; maximum reduction for GP-T sample 87.8±3.9%). nSNR was significantly higher for the SPACE sequence (241% of the TSE) but no significant difference in image quality was noted. Fewest MRI artefacts were observed for the Z-Z sample and largest for the CCT-T sample. Smaller and comparable artefact volumes were noted for the GP-T, ZC-T, and Z-T samples.
Conclusion: The optimised TSE performs better in terms of artefacts reduction. However, for materials with small differences in magnetic susceptibility the optimised SPACE sequence performs as good as the TSE sequence while offering a higher resolution and higher normalised SNR.

Multiparametric MRI of velopharyngeal inadequacy in patients who underwent primary palatoplasty
R. Magnani, N. Flor, F. Galli, M. Zaffaroni, S. Sbaraini, G. Carrafiello; *Milan/IT (roberta.magnani@hotmail.it)*

Purpose: To evaluate the prospectively role of MR in diagnosis and treatment of cleft palate patients who developed velopharyngeal inadequacy (VPI) and speech deficit, after primary palatoplasty.
Methods and Materials: After our institution review board approval, from January to May 2016 we recruited 17 patients (11 M; 6 F) older than 4 years-of-age (mean age 18; age range 4-42), who previously underwent primary palatoplasty, 10 with velopharyngeal inadequacy and 7 with normal speech function. We performed 1,5 T MR of the soft palate to all patients, without any sedation, at rest and during phonation of vowel "I". Statistical analysis was carried out by means of t-test and Pearson correlation coefficient.
Results: Among cleft palate patients with impaired speech the length and thickness of levator veli palatini muscle (LVP) and velar eminence angle are respectively shorter, thinner and wider in comparison with cleft palate patients with normal speech function (p-value $p<0.0015$, $p<0.02$ and $p=0.014$). All normal speakers have no lateral sphincterial gap during phonation, while most of the patients with speech deficit have.
Conclusion: MR is a consistent and well-tolerated test to investigate patients with velopharyngeal inadequacy, complementary to videofluoroscopy with the significative advantage of the absence of radiation exposure.

B-0069 10:54

Facial vascular anomalies: MRI and TRICKS-MR angiography diagnostic approach
O. Hassanien, U. Ghieda, R.L. Younes, E.A.I.N. Shaban; *Mehalla/EG (ekhlas_radiology@med.tanta.edu.eg)*

Purpose: To evaluate the role of MRI and TRICKS-MR angiography in diagnosis of facial vascular anomalies.
Methods and Materials: This prospective study was performed upon 30 patients presented with suspected facial vascular anomalies. Eight patients were excluded (5 patients because of lack proved diagnosis & 3 patients because of poor image quality secondary to inadequate sedation). The remaining 22 patients with proved facial vascular anomalies on basis of interventional/surgical procedures (n=19) or clinical follow up (n=3) were included .The age range, 2months-23 years; mean age 9 years) .They underwent routine MRI examination with TRICKS-MRA. Images were evaluated for lesion location, extent , signal characteristics, nidus size , presence of feeding arteries and draining veins
Results: AVM was diagnosed in 15patients, haemangiomas were in 5 patients and 2 patients were diagnosed as low flow venous malformation. TRICKS-MRA was more accurate in assessment of the size of AVM nidus and in detection of feeding arteries and draining veins. AVM patients were treated with sclerotherapy (4/15), embolization (6/15) and combined embolization and surgery (5/15). Surgery was done in 2patients with haemangioma while the other three patients underwent clinical follow up for 2 years with stationary course. The 2 patients with venous malformation underwent successful sclerotherapy.
Conclusion: MRI & TRICKS-MR angiography provide excellent diagnostic data for accurate assessment of facial vascular anomalies regarding their size and nature which greatly helps in planning of their therapeutic approach. We recommend addition of TRICKS- MR angiography in MR examination of cases with suspected facial vascular anomalies.

B-0070 11:02

Intravoxel incoherent motion imaging of the head and neck: comparison of quantitative parameters between turbo spin-echo and echo-planar imaging
R. Mikayama, H. Yabuuchi, K. Kobayashi, S. Sonoda, M. Kimura, H. Honda; *Fukuoka/JP (mt_mika_jan_5@yahoo.co.jp)*

Purpose: Echo-planar imaging (EPI), diffusion-weighted imaging (DWI) in the head and neck area is frequently deteriorated by susceptibility artifacts. On the other hands, turbo spin-echo (TSE)-DWI is less sensitive to susceptibility artifacts for using the repeated radio frequency refocusing pulse. The purpose of our study was to compare apparent diffusion coefficient (ADC) and intravoxel incoherent motion (IVIM) parameters between TSE-DWI and EPI-DWI of the head and neck.
Methods and Materials: Fourteen healthy volunteers underwent head and neck DWI of two sequences (TSE-DWI and EPI-DWI). All the examinations were performed using a 3T magnetic resonance unit with a 16-channel-SENSE neurovascular coil. We manually set the regions of interest (ROIs) in the bilateral submandibular glands, sublingual glands, and palatine tonsils, as large as possible avoiding vessels or grand ducts. ADC and IVIM parameters (true diffusion coefficient, D; perfusion fraction, f, respectively) in each ROI were calculated for the two DWI sequences. Bland-Altman analysis was performed to detect systematic errors and calculate limits of agreement (LoA) between TSE-DWI and EPI-DWI.
Results: There are no systematic errors; however, Bland-Altman analysis showed unacceptable LoA (minimum-maximum LoA for each parameter; ±22.8-33.6 % for ADC, ±32.5-56.6 % for D, and ±110.2-153.6 % for f) between TSE-DWI and EPI-DWI.
Conclusion: There are large variance in ADC and IVIM parameters between two sequences. ADC and IVIM parameters of TSE-DWI could not be used as equivalent parameters of EPI-DWI in the head and neck.

B-0071 11:10

Computed tomography of the head and neck region: comparison of dual energy vs single energy
M. May, R. Heiss, M. Wiesmueller, M. Uder, W. Wuest; *Erlangen/DE (wolfgang.wuest@uk-erlangen.de)*

Purpose: Aim of this study was to intra-individually compare the image quality obtained by dual-energy examinations and different virtual monoenergetic images to low kV single-energy scanning.
Methods and Materials: Third-generation dual-source dual-energy CT was performed in 49 patients with histologically proven malignant disease of the head and neck region. A second scan aligned to the jaw covering the oral cavity was obtained to reduce artefacts caused by dental hardware. Single energy with a 70kV setting was used for the second scan. Tube current settings in single- and dual-energy scans were adapted to obtain comparable radiation dose levels. Objective image quality was assessed as contrast to noise ratio (CNR) and subjective image quality on a 5-point Likert scale.
Results: For vessel attenuation, 40keV CNR (28±12) was significantly higher compared to all other keV and kV settings (all $p<0.05$). For tumour attenuation, 40keV and 60keV yielded the highest CNR (9.6±5.6 vs. 6.5±3.4) with no significant difference to each other ($p=0.09$ and 0.08). 60keV CNR was comparable to 70kV ($p=1.0$). Overall subjective image quality was comparable for 40keV, 60keV, 70kV and the weighted average image (all $p>0.05$). CTDIvol was not significantly different (70kV: 19.4 mGy vs. DE neck: 18.6 mGy, $p=0.10$).

Conclusion: 40keV yielded the highest objective image quality in comparison to the other keV reconstructions and to the 70kV scan. Scanning at 70kV might be an option in CT scanners not capable of the dual-energy technique.

B-0072 11:18

Dental implant artefact reduction using novel dual-layer spectral CT
M.J. Willemink, S. Wiersma, R.W. van Hamersvelt, B. Peltenburg, R. de Bree, P.A. de Jong, T. Leiner, J.W. Dankbaar; *Utrecht/NL (m.willemink@umcutrecht.nl)*

Purpose: Dental implant artefacts can be reduced with dual-energy CT (DECT) using virtual-monochromatic images at high photon energies (High-MonoE). However, image quality of virtual-monochromatic images is inferior to conventional images for current DECT systems. Dual-layer spectral CT (DLCT) is a novel DECT technique that uses an anti-correlated noise reduction algorithm. We evaluated artefact reduction and image quality of High-MonoE images of head and neck DLCT with anti-correlated noise reduction.
Methods and Materials: Sixty-one patients with dental implants who underwent a head and neck CT on a DLCT system were retrospectively included. Conventional images and High-MonoE (200keV) images were reconstructed from standard 120kVp-acquisitions. Dental artefact reduction was evaluated using a 5-point Likert scale on three levels adjacent and distal to the implants (resulting in 61*3*2=366 evaluations). Regions-of-interest (ROIs) were drawn at the mandible level in the sternocleidomastoid and spinal muscles and carotid arteries. CT-densities (HU), noise (standard deviations) and signal-to-noise ratios (SNRs) were calculated.
Results: Artefacts influenced adjacent structures in 254/366 evaluations (69.4%) on conventional images, which decreased to 203/366 (55.5%) for High-MonoE. Averaged muscle noise levels were 22.4±4.5HU at conventional images, whereas High-MonoE noise levels reduced to 17.4±3.6HU. Average CT densities of the carotid arteries decreased from 211.8±71.1HU on conventional images to 63.4±20.9HU on High-MonoE, respectively. As CT densities decrease at High-MonoE, averaged muscle SNRs were similar (3.0±0.7 vs 3.1±0.7, respectively).
Conclusion: Noise and dental artefacts reduced with anti-noise-correlated High-MonoE images acquired on novel DLCT compared to conventional CT. Therefore, this study indicates that DLCT may allow for head and neck evaluation on High-MonoE images with improved image quality.

Lateral position with gantry tilt further improves CT image quality reconstructed by single energy metal artifact reduction algorithm in the oral cavity
M. Onodera, K. Aratani, T. Shonai, K. Ogura, M. Hatakenaka; *Sapporo/JP (monodera8@gmail.com)*

Purpose: Single Energy Metal Artefact Reduction (SEMAR) algorithm reduces metal artefacts on CT. However, image quality is not sufficiently improved in cases with multiple dental metals. The objective of this study is to investigate whether lateral position (LP) with gantry tilt (GT) resolves this limitation in the oral cavity (OC).
Methods and Materials: Our institutional review board approved this prospective study and written informed consent was obtained from all patients. We recruited 74 patients (45 men and 29 women) who had dental metals in multiple locations, and underwent head and neck CT between September 2014 and March 2015 in two positions: First, standard supine position (SP) without GT, and second, LP with 15 degrees of GT. Both images were reconstructed with SEMAR. Two radiologists assessed image quality in two areas, outside (OUT) and inside the dental arch (IN), using a 4-point scale: 1= severe artefact, 2= moderate artefact, 3= slight artefact, 4= no artefact. Image-quality score was compared between two positions using Wilcoxon signed-rank test. A *P* value < 0.05 was regarded as statistically significant.
Results: The image-quality score was significantly higher in LP with GT than SP in both areas (OUT: 3.1±0.4 vs. 2.3±0.4; IN: 2.6±0.7 vs. 1.9±0.5; $P < 0.0001$).
Conclusion: LP with GT resolved the limitation of SEMAR in the OC, probably through separating right and left dental metals into different planes.

B-0074 11:34

Evaluation of laryngopharyngeal structures by CT scan using dynamic "eee" phonation maneuver
K.K. Obeng, P. Ignaciuk, J. Kim, F. Appiah, N. Darboe, E.J. Escott; *Lexington, KY/US (kob223@uky.edu)*

Purpose: To determine if we could prospectively produce clearer delineation of pertinent structures of the pharynx and larynx by imaging patients with head and neck ailments with dynamic "eee" phonation.
Methods and Materials: One hundred and sixty patients were randomly divided into 2 groups; group A (n=80) underwent CT imaging in 'quiet respiration and group B (n=80) underwent CT imaging with an "eee" phonation maneuver. A control group C (n=82) imaged prior to beginning the study were selected randomly from our PACS. Images were evaluated independently by; (1) a neuroradiologist evaluating by consensus with a senior radiology trainee and (2) a neuroradiologist alone. Each evaluated subject was assigned numerical values for the valleculae, piriform sinuses and laryngeal ventricles distention (0 - no distention to 2- excellent distension). True vocal cord position was also assigned a numerical value (0,1,2). Chi-square test was used to examine the relationship between the experiments outcome and the control. .
Results: There was a mild to moderately high agreement between the two reviewing personnel with respect to the experimental and control measures. There was a statistically significant delineation with respect to laryngeal ventricles (p-value=0.009), piriform sinuses (p-value<0.001), and true vocal cords (p-value<0.001), of the experimental groups compared to the control group.
Conclusion: There is improved delineation of pertinent laryngopharengeal structures when CT scan of the neck is performed by employing the 'eee' phonation maneuver.

B-0075 11:42

The role of CB-CT on the planning, surgical technique and follow-up of pterygoid implants: a controlled prospective study
G. Ferrero[1], F. Fiz[2], C. De Angelis[2], E. Fabbro[1], A. Corazza[2], D. Orlandi[2], I. Fiz[2]; [1]*Pietra Ligure/IT*, [2]*Genoa/IT (giulio.ferrero@gmail.com)*

Purpose: Pterygoid implant (PI) is an emerging treatment option for posterior maxillary edentulism. Pre-operatory planning is the key: CB-CT examination performed with the use of a radiologic template allows to obtain an accurate intraoperatory 3D-printed model as surgical referral, thus improving the surgical outcome. In this study, the PI made with the guidance of a preoperative CB-CT obtained with a radiologic template was compared with the traditional implanting technique without radiologic template.
Methods and Materials: Forty patients (group A:27 females, mean age 58, range 38-85) underwent 52 PI procedures with the guidance of a 3D intraoperatory model obtained from CB-CT performed with radiological template. Patients' comorbidities at the time of implant, PI positioning (I or II quadrant) and presence of post-operative pain were recorded. These parameters were compared with the ones derived from 40 patients (group B,controls: 14 females, mean age 59, range 35-93, 52 procedures), treated with CB-CT-based solutions without radiological template.
Results: Dental elements loss was less pronounced in group A with respect to group B, occurring in 2 patients (3/52 PI) in the first 12 months and in 17 patients (17/52 PI) in group B (p<0.001). Follow-up at 24 months up confirmed this trend (3/52 vs 29/52, p<0.001). Advanced age and diabetes mellitus resulted as risk factors for this occurrence (p<0.01). Persistent post-operative pain was less prevalent in group A patients compared with group B (5/40 vs 31/40, p<0.001) and was a hallmark of possible procedure failure (in 3/3 failed and 2/47 successful procedures of group A; in 17/17 failed and in 2/35 successful procedures in group B; p<0.001).
Conclusion: PI guided by CB-CT examination performed with the use of a radiologic template is a viable therapeutic option for posterior edentulism.

B-0076 11:50

Quantitative and analytic assesment of incidental findings in patients exposed to CBCT
M. Iodice; *Milan/IT (maiodice@gmail.com)*

Purpose: The aim of this study was to evaluate topology and incidence of incidental findings in patients who had undergone to cone-beam computed tomography (CBCT) and the consequences on diagnostic and therapeutic path.
Methods and Materials: A group of expert radiologist examined retrospectively 5000 CBCT reports of two diagnostic radiology centres (using respectively NewTom VGi Evo and Planmeca ProMax 3D Mid) executed between January 2013 and November 2015. We divided findings according to the anatomic belongings: odontogenic, airways, soft tissues, bone, and temporo-mandibular joint (TMJ). Moreover they were divided into three groups: a group 1 of patients who needed intervention or postponement, a group 2 of

patients with monitoring pathologies and a group 3 of patients who did not need intervention.
Results: On 5000 patients, we found 3021 incidental findings (60%). The most significative findings were referred to airways (68%), bone (15%), odontogenic (10,5%), soft tissues (5%), TMJ (1%) and blood vessels (0.5%). 21% of our findings belonged to group 1, 11% to group 2 and 68% to group 3. We did not find malignant neoplastic lesions.
Conclusion: This study underlines the necessity of accurate examination of all the anatomic parts included in the volume of acquisition of CBCT, to avoid the oversight of important clinical findings.

Targeted ultrasound for breast lesions detected at MRI: a systematic review and meta-analysis
N. Berger[1], J. Wiederer[2], N. Voyvoda[3], L.A. Carbonaro[4], R.M. Trimboli[4], G. Di Leo[4], F. Sardanelli[4]; [1]*Zurich/CH*, [2]*Würzburg/DE*, [3]*Derince/Kocaeli/TR*, [4]*San Donato Milanese/IT (Nicole.Berger@usz.ch)*

Purpose: To perform a systematic review and meta-analysis on the detection rate of second look ultrasound(SLUS) in breast lesions detected by Magnet Resonance Imaging(MRI).
Methods and Materials: No ethics committee approval was needed. A systematic literature search was performed (MEDLINE,EMBASE,WEB OF SCIENCE) for articles evaluating SLUS after MRI with follow up or histologic proof as reference standard. Three independent readers selected eligible articles published until April 2016. The quality of studies was assessed using the Quality Assessment of Diagnostic Accuracy Studies 2(QUADAS-2). Effect size with a 95% confidence interval(CI) and heterogeneity of the studies were calculated. The Egger test was performed for assessing the publications bias and a meta-regression was performed to analyze the publication date and the size of the lesions. Subgroup analyses were performed for cancers, mass lesions, non-mass enhancement and foci.
Results: Thirty-three articles were included. The study quality was mostly high. The detection rate of all lesions was very heterogeneous (I^2=93.7%; P=0.0001) with a point estimate of 64.2% (95%CI=57.5%-70.4%). The risk of publication bias was significant (P=0.033). Year of publication and mean lesion diameter were not significant (P=0.935 and 0.184, respectively). The detection rate at SLUS of cancers, mass lesions, non-mass enhancement and foci showed a point estimate of 77.5%, 66.5%, 37.5% and 48.1%, respectively.
Conclusion: SLUS is a reasonable examination-tool after finding a previously unknown lesion in breast-MRI, especially in cancerous or mass lesions. Nevertheless negative SLUS does not exclude malignancy and MRI-guided biopsies or follow-up examinations have to be considered for further work-up.

B-0078 10:38

How does switching from mammography to tomosynthesis impact the use of breast ultrasound
A. Stolz[1], A. Poncet[2], H. Stolz[2], N. Howarth[3], K. Kinkel[3]; [1]*Neuchâtel/CH*, [2]*Geneva/CH*, [3]*Chêne-Bougeries/CH (alexandre.stolz@h-ne.ch)*

Purpose: The aim of this study was to evaluate changes in the daily use of secondary breast ultrasound after mammography when switching from digital mammography (DM) to systematic digital breast tomosynthesis (DBT).
Methods and Materials: A total of 2000 women (mean age, 57,9yrs ; range, 46-69yrs) with diagnostic mammographies were evaluated between December 2014 and November 2015 in a breast clinic. Three experienced radiologists filled a questionnaire before performing or not any additional breast ultrasound (US). Questionnaires include age, menopausal status, hormonal treatment, indication for additional ultrasound decided by the radiologist (clinical either/or imaging findings, dense breasts, familial high risk or personal history of breast cancer) and the time required for completion of the US.
Results: Secondary ultrasound was performed in 447/476 (93.9%) patients after DM and in 1415/1524 (92,8%) patients after DBT and showed no difference in proportion. There were no significant differences in clinical findings, familiar risk and treated cancer patient between the DM and DBT groups. The proportion of examinations followed by US for positive imaging findings or dense breasts did not differ between the two groups. The mean time required for performing US after a DBT was 5.06min compared to 5.07min after a DM, the difference of -0.01 minutes, 95% CI [-0.26 ; 0.25], p = 0.9565) was not significant and did not differ when compared by radiologist.
Conclusion: The introduction of DBT does not change the proportion of secondary ultrasound of the breast after mammography nor the time required to perform it.

B-0079 10:46

Breast ultrasound: can 3D multiplanar reconstructions aid in the differentiation of benign from malignant lesions?
P. Kapetas, P. Clauser, R. Woitek, M. Bernathova, K. Pinker, T.H. Helbich, P.A.T. Baltzer; *Vienna/AT (panagiotis.kapetas@meduniwien.ac.at)*

Purpose: To evaluate the added value of three-dimensional (3D) multiplanar reconstructions (MPRs) to the two-dimensional (2D) B-mode ultrasound (US) for differentiating benign from malignant breast lesions.
Methods and Materials: 99 patients with 101 breast lesions planned to undergo US-guided biopsy were examined with 2D B-mode US. A 3D volume of each lesion was subsequently recorded. 2 readers (R) independently evaluated the 2D image of each lesion according to the breast imaging reporting and data system (BI-RADS) lexicon and assigned a BI-RADS classification. Then, they evaluated the MPRs of each lesion and assigned a new BI-RADS classification, while also recording the presence or absence of retraction in the coronal plane. They were also asked to score their degree of confidence for the BI-RADS classification in a 10-point scale. Receiver-operating characteristics analysis was used to evaluate reader performance and confidence. Logistic regression was used to evaluate the different BI-RADS descriptors in 2D and 3D US.
Results: 53 lesions were malignant and 48 benign. Area under the curve did not differ significantly between 2D and 3D BI-RADS classification for neither of the readers (R1:0.829 vs 0.866, p>0.05, R2:0.847 vs 0.810, p>0.05). Retraction phenomenon showed high specificity (R1:96.55%, R2:89.58%) but low sensitivity (R1:31.82%, R2:42.31%). In multivariate logistic regression significant association with malignancy was shown for margin (p<0.05) in 2D and margin (p<0.001) and shape (p<0.01) in 3D US. A (non-significant) tendency towards higher confidence was shown for 3D US.
Conclusion: 3D MPRs have a similar diagnostic performance as 2D breast US. A positive retraction phenomenon is highly suggestive of malignancy.

B-0080 10:54

Usefulness of computer-aided diagnosis conjunction to breast ultrasound depending on experience of breast imaging
J.-h. Choi[1], B. Kang[2], E. Kim[2], S. Kim[2]; [1]*Gyeonggi-do/KR*, [2]*Seoul/KR (mchjjh2@naver.com)*

Purpose: To evaluate the usefulness of computer-aided diagnosis (CAD) conjunction to breast ultrasound depending on the experience of breast imaging.
Methods and Materials: Between October 2015 and January 2016, the expert group of two breast radiologists consecutively performed general breast ultrasound for women with screening and diagnostic purposes. When there was suspicious or probable benign lesion, they added the newly developed CAD system (S-detect™) on them. And, they choose the proper BI-RADS lexicons and categories on general ultrasound, CAD, and general ultrasound with CAD. For the same cases, two first-grade residents without breast imaging experience choose the BI-RADS lexicons and categories on them (general ultrasound, CAD, and general ultrasound with CAD). And then an uninvolved expert radiologist concluded enrolment and assessed the final result correlated with mammography, old ultrasound, and histopathology. Finally we compared the diagnostic performance depending on the experience of breast imaging.
Results: A total of 200 cases were enrolled in this study. These were sensitivities of expert (91.7%), resident (75%), and CAD (75% & 66.7%). These were specificities of CAD (78.2% & 76.1%), expert (76.6%), and resident (71.8%). After combination with CAD, the specificity was improved (76.6% to 80.3%) without change of sensitivity (91.7%) in expert group. After combination with CAD, the sensitivity and specificity were improved in resident group (75% & 71.8% to 83.3% & 77.1%).
Conclusion: CAD is more useful for less experienced radiologists. When combined the CAD to ultrasound, the specificity is improved in any radiologists.

B-0081 11:02

Evaluation of a computer-aided-diagnosis system in breast ultrasound (S-Detect): intrinsic value and effect on junior radiologist's performance
M. Attard, S. Ammary, E. Pottier, F. Mihoubi, A. Dunant, C. Balleyguier; *Villejuif/FR (marie_attard@hotmail.fr)*

Purpose: To evaluate diagnosis performance and effect of S-Detect™ on junior radiologist's interpretation in breast ultrasound. This Computer-Aided Diagnosis (CAD) is based on Breast Imaging Reporting and Data System (BI-RADS).
Methods and Materials: 189 biopsied lesions were included, 111 were malignant and 78 were benign. CAD sensitivity and specificity was calculated.

Four junior radiologists read ultrasound images without and with CAD, and their sensitivity (Se), specificity (Sp), and Receiving Operating Characteristic (ROC) analysis were compared. Readers had classified lesions using American College of Radiology (ACR) BI-RADS score, and a binary classification benign/malignant (BM).
Results: CAD sensitivity and specificity were calculated respectively at 82% and 81%. Its use has resulted in an increasing trend with all reader's sensitivity for either classification used: reader 1: 92% vs. 90% (classification BM and BI-RADS score); reader 2: 78% vs. 77% (classification BM); 91% vs. 88% (BI-RADS score); reader 3: 85% vs. 80% and 98% vs. 97%; and reader 4: 90% vs. 88% (BI-RADS score); and also with the ROC for 3 readers: reader 1: 0.87 vs. 0.86; reader 3: 0.89 vs. 0.87; and reader 4: 0.81 vs. 0.78. These results were not statistically significant ($p > 0.01$). No significant decrease in specificity was identified after using CAD.
Conclusion: S-Detect™ has good intrinsic performances, but its use did not allow significant modifications for the 4 junior radiologists' performance; nevertheless, an improving trend could be noted.

B-0082 11:10

Breast ultrasound computer-aided diagnosis: diagnostic performance, merits and pitfalls

M. Jeong[1], B. Kang[2], E. Kim[2], S. Kim[2]; [1]*Gyeonggi-do/KR*, [2]*Seoul/KR*
(mkjpretty@gmail.com)

Purpose: The aim of this study was to evaluate diagnostic performance of a computer-aided diagnosis (CAD) system for breast ultrasound to distinguish between benign and malignant lesions and to analyse features of lesions interpreted with errors retrospectively.
Methods and Materials: Between October 2015 and August 2016, 338 women (mean age, 48.7± 11.5 years) with 397 lesions were enrolled and underwent breast ultrasound with ultrasound CAD system (S-detect™). We assessed accuracy, sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV). In addition, we evaluated causes and patterns of misinterpretation in false positive and negative groups.
Results: Accuracy, sensitivity, specificity, PPV and NPV of breast ultrasound CAD were 77.1 %, 81.6 %, 76.5 %, 32.7 and 96.7 %, respectively. Eight false negative lesions were all oval in shape and parallel in orientation. Among 82 false positive lesions, 31 lesions were benign lesions with suspicious features such as fat necrosis or post-operative change. Second leading cause of misinterpretation in 23 lesions was inappropriate demarcation of lesions due to heterogeneous echogenicity, large size, adjacent parenchyma or posterior acoustic shadowing. 21 lesions with suspicious features with good demarcation and proper description were confirmed as benign histologically. And 7 lesions with good demarcation and descriptions implying benignity showed possible malignancy as a final conclusion.
Conclusion: Breast ultrasound CAD is expected to be helpful in avoiding unnecessary biopsy due to its high NPV. And operators need to know characteristics of lesions prone to misinterpretation and to consider clinical history and findings of other imaging modality.

B-0083 11:18

Quantitative multiparametric ultrasound of the breast

P. Kapetas, R. Woitek, P. Clauser, K. Pinker-Domenig, M. Bernathova, T.H. Helbich, P.A.T. Baltzer; *Vienna/AT*
(panagiotis.kapetas@meduniwien.ac.at)

Purpose: To evaluate quantitative multiparametric ultrasound of the breast for the differentiation of benign and malignant lesions.
Methods and Materials: 118 patients, each with one biopsy-proven, sonographically evident lesion were included in this prospective, IRB-approved study. Each lesion was examined with B-mode ultrasound (US), elastography (Acoustic Radiation Force Impulse-ARFI), Doppler US and Contrast Enhanced US (CEUS). Quantitative indices were recorded for each modality as follows: Shear Wave Velocity (SWV) for ARFI, Pulsatility (PI) and Resistive Index (RI) for Doppler US, and Peak Enhancement (PE), Wash-in Area Under the Curve (WiAUC), Rise Time (RT), mean Transit Time (local) (mTTI), Time To Peak (TTP), Wash-in Rate (WiR), Wash-in Perfusion Index (WiPI), Wash-out AUC (WoAUC), Fall Time (FT) and Wash-out Rate (WoR) for CEUS. Paired and unpaired nonparametric statistics were applied for comparisons as appropriate. Diagnostic accuracy of measurements was compared using Receiver Operating Characteristics (ROC) analysis. Multivariate logistic regression was used to determine independent predictors of malignancy.
Results: 64 lesions were malignant and 54 benign. SWV and RI showed the highest diagnostic performance as measured by the area under the ROC curve (0,871 and 0,805 respectively). At a cut-off value of 3.1 m/s, SWV showed sensitivity of 85.94% and specificity of 85.19%. An RI cut-off of 0.68 revealed sensitivity of 77.78% and specificity of 80.56%. Multivariate logistic regression showed that SWV, RI and mTTI were independent predictors of malignancy.
Conclusion: Multiparametric ultrasound of the breast offers quantitative indices that can aid in the differentiation of benign and malignant breast lesions.

B-0084 11:26

Diagnostic performance of assist strain ratio (ASR) in computing fat-to-lesion ratio (FLR) in ultrasound breast elastography

R.G. Barr[1], R.A. Managuli[2]; [1]*Campbell, OH/US*, [2]*Seattle, WA/US*
(rgbarr@zoominternet.net)

Purpose: ASR is a new application tool developed to differentiate benign from malignant lesions in breast US elastography. This ASR would potentially eliminate current user dependency in outlining tumour and fat area while computing FLR manually. The objective here is to compare the clinical performance of ASR against manual strain ratio (MSR) in the computation of FLR.
Methods and Materials: 42 breast lesions (24 malignant and 18 benign) scheduled for biopsy were included in this IRB approved and HIIPA complaint study. Skilled physician (RGB) performed the elastography exam and selected a frame for computing FLR. MSR was computed manually while ASR was computed with minimal user input. Hitachi's HIVISION Ascendus with L75P was used for this study. An average of three measurements was used as a cut-off for differentiating lesions.
Results: Cut-off point were determined to be 2.2 for both MSR and ASR using Youden index. Diagnostic performance of MSR were: sensitivity-96%, specificity-67%, accuracy-83 %, PPV-79%, and NPV-92%. Corresponding performance of ASR were: sensitivity-96%, specificity-83%, accuracy-91%, PPV-89%, and NPV-94%. The AUC for MSR and ASR were 0.86 and 0.95, respectively and average coefficient of variation (COV) were 30% and 43% respectively.
Conclusion: ASR demonstrated excellent diagnostic performance compared to MSR. In addition, COV of ASR is lower than MSR implying reduced intra- and inter-operator dependency. Next, we will use auto-frame-select with ASR to minimise manual dependency in selecting the frame as well.

Strain elastography with quality control: auto strain ratio system

K. Nakashima, S. Sakurai, A. Mizutou; *Okayama/JP*
(urbandoc@med.kawasaki-m.ac.jp)

Purpose: Strain elastography (SE) and shear wave speed imaging provide us with tissue stiffness information, important for breast diagnosis. SE allows us to visualise tissue stiffness that reflects the pathological information. However, it can be associated with operator bias in image formation, scanning technique, the selection of the appropriate frame, and ROI setting for strain ratio measurement. To overcome these problems, we have developed an "Auto Strain Ratio System (ASRS)", which requires no manual compression whilst scanning, full auto frame selection on freeze and fully automatic ROI target selection. A preliminary prospective clinical study was performed in 2015.
Methods and Materials: 232 breast masses assessed as BI-RADS Category 3 or above by B-mode, were scanned using SE. The new ASRS was compared to conventional manual strain ratio measurement (MSR) by experienced doctors and the diagnostic performance and quality evaluated.
Results: There was a significant correlation between the MSR and ASRS with $R=0.79$ ($p<0.001$). The MSR (cut-off=3.8) had a sensitivity of 89%, a specificity of 75%, an accuracy of 78%, a positive predictive value (PPV) of 52%, and a negative predictive value (NPV) of 96%. The ASRS (cut-off=3.9) had a sensitivity of 82%, specificity of 89 %, an accuracy of 87%, a PPV of 69%, and a NPV of 94%. The AUCs were 0.88 on MSR and 0.89 on ASRS.
Conclusion: We have demonstrated that it is possible to quantify SE and control its accuracy. The ASRS is expected to contribute to the standardisation of breast elastography.

B-0086 11:42

Mass-like focal breast fibrosis a bening entity mimicking malignancy on ultrasound

E. Horvath, A. Altamirano S., M. Pinochet, E. Soto, M. Uchida, F. Pizzolon; *Santiago de Chile/CL (aleenaltamirano@gmail.com)*

Purpose: To determine the sonographic characteristics of core biopsy-proven mass-like focal breast fibrosis (MFBF).
Methods and Materials: IRB approved, retrospective study. Between April 2007 and January 2015, 3051 US-guided breast biopsies with 14G core needle, were performed, 251 of them with a diagnosis of stromal breast fibrosis. We excluded 128 cases where fibrosis was not the primary histologic diagnosis, only MFBF cases were included. Imaging features were tabulated and analysed. Follow-up imaging was reviewed to document lesion stability.

Results: In 121 women (median age: 50 years, range: 25-83) we found 123 cases of MFBF. Lesion size ranged from 4 to 35mm (median: 10mm), non-palpable in 94% of the cases. Eighty-seven (71%) of them developed in dense breast (ACR 4 and 3). Only 7 (6%) were evident on mammography. We identified two distinct sonographic patterns of MFBF. Pattern A (28%): well-circumscribed, hypoechoic, avascular mass. Pattern B (72%): ill defined, irregular, avascular, markedly hypoechogenic, spiculated with shadowing, located intraparenchymatous or under Cooper ligament. Sixty-seven (54%) lesions were reported as BI-RADS 5, 4C or 4B. MRI was performed in 7 patients with negative outcome. One lesion was surgically removed and 4 new biopsies were performed due to discordance, obtaining the same results. Patients remain in follow-up (30 months), without malignancy.
Conclusion: The MFBF is a benign entity with the potential to mimic malignancy. Is important that radiologists know the specific US patterns and if proven on core needle biopsy, it may be taken as a concordant diagnosis.

B-0087 11:50

Clinical usefulness of repeated short-term follow-up imaging in young patients with initial diagnosis of BI-RADS 3 lesions

M. Marcon, T. Frauenfelder, A. Becker, K. Dedes, A. Boss; *Zurich/CH (Magda.Marcon@usz.ch)*

Purpose: To evaluate the clinical usefulness of repeated short-term follow-up with ultrasound in patients younger than 35 years with a BI-RADS 3 lesion at first ultrasound examination and proven lesion stability at the 6-month follow-up.
Methods and Materials: In this IRB-approved study, 492 women, aged 18-34 years (mean±standard deviation, 28±4.5 years) with first breast ultrasound examination in 2012-2014 were retrospectively evaluated. Inclusion criteria were: at least one BI-RADS3 lesion and (a) biopsy/surgical excision or (b) follow-up of at least 18 months (including a 6-month follow-up). BI-RADS category assigned during follow-up and pathologic findings in cases undergoing biopsy/surgical excision were collected. Recommended biopsy rates (RBR) after 6 and 18 months and positive predictive value (PPV) for biopsy after recommendation due to interval changes (PPV_{bio}) were calculated.
Results: In 97 patients, 151 BI-RADS3 lesions were identified. Biopsy/surgical excision was performed after initial assessment in 25/151 (16.5%) lesions. At 6-month follow-up, assessment category was changed to BI-RADS 1 or 2 in 23/126 (15.3%) and to BI-RADS 4 in 9/126 lesions (7.1%) due to interval growth. Pathological diagnosis of these lesions was fibroadenoma in 5 cases and benign phyllodes tumour in 4 cases (RBR 7%, PPV_{bio} 44.4%). At 18-month follow-up one lesion was classified BI-RADS 4 due to interval growth and pathological diagnosis was fibroadenoma (RBR 1.1%, PPV_{bio} 0%).
Conclusion: Follow-up imaging performed after 18 months from a first BI-RADS3 diagnosis does not affect clinical treatment and 6-month follow-up may be sufficient to assess the stability of probably benign lesions and to discern those which entail further investigation.

Inter-rater variability when scoring CT scans in acute ischaemic stroke using the ASPECTS score

C. Goncalves[1], O. Joly[2], A.L. Kühn[3], S. Shah[1], S. Kelavkar[1], C. Law[4], P. Harman[1], I.Q. Grunwald[5]; [1]*Southend-on-Sea/UK*, [2]*Oxford/UK*, [3]*Worcester, MA/US*, [4]*Palo Alto, CA/US*, [5]*Chelmsford/UK*

Purpose: Plain computed tomography (CT) remains the most common imaging modality for acute ischaemic stroke. For mechanical thrombectomy, recommended selection criteria include an ASPECTS score of ≥ 6. However, detection of early ischaemic signs can be challenging, even for senior neuroradiologists. The purpose of our study was to assess the inter-rater agreement for the detection of early ischaemic signs in the ASPECTS regions between senior neuroradiologists.
Methods and Materials: Plain CT images from 132 patients with acute ischaemic stroke were included in this study. Three neuroradiologists, experienced with stroke imaging and evaluation of ASPECTS, independently scored all the cases. They were blinded to any clinical information. Cohen's Kappa and Fleiss' Kappa were computed both for 20 region-based agreement and for dichotomised ASPECTS (ASPECTS ≥6) as a measurement of agreement between the raters.
Results: At the regional level, paired Cohen's Kappa were 0.35, 0.51, 0.34. The regional agreement was summarised as a Fleiss' Kappa of 0.37. When considering dichotomised ASPECTS (≥6), paired Cohen's Kappa were 0.36, 0.51, 0.25. Overall dichotomised ASPECTS was summarised as a Fleiss' Kappa of 0.31.
Conclusion: We have found only a fair level of inter-rater agreement between neuroradiologists for the evaluation of early ischaemic changes. Our results are within the range of slight to moderate interrater agreement reported recently (Farzin et al., Neurology 2016). Clinicians should be encouraged to evaluate the inter-rater variability for evaluation of ASPECTS in their own center in order to design an optimal clinical pathway for acute stroke management.

Diagnostic accuracy for detection of intracranial haemorrhage in low-dose unenhanced head single-energy and dual-energy third generation dual-source computed tomography

J.-E. Scholtz, J.L. Wichmann, D.W. Bennett, D. Leithner, M.H. Albrecht, S. Martin, R.W. Bauer, T.J. Vogl, B. Bodelle; *Frankfurt a. Main/DE (janerikscholtz@gmail.com)*

Purpose: To determine diagnostic accuracy for detection of intracranial haemorrhage (ICH), image quality, and radiation dose of low-dose single-energy (SE) and dual-energy (DE) unenhanced head computed tomography (CT) on third-generation dual-source CT.
Methods and Materials: 123 patients with suspected ICH were examined on a 192-slice dual-source CT. Standard-dose SE (120-kV, Group A,n=36) and DE (80-/Sn150-kVp, Group B,n=30) images were compared with low-dose SE (Group C,n=32) and DE (Group D,n=25) using automated-tube-current-modulation (ATCM). Advanced-modeled-iterative-reconstruction (ADMIRE) was used for all protocols. Detection of ICH was performed by three blinded readers. Image quality was assessed quantitative and qualitative. Interobserver agreement was calculated using Fleiss' Kappa. Radiation dose was assessed as dose-length product (DLP).
Results: Detection of ICH was excellent (sensitivity,94.9-100%; specificity,94.7-100%) in all protocols (p=1.00) with perfect interobserver agreement (0.83-0.96). Qualitative ratings showed significantly better ratings for both standard-dose protocols regarding gray-matter-to-white-matter (GM-WM) contrast (p≤0.014), whereas highest GM-WM CNR was observed in low-dose DE-CT (all,p≥0.057). Lowest posterior-fossa-artifact-index was measured for standard-dose DE-CT with significantly lower values compared to low-dose protocols (both p≤0.034). Delineation of ventricular margins and subarachnoidal spaces sharpness were rated excellent in all protocols (p≥0.096). Low-dose SE lowered radiation dose by 26% (DLP, 575.0±72.3mGy*cm vs. 771.4±146.8mGy*cm, p<0.001) and by 24% in DE (DLP, 587.0±103.2mGy*cm vs. 770.6±90.2mGy*cm, p<0.001). No significant differences were observed between low-dose protocols (p=1.00).
Conclusion: Low-dose unenhanced head SE and DE-CT using ATCM and ADMIRE provide excellent diagnostic accuracy for detection of ICH with good quantitative and qualitative image quality in third-generation dual-source CT while allowing for significant radiation dose reduction.

Leptomeningeal score (LMs) on computed tomography angiography (CTA) and effect of endovascular reperfusion (ER) on clinical outcome in patients with acute ischaemic stroke (AIS)

E. Puglielli, R. Lattanzi, G. Esposito, V. Di Egidio; *Teramo/IT (edopug@hotmail.com)*

Purpose: Aim of this study was to review the importance of LMs on the outcome after ER and to evaluate a reliable score system for grading the collateral state.
Methods and Materials: In our database, we identified 125 consecutive AIS patients (mean age 59,8 y, April 2009 - September2016), with classic on-set, that undergoing to ET after basal CT/CTA. We assessed the baseline ASPECT on non-enhanced (NCCT), CTA images, collaterals, clot burden score (CBS) on CTA and degree of reperfusion after ET (TICI 0-III) with clinical data. Two readers, blinded to clinical informations, evaluated the images in parallel and LMs was based on scoring pial and lenticulostriate collaterals (0, no; 1, less; 2, equal or more prominent compared with matching region in opposite hemisphere) in 6 ASPECTS regions (M1-6) plus anterior region and basal ganglia. Good clinical outcome (GCO) was defined as mRS≤2 at 90 days.
Results: TICI III-IIb (OR 27.50; 95%-CI 9.34-81.63) and good collaterals (OR 9.76; 95%-CI 3.28-56.72) were independent predictors of favourable outcome,

such as female sex (OR 0.27; 95%-CI 3.45-8.63), younger age (OR 75.30; 95%-CI 7.44-87.31) and higher NCCT ASPECT (OR 2.56; 95%-CI 1.34-6.33). On multivariate analysis GCO well matched with good LMs and TICI III-IIb, but there was no statistical association between LMs and reperfusion (p=0.5).
Conclusion: LMs alone appear to be as a strong imaging parameter for GCO after ET in AIS patients and it might be suitable for imaging based selection.The effect of reperfusion on outcome seems to be strong as the LMs.

B-0091 10:54

Causes of acute intracranial large vessel occlusion in patients with acute ischemic stroke

K. Compagne[1], Y. Roos[2], D. Dippel[1], R. van Oostenbrugge[3], W. van Zwam[3], C. Majoie[2], H. Marquering[2], A. van der Lugt[1], B. Emmer[1]; [1]*Rotterdam/NL*, [2]*Amsterdam/NL*, [3]*Maastricht/NL (c.compagne@erasmusmc.nl)*

Purpose: Intracranial large vessel occlusion (LVO) in patients with acute ischemic stroke (AIS) has multiple pathogenic causes. Identification of the underlying cause of LVO may have major implications for clinical decisions, treatment, and outcome. The aim of this study is to identify the most likely cause of intracranial LVO.
Methods and Materials: Data (n=500) from the MR CLEAN trial which investigated the effectiveness of intra-arterial treatment were reanalysed. Patients with AIS are classified in one of the four pre-defined categories of presumed causes of AIS: carotid dissection, carotid atherosclerosis, cardiac embolism, or undefined. Categorization was based on clinical data (atrial fibrillation (AF) and myocardial infarction (MI)), electrocardiogram (ECG), and CT angiography (CTA). Atherosclerotic carotid disease was defined by the presence of an occlusion, stenosis (>50%), plaque ulcerations or severe calcifications (upper quartile of volume of calcifications at bifurcation) on the symptomatic side.
Results: Data of 426 patients could be analysed. Carotid dissection was identified in 21 patients (4,9%) and cardiac embolism in 126 (29,6%) patients (AF (n=92) and MI (n=47)). Carotid atherosclerosis was present in 154 (36,2%) patients subdivided in occlusion (n=61), significant stenosis (n=49), ulcerations (n=25), and severe calcifications (n=19). The cause of LVO could not be classified in 125 patients (29,3%) according to our criteria.
Conclusion: Based on clinical information, ECG and CTA the most likely cause of AIS due to LVO can be classified in more than 70% of the patients. Carotid vessel atherosclerosis and cardiac embolism are major causes of LVO in patients with AIS.

Acute ischaemic stroke CT imaging and clinical score in patients with isolated intracranial distal artery occlusion

A. Velasco González, N. Münnich, B. Buerke, W. Schwindt, J. Spieker, J. Minnerup, C. Sauerland, W. Heindel; *Münster/DE (Aglae.VelascoGonzalez@ukmuenster.de)*

Purpose: Evaluation of CT characteristics in patients with acute ischemic stroke by isolated intracranial distal artery occlusion in correlation with acute and subacute neurological symptoms due to the final infarction area.
Methods and Materials: 55 consecutive stroke patients with an acute distal cerebral artery occlusion were retrospectively analysed. The following criteria were evaluated: presence of infarct demarcation at stroke onset in the non-contrast CT (NECT), localisation of the thrombus and collaterals in CT-angiography [M2- and M3-segment of the middle cerebral artery (n =46), A2-segment of the anterior cerebral artery (n=5), P2-segment of the posterior cerebral artery (n=1) and superior cerebellar artery (n=1)], presence of mismatch in the CT-perfusion and final infarction in the follow up NECT after 24 hours. NIHSS scores of the first and the 4th day and type of therapy were evaluated.
Results: Initial versus follow up NECT showed no significant differences regarding rates of no infarct (49% vs 41.3%), partial (20% and 20%) and complete demarcation (30.9% vs 37.7%). Nevertheless, an overall significant improvement of the neurological symptoms was observed [mean initial NIHSS:11.2±5.6 versus NIHSS on day 4: 3.5±0.86(P=.017)]. Patients with an initial perfusion mismatch had no significant better outcome than those with an initial match. No significant better outcomes were found in the group treated with iv thrombolysis versus without iv thrombolysis or mechanical thrombectomy (P>0.05).
Conclusion: Our data suggest that distal intracranial occlusions without concomitant proximal stenosis or occlusion have a relative benign course poorly improved by the use of iv thrombolysis or mechanical thrombectomy.

B-0093 11:10

Intra-arterial thrombus detection by multi-echo SWI in acute ischaemic stroke patients

B. Kong, H. Choi, Y. Nam, J. Jang, S.-L. Jung, K.-J. Ahn, B.-S. Kim; *Seoul/KR (blacksky1218@hotmail.com)*

Purpose: Detection of intra-arterial thrombus is important to decide treatment plan and to monitor treatment response. Previously, precontrast CT, T2*-weighted gradient echo, FLAIR, and SWI were studied for detection of intra-arterial thrombus. However, to the best of our knowledge, there was no study using multi-echo SWI in detection of intra-arterial thrombus. The purpose of this study is to compare multi-echo SWI (mSWI) with single-echo SWI (sSWI), FLAIR and T2-weighted image (T2WI) in detection of intra-arterial thrombus in acute stroke patients.
Methods and Materials: Between March 2015 and April 2016, 89 consecutive patients with acute infarct (positive on DWI) were reviewed from stroke registry. Among them, 74 patients who were examined by MRI including multi-echo SWI, FLAIR, and T2WI were included in this study. Four MR sequences (mSWI, sSWI, FLAIR, and T2WI) were evaluated by two radiologists with consensus, where separate reading sessions for each sequences were made with the interval of 3 days. McNemar test was performed to compare detection rates of intra-arterial thrombus.
Results: The age of study population was 67.16±13.63 years (mean ± standard deviation). Detection rates of intra-arterial thrombus were 0.19 on mSWI; 0.09 on sSWI; 0.07 on FLAIR; and 0.04 on T2WI. The detection rate of mSWI was superior to sSWI (p=0.016), FLAIR (p=0.004), and T2WI (p<0.001).
Conclusion: Multi-echo SWI showed superior detection rate of intra-arterial thrombus compared with single-echo SWI, FLAIR, and T2-weighted image.

B-0094 11:18

Prediction of malignant cerebellar oedema development after acute ischaemic stroke using multiparametric CT

M.P. Fabritius, K.M. Thierfelder, F. Schuler, M.F. Reiser, W.H. Sommer, W.G. Kunz; *Munich/DE (matthias.fabritius@med.lmu.de)*

Purpose: Malignant cerebellar oedema (MCE) is a life-threatening complication after acute cerebellar stroke. Aim of this study was to identify imaging predictors using multiparametric CT including whole-brain CT perfusion (WB-CTP).
Methods and Materials: We consecutively selected all subjects with cerebellar WB-CTP alterations and follow-up-confirmed infarction from a cohort of 3254 patients who underwent multiparametric CT. Follow-up imaging was assessed for the presence of MCE, measured using an established 10-point scale, of which scores ≥4 are considered malignant. posterior-circulation-Acute-Stroke-Prognosis-Early-CT-Score (pc-ASPECTS) was determined to assess ischemic changes on non-contrast CT (NCCT), CT angiography (CTA), and on parametric WB-CTP maps (cerebral blood flow, CBF; cerebral blood volume, CBV; mean transit time, MTT; time to drain, TTD). Chi-square, Mann-Whitney-U tests and receiver operating characteristics (ROC) analyses were performed for statistical analyses.
Results: Forty-seven patients were included. 38 patients (80.9%) were categorized as MCE- and 9 (19.1%) as MCE+. MCE+ patients had larger CBF, CBV, MTT and TTD deficit volumes (each with p<0.001) and showed significantly lower median pc-ASPECTS assessed using WB-CTP (CBF: 5 vs. 8; CBV: 8 vs. 9; MTT: 5 vs. 8; TTD: 5 vs. 8; each with p<0.001) compared to MCE- patients, while median pc-ASPECTS on NCCT was not significantly different (9 vs. 10, p=0.097). ROC analyses yielded the largest area-under-the-curve values for CBF (0.977) and CBV deficit volumes (0.952) and pc-ASPECTS on CBF (0.934), whereas pc-ASPECTS on NCCT (0.681) and CTA (0.712) provided significantly less diagnostic value.
Conclusion: WB-CTP provides added diagnostic value regarding the prognosis of MCE development after stroke.

B-0095 11:26

Increased PS of basal ganglion on CTP predicting HT in acute ischaemic stroke patients with cerebral proximal large vessel occlusion

Q. Li, H. He; *Shanghai/CN (liqiao1227@gmail.com)*

Purpose: PS measured with CTP reflects the permeability of the blood-brain barrier, and is related to pathophysiology of haemorrhagic transformation (HT). Basal ganglia haemorrhage (BGH) can be found after treatment of cerebral proximal large vessel occlusion and is related with poor clinical outcome. We aimed to determine the relationship between BGH and the site of occlusion, PS of basal ganglia region, and collateral status.
Methods and Materials: 121 consecutive patients with acute ischaemic stroke (AIS) within 6 hours of symptom onset and with cerebral proximal artery occlusion were evaluated. CTP data were postprocessed into PS of ipsilateral and contralateral basal ganglion. A blinded reader assigned collateral score using a previous 5-point scale and proximal MCA -M1 status (with or without

absolute occlusion). We assessed the relationship between HT occurrence and PS value of BG.
Results: Increased basal ganglia PS were associated with earlier HT outcome after AIS. In logistic regression analysis after adjustment for age, sex, onset time, baseline NIHSS, poor collateral status (p=0.009; OR 7.8) and proximal MCA-M1 occlusion (p=0.045; OR 4.12, 95%CI 1.03-16.52;) were independently associated with increase of basal ganglia PS. The rPS value (AUC=0.94) was the most accurate parameter to predict HT, with an optimal threshold at 2.89.
Conclusion: Increasing basal ganglia PS predicts the HT after distal inter-carotid artery or M1 middle cerebral artery occlusion. In this situation, the absolute occlusion of proximal MCA-M1 was a prerequisite for PS aggravation, but poor collateral status appeared a critical determinant of ultimate outcome.

B-0096 11:34

Diffusion-MRI detects protection effects of DAPT treatment following stroke

X. Hao, Y. Yang, L. Yin, X. Zhang, J. Tian; *Shanghai/CN (haoxiaozhu123@sohu.com)*

Purpose: To evaluate the effects of γ-secretase inhibitor treatment after transient cerebral ischaemia using diffusion magnetic resonance imaging (d-MRI).
Methods and Materials: 20 middle cerebral artery occlusion (MCAO) rats were divided into two groups: control group (n = 10) and treated group (n = 10), receiving γ-secretase inhibitor (N-[N- (3,5-difluorophenacetyl)-1-alanyl]-S-phenylglycine t-butylester, DAPT) at 3 days after ischemia. All rats were performed with behavioral test, MRI and immunofluorescence staining (IF) at 24h and 7d after MCAO. Percent changes of all values of striatum (STR) were measured and compared between the two groups, that including MR T2 signal intensity (T2 SI), fractional anisotropy (FA), mean diffusivity (MD), mean kurtosis (MK), as well as intensity fluorescence of microglia/NICD.
Results: At 7 days after stroke, percent changes of all values in the treated group were more closer to the baseline compared to the control group (treated vs control: T2 SI, 19.67±7.23% vs 33.33±2.52%, P=0.037; FA, -24.67±6.02% vs -44.67± 5.51%, P=0.039; MD, -6.7±4.04% vs 16.67±8.51%, P=0.033; MK, 49±12.53% vs 123.67±40.15%, P=0.037). Corroborated by IF, microglia and Notch activation were markedly reduced in treated group (treated vs control: micrglia, 57±3.61% vs 125.67±6.43%, P=0.001; NICD, 33±7.51% vs 166.33±12.22%, P=0.000). Significant therapeutic DAPT effects on functional recovery were detected at 7 days after stroke (treated vs control: 4.25±0.5 vs 7.0±0.816, P=0.001).
Conclusion: Our data demonstrate that d-MRI can dynamically identify and quantitatively characterize white matter recovery after DAPT treatment. And DKI parameters in treated group, be closer to the baseline, were in agreement with reduced activation of microglia/NICD.

B-0097 11:42

Diagnostic importance of brain CT perfusion 4D in the detection of acute suptratentorial infarctions

K. Davidovic, A. Stankovic, J. Kostic, F. Crnovrsanin, D. Masulovic, R. Maksimovic; *Belgrade/RS (k_cina@yahoo.com)*

Purpose: CT brain perfusion 4D aids with assessing the certain part of the brain and evaluating perfusion deficits by displaying 4D-DSA views of blood flow in vessels and 3D perfusion maps. It can be performed rapidly and aids in the detection of salvageable tissue (penumbra) from the unsalvageable core infarct.
Methods and Materials: We included 258 patients with symptoms of acute ischemic stroke admitted to Emergency Room for the last 10 months CT perfusion was performed on 160-slice scanner (Toshiba Aquilion Prime) using 50 mL of nonionic iodinated contrast media. Total coverage was 80mm. This acquisition also allows generation of intracranial angiographic data as well as perfusion maps. Whole brain non-contrast CT (NCCT) was performed before CTP.
Results: The study was designed as a retrospective study and included 258 patients. We compared brain tissue involvement on NCCT with CTP (T max, cerebral blood volume [CBV], and cerebral blood flow [CBF]). The sensitivity of CTP (92,1%) was significantly higher compared with that of NCCT (15%). CTP detected significantly more ischemic lesions.
Conclusion: Perfusion CT has proven to be a valuable tool in the diagnosis of acute ischemic stroke. The use of CTP and the advances of this technology will hopefully lead to an extended time window for the use of drugs like tPA for the revascularization of the stroke-affected tissue.

Differentiation of thrombus composition using dual-layer computed tomography

J. Borggrefe[1], J. Kottlors[1], M. Mirza[2], V. Maus[1], C. Kabbasch[1], N. Abdullayev[1], V.-F. Neuhaus[1], D. Maintz[1], A. Mpotsaris[1]; [1]*Cologne/DE*, [2]*Galway/IE (Jan.Borggrefe@uk-koeln.de)*

Purpose: For differentiation of blood-clot-types in stroke-workups, we tested if dual-layer computed tomography (DLCT) can characterise predefined clots of varying red-blood-count (RBC) in native and contrast-enhanced scans.
Methods and Materials: Five clots of three ovine blood-clot-types (n=15) containing histologically confirmed RBC composition of 0% (fibrin-rich), 36% (intermediate) and 99% (RBC-rich) were provided by Neuravi-Ltd. (Galway, Ireland). The clots were scanned in a DLCT (Philips, Amsterdam, Netherlands) with 250 mAs, 120 kVp and 0.6 mm slice-thickness and three different settings; a) in a tube containing saline, b) 5 minutes and c) 3 days after exposure to a 1:50 dilution of Accupaque-350 (GE-Healthcare, Boston, USA). The ROI-density of the clots was measured in Hounsfield-units in regular CT datasets as well as Virtual-Non-Contrast (VNC) reconstructions of DLCT.
Results: In native saline-environment the clots differed in density (mean HU±SD) (fibrin-rich 23.6±1.1, intermediate 34.9±1.6, RBC-rich 46.7±1.6). Blood-clots did not show any overlap of density in the native scans and VNC-reconstructions at different time-points (p<0.0001 for each setting and clot-type).However, they could not be differentiated in the regular early contrast-enhanced scan (b) (fibrin-rich 108.5±7.8, intermediate 105.3±3.5, RBC-rich 104.8±3.8). In the late scan, the fibrin-rich clots showed a further increase of density due to uptake of contrast-medium (fibrin-rich 163.6±3.6, intermediate 138.3±4.1, RBC-rich 109.6±5.4).
Conclusion: DLCT allows differentiating the blood-clot-types both in native as well as contrast enhanced scans.The fibrin content of the clots is associated with uptake of contrast medium after prolonged exposure to contrast agents which can be used as an independent predictor of clot type.
Author Disclosures:
J. Borggrefe: Other; The blood-clots were provided by Neuravi LTD (Galway, Ireland). **M. Mirza:** Employee; Employee of Neuravi LTD.

A new low-dose multi-phase trauma CT-protocol and its impact on diagnostic assessment and radiation dose in multitrauma patients

Z. Alagic, A. Eriksson, S. Rezaei Motamed, M.C. Wick; *Stockholm/SE (zlatan.alagic@karolinska.se)*

Purpose: During spring 2015, the Karolinska University Hospital installed the latest generation of a 16cm-detector 258-slices Multi-Detector-Computed-Tomography (MDCT) scanner. Concomitantly, a modification of the multitrauma CT-protocol has been performed. This study investigates if a novel multitrauma CT-protocol, combining latest dose-reduction techniques with multi-phase whole-body-CT-(WBCT)-scans, is superior for trauma patients.
Methods and Materials: 109 patients (Group A) underwent acute trauma CT with the novel MDCT and multi-phase CT-protocol whereas 120 patients (Group B) underwent single-phase trauma CT at 64-slices MDCT. The diagnostic accuracy to trauma-related injuries, radiation dose, quantitative and qualitative image quality parameters, subjective image quality scorings, and workflow time parameters were compared.
Results: In group A, statistically significantly more arterial injuries (p=0.04) and arterial dissections (p=0.002) were detected. In group A, the mean (±SD) DLP value was 1681±183mGy*cm and markedly lower when compared to group B (p<0.001). SD of the mean HU-values of brain, liver and abdominal aorta were lower in group A (p<0.001). Mean SNRs for the brain, liver and abdominal aorta were significantly higher in group A (p<0.001). Group A had significantly higher image quality scores for all analysed anatomical locations (p<0.02). The mean time from patient registration until completion of examination was significantly longer for group A (p<0.001).
Conclusion: The novel multi-phase CT-protocol improves diagnostic accuracy for trauma-related arterial injuries and image quality at markedly reduced radiation. However, the amount of electronic information leads to an increase in examination time, which reduces work-flow for acute emergency situations when time is one of the most relevant factors.

Are follow-up ultrasound (US) studies of severely injured patients after negative multi-detector computed tomography (MDCT) a waste of time?

M. Schürer, T. Kahn, C. Josten, J.K.M. Fakler, P. Stumpp; *Leipzig/DE (Matti.Schuerer@medizin.uni-leipzig.de)*

Purpose: To evaluate the diagnostic significance and clinical relevance of routinely performed follow-up ultrasound studies on severely injured patients with initial whole-body MDCT.
Methods and Materials: Over a period of 48 months, we identified 611 severely injured patients, who received an initial whole-body MDCT and a follow-up US six hours afterwards. Patients were divided into two cohorts: patients with (A) and without (B) a trauma-related abdominal pathology in the initial MDCT. Both cohorts were then evaluated regarding the presence of findings in US, changes compared to initial MDCT and change of the therapeutic management.
Results: 150 patients have been categorised in cohort A and 461 in cohort B. Only 2 patients (1.3%) in cohort A showed new findings in the US and one of them needed clinical intervention. In cohort B, 6 patients (1.3%) showed minimal new findings in the form of small amounts of free fluid, and none of them needed any form of clinical intervention. This means that due to follow-up US, only in 1 of 611 patients (0.16%) the treatment plan had to be changed.
Conclusion: Since there were no new findings with need for clinical intervention in patients without trauma related pathology in the initial whole-body MDCT, this group of patients does not benefit from a routinely performed follow-up US.

B-0101 10:46

Blunt cervical spine injury in adult polytrauma: incidence, injury patterns and predictors of significant ligament injury on CT

G. Chilvers, U. Janjua, S. Choudhary; *Birmingham/UK (geoffreyschilvers@gmail.com)*

Purpose: Recent guidelines suggest the cervical spine can be safely cleared solely on multi-detector computed tomography (MDCT) scans. However, available literature defining CT findings of significant ligament injury in the absence of cervical spine fractures is limited. We aim to identify CT parameters which predict significant ligament injury in the cervical spine when fractures are absent or subtle.
Methods and Materials: In this retrospective study all polytrauma patients imaged with MDCT over a 5-year period were identified. Patients with cervical spine fracture and/or suspected ligament injury were collated based on CT report and their imaging was reviewed. Predefined predictors of ligament injury were recorded for each study with comparison to subsequent MRI as reference standard.
Results: CT predictors of significant ligament injury at the craniocervical junction include basion-dens interval >10mm, widened C0/C1 facet joint space >3mm or loss of congruity, widened C1/2 facet joint space >6mm, increased AADI >3mm and atlas offset >/=2mm. In the subaxial cervical spine, facet subluxation >50% was the only reliable predictor of ligament injury. Asymmetry of lateral atlanto-dens interval, subluxation at C1/C2 facet, subaxial facet joint widening or minor incongruence and asymmetry of disc space were seen in many studies with normal MRIs.
Conclusion: When fractures are absent, signs of significant ligament injury on CT at the craniocervical junction are increased basion-dens interval, lateral offset of atlas, widened or incongruent anterior atlanto-dens interval and widened C0/C1 and C1/C2 facet joints. In the subaxial cervical spine, >50% subluxation of a facet joint is an indicator of significant injury.

B-0102 10:54

Traumatic arterial injuries of the extremities: MDCT angiography evaluation in emergency setting

C. Liguori, G. Russo, T. Cinque, S. Daniele, N. Gagliardi, C. Acampora, L. Romano; *Naples/IT (carlo.liguori@gmail.com)*

Purpose: To retrospectively assess the accuracy of MDCT angiography as the initial diagnostic technique to depict arterial injury in patients with extremity trauma.
Methods and Materials: Over 36 months, 90 patients (16-87 y) with clinically suspected arterial injury after extremity trauma underwent 64-MDCT angiography and 80 ultimately underwent surgery or interventional radiology treatment. 67 pts had blunt injuries, and 23 had penetrating injuries. Each detected arterial lesion was then characterised as a spasm, stenosis, occlusion, pseudoanurism or rupture. 2 CT experienced radiologists performed separately images evaluation. The standard of reference was surgery (54 pts) or angiography (26 pts); clinical and radiologic follow-up was used in 10 pts. Image quality, lesion depiction, and artefacts were assessed.
Results: 72 traumatic arterial lesions were confirmed. MDCT showed sensitivity and specificity 95% and 87%, respectively, in vascular lesion depiction. Image quality and lesion depiction on MDCT angiograms were considered good and artefacts were considered mild with substantial interobserver agreement.
Conclusion: MDCT angiography provides significant and reproducible technique for detection and characterisation of arterial injuries to the extremities with high image quality and vascular delineation.

B-0103 11:02

Structured reporting of facial skeletal trauma CT scan as a tool to reduce report turnaround time (TAT)

B.M. Jain, K.A. Bhagwat, R.B. Shashikiran, P.T. Reddy, K. P, N. Rathod, M. Karanji, V. Dev; *Davanagere/IN (bharat454@gmail.com)*

Purpose: Treating patients with facial skeletal trauma is a multi-departmental task. In an emergency setting, the report turnaround time (TAT) is very crucial. Descriptive reporting of facial skeletal trauma was increasingly cumbersome. Hence we devised a structured reporting format in a tabular form in order to reduce the TAT and ease of inter departmental communication.
Methods and Materials: Structured report was designed keeping anatomical structures, laterality, accuracy and ease of reporting as main purpose. Prospectively we started reporting facial skeletal trauma using structured format as well as conventional method of reporting and recorded time taken to finalise the report by each of the methods by to separate double blinded radiologists. Total of 500 cases were included in the study.
Results: The average time taken for structured reporting was significantly less than traditional method. (10 to 11 minutes for traditional reporting Vs 6-7 minutes for structured reporting). This validated our assumption of structured reporting reducing the report turnaround time. We also noted that some findings were missed by traditional descriptive reporting as compared to structured reporting.
Conclusion: Structured reporting of facial trauma CT reduces report turnaround time, increases accuracy, ease of reporting findings, objectively conveys information to all treating team flawlessly. Total reduction in report turnaround time was by about 30- 40%. Structured reporting also opens the gate for Big Data analysis of facial skeletal trauma and also will be back bone for computer aided neural network based pattern matching and reporting of facial skeletal trauma in near future.

B-0104 11:10

CT injury score of blunt pancreatic trauma is useful in decision-making for treatment

Y.-C. Wong, L.-J. Wang, C.-H. Wu; *Taiwan/TW (ycwong@cgmh.org.tw)*

Purpose: To evaluate if CT injury score of blunt pancreatic trauma is useful for deciding the choice of treatment.
Methods and Materials: Between 2010 January to 2016 August, 44 patients of blunt pancreatic trauma were treated at our institution. Their clinical data and CT examinations were retrospectively analysed. Six patients were excluded because of poor CT quality (n=3) and unavailability of pre-treatment CT (n=3). A total of 38 patients (22 men, 16 women) with a median age of 28.5 years (IQR 19.0, 41.3 years) were finally included. All CT examinations were reviewed and each pancreas trauma was graded by a CT injury score based on a modified Wong's pancreas injury severity scheme. The CT injury scores were compared with the choice of management (observation or intervention). A p-value <0.05 was considered statistically significant.
Results: Of 38 pancreas trauma, 24 receive observational management, 14 underwent intervention (partial pancreatectomy=9, pancreas repair=1, pancreatic duct stenting=3, percutaneous catheter drainage=1). Their injuries included grade A (n=9), grade BI (n=6), grade BII (n=5), grade BIII (n=10), CI (n=5), CII (n=2), CIII (n=1). Among them, twenty had score 1, seven had score 2, eleven had score 3. Of twenty score 1, 20 (100.0%) received observational management. Four (4/7, 57.1%) patients of score 2 and ten (10/11, 90.9%) patients of score 3 underwent intervention. The comparison of CT injury scores with choice of management was statistically significant (p<0.001).
Conclusion: Injury score of pancreas trauma derived from CT severity is crucial in decision-making for choices of treatment.

B-0105 11:18

Correlation of traumatic skin and subcutaneous injuries with the severity of trauma - analysis of whole-body emergency CT scans in 250 patients

A. Klempka, C. Fischer, D. Spira, H.-U. Kauczor, M.-A. Weber; *Heidelberg/DE (Anna.Klempka@med.uni-heidelberg.de)*

Purpose: To assess correlations between skin and subcutaneous lesions such as bruises and haematomas, deep abrasions, soft tissue emphysema and internal post-traumatic injuries, as support by clinical triage of injured patients, to avoid unnecessary radiation by whole-body computed tomography (WBCT).
Methods and Materials: WBCT emergency scans for suspected polytrauma were retrospectively analysed in 250 patients from June until November 2015. The scan included the entire head, neck, thorax, and abdomen and was indicated after fulfilling criteria of standard operating procedures for WBCT emergency scans in our institution.

Results: A skin lesion of thorax wall was detected in 19 cases, whereas in 17 of those cases an internal injury of the thorax was present. Only two patients with haematoma of chest wall had no internal injury. Skin and subcutaneous lesions of the thorax had the strongest association with internal injury (Fisher's exact test, p<0.001). Skin lesions of abdominal wall were observed in 30 cases. In only 11 cases, these lesions were correlated with internal damages, such as fractures or active bleeding. Fifty-two skin and subgaleal lesions of the scalp were observed. In 20 of these patients an intracranial or internal injury was detected. In 3 patients skin abrasions of the neck were present, and in only one was connected with internal injury.
Conclusion: Clinical triage of injured patients is crucial to decide whether WBCT is appropriate. When cutaneous lesions are observed and the trauma mechanism is appropriate, an internal lesion must be taken into consideration.

B-0106 11:26

Assessment of CT scan need for patients with delayed presentation of head trauma

M.S. Khan, Y.B. Hadi, B. Ibrahim, M. Irfani, M. Aslam, U.F. Bhatti, W. Memon; *Karachi/PK (salmankhan3935@gmail.com)*

Purpose: The National Institute for Health and Care Excellence (NICE) guidelines are commonly used to triage patients presenting with head trauma for need of CT scan. This tool was validated and developed with data for patients presenting within 24 hours of trauma. Thus it is not clear whether these guidelines hold true for patients presenting after 24 hours of injury. Our purpose was to estimate the proportion of CT scans done for late presenters, compare their rate of abnormalities on CT with early presenters, and compare the sensitivity of NICE guidelines in both groups.
Methods and Materials: We conducted a retrospective cohort study of all CT head examinations performed in the Radiology department at Aga Khan University Hospital Karachi on adult patients presenting to the ER with head injury from July 2014 to 2016.
Results: Out of the 2009 eligible patients in the study period, 2002 patients with complete records were included. 52% showed some traumatic abnormality, and mortality rate was 2.3% in the cohort. 32.2% of scans were conducted on patients presenting after 24 hours of trauma. The proportion of CT scans with any traumatic finding was 46.7% for those presenting within and 63% for those presenting after 24 hours of injury. The sensitivity of NICE guidelines for intracranial injury was 93% for early and 83% for late presenters.
Conclusion: Patients presenting after 24 hours of head injury form a significant proportion. NICE guidelines are not as sensitive in this population, and may miss significant injuries.

B-0107 11:34

Maxillo-facial trauma: a surgical approach to CT reporting

G. Pasinati, A. Sorbo, F. Romano, M. Altiero, G. Avitabile, E. Laccetti, M. Scaglione; *Castel Volturno/IT*

Purpose: The role of radiology emergency in CT for the evaluation of maxillo-facial trauma identification and classifying fractures avoiding complications clearly apprising the surgeon to encourage a perfect management of patient.
Methods and Materials: 432 patients were evaluated who presented suspicious injuries or clinically evident maxillo-facial injuries. The research has been led to focus on sustaining structures and on soft tissue lesions.
Results: Our study showed that a ready fast and schematic reporting CT would be diriment for the treatment of these patients obviously giving clear information to the surgical team.
Conclusion: The quick and correct maxillo-facial fractures classification and their related complications allow to decisive patient surgical treatment.

B-0108 11:42

Structured reporting of calcaneal CT in trauma: a checklist for daily practice

I. Altmann-Schneider, K. Bartlema, I. Dekkers, A. van der Molen; *Leiden/NL (i.altmann-schneider@hotmail.com)*

Purpose: Neither on a national nor on an international level there is consensus on how to report CT examinations in calcanea trauma in a structured manner. We aimed to systematically review the literature on CT in calcaneal trauma and to develop an evidence-based checklist for structured reporting in daily practice.
Methods and Materials: A systematic review was performed using Pubmed. A search strategy was developed in consensus. All original studies written in English about CT in human calcaneal trauma from 1/1/2000 - 1/10/2016 were included. Reviews, letters and case reports were excluded. Included articles were used to determine the frequency of possible relevant reporting items and in case available reported prognostic value was scored.
Results: The search strategy yielded 156 articles of which 26 met the inclusion criteria. Sanders CT classification system of (intra-articular) calcaneal fractures was used most frequently (18 of 26 articles; 69%) and the only classification system which is of prognostic value for patient outcome. The following items are considered crucial in radiological reports of calcaneal CT in trauma: Congruence of the posterior talocalcaneal and calcaneocuboid joints and the middle facet and involvement of the anterior process of the talus (8 of 26 articles; 31%), Böhler angle and critical angle of Gissane (9 of 26 articles; 35%), joint relationship between talus and sustentaculum tali, hind foot widening, and calcaneal height (3 of 26 articles; 12%).
Conclusion: Based on a systematic literature review a checklist for structured reporting of CT in calcaneal trauma is proposed.

B-0109 11:50

Post-traumatic active bleeding in dual-phase CT: identification, characterisation and management implications

F. Guida, F. Romano, M. Altiero, E. Laccetti, I. Iadevito, M. Tanga, G. Pasinati, M. Scaglione; *Castel Volturno/IT (fraguida@hotmail.com)*

Purpose: To characterise active bleeding according to its entity using MDCT and, on this base, to establish a tailored management.
Methods and Materials: A retrospective study was performed by selecting in our department data (June 2015-March 2016) all high-energy blunt trauma patients with CT diagnosis of active abdominal bleeding. Bleeding was classified into three main categories, according to morphology (spot, jet and pooling) and origin (arterial or venous). All patients underwent a bi/triphasic contrast-enhanced dual-source CT, with iterative reconstruction algorithm. Spot was defined as punctiform self-limiting bleeding, jet as linear bleeding with no significant changes in morphology during different study phases while pooling was defined as active extravasation of intravenous contrast media with significant changes in its entity and morphology. Patients were randomised and two radiologists were asked to evaluate such bleedings. Interobserver agreement was assessed by the weighted Cohen kappa.
Results: 56 patients were selected in our study, classified as follows: 29 patients as spots, 16 patients as jets and 11 patients as poolings. 3/16 jet had worsened as pooling and were managed with surgery, while 13/16 jets and all spots were managed non-operatively. In particular, 18/29 spots and 11/13 jet underwent endovascular treatment. All the cases of pooling were managed with surgery. Overall interobserver agreement was k=0.98.
Conclusion: Although haemodynamic state represents the major factor influencing patient management in abdominal blunt trauma, it is mandatory to characterise the entity of active bleeding in MDCT for addressing therapeutic decisions, with almost perfect interobserver agreement.

Peripheral nerve ultrasound examinations without peripheral nerve abnormalities: prevalence and further assessment of extraneural findings

B. Bignotti, F. Zaottini, S. Airaldi, F. Rossi, G. Succio, C. Martinoli, A. Tagliafico; *Genoa/IT (bignottibianca@gmail.com)*

Purpose: To evaluate the prevalence and further assessment of extraneural findings detected during peripheral nerve US examinations.
Methods and Materials: A retrospective query of Institutional database identified 278 peripheral nerves US examinations of 229 patients performed between December 2014 and December 2015. Reports were reviewed to assess the number of US without peripheral nerve abnormalities and among these examinations, the prevalence and further assessment of extraneural findings. An extraneural finding was defined as a finding of non-neural origin (eg. muscle, tendon, bone). Standard statistic was used to describe extraneural finding and the 95% confidence interval (CI) was calculated.
Results: In a total of 107 peripheral nerve US examinations of 90 patients (49 male; 41 female; mean age: 55 ± 16 years) no peripheral nerve abnormalities were detected. Among these, extraneural findings were detected in 24 examinations (22.4%). A total of 15 of the 278 (5.4% [95% CI: 2.7%, 8.1%]) peripheral nerve US examinations performed in a year led to a recommendation for additional imaging or clinical evaluation of an extraneural finding.
Conclusion: At least 5.4% (15 of 278) of peripheral nerve US led to additional clinical or imaging assessment.

B-0111 10:38

Sciatic nerve diffusion tensor imaging in muscular disease

S. Keller[1], A. Golsari[1], Z.J. Wang[2], G. Adam[1], J. Yamamura[1]; [1]*Hamburg/DE*, [2]*Dallas, TX/US (j.yamamura@uke.de)*

Purpose: To assess the feasibility of sciatic nerve magnetic resonance neurography (MRN) using diffusion tensor imaging (DTI) adapted for skeletal muscle in patients with muscular dystrophy and healthy controls.
Methods and Materials: DTI of the thigh was conducted using b-values of 0 and 500 s/mm^2 on a 3T system in 12 consecutive patients (m:f 7:5, 52±17y) with various muscular disorders, and in 10 controls. For detection of the sciatic nerve, anatomical T1w images were co-registered geometrically to fractional anisotropy colour encoded images (FA CEI). The apparent diffusion coefficient (ADC), FA and fibre track length (FTL) were analysed by two operators using a *freehand-ROI* and a single-point ROI covering the sciatic nerve. Both ROI methods and the inter-operator agreement were statistically assessed using Bland-Altman analysis and parametric tests.
Results: The inter-operator agreement of DTI-metrics using the freehand-ROI and single-point-ROI technique showed no significant difference between both methods (mean bias 0.02 ± 0.07, 95% confidence interval -0.16 - 0.12). Three-dimensional visualization of sciatic fiber composition and maximum FTL was achievable using both techniques. DTI-metrics of the freehand-ROI and single-point ROI technique in controls corresponded to the literature (ADC 1.45 ± 0.14 mm^2/sx10^{-3}; FA 0.46 ± 0.07).
Conclusion: The skeletal muscle adapted DTI protocol shows a high reproducibility and inter-operator agreement for analysis of the sciatic nerve.

B-0112 10:46

Ultrasound anatomy of the infrapatellar branch of the saphenous nerve

G. Riegler, J. Mayer, C. Pivec, H. Platzgummer, P. Brugger, S. Jengojan, G. Bodner; *Vienna/AT (georg.riegler@meduniwien.ac.at)*

Purpose: Neuropathy of the infrapatellar-branch-of-the-saphenous-nerve (IPSBN) is a common iatrogenic complication of knee surgery and its diagnosis is limited. This study aimed to visualize the IPSBN with high-resolution-ultrasound (HRUS) and to provide a detailed description of its variable course.
Methods and Materials: HRUS with high-frequency probes (15-22MhZ) was used to locate the IPSBN in 14 fresh anatomical specimens. The correct identification of the IPSBN was verified by ink-marking and consecutive dissection. Moreover, the IPSBN was located in both knees of 20 healthy volunteers (n=40). The visibility of the branches was rated on a five-point scale (1= not visible, 5 excellent) and their course was marked on the volunteers' skin in the flexed-knee position. Distances were measured from the IPSBN branch closest to the median of the patella-base (D1), center (D2), and apex (D3), and in a 45°(D4) and 0°(D5) relation to the median patella-apex. Standardized photographs of all knees were mapped on one typically shaped knee. Descriptive statistics, coefficient of variation (CV), and paired t-tests were performed.
Results: Dissection confirmed the correct identification of the IPBSN in 12/14 knees (86%). In volunteers, the visibility-median was four. Significant intra-individual differences for distance measurements were observed for D1(p<.001) and D2(p=.002). The CV was highest for D5(0.86) and lowest for D1(0.14). Mapping of the nerve branches on a typical knee demonstrated a highly variable course for the IPBSN.
Conclusion: This study confirms the ability to reliably visualize the IPSBN and its variations with HRUS, which may allow for selective diagnosis of its neuropathy.

B-0113 10:54

Ultrasound of the median nerve in patients with diabetes

F. Steinkohl, A. Loizides, L. Gruber, M. Krapf, G. Mörsdorf, I. Gruber, B. Glodney, H. Gruber; *Innsbruck/AT (fabian.steinkohl@tirol-kliniken.at)*

Purpose: Carpal tunnel syndrome (CTS) is the most frequent nerve entrapment syndrome. Diabetes mellitus (DM) is a common metabolic disease and its steadily incidence is rising. Therefore there is a high probability of encountering patients with both CTS and DM. Ultrasound has a very important role in diagnosing CTS. Often the cross sectional area (CSA) of the median nerve is measured to calculate the Wrist-to-Forearm-Ratio (WFR). A ratio of >1.4 is considered pathologic. DM causes neuropathies, but it is unclear if this has an effect on the CSA. If this is the case, WFR should not be used in diabetic patients. We want to find out if WFR is a suitable method in diabetic patients.
Methods and Materials: 233 wrists of 153 patients were examined. Three groups were formed: Patients with DM and CTS, patients without DM and with CTS, and patients with DM and without CTS. CSA of the median nerve was obtained by using a linear array probe. WFR was calculated.
Results: Both diabetic patients without CTS and with CTS had significantly lower WFR values (p = 0.002 and 0.029, respectively) than non-diabetic patients with CTS. There was no difference between WFR of diabetics with and without CTS (p = 0.06). Diagnostic accuracy to discriminate diabetics with and without CTS was low for measurements of WFR and median nerve CSA and the carpal tunnel.
Conclusion: Our findings suggest that WFR in diabetic patients with CTS has a low diagnostic accuracy and should not be used in those patients.

B-0114 11:02

Role of real time and shear wave sonoelastography in the follow up of muscle thigh injuries in athletes: a three-years longitudinal study

A. Corazza[1], D. Orlandi[1], G. Ferrero[2], C. Messina[3], R. Sartoris[1], E. Silvestri[1], L.M. Sconfienza[3]; [1]*Genoa/IT*, [2]*Pietra Ligure/IT*, [3]*Milan/IT*

Purpose: The aim of the current study is to assess the reliability and effectiveness of real-time sonoelastography (RTE) and shear-wave sonoelastography (SWE) in the evaluation and follow-up of traumatic lower limb muscle tears in a cohort of professional athletes using MRI as a reference standard.
Methods and Materials: 143 male athletes (aged 27 ± 4) with MRI confirmed indirect thigh muscle injury was included in our study and evaluated with US over a period of 36 months. Muscle tears were evaluated with B-mode US, RTE and SWE using two different US machines (LOGIQ E9, GE Healthcare; RS80 Prestige, Samsung Medical) at baseline, 2, 4 and 6 weeks in order to evaluate the healing process of the injury also comparing the obtained results with the healthy contralateral side. Statistical analysis of the obtained data was performed, also assessing intra- and inter-observer reproducibility with the Bland-Altmann test.
Results: The results derived from the current study highlight a direct relationship between the clinical recovery of the injured muscle and the elastic features of the regenerative scar tissue. In particular SWE quantitative elasticity assessment was able to provide meaningful data about the quality of the regenerated tissue furnishing thresholds, with high measurement reliability index (RMI): 0.7 ± 0.2.
Conclusion: The dynamic features of US, combined with RTE and SWE techniques are able to provide qualitative and quantitative elasticity assessment of the healing process of an injured muscle. This can be crucial in the management and early recovery of athletes.

B-0115 11:10

Shear wave elastography of median nerve at carpal tunnel in upper extremity spasticity

H. Aslan, P.D. Analan; *Adana/TR (hul_yaaslan@hotmail.com)*

Purpose: To compare the median nerve elasticity of the paretic side with that of the nonparetic side of patients with wrist spasticity using shear wave elastography (SWE) at the carpal tunnel and to assess the correlations between shear wave velocities (V_s) and clinical outcomes.
Methods and Materials: This prospective study included 25 patients with one-sided wrist spasticity following stroke. The Modified Ashworth Scale (MAS) of wrist and the Brunnstrom's motor staging (BMS) of hand were performed. The patients underwent median nerve ultrasound (US) and SWE of their paretic and nonparetic sides at the carpal tunnel. V_{mean} and V_{max} of both sides were compared for each patient. The correlations between SWE results, duration of stroke and clinical outcomes were assessed.
Results: The mean age of the study population was 56.4±13.64 years. V_{mean} and V_{max} on the paretic side were 2.94 ± 0.51 and 3.11 ± 0.54 m/s, respectively, and on the nonparetic side were 3.01 ± 0.71 and 3.16 ± 0.78 m/s, respectively. No significant difference was found in the V_s of both sides (P > 0.05). Moreover, no significant correlation existed between the V_s of the median nerve with MAS and BMS scores and time since stroke (r < 0.3, P > 0.05).
Conclusion: These results suggested that SWE could not be a helpful imaging tool in detecting the possible changes in the median nerve following wrist spasticity, or less likely the median nerve could have increased the capacity to adapt to the long-standing effects of muscle spasticity.

B-0116 11:18

Quantification of muscle degeneration in patients with late-onset Pompe disease by MRI

A. Lollert, C. Stihl, A.M. Hötker, E. Mengel, J. König, K. Laudemann, C. Düber, G. Staatz; *Mainz/DE (andre.lollert@unimedizin-mainz.de)*

Purpose: To evaluate the value of two quantitative methods based on T1- and T2-weighted magnetic resonance imaging, to assess fatty muscular degeneration in patients with late-onset Pompe disease (LOPD) in comparison with the standard semi-quantitative visual evaluation.
Methods and Materials: MRI of the lumbar spine was performed using T1- and T2-weighted turbo spin echo (TSE) sequences in 41 patients with LOPD. Images were semi-quantitatively evaluated with respect to fatty degeneration of the psoas and paraspinal muscles by two independent observers, using a well-established 4-point scoring system (the Mercuri score), as well as quantitatively by manual signal intensity measurements, and semi-automated muscle and fat

tissue separation using the ImageJ programme. Correlations with clinical parameters were assessed.
Results: Inter-observer agreement was higher for the semi-automated compared to manual quantitative method. Mercuri scores correlated well with clinical parameters, especially for the six-minute walk test and forced vital capacity in the supine position. Measurements derived from the semi-automated method correlated well with MRC scores of muscle strength (P<0.001). Moderate correlations were found for the six-minute walk test (ρ=-0.52, P=0.001), the four-step stair climb test (ρ=0.52, P=0.001), and spirometry in the supine position (ρ=-0.587, P<0.001).
Conclusion: Quantification of fatty muscle degeneration using the semi-automated method resulted in a superior inter-observer agreement compared with manual signal intensity measurements, and greater accuracy than Mercuri-scoring. MRI-derived muscle-specific data correlate with clinical strength tests.

Automated artifact correction of diffusion tensor data allows unbiased muscle fiber tracking in the thigh

C. Giraudo[1], S. Motyka[1], M. Weber[1], C. Resinger[1], T. Feiweier[2], H. Traxler[1], U. Koller[1], S. Trattnig[1], W. Bogner[1]; [1]*Vienna/AT*, [2]*Erlangen/DE*
(chiara.giraudo@meduniwien.ac.at)

Purpose: To optimise a robust protocol for fiber tracking of thigh muscles and evaluate an automated post-processing method for correction of artifacts (i.e., signal loss areas) affecting STEAM-based DTI images.
Methods and Materials: Ten healthy volunteers (5 males; mean age 30.8 yrs) were scanned at rest on a 3T-MR using a STEAM-DTI sequence. Thighs' native images were automatically corrected using the formula $\mu_{weighted}=\sum_i^N w_i x_i / \sum_i^N w_i$, computing a weighted mean of all six averages (avg) for each DTI-direction and b-value.Fiber tracking of the entire datasets and of ROIs, placed where artifacts occurred, were done using the native images, with one and six averages (1avg, 6avg), and the corrected datasets (c6avg). Differences in tracts' mean number (tr_n), length (tr_l), volume (tr_v), fractional anisotropy (FA), mean- (MD), axial- (AD) and radial-diffusivity (RD) were investigated with one-way-ANOVA test post-hoc Bonferroni corrected Greenhouse-Geisser.
Results: In the entire datasets, tr_n, tr_l, tr_v increased comparing 1avg with 6avg and c6avg (+41.6%,+59.7%,+75.8% and +43.9%,+65.6%,+81.1%;all p<0.001).No significant changes occurred for FA (p>0.05);AD decreased whereas RD increased using 6avg and c6avg rather than 1avg (-1.8%,-1.9% and +3.2,+2.1%;all p<0.05).MD and RD decreased using c6avg rather 6avg (-0.6%,-1.1%;p<0.05).In the ROIs, tr_n, tr_l, tr_v increased comparing 1avg with 6avg and c6avg likewise 6avg with c6avg (+83.4%,+67.6%,+122.9% and +131.0%,+97.3%,+180.8% and +25.9%,+17.7%,+26%;all p<0.05);RD decreased comparing 6avg with c6avg (-2.1%;p=0.001).No significant changes occurred for MD, FA, AD (all p>0.05)
Conclusion: The STEAM-based DTI protocol including six averages and the artifact correction improved fiber tracking of thigh's muscle and it's expected to enable robust clinical DTI musculoskeletal applications.

Proton density fat-fraction of rotator cuff muscles is associated with isometric strength 10 years after rotator cuff repair: a quantitative MR imaging study of the shoulder

P.M. Jungmann, D.C. Karampinos, C. Holwein, S. Buchmann, S. Ruschke, A.B. Imhoff, E.J. Rummeny, T. Baum; *Munich/DE*

Purpose: To investigate the relationship of proton density fat fraction (PDFF) of the rotator cuff muscles with semi-quantitative MR-scores, cartilage T2 relaxation times and isometric strength measurements in patients 10 years after rotator cuff repair.
Methods and Materials: Bilateral shoulder MR imaging was performed in n=13 patients (11 male, 2 female; age 72±8 years) 10.9±0.4 years after unilateral autologous periosteal flap augmented rotator cuff repair (total shoulders assessed, N=26). Goutallier classification, muscle atrophy, rotator cuff tendon integrity and cartilage defects were determined based on morphological MR sequences. A paracoronal 2D multi-slice multi-echo sequence was used for quantitative cartilage T2 mapping. A chemical shift encoding-based water-fat separation technique (based on a six-echo 3D spoiled gradient echo sequence) was used for quantification of the PDFF of rotator cuff muscles. Isometric shoulder abduction strength was measured clinically. Mean and standard deviation, Pearson correlation and partial Spearman correlation were calculated.
Results: The mean PDFF of rotator cuff muscles was 11.7±10.4%. High supraspinatus PDFF correlated significantly with higher Goutallier scores (R=0.75, P<0.001) and with lower isometric muscle strength (R=-0.49, P=0.011), also after adjustment for muscle area measurements and tendon rupture (R=-0.41, P=0.048). More severe cartilage defects at the humerus were associated significantly with higher supraspinatus PDFF (R=0.44; P=0.023). Cartilage T2 values did not correlate with muscle PDFF (P>0.05).
Conclusion: Since MR imaging-derived rotator cuff muscle PDFF is associated with isometric strength independently of muscle atrophy and tendon rupture it may provide complementary, clinically important information in tracking rotator cuff muscle composition on a quantitative level.

Ultrasound elastography in detection of supraspinatus muscle atrophy and fatty degeneration in the reference to MRI

V. Gazhonova, M. Emelianenko, M. Onishchenko; *Moscow/RU*
(vx969@yandex.ru)

Purpose: To investigate the possibilities of US-sonoelastography (SE) in detection of supraspinatus muscle (SSM) atrophy and fatty degeneration (FD) with reference to MRI.
Methods and Materials: 29 patients with shoulder pain and disability underwent US with and without SE before MRI study. Occupational ratio of SSM with and without SE was calculated for evaluation of muscle atrophy in oblique sagittal plane. Modified Goutallier classification was used for assessment of FD on B-mode US and with SE. Soft areas on SE reflects fatty infiltration of SSM. All data was compared to MRI for atrophy and FD. Correlation finding of US alone and US SE in detection of SSM atrophy and FD was achieved in the reference to MRI. Interobserver variability was estimated for US SE data.
Results: US SE improved the diagnosis of fatty degeneration and atrophy compared to US alone. Inter-observer reliability of SE showed ''almost perfect agreement'', kappa 0.83. For SSM atrophy US SE had a positive correlation (r = 0.829, p=<0.001), without SE (r=0.679, p=<0.05) with reference to MRI. For FD grades US SE also had a positive correlation (r =0.873, p=<0.001), US alone (r= 0.713, p=<0.05) with reference to MRI. SE provided more accurate measurements of occupational ratio of SSM atrophy by highlighting area of FD.
Conclusion: US with SE had excellent interobserver reliability and better correlation with MRI findings than conventional ultrasonography for SSM atrophy and FD.

Evaluation of lower back muscle activity with functional magnetic resonance imaging

B. He; *Kunming/CN (henri5437@sina.com)*

Purpose: To evaluate the exercise-induced changes of transverse proton relaxation time (T2) and blood oxygenation level-dependent (BOLD) effect in the lumbar extensor muscles of healthy volunteers by applying muscle functional MRI (mfMRI).
Methods and Materials: In 20 healthy participants, mean age 27 years, the cross-sectional area (CSA), T2 and R2* values were calculated for the multifidus, longissimus and iliocostalis at the level of superior margin of L4 at rest and after following trunk extension exercise by using 3.0T MR.
Results: The CSA of all muscles at L4 level were significantly bigger after exercise than at rest (P<0.05). In resting state, the average T2 value of multifidus, longissimus and iliocostalis were 50.89±6.87ms, 49.35±5.00ms and 44.88±4.26ms, after loading which separately were 59.30±10.11ms, 56.81±7.99ms and 51.12±6.33ms. After exercise, the T2 value was significantly increased (P<0.05). In resting state, the average R2* value of multifidus, longissimus and iliocostalis were 42.90±5.06Hz, 43.88±5.28Hz and 41.89±5.32Hz, after loading which separately were 36.70±4.79Hz,36.72±4.60Hz and 37.63±4.48Hz. After exercise, the R2* value was significantly decreased (P<0.05).
Conclusion: Muscle functional MRI can be used to evaluate lower back muscle activity by measuring T2 and R2*.

Identification and quantification of multiple high-Z materials by spectral CT

M. Moghiseh, R. Aamir, J. Healy, A.P.H. Butler, N.G. Anderson;
Christchurch/NZ (mahdieh_moghiseh@yahoo.com)

Purpose: Spectral (multi-energy) CT using photon-counting x-ray detector technology has the potential to image multiple high-Z contrast agents whether targeted or non-targeted. The aim was to identify and quantify iodine, gadolinium, and gold contrast agents in a spectral CT scan of a mouse.
Methods and Materials: We used a multi-spectral micro-CT and Medipix3RX detector bonded to Cadmium-Zinc-Telluride, and four energy thresholds from 27-118 keV selected to include the K-edges of iodine (I), gadolinium (Gd) and gold (Au) containing contrast agents. We imaged a 38-mm PMMA (Polymethyl methacrylate) phantom containing Iodixanol (4.5, 9, 18 mg I/mL), gold nanoparticles (AuNPs) (2, 4, 8 mg Au/mL), gadopentetate dimeglumine (2.1, 8.4 mg Gd/mL) and calcium hydroxyapatite (HA) (200, 800 mg HA/mL) to determine calibration curves of attenuation versus concentration. Three mice injected intravenously with 16 mg iodine and 16 mg AuNPs, then 8 mg gadolinium introduced into the stomach and rectum were scanned with the same imaging protocol along with the calibration phantom.
Results: We identified, discriminated, and quantified all concentrations of iodine, gadolinium, and AuNPs. In the phantom, the material was correctly identified in 90%, 100% and 82% of voxels for 18 mg/mL iodine, 8 mg/mL gadolinium and 8 mg/mL AuNPs respectively. In the mice, iodine, gadolinium, gold, and hydroxyapatite could all be distinguished from each other.
Conclusion: Iodine, gadolinium, gold and hydroxyapatite were distinguished and discriminated simultaneously by spectral CT using an imaging protocol which could be translated to human imaging. If these agents can be targeted to different biomarkers, then simultaneous use of these agents may help imaging biological or disease processes on one scan.

Modified dual-energy-based three material decomposition for calcium plaque removal on spectral CT data

B. Schmidt[1], B. Krauss[1], A. Pourmorteza[2], D.A. Bluemke[2], K. Grant[3], T. Flohr[1];
[1]*Forchheim/DE*, [2]*Bethesda, MD/US*, [3]*Malvern, PA/US*
(bernhard.schmidt@siemens.com)

Purpose: Removal of calcified plaques from small vessels is one of the remaining challenges in CT. Threshold-based plaque removal typically fails due to calcium blooming. Traditional dual-energy (DE)-based 2-material decomposition into water and iodine leads to an incomplete subtraction of calcium. Here we assess the ability of a modified 3-material decomposition algorithm for the removal of calcium-related enhancement from iodinated vessels.
Methods and Materials: Instead of iodine and soft tissue alone, a 3-material decomposition into calcium as a first base material and a mixture of different contributions of soft tissue/iodine as the remaining materials, is performed. To evaluate our method, first tubes with different mixtures of calcium plaque equivalent solution and soft tissue/iodine were measured on a SOMATOM Force (Siemens) and on a prototype CT-system equipped with a detector using photon counting technology in an anthropomorphic environment and then decomposed. Second, specimen vessels with iodinate contrast and calcified plaques at different stenosis levels were evaluated with both CT technologies.
Results: For both CT technologies, decomposed images showed a good separation of calcium from soft tissue/iodine. The processed data from the specimen showed excellent calcium removal for medium and large calcifications. Data from photon counting technology showed a superior performance for small calcifications.
Conclusion: The presented modified 3-material decomposition allows for an improved visualisation of vessel lumen, and a more reliable removal of plaque. For smaller structures counting technology leads to slightly better results. The proposed technique may allow for substantially improved confidence in stenosis quantification.

Comparison of metal artefact reduction in dual- and single-source CT: a vertebra phantom study

P. Jagoda, D. Schmitz, S. Wagenpfeil, A. Buecker, P. Minko; *Homburg/DE (peterminko@yahoo.com)*

Purpose: To compare the capability of OMAR and iMAR, two algorithms for metal artefact reduction and FAST DE, a metal artefact reduction application for dual-source CT.
Methods and Materials: A bovine vertebra phantom with 16 artificial osteolyses and two osteosynthesis screws was scanned on two different single source CT scanners (Brilliance 64, Phillips and Somatom 64, Siemens) at 80, 100, 120 and 140kV with 150mAs and on a dual-source CT scanner with a selective photon shield (Force, Siemens) at tube voltages 100/150kV at doses identical to single source acquisition. Data sets were reconstructed with OMAR, iMAR and FAST DE. Blinded to the methods 3 independent observers evaluated metal artefacts, bone and muscular tissue using a 4-point scale. Depicted osteolyses were counted and screws diameters measured for each reconstruction.
Results: FAST DE showed the best metal artefact reduction capability among evaluated methods; overall artefacts were rated 1.0±0 for FAST DE, 3.1±0.7 for iMAR and 3.7±0.5 for O-MAR ($p<0.001$). FAST DE could provide better reconstructions of bone structure in vicinity to metallic hardware than OMAR or iMAR algorithm (1.4±0.5 FAST DE, 3.7±0.5 iMAR, 4.0±0 OMAR; $p<0.001$) and was superior regarding muscular tissue reconstruction (1.3±0.5 FAST DE, 3.2±0.6 iMAR, 2.9±0.5 OMAR; $p<0.001$). Meanwhile with 14.6±1.7 the detection rate for osteolyses was best on OMAR reconstructions (iMAR 13.1±1.3, FAST DE 12.1±0.7; $p<0.001$).
Conclusion: FAST DE application for dual-energy CT is superior to OMAR and iMAR algorithm regarding metal artefact reduction, tissues and metallic hardware reconstruction but is lacking in a total depiction of all osteolysis.

Metal artefact reduction in CT: objective evaluation of three commercial algorithms

K.N. Bolstad, S. Flatabo, D. Aadnevik, I. Dalehaug, N. Vetti; *Bergen/NO (kirsten.bolstad@helse-bergen.no)*

Purpose: Metal implants may introduce artefacts in CT images. The aim of this study was to evaluate metal artefact reduction algorithms (MAR) when imaging different metal implants using single energy acquisition.
Methods and Materials: Three clinical metal implants were taped on the leg of an anthropomorphic phantom; surgical steel, chromium cobalt (CrCo) and titanium. A tissue equivalent material was placed on top to simulate skin surface. Three commercial MAR were investigated; SEMAR (Toshiba), O-MAR (Philips) and iMAR (Siemens). The images were reconstructed without and with MAR. The images were analysed objectively by calculating the rate of HU pixels above 500HU in a region of interest around the metal.
Results: For steel, the rate of HU pixels above 500HU decreased from 39% to 24% when using O-MAR, 29% to 14% using iMAR and 33% to 10% using SEMAR. For CrCo, the rate of HU pixels above 500HU decreased from 35% to 25% when using O-MAR, 31% to 17% using iMAR and 32% to 12% using SEMAR. For titanium the rate of HU pixels above 500HU increased from 8% to 12% when using O-MAR, the rate decreased from 7% to 5% using iMAR and 13% to 6% using SEMAR.

Conclusion: MAR reduces metal artefacts and improves the image quality for CT images containing metal implants of steel and CrCo. SEMAR decreased the rate of HU pixels better than O-MAR and iMAR for CrCo and steel when using single energy acquisition. When using MAR on titanium, all algorithms introduced new visible artefacts.

Accurate reconstruction of x-ray spectra in CT from simple transmission measurements

C. Leinweber, J. Maier, M. Kachelrieß; *Heidelberg/DE (carsten.leinweber@dkfz.de)*

Purpose: To determine the x-ray spectra of CT systems from transmission measurements without additional hardware.
Methods and Materials: The proper knowledge of x-ray spectra is important for several CT applications. Often, assessing the x-ray spectrum requires the use of additional hardware. On the other hand, available methods to reconstruct the x-ray spectrum from nothing but transmission measurements are not very accurate. This is because the reconstruction of x-ray spectra from transmission measurements is a highly ill-conditioned inverse problem. We face this ill-conditioning in three steps. Prior to the calculation of a singular value decomposition (SVD) we weight the input data according to their signal noise. In the second step we regularize the SVD solution with help of the L-curve criterion. The resulting spectra accurately reproduce the incident transmission measurements. However they also tend to exhibit an unphysical shape that leads to deviations in reproducing transmission data that have not been included into the reconstruction process. We solve this by incorporating prior knowledge about the x-ray target material. Our method is applied to simulated and measured data.
Results: For noiseless simulated data our reconstructed spectra perfectly reproduce the input spectra. For noisy data we outperform the standard transmission-based spectrum estimation methods, in particular when testing absorbers that have not been included in the estimation process. These finding are confirmed by results of measured data.
Conclusion: Our hybrid spectrum reconstruction method is simple to use and accurate in reproducing both transmission data as well as the physical shape of the spectral distribution.

B-0126 11:10

Advanced electron density reconstruction for single-energy computed tomography

A. Ritter, R. Raupach, B. Schmidt; *Forchheim/DE (andre.ritter@siemens.com)*

Purpose: A new reconstruction allows estimating electron density images from single-energy computed tomography. We discuss the technical foundation of this method and show first results of a phantom evaluation.
Methods and Materials: The reconstruction is based on a water-bone material decomposition, computed partly in image and projection domain. The bone content is approximated via thresholding in the image domain. Water-bone decomposition is completed in the projection domain, using a scanner- and spectrum-specific relationship between attenuation and effective water and bone thicknesses. Both effective thicknesses are used to synthesize line integrals of electron density, from which images of electron density are reconstructed. The reconstruction is tested with the Gammex 467 Tissue Characterisation Phantom using different tube voltages.
Results: We observe that image values reconstructed with this method are nearly proportional to electron density. The accuracy of the electron density reconstruction increases with higher tube voltage. Additionally an intrinsic correction of beam hardening artifacts is included with this method.
Conclusion: The presentation provides a basic understanding of this new method and helps to assess its capabilities for potential applications, in the diagnostic and the radiation therapy field.

Iterative reconstruction algorithm in CT protocol optimisation

C.R. Gigliotti, A. Loria, F. De Cobelli, R. Nicoletti, G. Bianco, R. Calandrino, A. del Vecchio; *Milan/IT (gigliotti.carmen@hsr.it)*

Purpose: The use of the iterative algorithm for CT image reconstruction led to the possibility to drastically reduce patients' doses, maintaining, or even improving, the image quality. The aim of this study is to optimize the CT clinical protocols of the Philips Somatom Definition Flash 64 for different anatomical districts and clinical questions.
Methods and Materials: Different protocols, concerning four districts (head, thorax, abdomen, orthopedic) were investigated exposing Catphan 600 CT image quality phantom. The routinely used protocols were considered as references. Starting from reference protocol parameters, the medium current was gradually reduced while the level of the iterative algorithm (Philips iDose) was progressively raised. Non-uniformity, low contrast, noise power spectrum (NPS) and spatial resolution (MTF) were evaluated for each image reconstruction. Furthermore, the Rose and Impact quality indexes were evaluated.
Results: In order to preserve the radiologist image perception resulted necessary to select parameters that produce images with NPS shape and frequency peak comparable to the reference image ones. Furthermore, non-uniformity, low contrast details detectability and MTF resulted comparable to, or better than, the reference image ones. The protocols optimized in such a way were proposed to radiologists as alternatives to the reference ones permitting dose reduction between 15% and 35%.
Conclusion: The optimization of the iterative reconstruction algorithm use in clinical protocols permits to sensibly reduce patients' dose. It is mandatory to tailor this optimization on specific anatomical district and clinical question keeping constant the radiologists' image perception.

B-0128 11:26

Effects of five iterative reconstruction algorithms on low-contrast detectability in patients with varying abdominal diameters: a CT phantom study

A. Viry[1], D. Racine[1], C. Aberle[2], S. Schmidt[1], S. Schindera[3], F.R. Verdun[1], F. Becce[1]; [1]*Lausanne/CH*, [2]*Basle/CH*, [3]*Aarau/CH (anais.viry@chuv.ch)*

Purpose: To objectively compare the effects of FBP and various iterative reconstruction (IR) algorithms on low-contrast detectability (LCD) in patients with varying abdominal diameters.
Methods and Materials: An anthropomorphic abdominal phantom with an optional ring (equivalent diameters, 24cm and 35cm) and containing 5mm targets of 20HU contrast was scanned on four CTs using routine abdominal protocols (CTDIvol, 5.9-16mGy): Revolution, Discovery CT750 HD (GE), Somatom Definition Flash, Somatom Definition Edge (Siemens). Images were reconstructed using both FBP and various IR algorithms: statistical IR (ASIR50% on Discovery), statistical model-based IR (MBIR, ASIR-V50% on Revolution, SAFIRE3 on Flash, ADMIRE3 on Edge), or the full MBIR (VEO on Discovery). Slice thickness/interval were 2/1mm (Siemens) or 2.5/1.25mm (GE), except 0.625/0.625mm for VEO. A channelized Hotelling observer with 10 dense differences of Gaussian channels was used to assess LCD, with the area under the curve as a figure of merit.
Results: With the smaller phantom, we found no significant difference between FBP and various IR algorithms for all CTs ($p \geq 0.07$). For the larger phantom, a slight but statistically significant improvement in LCD was observed with statistical IR (2.3%, $p=0.0003$) and statistical MBIR algorithms (1.7%-2.3%, $p<0.0004$), as compared with FBP. VEO enabled a greater significant improvement in LCD (8.5%, $p<0.0001$) together with a four times higher longitudinal spatial resolution.
Conclusion: For smaller-sized patients, the various IR algorithms have no effect on LCD. For larger-sized patients, the full MBIR algorithm substantially improves LCD at higher longitudinal spatial resolution, whereas other IR algorithms have a smaller effect on LCD.

B-0129 11:34

The impact of new generation scanner CT and ASIR-V on dose reduction and image quality

M. Gatti, M. Fronda, D. Castellano, P. Isoardi, F. Marchisio, O. Rampado, R. Ropolo, P. Fonio, G. Gandini; *Turin/IT (marcogatti17@gmail.com)*

Purpose: To evaluate the impact on dose reduction and image quality of a new generation scanner CT equipped with adaptive statistical iterative reconstruction (ASIR-V) in oncologic patients.
Methods and Materials: 38 oncologic patients (66.3±10.0 years, 13 females, BMIndex 24.4±5.0kg/m^{-2}) acted as case-control undergoing during their follow-up a CT scan both with GE Healthcare Optima 660 + 50% ASIR (Optima+ASIR) and with a GE Healthcare Revolution CT + 40% ASIR-V (Revolution+ASIR-V). The image noise (IN) was measured by placing a circular region of interest (ROI) in three standard locations: liver parenchyma, gluteal subcutaneous fat and aorta. Absolute visual grading (AVG) analysis evaluating the subjective noise, sharpness, and diagnostic quality and relative visual grading (RVG) analysis evaluating the overall image quality on a 5-point scale were performed independently by 2 radiologists.
Results: Revolution+ASIR-V dose-length product [DLP=448.5(Interquartiles 362.8-489.1) mGy-cm] and CT dose index [CTDI=7.1(6.60-7.98) mGy] were significantly lower ($p<0.0001$) than those of Optima+ASIR [DLP=696.36(566.9-807.2) mGy-cm and CTDI= 12.20(10.57-14.22) mGy]. Revolution+ASIR-V significantly reduced IN: $IN_{Revolution+ASIR-V}$=10.46(9.61-11.58) vs $IN_{Optima+ASIR}$=12.37(11.65-14.21) for liver parenchyma ($p<0.0001$); $IN_{Revolution+ASIR-V}$=9.54(8.61-10.35) vs $IN_{Optima+ASIR}$=10.38(9.97-12.47), for gluteal subcutaneous fat ($p=0.003$) and $IN_{Revolution+ASIR-V}$=12.07(10.31-13.86) vs $IN_{Optima+ASIR}$=18.03(16.40-20.8), for aorta ($p<0.0001$). Revolution+ASIR had a higher AVG than Optima+ASIR for the subjective noise only ($p=0.01$), but the other parameters were similar.

Conclusion: New generation scanner CT equipped with ASIR-V facilitates a radiation dose reduction of 38% with a significant reduction of IN, a reduction of subjective noise and an equal subjective image quality when compared with the last generation scanner CT equipped with ASIR.

B-0130 11:42

Utilizing model-based iterative reconstruction to minimise radiation dose in chest CT examinations for diagnosing lung metastases of sarcoma patients: a phantom study

T. Kaasalainen, T. Mäkelä, A. Kelaranta, M. Kortesniemi; *Helsinki/FI (touko.kaasalainen@hus.fi)*

Purpose: To develop and evaluate ultra-low-dose chest CT protocols using model-based iterative reconstruction (MBIR) for diagnosing lung metastases in sarcoma patients.
Methods and Materials: An adult female anthropomorphic phantom was scanned using a 64-slice CT scanner with different ultra-low-dose and standard dose protocols. Mean absorbed organ doses in the chest area (lungs, liver, heart, thyroid gland and breasts) were measured with ten metal-oxide-semiconductor field-effect transistor (MOSFET) dosimeters. Additionally, Monte Carlo simulations were performed to validate the MOSFET measurements, and effective doses were calculated. Image quality in terms of image noise, contrast, and modulation transfer function (from cylinder contrast targets) was determined from the CT images reconstructed with conventional filtered back projection (FBP), adaptive statistical iterative reconstruction (ASIR), and MBIR algorithms. All the results were compared with those obtained using the standard dose protocol.
Results: Mean absorbed organ and effective doses were reduced by up to almost 95% when using the lowest ultra-low-dose protocol compared to the standard dose chest CT protocol, while still resulting in an acceptable image quality for diagnosing round-shaped lung metastases. The image noise level of the ultra-low-dose MBIR images was comparable to the standard dose FBP images.
Conclusion: According to our phantom study, patient organ and effective doses can be reduced remarkably when using the ultra-low-dose chest CT protocols and the MBIR technique to reconstruct images, while at the same time, image quality is maintained at a diagnostically acceptable level for detecting round-shaped lung metastases in the lungs.

Monte-Carlo simulation of iodine enhancement in an anthropomorphic abdomen phantom: effects of different primary MDCT x-ray spectra on energy deposition

A. Steuwe, H.-U. Kauczor, W. Stiller; *Heidelberg/DE (andrea.steuwe@med.uni-heidelberg.de)*

Purpose: To compare the effect of different primary MDCT x-ray spectra on energy deposition in organs in absence and in presence of iodinated contrast agents.
Methods and Materials: The influence of different primary x-ray spectra (Toshiba CXB-750D MegaCool measured in-house at 120kV$_p$, spectra of the "Siemens Healthcare Online tool for the simulation of x-ray Spectra" at 80/100/120/140kV$_p$ with/without aluminium filtration) on energy deposition in an anthropomorphic abdomen phantom was determined using Monte Carlo simulations with Geant4. Furthermore, energy deposition and relative energy absorption increase ($\Delta E_{rel}=[E_{iodine}-E_{native}]/E_{iodine}$) in presence of iodinated contrast agent (iodine weight fraction ψ=0.005; ~5mg/ml) in the organs pancreas, spleen, kidney, and liver were studied.
Results: Total energy deposition increases with increasing tube potential and mean spectral energy, independent of the presence of iodinated contrast agent. In its presence, energy absorption increases for the specified organs, but decreases (~-3%) in surrounding tissues. For the measured spectrum, Δ_{rel} was 44.0% (pancreas), 36.1% (spleen), 44.0% (kidney) and 29.5% (liver). For simulated spectra with 3.3mm aluminium filtration, Δ_{rel} ranges are: 43.4%-46.7% (pancreas), 32.9%-37.1% (spleen), 40.7%-44.5% (kidney), and 24.8%-30.3% (liver). At each respective tube potential, Δ_{rel} was lower in absence and higher in presence of thicker aluminium filtration.
Conclusion: Differences in ΔE_{rel} between different tube potentials are small. However, aluminium filtration enlarges the fraction $F_{55\text{-}74keV}$ of photon energies between 55keV and 74keV by suppressing the low-energy photon fraction of the spectrum, thereby increasing ΔE_{rel}. Maximizing ΔE_{rel} will cause a large difference between enhanced and non-enhanced tissues, thereby optimising image contrast.

Using of eye Bismuth shields in CT scan: its influence on ESD and image quality

P.A.T. Gamboa[1], A.P.N. Batista[2], M.M.C.P. Ribeiro[2], A.L.C.F. Vieira[2], H.N. Sousa[3]; [1]*Vila Franca de Xira/PT*, [2]*Lisbon/PT*, [3]*Torres Vedras/PT (patricia24.gamboa@hotmail.com)*

Purpose: Evaluate the impact of using the eye Bismuth shields in ESD (Entrance Skin Dose) and the effect on image quality in brain CT scans.
Methods and Materials: Two CT routine acquisitions of the brain were performed using a CT Activation 16 scanner and an anthropomorphic phantom RSD: with and without Bismuth shields placed over the orbital region. The ESD was evaluated by four TLD-100(LiF:Mg) dosimeters, two for each acquisition (one placed on the nasion -frontal bone - and the other on the inion - occipital bone). The acquisition parameters were fixed. The image quality was quantitatively analysed by five ROI's (two placed in the anterior, one in the middle and two in the posterior region of the brain), and qualitatively by three experienced neuroradiologists through a survey based on a comparative visual analysis test, under the criterias: image contrast; noise; anatomical evaluation; pathological evaluation, dose reduction and global image quality.
Results: The ESD values show a reduction of 61% in the crystalline, with the use of these shields (34,13mGy vs 58,03mGy in average). The observers considered their beneficial use in selected cases. The quantitative results show that the Bismuth shields cause artefacts and increase image noise in the frontal brain parenchyma.
Conclusion: The Bismuth shields are advantageous in certain areas/pathologies, and disadvantageous for studies of the anterior brain parenchyma. Radiographers and doctors should consider the advantages and disadvantages of these shields application in each specific case.

A multi-site head CT topogram acquisition protocol analysis based on DICOM metadata

M. Santos, L. Bastião, N. Rocha, A. Silva; *Aveiro/PT (mrs@ua.pt)*

Purpose: Several international initiatives and scientific studies emphasise the need to promote a greater focus on patient safety when choosing Computed Tomography (CT) scan parameters. This work aimed to analyse the CT Topogram dimension and scan parameters used in Head CT studies conducted in three distinct CT equipment and based on DICOM metadata stored at PACS facilities from two health institutions.
Methods and Materials: The metadata produced by three different Computed Tomography (CT) equipment and stored in two health care PACS facilities were systematically analysed using a DICOM Metadata mining approach. For studies characterisation several DICOM tags were analysed (e.g. mAs, KvP, Exposure Time, Modality, Patient Age) within different queries. The CT Topogram dimension was obtained from the Exposure Time value and the table feed during the topograma acquisition.
Results: The DICOM metadata from 1.274.927 images, bellowing to 19.180 studies performed on 16.169 patients (including 768 paediatric patients) were analysed. The number of CT Topogram images performed per patient ranged from 1 to 2,33 and its dimension between 20,76 cm and 25,16 cm depending on the equipment (CT1=20,8cm±0,04; CT2=24,01cm±0,4; CT3=25,01cm±0,5), namely in paediatrics studies (CT1=20,78cm±0,01; CT2=23,61cm±0,71; CT3=24,98cm±0,01). With regard to CT Topogram scan parameters, no significant changes were identified when the x-ray Tube Current (CT1=10mA±0,02; CT2=49,98 mA±0,03; CT3=39,47 mA±2,29) and KvP values were analysed (CT1= 119,54KvP±1,65; CT2=120,02KvP±0,04; CT3=90KvP).
Conclusion: The age groups (including the paediatric patients) are not factors determining significant changes in the values of the exposure factors and size of the area exposed to radiation upon topogram acquisition.

B-0135 10:55

Investigating optimal abdominal CT protocol for obese patients

A.A. Qurashi[1], L.A. Rainford[1], A. Ajlan[2], K. Khashoggi[2], L. Ashkar[2], M. Alraddadi[3], M. Alghamdi[2], M. Althobaiti[2], S. Foley[1]; [1]*Dublin/IE*, [2]*Jeddah/SA*, [3]*Medina/SA (qetharah@hotmail.com)*

Purpose: To investigate optimal CT parameters when scanning obese patients.
Methods and Materials: With ethical permission, abdominal CT scans for 47 obese patients (AP diameter>26cm, BMI>30kgm-2) were retrospectively collected from 3 different CT models from a single manufacturer over three-month period. Patients were scanned using 5 different protocols, due to various settings used locally (kV: 100/120, mAs: ATCM reference mA: 150, 190, 218, 250, 300). When available, images were retrospectively reconstructed using various SAFIRE strengths (2,3,4 and 5) and FBP. Subjective image quality was determined by three experienced radiologists using visual grading analysis in accordance to EUR 16262. Comparison between radiation dose and image quality was performed using one-way-anova test.
Results: Patients ranged in weight from 65-190 kg with DLP ranging from 345-1525mGy.cm. Mean dose was lowest (up to 60%) for the protocol using 100 kVp technique with statistical differences noted between this protocol and all other scanning techniques ($p<0.05$). All mean image quality scores for all the protocols being examined were deemed suitable for diagnostic interpretation. Images reconstructed with FBP for the protocol with 100 kVp were given the lowest score ($p<0.05$) compared to 120 kVp protocols, especially those with higher reference mAs. However, when the images for the low dose protocol were reconstructed using SAFIRE no significant difference was seen.
Conclusion: Numerous CT protocols are being used clinically for obese patients, with wide variations in dose and image quality. 100kVp protocols produced acceptable image quality for obese patients with up to 60% dose reduction than 120 kVp protocols when IR is used.

B-0136 11:03

Optimisation of CT via analysis of computational fluid dynamics in cerebral aneurysm

M. Ogasawara[1], T. Hirano[1], T. Yagi[2], M. Nakamoto[2], H. Nagahama[1]; [1]*Sapporo/JP*, [2]*Tokyo/JP (mogasawa@sapmed.ac.jp)*

Purpose: Computational fluid dynamics (CFD) in a cerebral aneurysm (CA) is a recently reported method for analyses of CA haemodynamics. However, the reliability of analytical data and optimal CT scan conditions remain unclear. The objective of this study was to investigate optimal scan conditions and contrast medium concentrations for CFD.
Methods and Materials: We performed scans using a 320-slice CT scanner (Aquilion ONE; Toshiba Medical Corporation) and CFD analysis software (hemoscope; EBM Co., Ltd). The hand-made CA phantom contained enclosed concentrations of contrast medium (CT values: 200-500 HU) and silicon (straight line and clinical model). We obtained images using varying noise index values and reconstruction FOVs and used these images to investigate wall shear stress (WSS).
Results: The CFD analytical results indicated a stable maximum WSS (WSSmax) at CT values of 300-500 HU and scan doses of SD20, SD15, and SD10 [straight line model: 2.63 ± 0.42 (16.1%) Pa, clinical model: 16.82 ± 3.80 (22.6%) Pa]. Our results indicated a tendency of the reconstruction FOV (image resolution) and WSSmax-WSSmin (exponential) to converge. Therefore, this technique seems to improve analytical accuracy by setting a smaller reconstruction FOV.
Conclusion: We determined that for CT-based CFD analysis of CA, the optimal scan conditions include a CT value >300 HU, scan dose >SD20, and smaller reconstruction FOV. Under these conditions, all users will be able to obtain a stable, accurate WSS analysis.

Evaluate the effect of contrast media on patient dose in CT examination of abdomen-pelvic performed with AEC

O. Seraydarmansour; *Tehran/IR (mansour.omid@yahoo.com)*

Purpose: The aim of our study was to investigate the relative dose increase when an abdomen-pelvic CT examination is carried out after administration of oral and IV contrast medium with respect to the same CT scan without contrast medium.
Methods and Materials: Forty patients who underwent both unenhanced and contrast-enhanced abdomen-pelvic CT scan. All examinations were performed using an automatic tube potential selection tool on a 16MDCT scanner (Ingenuity, Philips) with the following protocol: Collimation 16X1.5mm, 120Kvp, pitch 1.37, rotation time 0.5sec. All CT images were reconstructed at 5-millimeter section thickness with a standard reconstruction algorithm. The oral contrast agent was made up of 40ml of meglumine compound (370mgI/ml) mixes in 1 litre of water 3 hours before scanning. Iodinated contrast medium (Ultravist 350) containing 350mgI/ml was administered IV at a dose of 1.2ml/kg of patient weight. Contrast-enhanced CT examination was performed 60 seconds after the start of injection. Two abdominal radiologists evaluated the images for diagnostic confidence.
Results: CTDI vol values obtained for each patient on dose report at the end of CT examinations. An increase in patient dose was noted in all CT examinations with IV and oral contrast compared to unenhanced CT examinations. Average dose increase was 11%.
Conclusion: Our evaluation showed an increase in patient dose when iodinated contrast medium is used in CT examination of abdomen-pelvic basing on the increment in Hounsfield units on the organs.

Impact of acquisition protocol variations on effective dose for CT head examinations

M.R. Benhalim, A. England; *Salford/UK (A.England@salford.ac.uk)*

Purpose: For range of acquisition protocols, determine the most dominant acquisition factors which impact on effective dose for paediatric CT brain examinations.
Methods and Materials: An ATOM phantom (1-year old child) was implanted with metal oxide semiconductor field effect transducer (MOSFET) dosimeters; these were inserted into 24 organs (167 predrilled holes). Helical CT brain scanning was undertaken using 54 protocols; protocol variations included changes in rotation times, gantry angulation, tube current/potential and fixed slice thickness (0.5x16). ED was calculated for each acquisition protocol.
Results: ED ranged from 1.01 mSv and 4.81 mSv. Organs located within the scan volume consistently received the highest absorbed doses; organs at the periphery and outside of the scan volume still received a radiation dose. ED trends were as follows: ED increased consistently by around 33% when increasing kVp from 100 to 120 (mean ED 2.35 SD 0.75 mSv versus 3.52 SD 1.21 mSv, respectively; $P<0.05$). Changes in gantry angle had minimal effect on ED, when moving from a zero gantry angle to +27 degrees the mean ED decreased by 0.04 mSv ($P>0.05$). Changing the tube current from 120 to 200 mAs lead to increase in ED by 27.7% (mean ED 1.50 SD 0.40 mSv vice versa 2.23 SD 0.65 mSv, respectively; $P<0.05$). Increasing the rotation time from 0.5 seconds to 1 seconds showed increase in ED by 33.4% (mean 1.52 SD 0.46 mSv versus 2.25 SD 0.80 mSv; $P<0.05$).
Conclusion: The most dominant factors affecting ED are tube current, tube potential and scan rotation time.

B-0139 11:27

Effective dose comparison between fixed tube current FTC and automatic tube current ATC methods for abdominal CT examinations

M. Alrowily, A. England, P. Hogg; *Manchester/UK (P.Hogg@Salford.ac.uk)*

Purpose: Fixed tube current (FTC) and automatic tube current modulation ATCM are options used during abdominal CT exams. The aim of this study was to evaluate the effective radiation dose E when comparing FTC and ATCM techniques, using different detector configurations and pitch factors, for abdominal CT scans.
Methods and Materials: Using a Toshiba Aquilion 16 CT scanner 120 kVp, 0.5 seconds tube rotation an adult ATOM dosimetry phantom was exposed to a series of FTC and ATCM CT protocols with variation in detector configuration 0.5mmx16; 1.0mmx16 and 2.0mmx16 and pitch factors 0.688, 0.938 and 1.438. Effective dose E estimations were undertaken using two methods, one using mathematical modelling with k-factors and DLP and the other using Metal Oxide Semiconductor Field Effect Transistor MOSFET dosimeters and tissue weighting factors.
Results: The mean E for ATCM and FTC methods using MOSFET were 5.9mSv and 4.7mSv, respectively. The mean E using DLP and k-factors were 6.3mSv and 5.1mSv, respectively. Using both E estimation methods the radiation doses from ATCM techniques were around 20% higher $P<0.006$. Good correlation existed between ATCM and FTC doses $R^2>0.82$.
Conclusion: In this study, ATCM effective doses were higher than FTC using both dosimetry techniques. E estimated by DLP and k-factors were higher than when directly measured by MOSFET. Differences between the two methods could be due to the limitations of Monte Carlo modelling used in the DLP/k factors approach.

B-0140 11:35

Establishment of diagnostic reference levels in computed tomography

D. Castro, P. Sousa, S. Rodrigues, A.F. Abrantes, R.P.P. Almeida, K.B. Azevedo, L.P.V. Ribeiro; *Faro/PT (kbazevedo@ualg.pt)*

Purpose: To measure radiation dose levels in computed tomography of two regional public hospitals (A and B) and to compare them with international guidelines.
Methods and Materials: A survey of technical parameters (type of exam, patient age, *kV*, *mAs*, $CTDI_{vol}$ and DLP) from 446 CT exams was used to establish the Diagnostic Reference Levels (DRLs). For viability measurements, the dose rate and quality control using the RF detector Unfors Xi and PMMA (polymethylmethacrylate) phantom were carried out.
Results: The Diagnostic Reference Levels established for the Hospital A were 883.22 mGy.cm (Head), 302.18 mGy.cm (Neck), 371.46 mGy.cm (Cervical spine), 406.97 mGy.cm (Lumbar spine), 225.08 mGy.cm (Chest), 274.82 mGy.cm (Abdomen), 463.62 mGy.cm (Abdomen/Pelvis) and 582.78 mGy.cm (Ches/Abdomen/Pelvis). For the Hospital B and considering the same CT exams, DRLs values were, respectively, 959.37 mGy.cm, 339.45 mGy.cm, 306.73 mGy.cm, 480.73 mGy.cm, 243.59 mGy.cm, 278.24 mGy.cm, 606.22 mGy.cm and 674.33 mGy.cm. Despite the DRLs of the Hospital B being generally higher than the Hospital A, they are both lower than all international guidelines considered.
Conclusion: DRLs of both regional hospitals are in general greatly lower than the international guidelines. However, it is important to optimise the protocols used and similar studies in other hospitals are necessary in order to establish a National Dose Reference Level.

B-0141 11:43

Single- and dual-energy quantitative CT adjacent to acetabular prosthetic components: a reliability study

B.R. Mussmann, P.E. Andersen, T. Torfing, S. Overgaard; *Odense/DK (bo.mussmann@rsyd.dk)*

Purpose: Density measurements adjacent to acetabular prosthetic components are challenged by artifacts and the complex anatomy. Three-dimensional ROIs are needed to assess the bone stock. The purpose was to test the intraobserver agreement and reliability of custom segmentation software and to compare BMD measurements in single and dual energy CT (SECT and DECT).
Methods and Materials: 10 male patients with uncemented hip prosthetics were scanned and rescanned using 120 kVp SECT and DECT with virtual monochromatic images reconstructed at 130 keV. Hemispherical ROIs were defined slice-by-slice and bone mineral density was calculated using a calibration phantom. Median time between ROI drawings was 6 days.
Results: The mean BMD for repeated SECT scans was 430 mg/ccm with a between scan difference of 18 mg/ccm, p=0.001. ICC was 0.98 (95%CI: 0.73 to 1). For DECT the mean BMD was 162 mg/ccm with a difference of 11 mg/ccm, p<0.0001. ICC was 0.94 (95%CI: 0.36 to 0.99). Bland-Altman Limits of Agreement were -51 to 15 in SECT and -30 to 7 in DECT. Repeatability coefficients were 33 and 18 mg/ccm for SECT and DECT respectively. The difference was not statistically significant.
Conclusion: The intraobserver reliability was high for both scan modes with statistically significant differences between the repeated measurements in SECT and DECT. The limits of agreement were slightly narrower in DECT, but with no statistically significant difference between repeatability coefficients. The results suggest that the intraobserver agreement of the scan modes is equal. BMD cannot be measured interchangeably with SECT and DECT.

Reducing iodinated contrast agent concentrations with dual energy CT: a multivendor dynamic phantom study

R.W. van Hamersvelt[1], N.G. Eijsvoogel[2], C. Mihl[2], P.A. de Jong[1], N. Buls[3], M. Das[2], J.E. Wildberger[2], T. Leiner[1], M.J. Willemink[1]; [1]*Utrecht/NL*, [2]*Maastricht/NL*, [3]*Brussels/BE (R.w.vanhamersvelt-3@umcutrecht.nl)*

Purpose: To evaluate the feasibility of reduction of iodinated contrast agent (ICA) concentration with dual energy computed tomography (DECT) systems from 3 major vendors.
Methods and Materials: A circulation phantom simulating physiological conditions (heart rate 60bmp, blood pressure 120/80mmHg) was scanned with dual source CT (DSCT), rapid kVp switching CT (GSI) and dual-layer CT (DLCT). Reference scans were acquired using standard CT (SECT) mode at 120kVp. Subsequently, scans were made in SECT mode at lowest tube potential possible (70, 70, 80kVp) and DECT mode (80-150Sn, 80-140,140kVp respectively). ICA was injected in different concentrations (300, 240, 180, 120, 60, 30mgI/mL) using a fixed protocol (flow rate 6.0mL/s, volume 40mL). Virtual monochromatic images (VMI) between 40-120keV were reconstructed for each DECT acquisition. CT attenuation values (HU) were obtained in the coronary artery and aorta.
Results: Mean attenuation at reference (120kVp,300mgI/mL) was 361±7, 320±15 and 312±5HU for DSCT, GSI and DLCT. With SECT at lowest possible kVp, attenuation values at 180mgI/mL (DSCT and GSI) and 240mgI/mL (DLCT) were 429±13, 339±2.7 and 420±15HU and were significantly higher compared to the reference values (P<0.01). For all vendors in DECT mode, VMI at 40keV resulted in significantly higher HU (528±7, 442±5 and 430±8, respectively) at 120mgI/mL compared to reference (P<0.01). For both SECT and DECT, lower iodine concentrations yielded significantly lower attenuation compared to reference (P<0.01).
Conclusion: Standard CT at lowest possible kVp allows for iodine reductions of 20-40% without loss of intravascular attenuation. In DECT mode, VMI at 40keV allows for a further reduction down to 120mgI/mL (60% reduced), for all 3 vendors.

Individualisation of injection protocols to the individual patients blood volume and automated tube voltage selection in coronary CTA

N.G. Eijsvoogel, B.M.F. Hendriks, B. Horehledova, J.L. Willigers, B.L.J.H. Kietselaer, H.J.G.M. Crijns, J.E. Wildberger, M. Das; *Maastricht/NL (nienke.eijsvoogel@mumc.nl)*

Purpose: Assessing the performance of individualised contrast media (CM) protocols based on patients' blood volume (BV) and automated tube voltage selection (ATVS) in coronary computed tomography angiography (CCTA).
Methods and Materials: 110 consecutive patients referred for CCTA were included. Scans were prospectively ('High pitch'/'dual-step prospective triggering') or retrospectively helical ECG-triggered on a 3rd-generation dual-source CT (Somatom Definition Force, Siemens) with: 70-120 kV (ATVS) and 330 mAs_{ref}. CM volume and flow rate were adapted to BV (Nadlers' formula), scan time and kVp setting. Objective/subjective image quality (OIQ/SIQ) were assessed in a 17-segment model (AHA) with help of attenuation values (HU), contrast-to-noise (CNR), signal-to-noise (SNR) ratio and a 4-point Likert scale (1=poor/2=sufficient/3=good/4=excellent).
Results: Selected kVp settings: 55(70 kVp), 29(80 kVp), 15(90 kVp), 2(100 kVp) and 9(120 kVp). Mean BV (men/women): 5.0±0.9L/4.7±0.9L. Mean CM volume and flow rate were 30.6±6 mL and 3.3±0.5 mL/s (70 kVp); 41.7±6.7 mL and 4.6±0.6 mL/s(80 kVp); 54.5±8.1 mL and 5.8±0.6 mL/s(90 kVp); 55.9±1.3 mL and 5.9±1.0 mL/s(100 kVp); 66.5±16.8 mL and 6.3±1.4 mL/s(120 kVp). Mean attenuation was >300 HU for most proximal segments, 18 proximal

segments <300 HU due to late scanning/stenosis/artefacts. Distal segments were <300 HU due to stenosis/frail artery. Of 1.605 segments 93.5% was assessable (6.5% not assessable due to artefacts or frail arteries). Mean CNR/SNR was 9.4±3.4/9.9±2.4(70 kVp); 9.0±3.5/10.0±2.2(80 kVp); 7.9±2.9/9.0±2.0(90 kVp); 8.0±1.4/10.0±1.4(100 kVp); 11.8±4.3/10.2±2.4(120 kVp). No significant difference was found in CNR/SNR between groups. Overall SIQ was diagnostic in all scans (excellent in 50%) and excellent-sufficient in 89.9% of segments (poor due to artefacts/<HU).
Conclusion: Adaptation of CM protocols to BV and ATVS in CCTA is a promising technique for tailoring CM administration to the individual patient, while maintaining diagnostic image quality.

B-0144 10:46

Image quality and radiation dose of dynamic stress myocardial perfusion imaging at 70kV using third generation dual-source CT: comparison with second-generation scanner

M. Takafuji, K. Kitagawa, S. Nakamura, A. Yamada, Y. Goto, N. Nagasawa, H. Sakuma; *Tsu Mie/JP (amaranth.0521mt@gmail.com)*

Purpose: With the 2nd generation dual-source CT (2nd-DSCT), dynamic myocardial perfusion imaging (CTP) with 7cm z-axis coverage can be performed at 80kV with mean effective dose of 5mSv. The 3rd-DSCT has 50% wider coverage which is sufficient to cover the entire LV myocardium in most patients. However, increase of radiation as a result of the increased coverage should be avoided. New x-ray tube installed in 3rd-DSCT allows dynamic CTP at 70kV. The purpose of this study was to evaluate image quality and radiation dose of CTP using 3rd-DSCT in comparison with 2nd-DSCT.
Methods and Materials: Thirteen patients with known or suspected coronary artery disease who underwent stress CTP of 30 seconds using 2nd-DSCT at 80kV and 3rd-DSCT at 70kV with 24±7months interval were retrospectively enrolled. Tube current was determined by using automatic exposure control system with the quality reference of 350-mAs/rot at 120kV for both scans. Contrast-to-noise ratio (CNR) and dose length product (DLP) were compared.
Results: Dynamic CTP with 3rd-DSCT showed 7% higher maximal enhancement (708 ± 99 vs 661± 90HU; P=0.19) and 14% greater noise (20.4± 2.8 vs 17.8 ± 2.8; P=0.03) compared to 2nd-DSCT without significant difference in CNR (33.1 ± 7.1 vs 35.1 ± 6.6; P=0.42). Radiation dose was 28.6% lower with 3rd-DSCT (mean DLP, 229±53 vs 320±86mGy·cm; P=0.005).
Conclusion: Dynamic CTP can be performed with mean effective dose of 3.2mSv with 3rd-DSCT. In spite of the increased 10.5cm coverage in z-axis, 70kV imaging with 3rd-DSCT allows dose reduction without compromising image quality compared to 2nd-DSCT, which may expand the clinical utility of dynamic CTP.

Low injection speed study on prospectively high-pitch coronary CT angiography: iodinated contrast media injection protocol with a flow rate at 3.5 ml/s scanned at 70 kVp

L. Zhang, X. Liu, B. Feng; *Shenyang/CN (270973226@163.com)*

Purpose: To evaluate the feasibility and image quality of prospectively ECG-triggered high-pitch coronary CTA with low-contrast medium injection rate at 70 kVp.
Methods and Materials: 104 patients with suspected coronary artery disease (BMI<26 kg/m^2, sinus rhythm and HR<70 bpm) were prospectively enrolled in this study. All patients were randomly divided into two groups. Group A was set as experiment group in which 28 mL of 370 mg/mL iodinated contrast media was administrated at a flow rate of 3.5 mL/s. Group B was set as control group in which 40 ml of 370 mg/mL iodinated contrast media was administrated at a flow rate of 5 mL/s. All patients underwent prospectively ECG-triggered high-pitch coronary CTA on a dual-source CT system at 70 kVp. Main coronary artery CT value, noise, signal-to-noise ratio and contrast-to-noise ratio with regard to adjacent fat tissue were evaluated. Subjective evaluation was also performed based on AHA 15 segment model using 4-point grading scale.
Results: All patients successfully conducted CT examinations. Objective evaluation: CT values for main coronary arteries in both groups were all above 350 HU, SNRs and CNRs were of diagnostic quality. Subjective evaluation: no statistical difference in image quality was observed between the two groups (image quality scores: 3.04 ± 0.75 [group A] vs. 3.0 ± 0.79 [group B]; detectability ratio: 96.1% (50/52) vs. 94.2% (49/52).
Conclusion: Prospectively ECG-triggered high-pitch coronary CTA at 70 kVp with 28 mL of contrast media and injection rate of 3.5 mL/s could provide promising image quality for normal-weight patients with heart rate <70bpm.

B-0146 11:02

Systemic hypotension following intravenous administration of non-ionic contrast medium: a randomised controlled double-blinded phase IV clinical trial

G. Widmann, R. Bale, H. Ulmer, D. Putzer, P. Schullian, F.-J. Wiedermann, W. Lederer; *Innsbruck/AT (gerlig.widmann@i-med.ac.at)*

Purpose: Intravenous administration of non-ionic contrast medium may lead to self-limited systemic hypotension. Objective was to quantify this effect during CT scans in patients under general anesthesia with invasive blood pressure monitoring and to compare iso-osmolar iodixanol and low-osmolar iopromide.
Methods and Materials: In this study (EudraCT No.: 2013-002051-15) forty consecutive patients were randomly assigned to receive either iopromide or iodixanol. For each patient normo-saline solution (NSS) was administered as a placebo control. Systemic blood pressure and heart rate were recorded one minute before, during and three minutes after each administration of contrast medium and NSS. Per-hour urine output was recorded. Analysis of variance for repeated measurements together with t-testing and/or non-parametric testing was applied for significance testing of the study endpoints (α=0.05).
Results: Iopromide showed self-limited mean systolic/diastolic drops of 31/26mmHg (P<0.001). In contrast, iodixanol only produced mean changes for the lowest values of 2/0mmHg, similar to 3/2mmHg after NSS (P>.640). Compared with iodixanol, iopromide showed a statistically significant higher increase in heart rate (P=0.042) and 2-fold higher per-hour urine output (P=0.006).
Conclusion: Iso-osmolar iodixanol did not show the effect of systemic hypotension of low-osmolar iopromide. Radiologists and anesthetists should be aware of this effect during observation of anesthetized patients undergoing contrast-enhanced CT scans.

B-0147 11:10

The effect of iterative beam hardening correction on Agatston score: adaptive tube voltage modulation comes to calcium scoring

H. Haubenreisser[1], M. Meyer[1], N. Vogler[1], T. Allmendinger[2], S.O. Schönberg[1], T. Henzler[1]; [1]*Mannheim/DE*, [2]*Forchheim/DE (Holger.Haubenreisser@medma.uni-heidelberg.de)*

Purpose: To investigate the effect of lower tube voltages on Agatston scores processed with an adjusted iterative beam hardening correction (IBHC) filter.
Methods and Materials: 30 patients referred for cardiac CT examinations were included in the study. The patients were examined on a 3rd generation dual-source CT system, using 2 scans for calcium scoring. The first scan (gold standard) was done using accepted clinical parameters (120 kV tube voltage), while the second scan performed immediately after the first utilised adaptive tube voltage modulation (CareDose 4D, Siemens Healthcare, Forchheim, Germany), with an additional IBHC filter applied using an offline reconstruction workstation. The data was then re-imported to a clinical workstation and both scans (with and without IBHC) were each evaluated for vessel calcification.
Results: Compared to the gold standard, Agatston scored performed with lower tube voltages without an additional IBHC filter were found to vary by as much as ±27%. After the IBHC filter was applied, the overall variation was reduced to ±4%.
Conclusion: Utilising an adjusted IBHC filter for calcium scoring examinations opens up the possibility of performing these scans with adaptive tube voltage modulation activated, thus potentially reducing the applied radiation dose by a significant amount.

CT imaging of the tricuspid valve in patients with tricuspid regurgitation: tailored contrast media protocol and dynamic analysis of the annulus

R.M.M. Hinzpeter[1], M. Eberhard[1], P. Burghard[2], F.C. Tanner[1], M. Taramasso[1], R. Manka[1], F. Maisano[1], G. Feuchtner[2], H. Alkadhi[1]; [1]*Zurich/CH*, [2]*Innsbruck/AT (Ricarda.Hinzpeter@usz.ch)*

Purpose: To introduce a tailored contrast media (CM) protocol for visualization of the tricuspid valve (TV) with cardiac CT and to analyse the dynamic dimensions of the tricuspid annulus (TA) in healthy subjects and patients with functional tricuspid regurgitation(FTR).
Methods and Materials: Fifteen patients with no cardiac abnormalities (=controls), 15 patients with FTR<3+ and 13 with FTR≥3+ (determined by echocardiography) underwent a three-phasic CM protocol for optimised visualization of the right heart. Using a segmentation and image analysis software, the annular area, the entire annular circumference, its anterior,

posterior and septal annular parts, and the antero-posterior and septo-lateral diameters were measured by two independent, blinded readers in end-systole and mid-diastole in 3D and 2D. Attenuation and standard deviation of attenuation (indicating homogeneity) were determined.
Results: The homogeneity of attenuation in the right heart showed a negative correlation with the degree of FTR (r=-0.61, P<.001). The interreader agreement was excellent for all measurements (ICC=0.995-0.999). Annular area, annulus and diameters were larger in patients with FTR as compared to controls (P<.05). There were significant differences between systole and diastole in controls, patients with FTR<3+ and those with FTR≥3+ for the area and annulus (all, P<.05). Anterior, posterior, septal and entire annulus were significantly smaller (all,P<.05) in 2D compared to 3D measurements (systematic underestimation 1.0-1.3mm), the difference decreasing with increasing FTR grades.
Conclusion: Using a tailored CM protocol allows for the dynamic analysis of the TA with cardiac CT, showing differences within and between patients with FTR and demonstrates systematic errors for 2D assessments.

B-0149 11:26

False-positive calcifications and radiation dose in coronary artery calcium scoring using iterative reconstruction with a noise threshold
M. Garmer, C. Lehrenfeld, F. Metz, O. Klein-Wiele, B. Brandts, D. Grönemeyer; *Bochum/DE (garmer@groenemeyer.com)*

Purpose: To determine the effect of iterative reconstruction in coronary artery calcium (CAC) scoring on false-positive lesions and radiation dose using a noise threshold in a large patient population. Semiautomatic software-based quantification of calcifications may be impaired by reduced signal-to-noise ratio. Noise-based thresholds have been previously suggested to reduce false-positive lesions in lower dose protocols.
Methods and Materials: The institutional review board approved this retrospective study of 388 matched pairs of patients with identical sex, age±5 years and BMI±2 points. We performed CAC scoring using a 320-row CT scanner with standard dose filtered backprojection (FBP) and lower dose adaptive iterative dose reduction in 3D (AIDR 3D). Patient-dependent dose modulation was based on a noise threshold. Radiation dose, image quality, CAC scores and extent of false-positive calcifications were obtained.
Results: AIDR 3D versus FBP showed reduced effective radiation dose (median mSv 0.85 versus 1.04; p<0.001), less noise (median SD 14.71 versus 18.07; p<0.001) and higher signal-to-noise ratio (median 4.01 versus 3.14; p<0.001). Using AIDR 3D in 388 patients, a low quantity of false-positive calcifications was found in 302 patients, a moderate quantity in 76 patients and a high quantity in 10 patients, while using FBP, the corresponding distribution of patients was 79, 175 and 134 (p<0.001).
Conclusion: CAC scoring using iterative reconstruction and a noise threshold is an appropriate technique for the reduction of radiation dose and improvement of image quality with the avoidance of false-positive calcifications.

B-0150 11:34

57% dose reduction in coronary artery calcium scanning by using lower kVp and advanced modeled iterative reconstruction
M. Vonder[1], G. Pelgrim[1], T. Henzler[2], R. Vliegenthart[1], M. Oudkerk[1]; [1]*Groningen/NL*, [2]*Mannheim/DE (marleenvonder@gmail.com)*

Purpose: To develop a dose-reduced coronary calcium scan protocol by using advanced dose reduction techniques, yielding similar outcomes as a conventional protocol.
Methods and Materials: A calcium insert with 100 small calcifications (size: 0.5-2.0mm, density: 90-540mgHA) was placed inside a thorax phantom and was scanned with 3rd generation dual-source CT. Scans were acquired at 90 ref mAs with 70,80,90,100,110 kVp and reconstructed with filtered back projection (FBP) and ADMIRE levels 1-5, resulting in 30 different scan protocols. For protocols that showed similar results as the conventional protocol of 120kVp-FBP, extra scans were acquired at 18-72 ref mAs. Differences and trends in image quality and calcium scores between the dose-reduced and reference protocol were analysed using Mann-Whitney U test, Independent samples median test and Kendall's τ_b.
Results: Overall, the number of detected calcifications (detection) and calcium scores (Agatston, volume, mass) decreased at increasing tube voltage (τ_b<-0.679, p<0.001) and levels of ADMIRE. (τ_b<-0.825, p<0.001). Detection and calcium scores were similar for 90kVp-IR 3 (p>0.206) and 100kVp-IR1 (p=0.206) compared to the conventional protocol. Detection and calcium scores (p>0.206) remained similar at 36-72 ref mAs with 90kVp-IR3 and 72 ref mAs with 100kVp-IR1 and image quality were similar or higher than the conventional protocol (0.008<p<0.206). Dose reduction from the conventional dose of 0.46mGy could be reduced to 0.20mGy and 0.36mGy for respectively 90kVp-IR3 and 100kVp-IR1.
Conclusion: A dose reduction of 22-57% can be achieved at 90kVp-IR3 and 100kVp-IR1, yielding similar calcium scores and image quality as the conventional protocol.

B-0151 11:42

High-pitch coronary CT angiography using the 3rd generation dual-source CT: initial experience in patients with high heart rate
L. Zhang, X. Liu, B. Feng; *Shenyang/CN (270973226@163.com)*

Purpose: To evaluate the feasibility, image quality and radiation dose of prospectively high-pitch coronary CT angiography in patients with high heart rate using the 3rd generation dual-source CT.
Methods and Materials: 100 consecutive high heart rate (HR) patients (male=56, female=44, 70<HR<100bpm) with suspected coronary artery disease and sinus rhythm were enrolled into this study. All patients were divided into two groups. Patients in group A (n=46) were performed CCTA with prospectively Electrocardiogram (ECG)-triggered high-pitch scan mode, image acquisition was triggered at the end-systolic phase about 30% in the R-R interval. Patients in group B (n=56) were underwent prospectively Electrocardiogram (ECG)-triggered sequential acquisition mode with acquisition window at 30%-50% of the R-R interval. The ascending aorta CT value, noise, signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) with regard to adjacent fat tissue were evaluated. Subjective evaluation was also performed by using 4-point grading scale.
Results: In total, 100 patients, 400 coronary arteries and 1270 vessel segments were included in the statistical analysis. No statistical differences were found in image noise, SNR, CNR and subjective assessment of image quality between two groups. Diagnostic ratios were 89.1% vs 94.4% (patient-based), 95.1% vs 97.7% (vessel-based) and 97.8% vs 98.8% (segment-based), respectively (all p>0.05). However, radiation dose was significantly lower in group A (0.53±0.14mSv vs 1.33±0.17mSv, p<0.01).
Conclusion: In patients with HR > 70 bpm without cardiac arrhythmia, the prospectively high-pitch spiral acquisition at end-systolic phase can provide images with high diagnostic rate and significant low radiation dose as comparing with prospectively sequential acquisition mode.

B-0152 11:50

Non-inferior image quality in low-dose CCTA with knowledge-based iterative model reconstruction for overweight patient: unnecessary tube current modulation according to the body size
I.K. Park, C.H. Park, T.H. Kim; *Seoul/KR (serene@yuhs.ac)*

Purpose: The purpose of this study was to evaluate the feasibility of low-dose coronary CT angiography (CCTA), using knowledge-based iterative model reconstruction (IMR) and a fixed tube current in overweight subjects.
Methods and Materials: 40 non-overweight subjects (group A; body-mass index [BMI] < 25 kg/m2) and 40 overweight subjects (group B; BMI = 25-30 kg/m2), who underwent CCTA for coronary artery disease screening were retrospectively enrolled. All CT scans were performed on a 64-slice CT scanner at 100-kVp tube voltage and 150-mA tube current. CT images were reconstructed using IMR techniques. The CCTA images were qualitatively evaluated using a four-point scale (1=poor, 4=excellent) and further analyzed using a non-inferiority test with a pre-defined non-inferiority margin of -0.2.
Results: The mean noise of group A and group B was 26.0 ± 4.8 HU and 28.9 ± 4.3 HU, each (p = 0.005). The noise reduction ratio of IMR was 65.0% in Group A and 68.1% in Group B, compared to filtered back projection. The mean scale of image quality between two groups was insignificantly different (3.75 ± 0.04 vs. 3.71 ± 0.04, p = 0.478). The non-inferiority of the CCTA image quality in Group B was demonstrated using a pre-defined non-inferiority margin of -0.2 (mean difference = -0.043, 95% CI = -0.162-0.077).
Conclusion: Low-dose CCTA with IMR can be applied to overweight subjects, without tube current modulation based on the patient's body size.

Evaluation of paediatric radiology services in hospitals in the UK

K. Halliday[1], K. Drinkwater[2], D.C. Howlett[3]; [1]*Nottingham/UK*, [2]*London/UK*, [3]*Eastbourne/UK (kath.halliday@nuh.nhs.uk)*

Purpose: To compare paediatric radiology provision across the UK with national standards published by the Department of Health and the Royal College of Radiologists (RCR).
Methods and Materials: Audit standards and indicators for paediatric imaging were derived from "Delivering quality imaging services for children", "Standards for imaging in cases of suspected non-accidental injury" and "Improving paediatric interventional radiologyservices"and agreed jointly by the Clinical Radiology Audit Committee and the British Society of Paediatric Radiology. A questionnaire was sent to all hospitals and NHS trusts imaging children aged 16 or younger in the UK in October 2013. The target for all indicators was 100%. Eighty-seven of 196 (44%) eligible institutions submitted data.
Results: Only 65% of paediatric images were obtained by staff who had had specific training and only 60% were reported by radiographers or radiologists with appropriate training. Sixty-two percent of centres did not have access to a paediatric opinion 24 hours a day, 7 days a week all year; only 34% of radiographers who regularly imaged children had had any access to continuing professional development (CPD) in the 12 months of the audit. Although all hospitals had facilities for image transfer, only 57% had any formal funding arrangements in place for external reporting of images.
Conclusion: The standards set for a network approach to paediatric radiology provision in "Delivering quality imaging services for children" are largely unmet. This failure to make the most of the workforce and resources puts vulnerable children at risk.

B-0154 10:38

CT lung perfusion in the long-term follow-up of congenital left-sided diaphragmatic hernia: results in a cohort of 28 children

M. Remy-Jardin, T. Duchaussoy, A. Deschildre, V. Deken, A. Duhamel, J. Remy; *Lille/FR (martine.remy@chru-lille.fr)*

Purpose: To evaluate lung perfusion on dual-energy (DE) lung-perfused blood volume (PBV) images in the long-term follow-up of left-sided congenital diaphragmatic hernia.
Methods and Materials: CT angiographic examinations were obtained in 28 children (mean age: 10.9±-3.6 yr) with evaluation of the following parameters: (a) on CT angiograms, ipsilateral and controlateral lung appearance (volume; attenuation); (b) on iodine maps, the pattern of lung perfusion and level of attenuation on both sides.
Results: For 11 children (Group 1; 39%): (a) lung perfusion was homogeneous and symmetrical (left: 38.20±10.64HU; right: 42.01±14.24HU; p=0.08); (b) the left lung showed mild hypoplasia (6/11) or normal volume (5/11); (c) the right lung had normal volume and attenuation in all cases. For 17 children (Group 2; 61%): (a) lung perfusion on the left side was abnormal with a mean attenuation on iodine maps significantly lower than that measured on the right lung (39.0±17.9HU vs 52.53 ±20.97HU; p<0.0001); (b) the left lung showed various degrees of hypoplasia (15/17) or a normal volume (2/17); (c) the right lung showed morphological and/or perfusion alterations in 6 children (6/17). Perfusion alterations observed on the right lung were depicted in 21% of the study group (6/28), always seen in Group 2 patients.
Conclusion: Lung perfusion alterations were identified in the lungs of children who underwent congenital diaphragmatic hernia ipsilateral to the hernia side in 61% of cases and in the controlateral lung in 21% of cases.

High-temporal resolution chest CT examinations in infants and young children without sedation or general anesthesia: frequency and severity of motion artifacts

S. Khung, M. Remy-Jardin, N. Lassalle, T. Santangelo, A. Deschildre, J. Remy; *Lille/FR (martine.remy@chru-lille.fr)*

Purpose: To evaluate the frequency and severity of motion artifacts on chest CT examinations acquired without sedation nor general anesthesia in infants and children younger than 5 years.
Methods and Materials: The study population included all consecutively registered infants and young children (age <5 years) who had been referred for a standard chest CT examination on a third-generation, dual-source CT system (pitch: 3.0; rotation time: 250 ms). For each examination, we recorded (a) the number of acquisitions necessary to reach a diagnostic image quality, (b) the frequency and severity of motion artifacts using a 4-point scale (0: no artifact ; 1: mild; 2: moderate ; 3: severe) and (c) the diagnostic value of each acquisition.
Results: The study population comprised 343 patients (mean age: 14.92 months); the mean duration of data acquisition was 0.23±0.05s. For 330 patients (96.2%), the investigation comprised a single acquisition, rated as follows: (a) no motion artifact over the entire thorax (n=193); (b) presence of motion artifacts that did not affect the overall diagnostic value of the examination (n=137) with a mean score of artifact of 0.72. In 13 patients (3.8%): (a) the acquisition was rated as nondiagnostic due to the presence of severe artifacts (mean score: 1.62); (b) a second acquisition was then performed, rated as diagnostic in 13 cases (mean score of artifact: 0.47) and non-diagnostic in 1 patient.
Conclusion: Diagnostic image quality is obtained with a single examination in 96.2% of children scanned while freely breathing.

Functional magnetic resonance imaging compared to lung function in primary ciliary dyskinesia

S. Nyilas[1], G. Bauman[2], G. Sommer[2], O. Pusterla[2], F. Singer[1], O. Bieri[2], C. Heyer[3], C. Koerner-Rettberg[3], P. Latzin[1]; [1]*Berne/CH*, [2]*Basle/CH*, [3]*Bochum/DE (sylvia.nyilas@insel.ch)*

Purpose: Primary ciliary dyskinesia (PCD) is characterised by functional abnormalities of the cilia, leading to chronic airway infection and remodeling. Lung function tests like inert gas washout measurements detect ventilation inhomogeneity, but cannot determine its origin. Novel magnetic resonance imaging (MRI) methods such as Matrix Pencil (MP) decomposition MRI can visualise functional changes in the lung without the administration of contrast agents and the need for breathing maneuvers. This study investigates the correlation between functional and morphological MRI and lung function indices in patients with PCD.
Methods and Materials: Thirty-one patients with PCD (mean age 13.5 years, range 5-28) underwent MRI and lung function tests on the same day. Functional MP-MRI provided semi-quantitative measures of the perfusion (RQ) and ventilation (RFV) impairment as percentages of the affected lung volume. Morphological MRI was evaluated using a score derived from cystic fibrosis. Lung function tests provided information about global (lung clearance index, LCI) ventilation inhomogeneity.
Results: Both MP-MRI and inert gas washout measurements detected functional impairment in PCD: R_{FV} ranged from 12% to 27% and R_Q ranged from 11% to 28%. R_{FV} and R_Q were moderately correlated with LCI (r=0.5, p=0.03; r=0.4, p=0.05, respectively). Total morphology scores as well as sub-scores strongly correlated with LCI.
Conclusion: Functional MP-MRI is a novel, sensitive and non-invasive method to detect and visualise perfusion and ventilation abnormalities. For the first time we could show a correlation between a lung function test and a functional and structural MRI in patients with PCD.

B-0157 11:02

3T MR T1 mapping after arterial switch operation in patients with transposition of the great arteries

K. Rydén Suther, E. Hopp, O. Geier, H. Brun, B. Nguyen, A. Tomterstad, H. Lindberg, A.E. Fiane, C. de Lange; *Oslo/NO (kathrine79@me.com)*

Purpose: Coronary artery patency is of major concern in young patients corrected for transposition of the great arteries (TGA), but is there development of diffuse myocardial fibrosis? We explored coronary ostia and presence of myocardial fibrosis in this patient group corrected with arterial switch operation (ASO).
Methods and Materials: Thirty-three corrected TGA individuals(10-15 years) were examined with 3T MR and compared to 15 healthy controls(18-25 years).

Gd-enhanced 3D fast low-angle shot coronary MRA was performed (n=45), in addition to modified look-locker inversion recovery before (n=48) and after intravenous contrast (n=45) followed by late gadolinium enhancement (LGE) (n=45). Native T1 was measured and extracellular volume fraction (ECV) was calculated in the coronary artery distribution territories of the left ventricular wall. Statistical analyses were performed using independent t-test and Mann-Whitney test.
Results: No LGE was observed and all coronary artery ostia were visualised. Mean(SD) native T1 measurements were in right coronary artery (RCA) 1228(62) ms, left anterior descending artery (LAD) 1260(134) ms, circumflex artery (CX) 1226(86) ms in the TGA group, and in the controls 1226(57) ms, 1197(51) ms and 1168(59) ms respectively (p=.02). ECV was increased in all the coronary distribution territories in the TGA group; RCA 0,30(0,05), LAD 0,29(0,05) and CX 0,29(0,06) in comparison to the controls 0,27(0,04), 0,26(0,03) and 0,25(0,04), respectively (p<.02).
Conclusion: All ASO corrected TGA patients had patent coronary artery ostia but compared to controls they had increased pre-contrast T1 values and ECV. This indicates diffuse myocardial fibrosis in all distribution areas of the coronary arteries.

B-0158 11:10

Image quality comparison of applied and exploratory weight-dependent exposure charts of lower doses in paediatric chest radiography: a multi-centre study of a mobile DR systems
K. Shahgeldi, T. Svahn, R. Lesanu; *Gävle/SE*
(kaveh.shahgeldi@regiongavleborg.se)

Purpose: To compare the image quality of different applied exposure charts in paediatric chest radiography and settings associated with lower doses.
Methods and Materials: Two clinics employed imaging charts of different x-ray energy spectrum (tube load and tube voltage) for paediatric chest imaging (patient weight: 10-20 / 20-30kg) for the same model of mobile x-ray unit. Using these clinical charts, and settings of lower doses, images were acquired in the anterior-posterior projection view of a paediatric anthropomorphic phantom (~20 kg). Fourteen radiologists evaluated the quality of images in a blinded side-by-side study. The different settings were compared in a multiple-reader multiple-case analysis using one of the clinical charts as a reference. Effective dose for the different exposure settings was computed using a Monte-Carlo-based software, PCXMC (Finnish Radiation and Nuclear Safety Authority, Helsinki, Finland).
Results: The different clinical imaging charts, high vs. intermediate x-ray spectrum, had comparable image quality and resulted in approximately the same effective dose. When lowering the tube voltage from that of the applied exposure charts, the lower kV-settings (75/85kV) had comparable quality at a reduced effective dose with 35%. For settings resulting in 50% lower doses, differences were detected ($p < 0.05$) but were mainly recognised as being of slightly worse quality (relative the reference settings).
Conclusion: Effective dose could be decreased with up to 35% of that of the applied settings, while maintaining image quality. Lower energies in paediatric chest radiography offer dose savings by yielding a higher image quality/effective dose.

B-0159 11:18

Quality of paediatric AP/PA chest radiographs based on EC-guidelines - realisable in daily routine at an academic paediatric radiology division?
P.-C. Krüger, F. Schmidt, S. Otto, S. Langner; *Greifswald/DE*
(paul-ch.krueger@uni-greifswald.de)

Purpose: In a paediatric population, as the most radiation-sensitive patients, accurate collimination to reduce unnecessary irradiation and improve image quality are of utmost importance. For AP/PA chest radiographs the European Commission (EC) guideline 16261 provides minimal field size with an age-dependent tolerance. Quality criteria of this guideline were evaluated qualitatively and quantitatively in an academic paediatric radiological division.
Methods and Materials: During a one year period 1238 chest radiographs (58% male, 42% female, age: 0-17years) were evaluated using a semi-automatic tool. Quality criteria, minimal field size and overexposure were assessed based on EC guideline criteria.
Results: Overall only 4,4% of all images completely fulfilled the EC-guidelines. Most correct radiographs (14,1%) were made of infants (1-12 months). Generally, 46,3% were rated as under-, 43,9% as overexposed. Mean overexposure (52,2%±29,2%; range: 4,7% to 325,6%) and tissue overexposure (41,5%±27,5%; range: 0,0% to 272,7%) were differentiated. Diagnostic requirements were virtually confirmed, except deep inspiration and rotation/tilting. Age-dependently both criteria increased (successful deep inspiration: newborn: 21,2%; early adolescents: 81,6%). Furthermore, images were analysed to the commissioned radiological section. Overexposure was significantliy increased when images were acquired on newborn ICU (69,6%) compared to paediatric ICU (56,7%; $p<0.05$) and the radiological department (44,6%; $p<0.05$).
Conclusion: The EC-guidelines are indispensable to protect children from unnecessary radiation exposure. In daily routine the feasibility was constricted, especially on ICU. Semi-automated quality assessment is a fast and reliable tool to improve patient care.

Role of lung ultrasound in the evaluation of pneumonia in children
I. Sefic-Pasic, A. Dzananovic, A. Pasic, S. Vegar Zubovic; *Sarajevo/BA*
(irmina.sefic@gmail.com)

Purpose: To introduce basic principles of lung ultrasound (analysis of appearance of specific ultrasound artifacts) technique and ultrasound findings in community acquired pneumonia found in paediatric population, and to compare it with x-ray.
Methods and Materials: Lung ultrasound were performed prospectively (Feb 2015 - Sep 2016) in 40 children (23 boys and 17 girls) with positive clinical and laboratory signs of impaired pulmonary function, suspected to pneumonia and ultrasound findings were compared with chest x-ray. All ultrasound examinations were performed with linear-array probes 7,5 and 10 MHz. Right and left lung were examined with anterior, posterior and lateral approach. Interpretations of findings have been done by two radiologists, one blinded to x-ray study and vice versa and results were compared with statistical analysis.
Results: In the cohort of 40 patients, bacterial pneumonia was confirmed in 37. On ultrasound we found pathological findings presented with B lines, consolidation of parenchyma, pleural effusion, empyema and abnormalities of pleural line. Sensitivity of ultrasound was 97%, specificity 75%, positive predictive value 94.8% and negative predictive value of x-ray 60%. Low specificity of lung ultrasound can be explained with the fact that consolidations of lung parenchyma found in two patients have been differentiated as tuberculous infections,and were considered statistically as false positive.
Conclusion: Lung ultrasonography is suitable for routine use, diagnosing and follow-up, and it can sufficiently replace chest x-ray in mild and uncomplicated cases of pneumonia in children. It should be incorporated in diagnostic algorithm of lungs evaluation in paediatric population.

B-0161 11:34

Role of lung ultrasound in paediatric intensive care units: comparison with bedside chest radiography
M. Mughetti, G. Napoli, A.M. Chiesa, F. Ciccarese, P. Bertaccini, M. Zompatori; *Bologna/IT (martinamughetti@gmail.com)*

Purpose: To compare the diagnostic performance of lung ultrasonography and chest radiography for the detection of common pathologic abnormalities.
Methods and Materials: Thirty-three children admitted in intensive care-unit were prospectively studied, for a total amount of 64 LUS and 64 CXR performed. Consolidation, alveolar-interstitial syndrome, pneumothorax, and pleural effusion were evaluated.
Results: Pleural effusion was demonstrated in 6 CXR examinations, while 20 LUS exams resulted positive. Pneumothorax was detected in 1 CXR exam as well as in LUS. Alveolar-interstitial syndrome was detected in 44 CXR while in 39 LUS. Consolidation was diagnosed in 33 CXR while in 43 LUS. Agreement analysis showed perfect overall agreement between LUS and CXR for pneumothorax diagnosis (100% agreement, Cohen Kappa coefficient 1), substantial agreement for pulmonary consolidation (84%, K 0,68), moderate agreement for alveolar-interstitial syndrome (76%, K 0,49) and fair agreement for pleural effusion (75%, K 0,28). The Z score was statistically significant for the 4 abnormalities detected with CXR and LUS. 3 LUS examinations were negative versus 7 negative CXR (94% agreement, K 0,000).
Conclusion: LUS is both feasible and convenient in the critical care paediatric units and may eventually replace CXR and HRCT at least if it results negative and eventually for the follow up of these common pathologic entities.

B-0162 11:42

The effect of iodinated contrast administered during a CT pulmonary angiogram during pregnancy on neonatal thyroid function
S. Culleton, A. Egan, B. Buckley, T. Tarmey, D. O'Donovan, P. Mayne, D. Sheppard; *Galway/IE (cullets@tcd.ie)*

Purpose: CT pulmonary angiogram (CTPA) is a frequently performed test to evaluate for pulmonary emboli in pregnancy. Current guidelines recommend checking neonatal thyroid function in the first week of life as there is a risk of hypothyroidism. This retrospective study assessed the effect of in utero exposure to iodinated contrast on neonatal thyroid stimulating hormone (TSH) screening results.
Methods and Materials: All CTPAs performed on pregnant females at Galway University Hospital during 2011-2015 were reviewed. The neonatal TSH screening records were reviewed. A control group of 106 unexposed infants was from same time period were chosen.
Results: TSH neonatal screening records for 81 babies were identified. In the exposed group two infants had abnormal screening results and were normal when repeated. There were no confirmed cases of neonatal hypothyroidism

due to exposure to contrast in utero. The control group of 106 neonates had no abnormal results. There was no statistically significant difference between the control and exposed values for TSH (p =0.4). This study also looked at the number of weeks pre-delivery that the babies had been exposed to iodine from weeks 1-5, 5-10 and greater than 10 weeks and there was no significant difference between the groups (p =0.6).
Conclusion: This study showed no adverse effect on neonatal thyroid function following a single exposure to iodinated contrast in utero.

B-0163 11:50

Effect of high concentration iodinated contrast medium in euthyroid children

A. Clemente, F. Avogliero, A. Di Giambattista, D. Della Latta, D. Chiappino; *Massa/IT (andreadigia@gmail.com)*

Purpose: To assess the effect of administration of high concentration iodinated contrast medium (HCICM) on the thyroid function in a population of children <4 years of age undergoing CT-angiography for cardiac surgery planning.
Methods and Materials: We evaluated 46 patients (m = 26, f = 20, mean age:1 ± 0.86 years) from April 2013 to October 2015 admitted for congenital heart disease. Preoperative CTA was performed by administration of non-ionic triiodate contrast medium (iopromide 370 mg / ml, 1.14± 0.17 ml / kg). Exclusion criteria: thyroid hormone abnormalities at admission. TSH, fT3, fT4 were collected at admission, 48 hours after the CT scan and at discharge (20 ± 21 days) and indexed for haematocrit.
Results: TSH/Ht (admission): 0.11±0.10; TSH/Ht (48h): 0.02±0.03; TSH/Ht (discharge):0.08±0.06. fT3/Ht (admission): 0.08±0.02; fT3/Ht (48h): 0.07±0.03; fT4/Ht (discharge): 0.09±0.03. fT4/Ht (admission): 00:03±0.01; fT4/Ht (48 h): 0.03±0.01; fT4/Ht (discharge):0:03±0.01. Compared to admission values, a significant decrease was found in TSH at 48h ($p<0.05$). TSH to 48 hours was reduced respect to normal values indexed for haematocrit in 29 patients (63% of cases). A non-statistically significant trend was found in reduction of fT3 at 48 h (14 cases, 30%). No significant differences were found in comparison of the other values.
Conclusion: The use of HCICM in children is associated with a temporary but significant reduction in TSH values at 48h with normalised valued at discharge. Thyroid hormonal status in not significantly altered by HCICM in euthyroid children.

Histogram analysis of ADC from whole-body DW-MRI (WB DW-MRI) to predict very early response to chemotherapy in patients with metastatic colorectal cancer (mCRC): preliminary results

I. Lavdas, E. Daulton, A.G. Rockall, L. Honeyfield, K. Kozlowski, E. Aboagye, R. Sharma; *London/UK (emilydaulton@doctors.org.uk)*

Purpose: We evaluated apparent diffusion coefficient (ADC) histogram analysis parameters from WB DW-MRI as very early predictors of response to chemotherapy in patients with mCRC.
Methods and Materials: 11 patients with histologically confirmed mCRC were scanned with WB DW-MRI (b=0, 50, 150, 500, 900 s/mm^2) at 1.5T, before and 10.8±2.7 days after commencing chemotherapy. Response was assessed by the final clinical RECIST 1.1. For analysis, patients were grouped as progressive or non-progressive disease. Mean ADC and histogram analysis parameters (skewness, kurtosis, 25th., 50th. and 75th. percentile) were calculated. Parameters were compared between baseline and follow-up scans using a Wilcoxon signed rank test.
Results: 8 patients did not progress and 3 patients progressed on treatment. Skewness and kurtosis were significantly lower at follow-up (2.57±2.65 vs. 0.93±1.09 and 26.6±36.1 vs. 5.9±6.5 with P=0.003 and P=0.001 respectively) for non-progressors, whilst for progressive disease skewness and kurtosis was higher at follow-up (1.16±0.63 vs. 1.35±1.30 and 6.08±3.44 vs. 11.10±14.04 with P=0.89 and P=0.57 respectively). There was no significant difference between baseline and follow-up in the mean ADC and percentiles for any of the groups.
Conclusion: Skewness and kurtosis are ADC histogram parameters that can potentially separate between progressive and non-progressive disease in patients with mCRC, scanned with WB DW-MRI. This promising 'one-stop-shop' response assessment methodology is ready for use in a larger trial.

B-0165 10:38

Comparison of imaging response criteria in metastatic melanoma patients treated with immune checkpoint inhibitors: a single institution analysis

M. Morone[1], L. Spain[1], J. Winfield[2], T. Schmid[2], D.-M. Koh[1], C. Messiou[1], D. Collins[1], A. Sohaib[1], J. Larkin[2], M. Bali[1]; [1]*Sutton/UK*, [2]*London/UK (mariomorone@libero.it)*

Purpose: Immune-related response criteria (irRC) is increasingly used for assessing tumour response in patients treated with immunotherapy. However, it is unclear how response categorisation by irRC is directly compared with other criteria. We applied Response Evaluation Criteria in Solid Tumours (RECIST 1.1), irRC, Choi and revised-Choi response criteria and compared their associated progression free survival (PFS) and overall survival (OS) in melanoma patients treated with immunotherapy.
Methods and Materials: After institutional review board approval, 144 patients (65% male, mean age 59) treated with Ipilimumab (Group 1, n=100) and Pembrolizumab or Nivolumab (Group 2, n=44) were identified. CT images acquired at baseline, 3- and 6-months after treatment were analysed. A radiologist categorised response according to the above four criteria. Patients demonstrating complete response (CR), partial response (PR) or stable disease (SD) were responders (R); patients with disease progression (PD) were non-responders (NR).
Results: For Group 1, all criteria showed significant differences between R and NR for PFS and OS at 3- and 6-months after therapy (log-rank test $p<0.05$; hazard ratio between 2.7 and 3.6 for PFS, and between 2.2 and 3.4 for OS, across four criteria). For Group 2, all criteria showed significant differences between R and NR for PFS at 3- and 6-months ($p<0.05$; hazard ratio between 4.2 and 14.4) but not for OS ($p>0.05$).
Conclusion: The four imaging response criteria were comparable for patient categorisation of R and NR and for stratification of PFS and OS. IrRC may not provide additional information for the majority of patients on immunotherapy.

B-0166 10:46

3D imaging biomarkers: prediction of survival in patients with non-small cell lung cancer brain metastases treated with stereotactic body radiation therapy

M. Della Seta[1], D. Kaul[1], J. Chapiro[2], B. Hamm[1], F. Collettini[1]; [1]*Berlin/DE*, [2]*New Haven, CT/US (marta.della-seta@charite.de)*

Purpose: To investigate the value of 3D-quantitative tissue enhancement as an early imaging biomarker for patient survival in patents with non-small cell lung cancer (NSCLC) brain metastases treated with stereotactic body radiation therapy (SBRT).
Methods and Materials: 27 patients with NSCLC brain metastasis were treated with SBRT. Baseline contrast-enhanced MRI (ceMRI) was used for image analysis using the qEASL tool (IntelliSpace Portal V.8, Philips Healthcare). A segmentation-based 3D-quantification was performed in each patient to measure the relative tumour enhancement in each lesion. A cut-off value of 65% lesion enhancement was used to stratify the patient cohort in two groups (<65% and >65% volumetric lesion enhancement). Survival was evaluated using Kaplan-Meier analysis and compared using the Mantel-Cox Log-rang test as well as proportional hazard ratios (HR).
Results: Median OS of the entire population was 6.0 months. The stratification of the cohort according to the 65% cut-off for the relative enhancing tumour volume achieved statistical significance p=0.0452 (HR, 2.2 [95% CI, 1.1-6.8]). Patients with >65% enhancing lesion volume survived significantly longer than patients with relatively less-enhancing tumour lesions (8.15 months vs. 2,09 months [HR 0.25; 95% CI, 0.11-0.58], respectively). The total tumour volume did not achieve a statistically significant separation of survival curves.
Conclusion: As opposed to the total tumour which currently is the most commonly used staging marker, volumetric assessment of metastatic NSCLC lesion enhancement on baseline ceMRI is strongly associated with patient survival after SBRT. Specifically, patients with hyper-enhancing lesions demonstrated improved survival as compared to those with hypo-enhancing lesions.

DWI and ADC in assessing early response to angiogenesis inhibitors in metastatic renal cell carcinoma

C. Marigliano, C. Sgrazzutti, A. Vanzulli; *Milan/IT (kiarmn@gmail.com)*

Purpose: Angiogenesis inhibitors have a potential role in treating metastatic renal-cell carcinoma, but it is still not clear why only some patients can benefit of this treatment protocol. Objective was to look for DWI parameters able to identify early response to angiogenesis inhibitors in patients with metastatic renal-cell carcinoma, considering RECIST1.1 as reference Standard.
Methods and Materials: We prospectively enrolled twenty-four patients candidate to start angiogenesis inhibitors with at least one target lesion and who underwent 1,5T MRI examination with multiple b-values DWI sequences (0,40,200,300,600) in specific timeline: one week before (T0), 2 weeks after (T2) and 8 weeks after (T8) treatment beginning. ADC value was calculated drawing ROIs on the lesions. Twenty-one patients with 30 lesions had adeguate data for comparative evaluation.
Results: At T2 six patients had early response. At T8 4 patients had partial response (PR), 15 disease control (DC), 2 progression disease (PD); average progression free survival was 273 days. PR group, as compared to DC or to PD showed higher T0 ADC values at b40 (respectively 5,5(1,4),3,6(1,2), 1,7(0,9) avg(SD)): we can assess that more vascularised lesions are more responsive to treatment. PD group have significantly lower ADC values then both other groups, at T0, T2 and T8, for all b-values.
Conclusion: Results show that ADC at T0 may help selecting patients with promising good response to angiogenesis inhibitors. Moreover at T0 and at T2 ADC has the potential to select patients who wouldn't benefit from treatment (early progression disease).

B-0168 11:02

CT texture analysis as a predictor of response to therapy and prognosis in patients with metastatic renal cell carcinoma treated with first-line tyrosine kinase inhibitors

G. Bonera, G. Agazzi, M. Ravanelli, D. Farina, V. Ferrari, A. Berruti, R. Maroldi; *Brescia/IT (gei.bonera@gmail.com)*

Purpose: To investigate if texture analysis (TA) on pretreatment contrast-enhanced CT (CECT) images can predict response to tyrosine kinase inhibitors (TKI) and prognosis in patients with metastatic renal cell carcinoma (mRCC).
Methods and Materials: 65 pretreatment CECT studies of mRCC patients treated with first-line TKI were retrospectively reviewed. Objective response was assessed every 3 months according to RECIST 1.1 and modified Choi (mChoi) criteria. TA was performed on a 5-mm-thick central slice for each target lesion using a commercially available software (TexRAD Ltd, UK). Primary texture features and a novel HeteroDensity Index (HDI), accounting for size-standardised heterogeneity and mean pixel density, were quantified using different spatial-scale filters (ssf). Per-patient texture features were correlated with objective response, progression-free and overall survival (PFS, OS) using logistic regression and survival analysis, statistical significance was corrected to control false discovery rate.
Results: Primary texture features were not able to discriminate responders and non-responders. HDI obtained with a 3-mm ssf (ssf3) was positively correlated with objective response (odds ratio 0.14 for RECIST and 0.2 for mChoi criteria, p 0.018 and 0.026, respectively). Low ssf3 HDI was associated with worse PFS (hazard ratio 4.14, p 0.0001) and OS (hazard ratio 3.36, p 0.0008).
Conclusion: TA on pretreatment CECT helps to predict objective response and prognosis in mRCC patients treated with first-line TKI.

B-0170 11:10

DCE-MRI to assess pathological response to neoadjuvant chemotherapy for high-grade soft tissue sarcomas

A. Crombe[1], X. Buy[1], N. Alberti[2], M. Toulmonde[1], E. Stoeckle[1], J.-M. Coindre[1], A. Italiano[1], M. Kind[1]; [1]*Bordeaux/FR*, [2]*Contamines-sur-Arve/FR (crombeamandine2@gmail.com)*

Purpose: Aim of this pilot study is to determine if DCE-MRI parameters or their changes show significant differences between good and poor responders to neoadjuvant chemotherapy in high-grade soft tissue sarcomas.
Methods and Materials: 23 patients underwent DCE-MRIs after 2 courses of chemotherapy (MRI-1) and at the end of neoadjuvant protocol, before curative surgery (MRI-2), in our tertiary referral center. 17/23 patients had an available initial MRI (MRI-0). MRIs were performed on two 1.5T-MR-systems with same acquisition parameters and post-processing. Surgical specimens pathological analysis was the gold standard: good response was defined as <10% of viable tumour (11/23) and poor response as ≥50% (12/23). Morphological features on conventional sequences and their changes were reported by two radiologists. For DCE-MRI analysis, ROIs were manually and consensually drawn on tumoural tissue component and on healthy muscle to obtain ratio for each parameter. The wash-in (WI), peak-enhancement (PE), area-under-curve 180s (AUC180) were calculated for semi-quantitative analysis using Olea software. The volume transfer constant (Ktrans) was calculated using extended-Tofts-Kety model. Permeability-curves and AUC180 density-histogram were obtained and scored according to an 8-points qualitative scale.
Results: WI-ratio, PE-ratio, AUC-ratio and Ktrans-ratio on MRI-2 were significantly decreased in good responders (respectively, p=0.04, 0.015, 0.017, 0.018) while differences did not reach significance on early MRI-1. Evaluation of permeability-curve and AUC180 histogram showed early and late significant modifications (p=0.025 and 0.0005).
Conclusion: Qualitative, semi-quantitative and quantitative DCE-MRI may be helpful as an additional technique in evaluating response to chemotherapy in high-grade soft tissue sarcoma.

B-0171 11:18

Response to neoadjuvant chemotherapy of skeletal-osteosarcoma/Ewing sarcoma on the basis of MRI 18-FDG-PET by correlating with pathological necrosis

D.P. Wali[1], S. Gupta[2]; [1]*Bangalore/IN*, [2]*Mumbai/IN (wali.praveen@gmail.com)*

Purpose: To establish pre/post-chemotherapy MRI and PET-CT scans are as effective as histopathological assessment in assessing response to neoadjuvant-chemotherapy.
Methods and Materials: 34 biopsy proven patients of osteosarcoma/Ewing sarcoma prospectively studied pre/post-chemotherapy for response evaluation by MRI and PET-CT in P. D. Hinduja Hospital-Mumbai. Comparison by assessing post-chemotherapy response in these patients using dynamic contrast MRI/DW-MRI. Post-chemotherapy scans analysed by radiologist and nuclear-medicine specialist without knowledge of neoadjuvant-chemotherapy status.
Results: Paired sample t-test used to analyse change in percentage volume of tumour in pre/post-chemotherapy patients. Mean ADC values in pre/post-chemotherapy were 0.8964 and 2.8043. ADC values in post-chemotherapy responders and non-responders were 3.5437 and 1.8536. Positive correlation between necrosis rate and increased ADC values in post-chemotherapy patients was observed. In post-chemotherapy patients positive correlation was observed between percentage change of volume and percentage change of SUV value. Change in DCE curve types in post-chemotherapy patients were evaluated using chi square test.
Conclusion: Advanced MRI techniques complement standard MRI but remain insufficiently used. DWI/DCE sequences are significantly effective in preoperative response evaluation to chemotherapy in patients with osteosarcoma/Ewing sarcoma patients. Conventional MRI not effective in response evaluation to chemotherapy as much as PET-CT. Preoperative response evaluation by non-invasive imaging modality like MRI helps deciding management and surgical procedure to be either limb salvage or amputation.

B-0172 11:26

Can diffusion-weighted MR imaging be used for prediction and monitoring of treatment response in gall bladder carcinoma?

L. Singh, R. Sharma, D. Kandasamy, M. KS, S. Gamanagatti, R. Sahoo, A. Sharma, P. Garg, P. Sahni; *New Delhi/IN (luv_ldh@yahoo.co.in)*

Purpose: Response evaluation in gall bladder carcinoma (Ca GB) is traditionally done after completion of 3-4 cycles of chemotherapy according to size criteria based on Response Evaluation Criteria in Solid Tumours (RECIST). We hypothesised that apparent diffusion coefficient (ADC) value can be used as an early marker of response to chemotherapy in Ca GB.
Methods and Materials: In this study 23 patients were evaluated. MRI was done at baseline, after 1st (early time point) and 3rd cycle of chemotherapy. Percentage change in size after 3 cycles of chemotherapy was taken as the gold standard to assess response based on RECIST. Total 22 primary masses, 32 lymph nodes and 18 liver metastases were evaluated. Baseline ADC was compared between responders and non-responders. To assess response to chemotherapy percentage ADC change at early time point was compared between responders and non-responders.
Results: Mean percentage increase in ADC at early time point for primary mass, lymph nodes and liver metastases was significantly higher in responders (24.8%, 29.6%, 15.9%) than non-responders (11.5%, 6.9%, 0.8%) respectively (p= 0.02, 0.0001, 0.04). There was no significant difference between baseline ADC of responders and non-responders in primary mass (p= 0.46). Area under curve (AUC) for percentage change in ADC for differentiating responders at early time point was 0.79 for primary mass, 0.89 for lymph nodes 0.79 for liver metastases respectively.
Conclusion: Increase in ADC can be used for early assessment of response to chemotherapy in Ca GB. However baseline ADC cannot predict response to chemotherapy.

B-0173 11:34

CT-based tumour heterogeneity analysis in pancreatic carcinoma allows prediction of progression

J.P. Steinacker[1], N. Stanescu-Siegmund[1], T. Ettrich[1], M. Baumhauer[2], T.F.E. Barth[1], M. Kornmann[1], A. Beer[1], M. Beer[1], S.A. Schmidt[1]; [1]*Ulm/DE*, [2]*Dossenheim/DE*

Purpose: Imaging in pancreatic cancer is a challenge regarding therapy response evaluation. Tumour size, attenuation, and perfusion are widely used as measurable parameters, but are often limited by blurry tumour borders and missing qualitative parameters. We tested this new CT-based approach of tumour heterogeneity feature analysis for monitoring therapy response.
Methods and Materials: 13 patients with pancreatic adenocarcinoma undergoing portalvenous abdominal computed tomography according to standard as baseline imaging with clinical follow-up and imaging (timespan median 64 days) under systematic therapy (FOLFIRINOX/Gemcitabin) were retrospectively analysed. Progression was defined as new lesions (6 patients) and local tumour spread (3 patients). Tumour heterogeneity analysis was performed using mintLesion®. Image features included tumour volume, entropy, kurtosis, mean positivity of pixels (MPP), skewness, uniformity of distribution of positive pixels (UPP), and uniformity of pixels. Statistical analysis were performed with spearman's rank correlation and Mann-Whitney-U-test.
Results: During follow-up tumour volume did not significantly change between our groups with overall progression (local and systemic) and progression free patients (p=0,661). MPP values were significantly higher in patients without progression compared to patients with progression (p=0.030). There was a significant negative correlation between changes in kurtosis and the time till local tumour spread (p=0.008) or systemic progression (p=0.017).
Conclusion: Results suggest that analysis of tumour heterogeneity may provide valuable information from routine acquired images regarding therapy response evaluation; this may help adjusting therapy regimes and is easily integrated in clinical workflows. Furthermore, this procedure may predict therapy response and, hence may regarded as a marker for progression-free survival.

B-0174 11:42

Sarcopenia is an independant prognostic factor for poor overall survival among patients with pancreatic adenocarcinoma

A. Lambert, J. Salleron, C. Gavoille, A. Viard, A. Ayav, T. Conroy, V. Laurent; *Vandoeuvre-lès-Nancy/FR (a.lambert@nancy.unicancer.fr)*

Purpose: Our purpose was to evaluate sarcopenia as an independent prognostic factor for overall survival in patients with pancreatic adenocarcinoma to predict early relapses or progressive disease and to help decision-making for treatments.
Methods and Materials: From 2009 to 2015, all the patients with pancreatic adenocarcinoma were retrieved (N=114). A retrospective review of the total psoas area (TPA) was performed for each scan (N=713). The TPA was measured on a single cross-sectional image through the third lumbar vertebrae normalised for stature. The percentage decrease in the value of the TPA during the follow-up was also analysed.
Results: In univariate analysis, a TPA level under 420 during the follow-up whatever the time of the measure HR=3.419 ([2.168;5.394]; 95% CI; p<0.0001) and a TPA decrease of more than 20% from baseline HR=7.169 ([4.526;11.353]; 95% CI; p<0.0001) were independent prognostic factors of death. The multivariate analysis, confirmed the results with HR=5.799 ([3.418; 9.839]; 95% CI; p<0.0001) in the non-surgical group and HR=8.089 ([2.157; 30.339]; 95% CI; p=0.0019) in the surgical group for TPA decrease of more than 20% from baseline during the follow-up.
Conclusion: Our analysis shows that regardless of the time of the measurement, a TPA value under 420 and a TPA decrease of more than 20% during the follow-up are strong and independent death risk prognostic factors in patients with pancreatic adenocarcinoma. We now provide a tool to evaluate patients at diagnosis or during iterative consults of treatment or surveillance.

Microbleed location is related to white matter lesion morphology

L.G.M. Cremers, J.G.J. Verbruggen, M. de Groot, W.J. Nlessen, M.A. Ikram, M.W. Vernooij; *Rotterdam/NL (l.g.m.cremers@erasmusmc.nl)*

Purpose: The location of microbleeds is thought to reflect the underlying pathology, with lobar microbleeds suggestive of cerebral amyloid angiopathy and deep microbleeds more related to hypertensive or atherosclerotic microangiopathy. Such dichotomy is also presumed to be present for white matter lesions (WML), but has not been studied in relation to WML morphology. We hypothesize that WML differs morphologically, depending on location of concomitant microbleeds and underlying pathology.
Methods and Materials: This study is embedded within the Rotterdam study. Participants underwent multi-sequence MRI scanning to assess microbleed presence and location, and presence and morphology of WML. We calculated the surface-to-volume ratio of the WML. A high surface-to-volume ratio indicates punctate WML, while a low ratio indicates larger, more confluent lesions. We assessed differences in WML morphology between presence of lobar versus deep microbleeds using linear regression models.
Results: We found 601 (13.0%) participants with solely lobar microbleeds and 145 (3.2%) participants with solely deep microbleeds. WML found in participants with solely lobar microbleeds had a higher surface-to-volume ratio compared to WML in persons with deep microbleeds, after adjusting for age and sex (B= 0.04, 95%CI=0.01; 0.06, p<0.01). The association attenuated after correcting for intracranial volume, total white matter volume and WML volume, but remained borderline significant (B=0.01, 95%CI= -0.00; 0.03, p=0.08).
Conclusion: WML in people with solely lobar microbleeds have a more punctate morphology compared to larger, confluent WML in people with solely deep microbleeds. These findings warrant further investigation of lesion morphology in relation to the location of cerebral microbleeds.

MR features and cerebrospinal fluid and plasma oxidative stress biomakers in different clinical phenotypes of neuroinflammatory acute attacks

D. Stojanov, S. Ljubisavljević, I. Stojanovic, S. Vojinovic; *Nis/RS (drstojanov@gmail.com)*

Purpose: To correlate MRI features with plasma and CSF lipid peroxidation product-malondialdehyde (MDA), catalase (CAT), and superoxide dismutase (SOD) activity in patients with clinically isolated syndrome (CIS) and relapsing remitting multiple sclerosis (RRMS).
Methods and Materials: Cross-sectional study included 50 CIS patients, 57 RRMS patients, and 20 control patients with nonspecific neurological symptoms. We calculated the number of T2W hyperintense lesions and load of T1W Gd-enhancing lesions as volume. Patients were divided into those with mild and severe MRI changes. Concentration of MDA was determined by modified TBA method. SOD and CAD were measured by spectrophotometry.
Results: MDA values were higher in plasma and CSF of all study patients with a higher number of total T2W lesions (p<0.05). The CSF/plasma MDA ratio was higher in RRMS patients. CAT activity was higher in CIS and RRMS patients with lower number of T2W lesions (p<0.05). SOD activity was higher in CIS and RRMS patients with lower number of T2W lesions, but these differences were significant only for plasma SOD activity changes (p<0.05). The positive correlations were observed in MDA levels in plasma and CSF, and Gd-enhancing lesion volume, for CIS and RRMS patients, and a negative correlation in SOD activity in plasma ad Gd-enhancing lesions volume, only for CIS patients (p<0.01).
Conclusion: Beyond MDA plasma, CSF values, SOD activity in plasma of CIS patients, and their MRI features, no correlation was observed between MRI and other biomarkers. It may be the consequence of a relatively small number of MRI scans.

B-0177 10:55

Decreased white matter integrity (WMI) in SLE patients: a DTI study

J.S.B. Nystedt, M. Nilsson, A. Jönsen, P.M. Sundgren; *Lund/SE (jessika.nystedt@med.lu.se)*

Purpose: To investigate WMI in SLE patients without neuropsychiatric complaints and relation to the concomitant depression and fatigue commonly described in lupus patients.
Methods and Materials: 26 female SLE patients (age: 23-52 years, mean: 36 years) and 20 aged-matched, healthy controls (age: 19-52 years, mean: 36 years) underwent cognitive testing (CNS-VS) and self-assessment questionnaires screening for depression and fatigue. All patients underwent 3T MRI and DTI. Software used for analyses of DTI data was developed in-house in Math-lab. The diffusion tensor was fitted using linear least squares minimisation. FA and MD were measured in the corpus callosum (CC) and the cingulum bundle, both associated to the default mode network. The cinguli were segmented primary focusing on the rostral and hippocampal parts. CC was segmented with main interest in the forceps minor which has been related to depression and fatigue. For statistical evaluation of WMI Kruskal-Wallis test was used. For correlation analysis, Spearman's Rho was used.
Results: Decreased FA values was demonstrated in rostral cinguli (p=0.044) and in left rostral cingulum in SLE patients (p= 0.03). Decreased MD was demonstrated in the left hippocampal cingulum (p=0.036) and decreased FA (p=0.002) and MD (p=0.042) was observed in the forceps minor of the lupus group and was associated with fatigue (rho=-0.015) and depression (rho=-0.026).
Conclusion: WMI in areas crucial for attention, mood and cognitive functions such as verbal memory, and consolidation of memories, might be altered in lupus patients without neuropsychiatric complaints. The disintegrity of the left hippocampal cinguli could contribute to the cognitive decline common in lupus patients.

B-0178 11:03

Phase sensitive inversion recovery improved identification of intracortical lesions in multiple sclerosis comparison with FLAIR and T2WTSE MR imaging

H. Naghibi, K. Firouznia, M. Shakiba, A. Azimi, V. Shahabian, H. Soroush, P. Sabet Rasekh; *Tehran/IR*

Purpose: Accurate detection and classification of purely intracortical lesions in multiple sclerosis (MS) are important in understanding their role in disease progression and impact on the clinical manifestations of the disease. Conventional MRI can not show cortical lesions, but some new MRI sequences have been proposed to be dedicatein this relation.Here, we want to evaluate efficacy of phase-sensitive inversion recovery (PSIR) for detection of cortical lesions of MS patients.
Methods and Materials: Fifty MS patients underwent MRI scanning on a 1.5 Tesla scanner. PSIR, T2W-TSE and fluid-attenuated inversion recovery (FLAIR) images were acquired and inspected by 2 experts, aNeuroradiologist and a MS *Fellowship*. The lesions were classified as purely intracortical, mixed gray-white matter, and juxtacortical. The difference in the number of lesions detected in each category was compared between PSIR and FLAIR and T2W-TSE.
Results: Cortical brain lesion load and the number of lesions were significantly higher on PSIR compared to both FLAIR and T2-TSE (P<0.001). Also the contrast between GM-WM was excellent in PSIR. PSIR consistently allowed a clearer classification and delineation of MS plaque.
Conclusion: PSIR is a promising technique to detect cortical lesions and could be beneficial in monitoring of cortical damage and disease progression in MS patients.

B-0180 11:11

The role of multivoxel proton MRS in differential diagnosis of multiple sclerosis disease courses

A. Bogdan, J. Khomenko, G. Kataeva, L. Prakhova, A. Ilves; *St. Petersburg/RU (andrey.a.bogdan@gmail.com)*

Purpose: Evaluation of brain metabolic changes in relapsing-remitting and secondary-progressive multiple sclerosis (RRMS and SPMS) with proton magnetic resonant spectroscopy (H-MRS).
Methods and Materials: Concentration ratios of main MRS-detectable metabolites of 47 patients with multiple sclerosis (MS) including 27 RRMS and 20 SPMS, and 21 normal subjects where compared in 9 regions of interest (ROI) of supraventricular normal appearing white matter (NAWM) and medial cortex. H-MRS was performed on Achieva 3T (2D PRESS, TE/TR=144/2000 ms). Localization: multivoxel MRS study (8*9 voxels (10*10*15 mm), whole volume 80*90*15 mm) was divided into 6 ROIs (anterior, medium and posterior ROIs bilaterally) in NAWM and 3 ROIs of gray matter (GM) in medial cortex. NAA/Cr, NAA/Cho, Cho/Cr ratios (NAA - N-acethylaspartate, Cr - creatine, Cho - choline) where analyzed.
Results: NAA/Cr ratio was significantly lower in RRMS-patients in NAWM (posterior frontal lobe bilaterally) and medial frontal lobe cortex compared to healthy subjects. In SPMS-patients NAA/Cr was significantly lower in all observed regions compared with RRMS-patients. NAA/Cho ratio was lower in NAWM of posterior frontal lobe bilaterally in RRMS-patients and, in case of SPMS in all observed regions, compared with normal controls. Ratio of Cho/Cr did not show any difference between the investigated groups.
Conclusion: In MS, metabolic changes precede the structural ones. The markers of neuronal and axonal dysfunction (decrease of NAA/Cr in the NAWM and GM) are registered in the early stages and aggravate during disease courses. Differences in metabolic ratios levels can be useful in differential diagnosis of MS disease courses.

B-0181 11:19

Diagnostic value of contrast-enhanced T2 FLAIR in multiple sclerosis disease: a preliminary experience in 49 patients

M. Perri[1], R. Balzano[1], R. Izzo[2], G. Guglielmi[1], T. Popolizio[1]; [1]*San Giovanni Rotondo/IT*, [2]*Naples/IT (marco-perri@tiscali.it)*

Purpose: The aim of this study is to assess the diagnostic value of CE-FLAIR for the detection of new active plaque in clinically suspected relapsing phase of the Multiple Sclerosis (MS) disease.
Methods and Materials: The institutional review board approved this prospective study in which all subjects provided written informed consent. A total of 49 patients with clinically definite MS disease underwent brain MRI. All examinations were performed using 1.5 T MR scanner, with standard protocol for brain including pre and post contrast SPGR T1-Weighted Image (CE-T1WI) and in adjunct Susceptibility Weighted Imaging (SWI) and CE-FLAIR. Two neuroradiologists, blinded to the clinical disease activity, evaluated by consensus all images to assess presence or absence of enhancement in MS lesions. Chi- square and T student tests were used for testing variables.
Results: Fourteen out of 49 patients had no active plaques in post contrastographic sequences being in remitting phase; SWI confirmed only the presence of iron storage as disease biomarker in white matter. A total number of 83 enhanced lesions was detected in 35 patients. CE-T1WI detected 51 lesions (61.4% of total) in 22 patients; all these lesions showed an enhancement in the post-contrast FLAIR sequence while CE-FLAIR images showed 32 (38.5%) new enhanced lesions in 13 patients, therefore classified as in a new relapsing phase.
Conclusion: Our results demostrate that CE-FLAIR sequence has a very high sensitivity in the detection of enhanced MS lesions compared to conventional CE-T1WI sequence.

B-0182 11:27

Subpial cortical demyelination (SCD) in multiple sclerosis: a MRI study in patients of recent onset

S. Iafrate, L. Panebianco, S. Quarchioni, L. Patriarca, M. Varrassi, A. Splendiani, C. Masciocchi; *L'Aquila/IT (sonia.iafrate87@gmail.com)*

Purpose: A growing body of evidence shows that subpial cortical demyelination (SCD) is associated with demyelinated cortex in patients affected by multiple sclerosis (MS). SCD is also found in biopsy cases with early MS and in experimental model. Recently, it has been shown that local meningeal inflammatory cells infiltrations contributes to the pathogenesis of SCD. In this study, we aimed to investigate the subpial cortical demyelination (SCD), in patients affected by recent-onset multiple sclerosis (MS).
Methods and Materials: We enrolled 146 recent-onset (< 6 months) MS patients, fulfilling Mc Donald's criteria, in a prospective study. All patients underwent 3T MRI exams; SCD was evaluated performing post-contrast axial Flair images on 3T MRI scan.
Results: Post-contrast axial Flair images showed the presence of enhanced meningeal rim referable to SCD in acute phase in 32% of our population. A large percentage (78%) of patients with SCD showed female gender. In 17% of our cases, SCD precedes the appearance of classic white matter plaques.
Conclusion: The evaluation of SCD may suggest a possible pathogenic role of meningeal inflammation in recent-onset MS patients. Targeting the cells and molecules mediating these inflammatory responses within the meninges may offer future promising therapies for MS.

B-0183 11:35

Perfusion and brain volume changes connected to cognitive dysfunction in multiple sclerosis patients

I. Krotenkova; *Moscow/RU (irina.krotenkova@mail.ru)*

Purpose: To investigate perfusion changes in NAWM and thalamus in relapsing-remitting MS (RRMS), secondary progressive MS (SPMS), to access volume changes and to investigate the correlation between these measures and neurological disability and cognitive status.
Methods and Materials: 20 RRMS and 20 SPMS patients underwent conventional MRI, 3D T1 MPRAGE for VBM, CT-perfusion and neurological examination, including EDSS and MSFC with PASAT for cognitive function.

Different perfusion characters were detected in thalamus and NAWM. 20 healthy controls underwent MRI.
Results: Compared to RRMS, SPMS patients experienced decrease of perfusion measures in frontal NAWM and thalamus. RRMS showed a negative correlation between amount of correct answers in PASAT and TTD, MTT in frontal NAWM (r= -0,38, p=0,01 and r= -0,36, p=0,018, respectively). SPMS showed a negative correlation between amount of correct answers in PASAT and PMB in parietal NAWM, that reflects changes in blood-to-brain barrier permeability (r=-0,46, p=0,032) and cortical left temporal lobe volume(r=0,677, p=0,011). RRMS, SPMS patients experienced significantly higher thalamus atrophy (p<0.05) compared to healthy controls, but there was no significant difference between both types of MS. There were no correlations between blood flow and thalamus volume in any of groups.
Conclusion: This study shows reduced cerebral blood perfusion in SPMS compared to RRMS patients in thalamus and normal appearing white matter, that means a presence of pathologic process in intact brain matter either in demyelination lesions. Cognitive functions are connected to pathology of normal appearing white matter and cortical GM atrophy.

MRI characteristics of early cerebral lesions in asymptomatic boys with X-linked adrenoleukodystrophy
P.A. Caruso; *Boston, MA/US (pcaruso@partners.org)*

Purpose: X-linked adrenoleukodystrophy (ALD) a rapidly progressive form of inflammatory demyelination. Identification of cerebral lesions prior to onset of symptoms is paramount in selecting patients who will benefit from rescue therapies. We set out to analyse cerebral lesions in a unique cohort of asymptomatic boys with CCALD.
Methods and Materials: We reviewed 193 brain MRIs from 44 neurologically asymptomatic (neurologic functional scale=0) boys with biochemical or genetically confirmed ALD followed at Massachusetts General Hospital between 2001 and 2015. Two neuroradiologists blinded to clinical information recorded the number of patients with lesions, the Loes score, the pattern of white matter involvement, and the presence and pattern of enhancement.
Results: Of the 44 boys, 59% (26) showed small subtle brain lesions (median age 6.7 years; range 3.6-15.5 years). The median Loes score found was 3.0 points (range 0.5-11). The most frequent lesion pattern was parieto-occipital white matter and splenium of corpus callosum (58%) followed by frontal white-matter and genu of corpus callosum, and frontopontine/corticospinal tracts. Among all patients with lesions, 85% (22/26) had contrast enhancement, either at baseline (50%) or on follow-up MRI (50%). Ten patients showed normal baseline MRI and subsequently converted to CCALD (median age 6.4 years).
Conclusion: MRI can detect brain lesions and development of disease in the absence of neurological symptoms. As newborn screening is implemented, familiarity with the characteristics of early lesions will help improve disease detection and guide monitoring and treatment in ALD.

Transient severe motion artifact related to gadoxetic acid enhanced liver MRI: incidence and risk evaluation at a European institution
L. Well, V.H. Rausch, G. Adam, F.O. Henes, P. Bannas; *Hamburg/DE (l.well@uke.de)*

Purpose: Varying incidences (5-18%) of contrast-related transient severe motion (TSM) imaging artifacts during gadoxetic disodium-enhanced arterial phase liver MRI have been reported. Since previous reports originated from the United States and Japan, we aimed to determine the incidence of TSM at a European institution and to correlate it with potential risk factors and previously published results.
Methods and Materials: Two age and sex matched groups were retrospectively selected (gadoxetate disodium n=89; gadobenate dimeglumine n=89) from dynamic contrast-enhanced MRI examinations. Respiratory motion related artifacts in non-enhanced and dynamic phases were assessed independently by two readers blinded to contrast agents on a 4 point scale. Scores of ≥ 3 were considered as severe motion artifacts. Severe motion artifacts in arterial phases were considered as TSM if scores in all other phases were < 3. Potential risk factors for TSM were evaluated via logistic regression analysis.
Results: For gadoxetate disodium, the mean score for respiratory motion artifacts was significantly higher in the arterial phase (2.2±0.9) compared to all other phases (1.6±0.7) (p<0.05). Incidence of TSM was significantly higher with gadoxetate disodium (n=19; 21.1%) than with gadobenate dimeglumine (n=1; 1.1%) (p<0.001). The incidence of TSM at our institution is in the upper range of previously published reports. Logistic regression analysis did not show any significant correlation between TSM and risk factors (all p>0.05).
Conclusion: No associated risk factors for TSM could be identified. However, we revealed a high incidence of TSM at a European institution, undermining the importance of a diagnosis-limiting phenomenon.

B-0186 14:08

Liver function is significantly correlated with liver to portal vein contrast ratio during the hepatobiliary phase with Gd-EOB-DTPA-enhanced MR at 3 Tesla
W. Zhang, C. Hu; *Suzhou/CN (jszwgys@163.com)*

Purpose: To quantitatively evaluate the correlation of the liver-to-portal vein contrast ratio (LPC) and liver function on gadolinium ethoxybenzyl diethylenetriamine pentaacetic acid (Gd-EOB-DTPA)-enhanced MR imaging.
Methods and Materials: A total of 102 patients who underwent Gd-EOB-DTPA-enhanced 3Tesla MR imaging (normal liver, n=20; Child-Pugh class A, n=55; B, n=21; and C, n=6) were included in this restrospective study. LPC was defined as the enhancement ratio of hepatic parenchyma and potal vein at hepatobiliary phase(HBP) 20min, and it was compared between normal and cirrhosis livers. The correlation between LPC and hepatic function parameters at HBP after injection was quantitatively analysed as well.
Results: The degree of LPC differed between normal and cirrhosis livers (P<0.001) significantly. LPC constantly and significantly decreased as the severity of cirrhosis increased at HBP imaging (P<0.001). Total bilirubin (P<0.001), albumin (P<0.001), platelet count (P<0.001), and model for end stage liver disease score (P<0.001) were independent predictors of LPC at HBP imaging.
Conclusion: The index of hepatic LPC on Gd-EOB-DTPA HBP imaging can predict the severity of cirrhosis and is correlated with clinical hepatic function parameters.

B-0187 14:16

Magnetic resonance elastography for prediction of radiation-induced liver disease after stereotactic body radiation therapy
S. Ichikawa, U. Motosugi, M. Oguri, H. Onishi; *Chuo-shi, Yamanashi/JP (si99006@yahoo.co.jp)*

Purpose: To evaluate the usefulness of magnetic resonance elastography (MRE) for prediction of radiation-induced liver disease (RILD) after stereotactic body radiation therapy (SBRT) in patients with hepatocellular carcinoma (HCC).
Methods and Materials: Seventeen patients who underwent SBRT (dose: 28-60Gy in 4-10 fractions) for HCC (size: 14-68mm) had pretreatment liver stiffness measured by MRE. Diagnosis of RILD was determined by the following criteria: (i) anicteric elevation of alkaline phosphatase to a level at least twice the upper limit of the normal level, or (ii) elevation of transaminases, to at least five times the upper limit of the normal, or five times the pretreatment level within 16 weeks after SBRT. The following variables were analysed as potential predictors of RILD: age; sex; body weight; etiology of hepatitis; liver stiffness measured by MRE; tumour size blood test results; tumour markers; Child-Pugh score; Karnofsky performance status; indocyanine green retention rate at 15min; and parameters of SBRT (fraction size, total dose, V20 (percentage of normal liver volume that received >20Gy), and VS15 (volume spared from ≥15Gy)).
Results: Pretreatment liver stiffness measured by MRE in patients with RILD (n=4; median 8.3kPa) was significantly higher than that in patients without RILD (n=13; median 5.0kPa) (P=0.0090). Other variables showed no significant differences between the two groups. No patient died of RILD.
Conclusion: Pretreatment liver stiffness measured by MRE can be a predictor of RILD after SBRT in patients with HCC.

B-0188 14:24

Self-gated 4D-MRI of the liver: comprehensive real-time imaging of hepatic enhancement
J. Weiss, A.E. Othman, P. Martirosian, M. Kolb, C. Ruff, J. Taron, K. Nikolaou, M. Notohamiprodjo; *Tübingen/DE (jakob.weiss@uni-tuebingen.de)*

Purpose: To evaluate a free-breathing self-gated volumetric interpolated breath-hold examination (VIBE) with compressed sensing (CS) for continuous dynamic contrast-enhanced (DCE) MR imaging of the liver.
Methods and Materials: 25 patients underwent gadobutrol contrast-enhanced MRI of the liver on a 1.5T scanner. A free-breathing prototype VIBE-sequence

with CS and automated respiration gating ($VIBE_{CS}$) was continuously acquired for 128 seconds starting with the administration of the contrast agent. From the acquired raw data, 16 consecutive series with a temporal resolution of 8 seconds and spatial resolution of 1.2x1.2x3 mm were reconstructed. The unenhanced, arterial, portal-venous and venous phase series with the subjectively most satisfying image quality were selected and compared to a clinical routine VIBE-sequence ($VIBE_{std}$). Image quality was assessed qualitatively (overall, sharpness, lesion conspicuity, motion/other artefacts; two readers independently; 5-point-Likert scale; 5=excellent) and quantitatively (coefficient-of-variation (CV); mean liver SI).
Results: Overall image quality, lesion conspicuity and motion artefacts showed no significant differences between the sequences (p≥0.07). Image sharpness was significantly higher in the portal-venous (4.9±0.2) and venous phase (4.9±0.3) images of $VIBE_{CS}$ as compared to $VIBE_{std}$ (4.2±0.6; p=0.01). However, $VIBE_{CS}$ showed a significant appearance of bow-like reconstruction artefacts (3.8±0.5), which were not present in $VIBE_{std}$ (5.0±0.0; p≤0.001). Mean liver SI was significantly higher in $VIBE_{std}$ (200.1±85.1) than in $VIBE_{CS}$ (170.3±68.3; p=0.002) whereas CV calculations revealed no significant differences among the sequences (p=0.1).
Conclusion: $VIBE_{CS}$ is applicable for continuous self-gated DCE-MRI of the liver with similar overall image quality and lesion conspicuity and improved image sharpness as compared to a $VIBE_{std}$.

B-0189 14:32

Evaluation of transient dyspnea during gadoxetic acid-enhanced liver MRI using free-breathing T1WI

J. Yoon[1], M. Yu[1], B. Hur[2], G. Robert[3], Y. Son[1], B. Kiefer[3], K. Block[4], H. Chandarana[4], J. Lee[1]; [1]*Seoul/KR*, [2]*Goyang/KR*, [3]*Erlangen/DE*, [4]*New York, NY/US (jmlshy2000@gmail.com)*

Purpose: To observe transient dyspnea pattern after gadoxetic acid administration and prove clinical feasibility of free-breathing gadoxetic acid-enhanced liver magnetic resonance imaging (MRI) using golden-angle radial sparse parallel imaging (GRASP) with respiratory gating.
Methods and Materials: In this IRB-approved prospective study, 60 patients have been enrolled and informed consent was obtained from all patients. Dynamic T1-weighted image (T1WI) was obtained using GRASP in free-breathing manner. Development of transient motion after gadoxetic acid administration was monitored using respiratory motion recording. In addition, subjective symptom, oxygen saturation and heart rate were monitored. Early arterial, late arterial and portal venous phases with different temporal resolution (13sec vs. 6sec) and respiratory gating were reconstructed for evaluating image quality and motion artifact.
Results: In 40.0% (23/59), transient motion (mean duration: 21.5±13.0 seconds) was observed and it developed in 15 seconds after gadoxetic acid administration in 73.9% (17/23). There were no significant difference of subjective symptom and vital signs between groups with and without transient motion (P=0.25~0.99). Motion artifact reduced after respiratory gating, and there was no significant difference of motion artifact on early and late arterial phases between the two groups (P=0.42) whereas significantly higher motion artifact was observed on non-gated 13sec-T1WI in patients with transient motion (P=0.001). Gated 6-sec-T1WI provided significantly lower image quality than gated 13-sec-T1WI.
Conclusion: Free-breathing T1WI using GRASP and incoherent undersampling technique provided timely and acceptable arterial phase consistently in patients with transient motion which is potentially influential on arterial phase.

Rapid continuous multiarterial MRI of hepatic arterial dominant phase during free-breathing

A. Othman, J. Weiss, K. Nikolaou, M. Notohamiprodjo; *Tübingen/DE (ahmed.othman@uni-tuebingen.de)*

Purpose: To evaluate the feasibility of multiarterial MRI of hepatic arterial dominant phase (HAD) using a free-breathing self-gated spoiled gradient-echo sequence with compressed sensing (CS).
Methods and Materials: 40 patients who underwent contrast-enhanced liver MRI with gadobutrol were included. Each 20 patients were examined in 1.5 and 3T (Magnetom Aera and Skyra, Siemens Healthineers), respectively. Multiarterial imaging was performed for 64s beginning with contrast injection using a rapid free-breathing prototype volume-interpolated-breath-hold examination (VIBE) sequence with CS and automated respiration gating (iVIBE, 1,2x1,2x3mm^3). 8 consecutive arterial subphases were reconstructed (8s/phase). Two readers selected and assessed the best HAD phase on a five-point Likert scale (5=excellent) regarding image quality, respiratory artefact compensation, enhancement of abdominal aorta and hepatic artery, lesion detectability and diagnostic confidence. Signal intensity (SI) and SNR were measured in the liver and in the abdominal aorta.
Results: HAD phase varied among patients (3rd - 7th phase). Image quality and respiratory artefact compensation were good (median=4, 3-5) without significant differences among field strengths (p≥.089). Lesion detectability, contrast enhancement of aorta and diagnostic confidence were excellent (median 5, 3-5) without significant differences among field strengths (p≥.165). Signal intensity and liver SNR were significantly higher in 3T (p≤.015). SNR in abdominal aorta was high in both field strengths without significant differences (p.=637).
Conclusion: Acquisition of continuous multiarterial MRI of hepatic arterial dominant phase during free-breathing using iVIBE is feasible and yields good image quality and excellent arterial enhancement with good compensation of respiratory artefacts resulting in excellent diagnostic confidence in both 1.5T and 3T.

B-0191 14:48

Gadoxetic acid-enhanced MR imaging of transient hepatic enhancement difference: another cause of hypointense observation on hepatobiliary phase

C. Torrisi, D. Picone, M. Midiri, G. Brancatelli; *Palermo/IT (chiaratorrisi84@gmail.com)*

Purpose: To determine the frequency, natural history and factors associated with the presence of transient hepatic enhancement difference (THED) showing hypointensity in the hepatobiliary phase (HBP) of gadoxetic acid-enhanced MR imaging.
Methods and Materials: Gadoxetic acid-enhanced MR imaging of 125 patients (91 males; mean age: 68 years; range 26-84 years) with THED were retrospectively reviewed. Three readers qualitatively and quantitatively evaluated MR imaging features of THED and evolution at follow up. Fisher's exact test and Mann-Whitney-Wilcoxon test were used for statistical analysis.
Results: THED were wedge-shaped (n=106 (85%)), hypervascular on HAP (125 of 125; 100%) and isointense on both HBP (105 of 125; 84%) and fat-suppressed T2-weighted imaging (n = 100 (80%)). Hypointense THED on hepatobiliary phase were more commonly wedge-shaped (P < .05), hyperintense on T2-weighted imaging (P < .05), and were associated with previous locoregional treatment (P < .05). Of 12 patients with hypointense THED on HBP who had follow-up MR, nine showed reduction in size.
Conclusion: Hypointensity on HBP is not uncommonly observed in THED, and might be explained with chronic portal hypoperfusion and or biliary obstruction resulting from previous locoregional treatment of adjacent tumour and leading to hepatocellular dysfunction, fibrotic changes and parenchymal atrophy.

B-0192 14:56

Intravoxel incoherent motion diffusion-weighted imaging of hepatic warm ischemia-reperfusion injury in a rabbit model

Q. Ji, Z. Chu, W. Shen; *Tianjin/CN (jiqianq@aliyun.com)*

Purpose: To investigate the diagnostic efficacy of intravoxel incoherent motion (IVIM) MRI in the grade of hepatic warm ischemia-reperfusion injury (WIRI) in rabbit models.
Methods and Materials: Fifty rabbits were randomly divided into sham-operation group (n=10) and four test groups (n=10 for each group) according to different hepatic warm ischemia time. IVIM was performed on a 3T MR scanner with 11 b values of 0 to 800 s/mm^2. Rabbits were sacrificed for biochemical and histomorphological analysis. Interobserver variability, the parametric, non parametric methods and receiver operating characteristic (ROC) curves were used to determine diagnostic efficacies.
Results: Apparent diffusion coefficient (ADC), true diffusion (Dslow), pseudodiffusion (Dfast) and perfusion fraction (PF) showed moderate to excellent interobserver reproducibility. Significant differences were found between different grades of hepatic WIRI by ADC, Dslow, Dfast, and PF (P <0.001). IVIM parameters corresponded well with biochemical parameters (P <0.01). ROC analysis showed that the differences in ADC, Dslow, Dfast, and PF among different grades of hepatic WIRI were significant (P <0.05), and the area under the ROC curve (AUC) of PF was the largest.
Conclusion: The grades of hepatic WIRI could be effectively evaluated by using IVIM in a rabbit model, with PF being the most accurate parameter.

B-0193 15:04

Liver function evaluation at magnetic resonance imaging: comparison between liver enhancement and MELD

M. Di Martino, V. Ceci, S. De Vizio, A. Capalbo, K. Koryukova, C. Catalano; *Rome/IT (micdimartino@hotmail.it)*

Purpose: To evaluate the enhancement of the liver parenchyma in patients with different grade of liver cirrhosis.
Methods and Materials: Seventy-five patients scheduled for liver transplantation were divided according to the MELD (< 15 and ≥ 15) and Child-Pugh (A, B, C) classifications for liver cirrhosis. Fourty-one patients reported also hepatocellular carcinoma with 63 lesions (1-4 per patients). All subjects underwent MRI at 1.5T (Avanto, Siemens). MR acquisitions comprised unenhanced breath-hold T2W images and volumetric 3D gadoxetic acid enhanced (0.1 mmol/kg bodyweight) T1W GRE images acquired at 25s, 60s, 180s (dynamic phases) and 20 minutes (hepatobiliary phase). Quantitative analysis comprised: enhancement ratio (ER) of liver parenchyma, signal-to-noise ratio of liver parenchyma (SNR) and contrast-to-noise ratio (CNR) between signal intensity of lesions and liver parenchyma. Comparisons among different classes were performed with ANOVA or Kruskall-Wallis test and Mann-Whitney U and Student's t test. P values of < 0.05 were considered statistically significant.
Results: Patients with MELD score lower than 15 reported a significant higher ER and CNR (0.47 vs 0.35 and -11.6 vs -0.09). The same result was observed between Child-Pugh groups A - B and C (0.46 - 0.52 and 0.31). Regarding CNR a significant difference was found between class B and C (-11.8 vs. -0.929; p=0.03). No significant differences were reported on SNR.
Conclusion: Liver enhancement during the hepatobiliary phase should be useful to distinguish different grade of liver function.

B-0194 15:12

Prediction of liver stiffness measurement using liver surface analysis on CT scan

M. Seong, T. Kang, M.-R. Kwon, J. Kim, S. Yang, J. Lee; *Seoul/KR (seong.minjung@gmail.com)*

Purpose: To develop a prediction method using liver surface analysis based on the computed tomography (CT) for liver stiffness measurement in patients with liver cirrhosis.
Methods and Materials: This retrospective study was approved by the institutional review board, and the requirement for informed consent was waived. 47 patients with liver cirrhosis who had received transient elastography for liver stiffness measurement and liver CT were retrospectively analyzed. We assessed the inflection/length of liver surface (left lateral segment) using auto-segmentation method based on the CT images to evaluate the degree of surface serration. The correlations between inflection/length of liver surface and the degree of fibrosis stage F1 from F4 on the METAVIR scale were assessed using simple regression analysis.
Results: Median liver stiffness values measured using transient elastography was 8.9 kPa (range, 7.2-52.3 kPa). The degrees of liver stiffness according to the fibrosis stage in the patients included were 2.4-7.1 in F1, 7.2-8.0 kPa in F2, 8.1-10.9 kPa in F3, and 11.0-52.3 kPa in F4, respectively. The inflection/length of liver surface using auto-segmentation method showed a stepwise increase with increasing degree of fibrosis stage ($\rho = 0.43$; $p = 0.018$).
Conclusion: Liver surface analysis using CT auto-segmentation method could stratify the degree of liver fibrosis in patients with liver cirrhosis.

B-0195 15:20

Baseline values of DCE-CT of liver in patients with colorectal cancer

A. Bevilacqua[1], S. Malavasi[1], M. Ronot[2], J.-L. Daire[2], B.E. Van Beers[2], V. Vilgrain[2]; [1]*Bologna/IT*, [2]*Clichy/FR (s.malavasi@unibo.it)*

Purpose: Assessment of baseline values in CT perfusion (CTp) studies is as much difficult as it plays a crucial role for an accurate computation of perfusion parameters. Besides that, the unenhanced stage of CTp provides repeated measures of baseline. This study aims at computing and analysing the voxel-based baseline values of normal liver in a set of patients with colorectal cancer.
Methods and Materials: 40 patients with colorectal cancer, free from any hepatic diseases, underwent axial CTp examinations of liver at colorectal cancer diagnosis. A large region of interest (ROI) was drawn on one central section of the liver, avoiding large vessels. Baseline portion (BP) of each TCC of the ROI was determined through the use of an adaptive 3D filtering and the relative baseline value (HU) was computed as the mean of the TCC concentration values over BP. Mean, median, and standard deviation values were computed for each patient as well as for the entire cohort.
Results: For each patient, mean and median baseline values coincide, thus suggesting quite symmetric distributions. The average and standard deviation (std) of baseline mean values of all patients are 61.7HU (range 32-79HU), and 10.1, with 73% of values within one std interval (51-71HU). Moreover, baseline colorimetric maps showed a high spatial correlation.
Conclusion: Baseline values of normal liver of patients with colorectal cancer are compliant with values of normal liver in healthy subjects reported in the literature. The spatial coherence hints at a local similarity of tissue features.

Costs of a colorectal cancer screening with CT colonography in Italy

P. Mantellini, G. Lippi, L. Sali, G. Grazzini, B. Mallardi, M. Falchini, M. Mascalchi, L. Ventura, M. Zappa; *Florence/IT (lapo.sali@unifi.it)*

Purpose: Unit costs of screening CT colonography (CTC) can be useful for cost-effectiveness analyses and for health care decision-making. We evaluated the unit costs of CTC as a primary screening test for colorectal cancer in the setting of a randomised trial in Italy.
Methods and Materials: Data were collected within the randomised SAVE trial. Subjects were invited to screening CTC by mail and requested to have a pre-examination consultation. CTCs were performed with 64- and 128-slice CT scanners after reduced or full bowel preparation. Activity-based costing was used to determine unit costs per-process, per-participant to screening CTC and per-subject with advanced neoplasia.
Results: Among 5242 subjects invited to undergo screening CTC, 1312 had pre-examination consultation and 1286 ultimately underwent CTC. Among 129 subjects with a positive CTC, 126 underwent assessment colonoscopy and 67 were ultimately diagnosed with advanced neoplasia (i.e. cancer or advanced adenoma). Cost per-participant of the entire screening CTC pathway was € 196.80. Average cost per-participant for the screening invitation process was € 17.04, while it was € 9.45 for the pre-examination consultation process. Average costs per-participant of the CTC execution and reading process was € 146.08 and of the diagnostic assessment colonoscopy process was € 24.23. Average cost per-subject with advanced neoplasia was € 3777.30.
Conclusion: Our data suggest that the more relevant cost of screening CTC, amenable of intervention, is related to CTC execution and reading process.

B-0197 14:08

Retrospective analysis of patient position errors and impact of MSCT dose in virtual colonscopy: single centre experience

C. Tudisca, S. Salerno, L. Scopelliti, M. Marrale, C. Terranova, G. Lo Re, G. La Tona, A. Lo Casto, R. Lagalla; *Palermo/IT (chiaratudisca@gmail.com)*

Purpose: Virtual-colonoscopy (VC) is a well known and valid technique for evaluation of colon wall and detection of new lesions. The main drawback for its execution is patient exposition to ionizing radiations. Indeed, guidelines recommend standardized low dose acquisition procedures aimed to minimize radiation exposition. We retrospectively examined the impact in term of radiation exposure of patient position and scan length mislead.
Methods and Materials: A two-year retrospective analysis of multi-slice-computed-tomography (MSCT) acquisition data of 106 patients that underwent a VC at our institution. Exams were performed in a MSCT 128 slice with low-dose protocol. The parameters that characterise the examinations and could induce an increase of absorbed dose were: patient position with respect to the gantry isocenter and scan length that could exceed the area of interest.
Results: Mean value of patient position resulted below isocenter for 48±25mm and 29±27mm in prone and supine positions, respectively. On the basis of previous literature experience the dose increase in our patient population, due to the incorrect positioning, was estimated to be about 30% (~1.5mSv) and 20% (1mSv) for prone and supine positions, respectively.Moreover, we found that the scan exceeded the correct position below the anal orifice for an average length of 36±25mm e 48±28mm in prone and supine positions, respectively, exposing sensitive anatomic organs.
Conclusion: Errors in acquisition parameters, eluding the optimized protocols, should be avoided given the increase in the dose.Nowadays acquisition technique is one crucial focus on daily practice, giving the major spread of ionizing radiations in routine exams.

B-0198 14:16

Accuracy of CT colonography in staging colon cancer: a metanalaysis

M.J. Lahaye[1], E. Nerad[2], D.M.J. Lambregts[1], M. Maas[1], G.L. Beets[1], R.G.H. Beets-Tan[1]; [1]*Amsterdam/NL*, [2]*Eindhoven/NL (nerad19@hotmail.com)*

Purpose: Computed tomography colonography (CTC) is an established tool in the screening for colon cancer. Furthermore CTC can be used in the staging of colon cancer, which is imperative with the possibility of neo-adjuvant treatment in the nearby future (FOXTROT trial). Therefore the aim of this study is to determine the accuracy of CTC in the detection of important prognostic factors being; tumour invasion beyond the bowel wall and nodal involvement of colorectal carcinomas.
Methods and Materials: A literature search was performed in Ovid, Embase and Pubmed to identify studies reporting on the accuracy of CTC for local staging of colon cancer with histology as reference standard. Data were extracted by two observers in consensus. A hierarchical summary ROC (HSROC) model was used to construct a summary ROC curve and to calculate summary estimates of sensitivity, specificity and diagnostic odds ratios (DOR).
Results: Fourteen studies fulfilled the inclusion criteria for detection of tumour invasion beyond the bowel wall (combined total of 1257 lesions). The pooled sensitivity, specificity and DOR were 90% (95% CI: 88-92%); 87% (95% CI: 83-90%) and 19,6 (95% CI: 10,2-41,5) respectively. For nodal involvement nine studies were included (combined total of 525 patients) the estimates were 84% (95% CI: 80-88%); 66% (95% CI: 59-72%); 5,8 (95% CI: 2,5-9,4) respectively.
Conclusion: CTC is an accurate tool in the staging of colon cancer with a good sensitivity for the detection of T3/T4 tumours and an improved specificity than standard CT. However, the accuracy in detecting nodal involvement is mediocre.

B-0199 14:24

Colorectal cancer vs chronic diverticular disease: differential diagnosis at CT colonography

M. Chincarini, M. Signorini, N. Faccioli, R. Pozzi-Mucelli; *Verona/IT (marco.chincarini@gmail.com)*

Purpose: To retrospectively identify the most significant morphologic findings at CT colonography (CTC) for differentiating between sigmoid cancer and chronic diverticular disease.
Methods and Materials: Two experienced radiologists reviewed the CTC examinations of 54 Patients, 33 with proven chronic diverticular disease and 21 with proven sigmoid cancer, and identified a subgroup of 26 Patients with a mass lesion (15 Patients with chronic diverticular disease and 11 with carcinoma). The readers looked at specific morphological criteria established from a literature review for CT findings of chronic diverticular disease and colon cancer. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and interval of confidence were calculated.
Results: The most suggestive morphologic findings for carcinoma are: absence of diverticula in the affected segment (NPV 82.6%, PPV 93.5%); straightened growth pattern (NPV 83.3%, PPV 83.3%); presence of shoulder phenomenon (NPV 93.1%, PPV 76%); completely distorted mucosal folds pattern (NPV 96.2, PPV 71.4). In the “mass lesion subgroup”, the distortion of mucosal folds (NPV 87.5%, PPV 55.6%) and the straightened growth pattern (NPV 75%, PPV 70%) have significantly lower diagnostic performance. In this latter group, the two strongest morphological features suggestive of carcinoma are the absence of diverticula in the affected segment (NPV 93.3%, PPV 90.9%) and the presence of shoulder phenomenon (NPV 91.7%, PPV 71.4%).
Conclusion: The most useful morphological sign to differentiate chronic diverticulitis from colorectal cancer is the presence of diverticula in the affected segment.

B-0200 14:32

CT colonography: effect of electronic cleansing of tagged fecal residuals on the size of submerged colorectal polyps in screening patients

C. Bräuer[1], H. Ringl[1], P. Lefere[2], S. Gryspeerdt[2], P. Apfaltrer[1], M. Scharitzer[1], D. Berzaczy[1], A. Graser[3], T. Mang[1]; [1]*Vienna/AT*, [2]*Roeselare/BE*, [3]*Munich/DE (christian_braeuer@msn.com)*

Purpose: To assess whether there is a difference in the size of colorectal polyps before and after electronic cleansing (EC) of tagged residuals in screening CT colonography (CTC) studies.
Methods and Materials: A database of 894 colonoscopy-validated CTC patient-datasets of a low prevalence cohort was retrospectively reviewed to identify patients with polyps ≥6mm that were entirely submerged in tagged residuals in at least 1 of 2 scanning positions. 2D measurements of the largest diameter of each identified polyp were performed independently by ten radiologists before and after EC in colon, bone, and soft tissue windows in a fully randomised order. Differences of size and of polyp count before and after EC were calculated for size-categories ≥6mm, ≥10mm. Statistical testing involved 95% CI, Intraclass Correlation and mixed model ANOVA.
Results: 37 patients with 48 submerged polyps (34 adenomas, 14 non-adenomas) ≥6mm were identified by reference-standard. Mean polyp size before EC was 9.8mm in colon, 9.9mm in bone and 8.2mm in soft tissue windows. After EC the mean polyp size decreased significantly to 9.4mm in colon, 9.1mm in bone, and 7.1mm in soft tissue windows. Compared to the unsubtracted colon window, EC, performed in bone and soft tissue windows, leads to a shift of 10 (20.8%) and 25 (52.1%) polyps ≥6mm and 1 (6.7%), and 5 (33.3%) polyps ≥10mm into the next smaller size category.
Conclusion: EC significantly reduces the size of polyps submerged in tagged residuals. Polyp measurements should be performed in unsubtracted image data in a colon window setting.

B-0201 14:40

Diagnostic performance and influence on computer-assisted-diagnosis (CAD) of ultra-low dose CT colonography (ULD-CTC) with model-based iterative reconstruction (MBIR)

G. De Paoli Barbato, M. Bassi, E. Raimondi, A. Spiller, R. Rizzati, M. Tilli, M. Giganti, G. Benea; *Ferrara/IT (dplgcm@unife.it)*

Purpose: To compare perfomance of standard-dose (SD) and ultra low-dose (ULD) in CT-Colonography (CTC), using hybrid-iterative reconstruction (HIR) and model-based iterative reconstruction (MBIR), and to asses the effect of different reconstruction algorithms on computed-aided diagnosis (CAD).
Methods and Materials: Fifty patients (31 males, 19 females, mean age 69,7) underwent CTC with SD (120kV, 50mAs 4,6±1,3mSv) and ULD (120kV, 10mAs, 0,95±0,2mSv); images were reconstructed with HIR and MBIR; CAD system was applied complementary to all reconstructions. Two independent radiologists review obtained images separately randomized to avoid recall-bias, and recorded colonic findings (polyps/cancer), extracolonic findings and CAD detections. Polyps were classified by size (<5mm, =5-10mm, ≥10mm), shape (flat, sessile, peduncolated) and location (rectum, sigmoid, descending, transverse, ascending, caecum). Extracolonic findings ≥E4 (C-RADS) were recorded. CAD results were reported and significant findings were selected.
Results: Nine polyps were found in 8 patients, six <5mm, two between 5-10mm and one ≥10mm; 8 were peduncolated and 1 flat, 2 were in caecum, 3 ascending, 2 transverse, 1 descending, 1 sigmoid tract; colonic-findings records were super-imposable for both radiologist between SD and ULD reconstructions; 2 extracolonic findings ≥E4 were recorded in all reconstructions. MBIR-CAD results compared to HIR-CAD showed a mean 13,56% increment at SD and 32,92% at ULD, with no change in terms of significant results. Colonic findings were confirmed by optical-colonscopy (OC).
Conclusion: ULD-MBIR CTC showed promising results in terms of diagnostic performance and inter-reader reproducibility for intra-colonic findings. CAD detection was influenced by MBIR, with no decrease in diagnostic value.

B-0202 14:48

Protocol optimisation of MR colonography for polyp detection using pig colonic phantom: influence of magnetic field strength, colonic distension technique, and MRI sequence

E.-S. Cho, J. Kim, J. Choi, Y. Choi; *Seoul/KR (jjondol@yuhs.ac)*

Purpose: To compare the diagnostic performance and image quality of MR Colonography (MRC) using pig colon phantoms and to evaluate the influence of magnetic field strength (1.5-T or 3.0-T), colonic distension technique (bright- or dark-lumen), and MRI sequences.
Methods and Materials: Six pig colon segments (60-92 cm) with 56 artificial colon polyps (0.4-1.6 cm) were placed in plastic container containing soybean oil. The colon was distended using room air for dark-lumen MRC and with tap water or a gadolinium-chelate based enema fluid for bright-lumen MRC. Each colon phantom was scanned on both 1.5-T and 3.0-T scanners using the following sequences: 2D fast-imaging with steady-state precession, T2-weighted 2D single-shot fast-spin-echo (SSFSE), and/or T1-weighted 3D gradient-echo (GRE) sequences. Two radiologists evaluated the presence of polyps and analysed the image quality.
Results: For polyp detection sensitivity and image quality, MRC obtained at 1.5-T was better than that obtained at 3.0-T, and a bright-lumen technique was superior to a dark-lumen technique. Bright-lumen MRC at 1.5-T was most sensitive for polyp detection ($p < 0.001$) and gave the highest image quality ($p < 0.05$) regardless of polyp size and shape (flat or sessile). SSFSE and 3D GRE sequences at bright-lumen MRC at 1.5-T had highest sensitivity for polyp detection (83.9% and 83.0%, respectively) and highest image quality.
Conclusion: The most effective sequences of MRC for polyp detection were SSFSE- or 3D GRE-based bright-lumen MRC obtained with a 1.5-T scanner. These sequences had the highest polyp detection rate and the best image quality.

B-0203 14:56

Apparent diffusion coefficient as a potential marker of tumour aggressiveness in colon cancer

E. Nerad[1], A. Delli Pizzi[2], D.M.L. Lambregts[3], M. Maas[3], F. Bakers[4], G.L. Beets[3], R.G.H. Beets-Tan[3], M.J. Lahaye[3]; [1]*Eindhoven/NL*, [2]*Chieti/IT*, [3]*Amsterdam/NL*, [4]*Maastricht/NL (nerad19@hotmail.com)*

Purpose: To investigate the role of magnetic resonance imaging (MRI) as a potential tumour marker in predicting the aggressiveness of colon cancer tumours with the apparent diffusion coefficient (ADC), and its potential in discriminating between low and high-risk colon cancer patients.
Methods and Materials: Thirty patients (21M, 9F) were included retrospectively. All patients received a 1.5T MRI of the colon including T2 and DWI sequences. ADC maps were automatically constructed for all diffusion weighted magnetic images with b factors of 0 and 1000 s/mm(2). ADC measurements of each colon tumour were performed by two readers in concensus using regions of interest with IntelliSpace Discovery research platform (Philips Healthcare, The Netherlands). High-risk colon cancer patients were defined if one or more of the following parameters were present with histology as the reference standard: direct invasion of tumour into surrounding structures/organs (T4), nodal involvement (N+) and/or distant metastasis (M+). The student t-test was used to assess the differences between the ADC means of low and high-risk colon cancer tumours.
Results: The mean ADC of the high risk patients (n=16) was 1129.7 and for low-risk patients (n=14) 1231.8 with a significant difference between the mean ADC intensity of high versus low risk tumours (p=0.002). The optimal cut off value was 1178.8 with an area under the curve (AUC) of 0.83 and a sensitivity and specificity of 81% and 86% respectively.
Conclusion: ADC has potential to discriminate between low and high-risk colon cancer patients with lower ADC values significantly associated with high-risk colon tumours.

B-0204 15:04

CT differentiation of poorly-differentiated colorectal neuroendocrine tumours from well-differentiated neuroendocrine tumours and colorectal adenocarcinoma

J. Kang, S. Kim, J. Han; *Seoul/KR (kangjihee1@gmail.com)*

Purpose: To find differential CT features of colorectal poorly-differentiated neuroendocrine tumours (PD-NETs) from well-differentiated NETs (WD-NETs) and adenocarcinomas (ADCs).
Methods and Materials: CT features of 25 pathologically-proven colorectal WD-NETs, 36 PD-NETs and 36 ADCs were retrospectively reviewed. The following CT items were analysed: size, longitudinal location, morphology, homogeneity, the presence of intact overlying mucosa, necrosis, calcification, homogeneity, degree of enhancement on each CT phase, the presence of enlarged lymph node (LN), and metastasis. Significant CT variables were determined using the chi-square test, Fisher's exact test, and Student t-test. Receiver operating characteristic analysis was used to determine the optimal cut-off value of tumour and LN size.
Results: Large size, rectum location, ulceroinfiltrative morphology, absence of intact overlying mucosa, heterogeneous CT attenuation with necrosis, presence of ≥3 enlarged LNs, and metastasis were found to be significant variables to differentiate PD-NETs from WD-NETs (P<0.05). The optimal cut-off value for tumour size in differentiating PD-NETs from WD-NETs was 1.5cm (AUC=0.958, sensitivity=100%, specificity= 84%, P<0.0001). High attenuation on arterial phase, persistent high enhancement pattern, presence of ≥6 enlarged LNs, large LN size, and wash-in/wash-out enhancement pattern of liver metastasis were significant variables to differentiate PD-NETs from ADCs (P<0.05).
Conclusion: Compared to WD-NETs, colorectal PD-NETs usually appear as large, ulceroinfiltrative, heterogeneous rectal mass without intact overlying mucosa and accompany with enlarged LNs and metastasis. High attenuation on arterial phase, presence of enlarged LNs with larger size and greater number, and wash-in/wash-out enhancement pattern of liver metastasis can be useful CT discriminators of colorectal PD-NETs from ADCs.

B-0205 15:12

Value of MR defecography parameters used in diagnosis of obstructed defecation

K. Schawkat[1], H. Heinrich[1], H. Parker[1], B. Barth[1], R.P. Mathew[1], D. Weishaupt[1], M. Fox[2], C.S. Reiner[1]; [1]*Zurich/CH*, [2]*Basel/CH (k_schawkat@hotmail.com)*

Purpose: To assess the value of MR-defecography (MRD) parameters used in diagnosis of obstructed defecation.
Methods and Materials: Twenty-two consecutive patients (16 women, 6 men; mean age 51±19.4) with obstructed defecation and twenty healthy volunteers (11 women, 9 men; mean age 33.4±11.5) underwent MRD in a closed-configuration 3.0T MRI-system in supine position. MRD included midsagittal T2-weighted images at rest and during defecation after filling the rectum with 250ml water-based gel. Two independent and blinded radiologists measured pelvic floor descent in reference to the pubococcygeal line (PCL) and HMO-lines during defecation, anorectal angle (ARA), qualitatively assessed grade of evacuation (GE), paradoxical contraction (PC), and missing sphincter relaxation (MSR).
Results: Interreader agreement for PCL-, HMO-, and ARA-measurements was good to excellent (Intraclass-correlation-coefficient [ICC], 0.60-0.99), for GE excellent (κ-value, 0.76-0.80), and for PC and MSR fair to moderate (κ-value, 0.24-0.47). Posterior compartment descent, H-, M-line and ARA were significantly greater in patients compared to volunteers (p<0.05). 30-50% of volunteers had mild anterior and middle compartment descent and hiatal enlargement. 50% of volunteers had moderate rectal descent. Impaired evacuation was seen in 9/20 (45%) volunteers and 9/22 (41%) patients. Also PC and MSR were equally found in volunteers (40%, 40%) and patients (41%, 32%).
Conclusion: Quantitative, but not qualitative MRD-parameters show both excellent interreader agreement and ability to differentiate patients with obstructed defecation from healthy volunteers. However, pelvic floor descent values considered abnormal according to PCL and HMO-system are found in a substantial number of healthy volunteers and therefore need to be redefined.

B-0206 15:20

Dynamic MRI of the pelvic floor in different body positions: success rate of MR defecography in supine vs left lateral body position

K. Schawkat[1], B. Pfister[1], H. Parker[1], H. Heinrich[1], B. Barth[1], D. Weishaupt[1], M. Fox[2], C.S. Reiner[1]; [1]*Zurich/CH*, [2]*Basle/CH (k_schawkat@hotmail.com)*

Purpose: To assess the success rate of MR-defecography (MRD) performed in supine versus lateral body position and assess differences in pelvic floor measurements.
Methods and Materials: 22 consecutive patients (16 women, 6 men; mean age 51±19.4) with obstructed defecation underwent MRD in a closed-configuration 3.0T MRI-system in supine and lateral position. MRD included midsagittal T2-weighted images at rest and during defecation after filling the rectum with 250ml water-based gel. Two independent radiologists measured pelvic floor descent in reference to the pubococcygeal line (PCL) and assessed grade of evacuation (GE) in both body positions. Image quality (IQ) was rated on a 5-point-scale (5=excellent, 1=poor).
Results: Grades of middle and posterior compartment descent were similar in supine and lateral position (p>0.05). Anterior compartment descent was significantly higher in lateral position, but still normal to small in the majority of patients (4.6±23.1 cm vs. 8.9±25.2 cm, p<0.042). When attempting to defecate in supine position 6/22 (27%) patients showed no evacuation, while in lateral position only 3/22 (14%) were not able to evacuate. Image quality was equal at rest (4.4±0.5 and 4.7±0.6, p>0.05) and slightly better in supine compared to the lateral position during defecation (4.5±0.4 vs. 3.9±0.9, p<0.017).
Conclusion: In lateral position more patients were able to evacuate with similar grades of pelvic floor descent compared to supine position. Image quality was slightly degraded during defecation in lateral position. MRD in lateral position is a valuable alternative for patients unable to defecate in supine position.

Correlation of cerebrovascular reactivity and MRI pattern of carotid atherosclerotic plaque
A. Maksimova, E. Bobrikova, I. Bukhovets, M. Plotnikov, W. Ussov; *Tomsk/RU (asmaximova@yandex.ru)*

Purpose: Comparison of patients with carotid atherosclerosis, the structure of atherosclerotic plaques imaged using MRI with cerebral vascular reactivity quantified by echo.
Methods and Materials: Everyone of 21 persons with carotid artery stenosis >70%, quantified with high-resolution MRI of arterial wall. To assess the cerebrovascular reactivity transcranial ultrasound of middle cerebral artery was carried out with quantification of blood flow parameters at rest and during the stress tests: first with breath holding test and then with hyperventilation one, with calculation of reactivity index (RI). The patterns of auto-regulative reaction to the stress test were assigned to the following conventional types: positive reaction (RI=1.1-1.4); negative reaction (RI=0.9-1.1); paradoxical reaction (RI<0.9). From visual evaluation of MRI of carotid stenoses four types of plaques were assembled: mixed plaque with severe fibrosis and lipid core, plaque with lipid component, with intraplaque haemorrhage and calcified plaque.
Results: It was found that at breath holding hypercapnic test there is a statistically significant association between MRI plaque structure and type of the reaction, whereas at the test with hyperventilation no significant differences were found. At breath hold test in 56% of patients with MR images of plaque hypointense on T1-weighted scans and hyperintense on T2-weighted ones unidirectional positive response was observed; pathologic unidirectional negative response or multidirectional response were observed in patients with MR evidence of haemorrhagic plaques hyperintense on T1-weighted scans and hypointense on T2-weighted ones.
Conclusion: Atherosclerotic lesions of the internal carotid artery with intra-plaque haemorrhage are accompanied with critical deterioration of cerebrovascular reactivity.

B-0209 14:17

Spontaneous intracranial artery dissection: HR-MRI and MRA diagnosis
M. Dreval, M.V. Krotenkova, L.A. Kalashnikova, L.A. Dobrynina; *Moscow/RU (shusheek@yandex.ru)*

Purpose: To compare the diagnostic capabilities of MRA and HR-MRI in spontaneous intracranial dissection detection.
Methods and Materials: The study included 61 patients (27 males, 31 females) with spontaneous artery dissection manifested by ischaemic stroke or isolated head or neck pain. In every time point MRI was performed on 1.5 T scanner. Data of 3D TOF MRA of the cervical and intracranial arteries and 3D spc T1 fat suppression sequence of the neck and head were obtained. Intramural haematoma (IMH), and muscle signal intensity was measured and contrast index was calculated.
Results: After statistical analysis of the data with the use of non-parametric statistical methods (Mann-Whitney U test) it was revealed that value of the contrast index of IMH in 3D spc T1 fat suppression sequence was higher than that in 3D TOF MRA ($p<0.05$). The contrast index of IMH in intracranial and cervical artery dissection did not differ significantly in 3D spc T1 fat suppression sequence. The subjective visual analysis showed the same results.
Conclusion: 3D spc T1 fat suppression sequence of the neck and head has the advantage of identifying both intracranial and cervical artery dissection before 3D TOF MRA and allows reducing the study protocol up to one sequence.

B-0210 14:25

The risk of MR-detected carotid plaque haemorrhage on recurrent or first-time stroke or any cerebrovascular events: a meta-analysis of individual patient data
A.T.R. Schindler[1], R. Schinner[1], N. Altaf[2], M.E. Kooi[3], A.R. Moody[4], H. Poppert[1], M.F. Reiser[1], D.P. Auer[2], T. Saam[1]; [1]*Munich/DE*, [2]*Nottingham/UK*, [3]*Maastricht/NL*, [4]*Toronto, ON/CA (Andreas.Schindler@med.uni-muenchen.de)*

Purpose: To obtain precise estimates on the cerebrovascular risk of MR-detected carotid-plaque-haemorrhage (PH) during follow-up in symptomatic and asymptomatic individuals in a meta-analysis based on individual patient data.
Methods and Materials: Individual patient data of published cohorts on the association of PH with ischaemic symptoms was collected, including clinical course from diagnosis of PH until first treatment or last available follow-up. Risk of ischaemic stroke alone and of ischaemic events (stroke, TIA, amaurosis fugax) after 3, 12, and 24 months was estimated by survival-analysis. Baseline predictors of outcome were investigated by an adjusted COX/Frailty model.
Results: Datasets of 722 individuals from seven studies were obtained (symptomatic=77.6%, prevalence of PH at baseline=46.8%). During 1.205 person-years of follow-up 70 strokes (annualised event rate; AER=5.81%), and a total of 131 ischaemic events were observed (AER=10.9%). Presence of PH increased the risk of stroke in symptomatic, asymptomatic, and all patients by 7.1-, 3.5-, and 6.1-fold, and for ischaemic symptoms by 4.8-, 5.8-, and 5.3-fold, respectively. Cumulative risk for ischaemic stroke after 3, 12, and 24 months was 6.3, 13.7 and 24.4% in PH^+ vs. 0.5, 0.9, and 2.5% in PH^- patients. In the adjusted model presence of PH (HR 9.1, 4.6-18.1; $p<0.0001$), and diabetes (1.9, 1.1-3.2; $p=0.0192$) significantly increased the risk of recurrent ischaemic stroke.
Conclusion: This IPD meta-analysis overcomes limits of previous meta-analyses and provides more precise risk estimates on the association of PH with ischaemic symptoms and -more importantly- for ischaemic stroke alone which can be used for planning of intervention trials.

B-0211 14:33

A population-based investigation of cerebral vascular stenosis
S. Yan, M. Li, F. Zhai, Y. Zhu, S. Zhang, Z. Jin; *Beijing/CN (ysh19a@163.com)*

Purpose: To investigate the population-based prevalence of cerebral vascular stenosis and the relationship between it and other vascular diseases.
Methods and Materials: This research comprised 1183 participants (aged 55.8±9.57 years, 38.1% male) from an ongoing community-based cohort study. All the participants underwent brain MRI and carotid ultrasound. MRI images were collected at 3T MRI scanner and the sequences mainly included 3D T1 MPRAGE, T2-FLAIR, SWI and TOF-MRA. Used kappa test to estimate the inter-observer agreement and logistic regression adjusted for vascular risk factors to evaluate associations between cerebral vascular stenosis and other imaging biomarkers.
Results: Based on the MRA images, we observed cerebral vascular stenosis in 13.9% persons of all the participants, included 8.9% persons with mild stenosis and 5% with severe stenosis and occlusion. The value of inter-observer agreement was 0.755. There was a significant association between higher prevalence of cerebral vascular stenosis and the presence of carotid plaque, odds ratio (OR) = 2.040 (95% confidence interval [CI]: 1.471-2.830), $p < 0.001$. Also the prevalence of cerebral vascular stenosis was significantly associated with the deep white matter hyperintensities (OR=1.497, 95%CI: 1.071-2.093, p=0.018) and lacunes (OR=2.563, 95%CI: 1.442-4.554, p=0.001).
Conclusion: This high prevalence of cerebral vascular stenosis might remind us of the prevention of cerebral ischaemic diseases in the future. The outcomes of logistic regression might help us reveal the relationship between intracranial and extracranial stenosis, also showed evidences of the relationship between cerebral vascular atherosclerosis diseases and cerebral small vessel diseases.

B-0212 14:41

Variants of the circle of Willis and association with internal carotid artery stenosis
A. Varga[1], G. Di Leo[2], P.V. Banga[1], C. Csobay-Novak[1], M. Kolossvary[1], K. Hüttl[1]; [1]*Budapest/HU*, [2]*Milan/IT (vargand26@yahoo.com)*

Purpose: To provide an overview of anatomical variants of the circle of Willis (CoW) in patients with internal carotid artery (ICA) stenosis, in relation to clinical data.
Methods and Materials: After Institutional Review Board approval, two independent readers retrospectively studied 544 patients (331 males, mean age 69±8 years) that underwent carotid endarterectomy without shunting and had an adequate carotid and cranial CT angiography. The presence and the diameter of the individual segments and the anterior and two posterior parts of the CoW were evaluated as well as four reclassified groups based on the

number of hypoplastic and absent segments. Intraobserver and intraobserver agreement were estimated.
Results: Variants of CoW were found in 97% of patients. Aplasia of the posterior communicating artery (41%) was the most common finding; compromised posterior collaterals were observed in 78% of patients; circles with ≥2 hypoplasic or ≥1 absent segments in 86%. Compromised CoW was more frequent in patients with symptoms and was also correlated to ICA stenosis (p=0.012). Intraobserver and intraobserver agreement was excellent for almost all segments of the CoW.
Conclusion: A high prevalence of CoW variants and compromised CoW, in particular compromised posterior collaterals, was observed in a large cohort of patients undergoing carotid endarterectomy. The CoW variations reported here may contribute to our understanding of cerebral collateralisation in steno-occlusive carotid disease.

B-0213 14:49

Coexistence of cardiovascular risk factors and the volume of carotid bodies determined by computed tomography angiography of the carotid arteries

P. Jazwiec, P. Gac, M. Poreba, G. Mazur, R. Poreba; *Wroclaw/PL (pawelgac@interia.pl)*

Purpose: The study aimed at evaluation of the relationship between comanifestation of cardiovascular risk factors (CVRF) and the volume of carotid bodies (CB) determined by computed tomography angiography (CTA) of the carotid arteries.
Methods and Materials: The study was conducted on 52 persons (mean age of 68.32±12.31 years). Anamnesis, physical examination and laboratory tests allowed to characterise every patient in respect to CVRFs, i.e. smoking of cigarettes, arterial hypertension, hypercholesterolaemia, hypertriglyceridaemia, type 2 diabetes mellitus and overweight/obesity. Among the participants, subgroups were distinguished with 1-2 CVRF (group A, n=23), with 3-4 CVRF (group B, n=21) or with 5-6 CVRF (group C, n=8). In all patients, the volume of carotid bodies was evaluated at the basis of scans obtained by CTA of the carotid bodies.
Results: The volume of carotid bodies proved to be significantly higher in groups B and C than in group A (A: 23.66±12.02 mm^3, B: 42.17±14.85 mm^3, C: 45.77±24.71 mm^3, $p_{A-B, A-C}<0.05$). Positive correlation could be noted between the number of CVRF and the volume of carotid bodies (r=0.56, p<0.05). Regression analysis allowed to demonstrate that in the study group manifestation of arterial hypertension, followed by type 2 diabetes mellitus and smoking of cigarettes, were linked to the highest probability of the increased volume of carotid bodies.
Conclusion: In the study group, a positive relationship was found between the number of cardiovascular risk factors and the volume of carotid bodies. Arterial hypertension involved the CVRF linked to the highest probability of the increased volume of carotid bodies.

B-0214 14:57

Carotid resistive index as a marker of cardiovascular risk in adults without symptomatic cardiovascular disease

K.D. Hurtado Ortiz, F. Lubinus Badillo, V.M. Herrera; *Floridablanca/CO (kevinkorporation@hotmail.com)*

Purpose: Equations and markers of atherosclerosis such as the intima-media thickness (IMT) allows risk stratification in cardiovascular disease. The resistive index, an easily measured haemodynamic marker, might contribute this task; however, little is known about its relationship to cardiovascular risk factors (CVRFs) or IMT.
Methods and Materials: We conducted a cross-sectional study in adults (>40) from Bucaramanga, Colombia. Non-current smokers and individuals without symptomatic cardiovascular disease (i.e. myocardial infarction, stroke or peripheral artery disease) were eligible. CVRFs were determined by interview, anthropometry, ambulatory blood pressure (BP) monitoring, and quantification of fasting blood glucose and lipid fractions. IMT and RI were measured by ultrasonography (Toshiba Aplio 500 PLT-805AT) at the common carotid (CCA), and CCA and internal carotid (ICA) arteries, respectively.
Results: We evaluated 429 participants (mean age: 57.3 years; 22% male). IMT was larger at the posterior compared to the anterior CCA walls (0.69 vs. 0.64; p<0.05) and RI was larger in the CCA than the CCI (0.73 vs. 0.64, p<0.05). RI was associated with IMT (β [age and sex-adjusted] = 0.006 per 0.1 mm, p<0.05) without hypertension or atheromatous plaque-by-interaction. RI was larger in men than in women, and positively correlated to age, waist-to-hip ratio, BP, and glucose; however, in multivariate analyses only BP was a statistically significant predictor (0.022 per 10 mmHg [systolic] and -0.019 per 5 mmHg [diastolic]).
Conclusion: Our results, first from a Latin American population, confirms RI as a marker of cardiovascular risk, mainly explained by BP, and haemodynamic correlate of subclinical structural abnormalities.

B-0215 15:05

Effects on radiation dose, image quality and accuracy for the detection of carotid stenosis of 90-kVp low-tube-voltage carotid and intracerebral CT-angiography combined with ADMIRE

D. Leithner, J.L. Wichmann, L. Lenga, S.S. Martin, S. Mahmoudi, M. Beeres, M.H. Albrecht, T.J. Vogl, J.-E. Scholtz; *Frankfurt a. Main/DE*

Purpose: To evaluate radiation exposure, image quality, artefact and detection of carotid stenosis of low-tube-voltage 90-kVp acquisition combined with advanced modelled iterative reconstruction algorithm (ADMIRE) for carotid and intracerebral CT-angiography (CCTA).
Methods and Materials: We evaluated 43 patients (33 male; mean age: 61.7) retrospectively who underwent dual-energy CCTA on a third-generation 192-slice dual-source CT. 90-kVp and linearly-blended 120-kVp images were compared. Attenuation and noise of CCA at shoulder height, CCA at bifurcation, ICA at carotid syphon, MCA and BA were measured to calculate contrast-to-noise ratio (CNR). Subjective image quality was rated by three independent reviewers using 5-point grading scales regarding artefact and suitability. Detection and grading of carotid stenosis was performed. Interobserver agreement was calculated using intraclass correlation coefficient (ICC). Radiation dose was expressed as dose-length product (DLP).
Results: Attenuation and noise of all arteries were higher in 90-kVp compared to standard 120-kVp (all p<0.001), resulting in significantly increased CNR in 90-kVp (ICA, 38.2±13.5 vs 22.4±8.0 HU; p<0.001). Artefact and suitability were excellent in both series without significant differences.Highest artefact level, still with excellent suitability was rated at shoulder height without significant difference (90-kVp, 4.9±0.4; 120-kVp, 4.8±0.5). Detection of carotid stenosis was excellent in both series with no significant difference (stenoses in 32 of 129 segments; ICC, 0.94).DLP was reduced by 40.3% using 90-kVp acquisition (110.6±32.1 vs 185.4±47.5 mGy·cm, *P*<0.001).
Conclusion: 90-kVp CCTA combined with ADMIRE results in increased CNR, excellent suitability with low artefacts and significant reduction of radiation dose. Detection and quantification of carotid stenosis maintains excellent.

B-0216 15:13

Wavelet-based angiographic reconstruction of CT perfusion data: diagnostic value in cerebral venous sinus thrombosis

W.G. Kunz, F. Schuler, M.P. Fabritius, L. Havla, M.F. Reiser, W.H. Sommer, K.M. Thierfelder; *Munich/DE (wolfgang.kunz@med.lmu.de)*

Purpose: To test the diagnostic value of wavelet-based angiographic reconstruction of CT perfusion data (waveletCTA) to detect cerebral venous sinus thrombosis (CVST) in patients who underwent whole-brain CT perfusion (WB-CTP).
Methods and Materials: Datasets were selected from a cohort of 2863 consecutive patients who underwent multiparametric CT including arterial CTA (artCTA) and WB-CTP. The angiographic waveletCTA signal is generated by voxel-based wavelet-transform of time attenuation curves (TAC) from WB-CTP data. Two blinded readers analysed waveletCTA for presence of CVST. Venous CT/MR angiography (venCTA/venMRA) served as reference standard. Diagnostic confidence for CVST detection and quality of depiction for 13 different venous sections were evaluated on 5-point Likert scales. Thrombus length and the flowing blood-to-thrombus (FBtT) ratio of mean CT attenuation and waveletCTA signal were quantified.
Results: Sixteen patients were included: 10 with venCTA-/venMRA-confirmed CVST, and 6 with artCTA-suspected but follow-up-excluded CVST. waveletCTA reconstruction was successful in all patients. Among patients with confirmed CVST, waveletCTA correctly demonstrated presence, location and extent of the thrombosis in 10/10 cases. Among the patients with artCTA-suspected but follow-up-excluded CVST, waveletCTA correctly ruled out CVST in 5/6 patients. Additional reading of waveletCTA significantly increased diagnostic confidence compared to artCTA (4.4 vs 3.6, p=0.044). waveletCTA provided higher FBtT ratios (146.2 vs 2.6, p<0.001) and better depiction of all venous sections (4.2 vs 2.6, p<0.001) compared to artCTA.
Conclusion: waveletCTA was technically feasible in CVST patients and reliably identified CVST. waveletCTA might serve as an additional reconstruction to rule out or incidentally detect CVST in patients who underwent WB-CTP.

Personalised dose feedback to medical staff involved in fluoroscopy-guided interventions: a new era in radiation dose monitoring

A.M. Sailer[1], L.W.M. Vergoossen[2], L.E. Paulis[2], W.H. van Zwam[2], M. Das[2], J.E. Wildberger[2], C.R.L.P. Jeukens[2]; [1]*Stanford, CA/US*, [2]*Maastricht/NL (laura.vergoossen@mumc.nl)*

Purpose: Ionizing radiation is a major concern for the medical community as well as society. We hypothesize that providing weekly personal dose feedback will increase awareness and ultimately will lead to optimized behaviour. Therefore, we designed and implemented a personalized feedback of procedural and personal doses for medical staff involved in fluoroscopy-guided interventions.
Methods and Materials: Staff (physicians and technicians, n=27) involved in fluoroscopy-guided interventions were equipped with electronic personal dose meters (PDMs). Procedural patient dose data including the dose area product (DAP) and effective doses from PDMs were prospectively monitored for each procedure over an 8 months period (n=1082). A personalized feedback form was designed displaying the DAP individually and personal dose per procedure, as well as the relative and cumulative doses. This study consisted of two phases: (1) month 1-5: staff did not receive feedback (n=701); (2) month 6-8: staff received weekly individual dose feedback (n=381).
Results: For the first technician, the average relative dose was significantly lower in the feedback phase compared to the pre-feedback phase (mean relative dose±SD: 0.60±1.42 µSv/Gy·cm² (phase 1) versus 0.32±0.95 µSv/Gy·cm² (phase 2), p=0.002). The average relative first physician dose showed a non-significant trend towards a lower relative dose during the feedback phase (mean relative dose ±SD: 1.19±1.81 µSv/Gy·cm² (phase 1) versus 0.95±1.32 µSv/Gy·cm² (phase 2), p=0.099).
Conclusion: Personalized dose feedback to staff involved in fluoroscopy-guided interventions proofed feasible and valuable to improve individual awareness and overall radiation safety.

B-0218 14:08

Evaluation of radiation exposure in central venous catheter (CVC) placement in paediatric patients using two fluoroscopy protocols on a flat-panel system

R. Gerasia[1], S. Degiorgio[2], C. Tafaro[1], G.S. Gallo[1], A. Cucchiara[1], K. Cortis[2], L. Maruzzelli[1], R. Miraglia[1]; [1]*Palermo/IT*, [2]*Msida/MT (ctafaro@ismett.edu)*

Purpose: Evaluation of radiation exposure in paediatric patients undergoing image-guided CVC placement procedures using two different fluoroscopy protocols (FP).
Methods and Materials: We reviewed 110 consecutive CVCs placed in 62 paediatric patients in our centre between 7/2010 and 9/2016. Mean age was 14±12 months (median 12, range 1-48); mean weight was 8.3±3.3kg (median 8,8, range 3.5-13.5). 62 CVCs were placed using 50% of the nominal dose (FP50) whereas 58 CVCs were placed using 35% of the nominal dose (FP35) with technical parameters adjusted for paediatric protocol. DAP and fluoroscopy time (FT) were recorded for each procedure. DAP was normalised (nDAP) per unit fluoroscopy time and means for both groups were compared. Every FP35 procedure was completed successfully without changing protocol. No complications were recorded during these procedures. In addition, between October 2015 and September 2016 (20 procedures), radiation dose to operators was measured using electronic personal dosimeters, and effective dose (E) calculated.
Results: For FP50 protocol, mean nDAP was 0.30±0.17cGy*cm^2/s (median 0.25, range 0.09-0.75). For FP35 protocol, mean nDAP was 0.18±0.11cGy*cm^2/s (median 0.15, range 0-0.41). The difference between mean nDAP was statistically significant (p=0.004). E for radiologist was 0.04±0.07µSv (median 0, range 0-0.24), for anesthesia nurse 0.01±0.01µSv (median 0, range 0-0.03) and for radiographer 0±0.01µSv (median 0, range 0-0.03).
Conclusion: The use of low-dose paediatric adjusted protocols for CVC placement results in a statistically significant radiation exposure reduction by 39.5% and a very low effective dose to operators performing it.

B-0217 14:16

Procedural DAP can be used for relative dose estimation for staff dose in fluoroscopy-guided interventions

L.W.M. Vergoossen[1], A.M. Sailer[2], L.E. Paulis[1], J.E. Wildberger[1], C.R.L.P. Jeukens[1]; [1]*Maastricht/NL*, [2]*Stanford, CA/US (laura.vergoossen@mumc.nl)*

Purpose: Monitoring of effective staff doses only does not allow for judgment whether individual and procedural radiation safety can be optimized. Therefore, the relative dose was introduced, which relates the personal staff dose to a reference, measured by personal dose meters (PDMs). Our aim was to investigate the correlation between dose-area-product (DAP) and reference PDM dose and furthermore whether relative staff dose can be estimated by using the DAP.
Methods and Materials: Staff members (n=27) were equipped with PDMs and a reference PDM was mounted at a fixed position on the C-arm of the fluoroscopy system, thereby measuring scattered radiation. Clinical procedures (n=1082), grouped by procedure type were monitored prospectively. The median relative staff dose ($Dose_{Staff}/Dose_{Reference}\cdot100\%$) was calculated. The correlation between DAP and reference PDM dose was analyzed by comprehensive measurements with an Alderson anthropomorphic phantom for different scenarios of patient anatomy, operator height, acquisition techniques and C-arm angulations. Phantom measurements were compared to clinical data.
Results: DAP correlated strongly with reference PDM dose in clinical procedures (R^2=0.94, R^2=0.91, R^2=0.93 for cerebral, thoracic and abdominal procedures, respectively). Phantom measurements indicated that this correlation was mainly depending on the spectrum, i.e. kVp (mean grouped by kVp R^2=0.97, all data-points R^2=0.93; slopes: 4.07, 4.76, 5.75 µSv/Gy·cm^2 for kVp <70, 70-75, 75-80, respectively) and additional filtration, which is influenced by patient anatomy and acquisition technique.
Conclusion: We conclude that procedural DAP can be used as a reliable substitute to calculate a relative staff dose measure, increasing its applicability in daily practice.

B-0220 14:24

Radiation dose estimation for lumbar spine pain relieving interventional procedures: comparison of CT fluoroscopy and conventional CT techniques

N. Rasouly; *Kabul/AF (nrasouly@gmail.com)*

Purpose: The purpose of this study is to compare the radiation dose in lumbar spine pain relieving interventional procedures (steroid and local anesthetic injection in the facet joint, perineural and epidural spaces) under conventional computed tomography (CT) and computed tomography fluoroscopy (CTF) guidance.
Methods and Materials: From Jan 2008 to March 2014, we retrospectively obtained the data from 80 CT-guided and 56 CT fluoroscopy-guided interventional procedures performed in 74 patients with injections of steroid and local anesthetics in the facet joints, epidural space and neural foramina to estimate the radiation dose in the radiology department of Jean Minjoz university hospital, Besancon France. The data consisted of starting time, ending time, DLP measurements, patient's age and sex, site of procedure and number of procedures.
Results: 74 patients with total number of 136 procedures were included in the study, 30 (42%) male and 44 (58%) female with mean age of the 56.6 years (age range, 23-93 years). The mean DLP differed significantly between the two procedures showing marked dose reduction using CT fluoroscopy compare to conventional CT scan.
Conclusion: CT fluoroscopy significantly decreases the overall procedure time with marked reduction in radiation dose compared with conventional CT scan technique.

Comparison of shoulder strain relief between radiation protection aprons

A.M. Koenig[1], D. Sasse[1], R. Etzel[2], A.H. Mahnken[1]; [1]*Marburg/DE*, [2]*Giessen/DE*

Purpose: In interventional radiology radiation protection for staff has become increasingly important during the last recent years. In this study, we compared different commercially available staff's radiation protection concepts regarding their shoulder strain relief.
Methods and Materials: The tested radiation protection systems were a one-piece coat apron, a two-piece apron (vest and skirt), and the zero-gravity system (Biotronik, Germany). Shoulder strain was measured by a pressure sensor (FSR 406, Interlink Electronics, USA), which changes the electrical resistance depending on the applied pressure. This electrical resistance was measured using a portable multimeter (VC850 with bluetooth-adapter VC810,

Voltcraft, Switzerland). By generating a calibration graph, we were able to calculate the physical force of the shoulder pressure. Each apron was measured on two subjects, with focus on the right and on the left shoulders.
Results: The physical force of the shoulder pressure obtained from the one-piece coat apron, the two-piece apron, and the zero-gravity system was measured to be 29.2±2.1 N, 19.2±4.0 N, and 6.2±0.5 N, respectively. Inter-comparison between both shoulder sites showed different pressure values: the one-piece apron showed a shoulder weight of 27.4±1.5 N and 30.8±0.7 N for the right and left shoulder, respectively. While the two-piece apron was measured to be 16.9±2.1 N (right) and 21.8±4.0 N (left).
Conclusion: Compared to a one-piece coat apron, both the two-piece apron and the zero-gravity system showed substantial shoulder strain relief. Besides, we detected a significant higher pressure on the left shoulder when wearing the one-piece or two-piece aprons.

B-0222 14:40

Characteristics of a new C-arm imaging system used during uterine artery embolisation for uterine fibroids treatment: reduced radiation exposure and improved image quality

R. Schernthaner[1], R.R. Haroun[2], S. Nguyen[2], R. Duran[2], K. Hong[3], J.-F.H. Geschwind[2], M. Lin[4]; [1]*Vienna/AT*, [2]*New Haven, CT/US*, [3]*Baltimore, MD/US*, [4]*Cambridge, MA/US*
(ruediger.schernthaner@meduniwien.ac.at)

Purpose: To compare radiation exposure and image quality between a new C-arm system and the preceding generation system during uterine artery embolisation (UAE).
Methods and Materials: In this retrospective, IRB approved two-arm trial, 54 patients with symptomatic uterine fibroids were treated with UAE on two different C-arm systems. The new system includes optimised acquisition parameters and real-time image processing algorithms. Air Kerma (AK), dose area product (DAP) and acquisition time for digital fluoroscopy (DF) and digital subtraction angiography (DSA) were recorded. Body mass index was noted as well. DF image quality was assessed objectively by image noise measurements. DSA image quality was rated by two blinded and independent readers on a four-rank scale. Unpaired t tests and Wilcoxon rank-sum tests were used to assess statistical differences between the systems.
Results: There was no significant difference between the patients treated on the new (n=36) and the old system (n=18) regarding age (p=0.10), BMI (p=0.18), DF time (p=0.35) and DSA time (p=0.17). The new system significantly reduced the cumulative AK and DAP by 64% and 72%, respectively (median 0.58 Gy and 145.9 Gy*cm^2 vs. 1.62 Gy and 526.8 Gy*cm^2, p<0.01 for both). Specifically, DAP for DF and DSA decreased by 59% (75.3 vs. 181.9 Gy*cm^2, p<0.01) and 78% (67.6 vs. 312.2 Gy*cm^2, p<0.01), respectively. The new system achieved a significant decrease in DF image noise (p<0.01) and a significantly better DSA image quality (p<0.01).
Conclusion: The new imaging system significantly reduced radiation exposure and significantly improved image quality during UAE procedures.

Evaluation of reduction in time and radiation exposure using a robotic tracking system for CT-guided percutaneous bone procedures - our experience

S. Quarchioni, F. Bruno, F. Smaldone, F. Arrigoni, S. Mariani, L. Zugaro, A. Barile, C. Masciocchi; *L'Aquila/IT (di.gao@hotmail.it)*

Purpose: To evaluate the advantages of using a robotic tracking system for CT-guided percutaneous bone procedures in terms of technical success, procedure's time, perfect centering of the lesion and radiation exposure to the interventional radiology (IR) and patients.
Methods and Materials: In the period between June 2015 and February 2016 we performed 28 CT-guided percutaneous procedures of bone's lesion in 28 patients (16 biopsy, 6 crioablations, 6 RFA). 14 procedures (7 biopsy, 3 crioablations, 4 RFA) were performed with "free hand" standard technique, meanwhile 14 procedures (7 biopsy, 3 crioablations, 4 RFA) were performed using a robotic tracking system. For all procedures the final positioning of the needle was confirmed with Fluoro-CT. We used for the CT scans the following parameters: 50mAs, 120Kv, Slice Thickness 3mm.
Results: Fluoro-CT scans confirmed the correct position of the needle using the robotic tracking system with a single entry in 12 patients (92%). Technical success for both procedures was 100%. The mean execution time was 16 minutes for the procedures assisted with the robotic system and 25 minutes for the standard procedures. The mean radiation dose for the patients after the first CT-scans used for the visualisation of the lesion, was 3.5±1mSv in the standard procedures, and 0.92±0.78mSv in the procedures with the robotic system. The radion dose for the IR was 0.
Conclusion: The robot tracking system is an innovative medical device that allows to reduce the procedure's time, the number of CT-scans and consequently the radiation's dose for the patients and IR.

B-0224 14:56

Evaluation of a novel needle positioning system for CT-guided interventions: preliminary results

W.J. Heerink[1], M. Arnolli[2], R. Vliegenthart[1], J.-P. Pennings[1], G. Sieders[1], I.A.M.J. Broeders[2], M. Oudkerk[1], K.P. de Jong[1]; [1]*Groningen/NL*, [2]*Enschede/NL (w.j.heerink@umcg.nl)*

Purpose: To determine the accuracy of a novel table-mounted needle placement system (NPS) and compare it to regular free-hand CT-guided needle placement.
Methods and Materials: A novel table-mounted needle placement system (DEMCON, Enschede, the Netherlands) for CT-guided interventions is introduced and tested in a gelatin phantom, with chamois leather skin, containing 12 targets (six in-plane and six out-of-plane) at a depth of 12cm. Two experts approached 6 of the targets with regular free-hand CT-guidance and 6 using the NPS, for a total of 24 approaches.
The distance between the tip of the needle and the center of the target was measured as placement error. The needle was not repositioned if it was within 5mm of the target or after 5 needle manipulations. The mean (range) of the placement error, the number of needle manipulations and the number of CT scans acquired were determined for the NPS and free-hand group and were compared using independent samples t-tests.
Results: The mean placement error was 2.3mm (0.8-4.8mm) and 6.6mm (2.7-13.2mm; p=0.001), the mean number of needle manipulations was 1 (1-1) and 4.6 (3-5; p<0.001), and the number of CT scans was 3.2 (2-4) and 5.9 (3-8; p<0.001), for the NPS and free-hand group, respectively.
Conclusion: The use of the NPS increases the accuracy of needle placement and reduces the number of repositioning attempts and CT scans. It has the potential to reduce complications and patient radiation in CT-guided biopsy and ablative procedures.

Increased freedom in AEC parameter selection can reduce dose and increase efficiency in interventional cardiology x-ray systems

M. Dehairs, N. Marshall; *Leuven/BE (michiel.dehairs@uzleuven.be)*

Purpose: This work compares 3 exposure parameter (3P) AEC control to a more flexible 5-parameter (5P) method to investigate the possible benefits of increasing AEC parameter freedom.
Methods and Materials: A phantom composed of 15 composite PMMA/aluminium plates, was imaged on a Siemens Artis Q interventional cardiology system. Standard 3P acquisition parameter settings (tube potential, tube current, pulse length) vs 5P settings (extra copper filtration, focus size) and entrance air kerma rate (EAKR) were measured vs phantom thickness. Signal difference to noise ratio (SDNR) was measured using an iron insert, centred in the phantom. SDNR was then multiplied by MTF based correction factors for focal spot and motion blurring, giving a spatial frequency dependent parameter: SDNR(f). These MTF correction factors were evaluated at a spatial frequency of 1.4mm^{-1} and object motion of 25mm/s, which are typical for cardiac imaging. A generalised figure of merit (FOM) SDNR(f)²/EAKR was calculated for the 3P and 5P data.
Results: AEC control using 5P versus 3P technique showed clear improvements, when considered over all thicknesses (~78mm to ~390mm water equivalent): EAKR was reduced by 24% and 34% for fluoroscopy and acquisition modes respectively, while the FOM increased by 27% and 87% respectively. Averaging over smaller thicknesses (~78mm to ~209mm) gave even higher increases in FOM of 50% and 139% for fluoroscopy and acquisition, respectively, suggesting further benefit for paediatric procedures.
Conclusion: Increasing the number of controlling AEC parameters from three to five enables increased image quality at reduced entrance air kerma for interventional cardiology systems.

Occupational radiation doses to operators performing fluoroscopically guided diagnostic and therapeutic hepatobiliary interventional procedures: a single-centre study

R. Gerasia[1], S. Degiorgio[2], C. Tafaro[1], G.S. Gallo[1], A. Cucchiara[1], K. Cortis[2], L. Maruzzelli[1], R. Miraglia[1]; [1]*Palermo/IT*, [2]*Malta/MT (rgerasia@ismett.edu)*

Purpose: Evaluation of effective radiation doses (E) of radiologist, nurses and radiographers performing hepatobiliary FG procedures.
Methods and Materials: Over a 10-month period (October 2015-August 2016), 459 FG hepatobiliary procedures were performed in a single center in 240 adult patients. Electronic personal dosimeters were used to measure radiation doses to radiologist, anaesthesia nurse and radiographer. Patients' radiation dose was measured using Dose Area Product (DAP) and Fluoroscopy Time (FT).
Results: Chemoembolisation of HCC: mean E for the radiologist was 0,66 µSv (SD 1.09, range 0-9.96), for the anaesthesia nurse 0.18 µSv (SD 0.49, range 0-4.65), for the radiographer 0.05 µSv (SD 0.10, range 0-0.99); range for patients' DAP was 4.68-421.98 Gy*cm^2, for FT range 115-4035 sec. Percutaneous biliary procedures: mean E for the radiologist was 2.86 µSv (SD 3.26, range 0-54.54), for the anaesthesia nurse 0.261 µSv (SD 0.59, range 0-4.05), for the radiographer 0.43 µSv (SD 3.04, range 0-38.01); range for patients' DAP was 0,29-218.49 Gy*cm^2, for FT 35-4192 sec. TIPS: mean E for the radiologist was 1.37 µSv (SD 2.50, range 0.15-12.18), for the anaesthesia nurse 0.20 µSv (SD 0.62, range 0-3.99), for the radiographer 0.57 µSv (SD 1.02, range 0-4.83); range for patients' DAP was 7,22-644,44 Gy*cm^2, for FT range 213-2604 sec.
Conclusion: Mean E of operators varies with complexity of procedure performed, position of operator in angiosuite and use of adjunct leaded shield when possible.

B-0227 15:20

Radiation dose reduction during bronchial artery embolisation with a new imaging technology

C. Spink, M. Avanesov, T. Schmidt, M. Grass, G. Schoen, A. Koops, G. Adam, H. Ittrich, P. Bannas; *Hamburg/DE (c.spink@uke.de)*

Purpose: To compare the patient radiation doses during bronchial artery embolisation (BAE) before and after an imaging processing technology upgrade.
Methods and Materials: In a retrospective single-center-study, cumulative air kerma (AK), cumulative dose area product (DAP), total fluoroscopy time and contrast agent were gathered from a BMI- and age-matched population of 60 patients during BAE. 32 procedures were performed before and 28 after the technology upgrade from Philips Allura Xper to Philips AlluraClarity. Mean values were compared using two-tailed t-tests. Independent readers assessed DSA image quality using a four-rank likert scale and the Wilcoxcon test.
Results: Using the new imaging technology a significant reduction in mean DAP (187.7 vs 77.3 Gycm^2, p<0.001) and a significant reduction in mean AK (1.5 vs 0.6 Gy, p<0.001) could be achieved. The number of exposure frames (251 vs 231 frames, p=0.60), fluoroscopy time (35.3 vs 33.5 min, p=0.68) and amount of contrast agent (139.5 vs 155.1 ml, p=0.29) did not differ significantly between the two groups. Image quality after the technology upgrade was not rated significantly inferior (2.81 vs 2.94, p=0.62).
Conclusion: The new imaging technology significantly reduces patient radiation dose up to 58% maintaining an adequate image quality. Fluoroscopy time, the number of exposure frames and the amount of contrast agent did not significantly increase.

Is CT visual score able to demonstrate significant differences in distribution and progression of IPF abnormalities on the basis of smoking habit and treatment?

C. Romei, E. Perrone, A. De Liperi, L. Tavanti, D. Nieri, L. Carrozzi, R. Morganti, A. Palla, F. Falaschi; *Pisa/IT (chiara.romei@gmail.com)*

Purpose: To evaluate the role of smoking habit in patients with idiopathic pulmonary fibrosis (IPF) regard to the distribution of the main CT abnormalities (honeycombing and reticulation) and their progression during the follow-up. To assess the mortality of these patients in relation to smoking habit and treatment.
Methods and Materials: 56 patients with multidisciplinary diagnosis of IPF were distributed into three groups on the basis of smoking habit (18 non-smokers, 14 ex-smokers less than 20 pack-year (PY) and 24 ex-smokers more than 20 pack-year). We also classified the population in two groups; treated with Pirfenidone and untreated. The distribution of different abnormalities were visually scored by a radiologist at baseline and during the follow-up. The correlation with mortality rate were assessed.
Results: In the 3 groups no significant differences in the distribution of reticulation and honeycombing were found. A significant increase of honeycombing and reticulation in ex-smokers was demonstrated. The percentage of reticulation and honeycombing increases faster in untreated patients; the progression was quantified in 1,6 versus 2,3 points/year for honeycombing and 0,5 vs 3 points/year for reticulation. No significant difference in mortality rate was observed.
Conclusion: In our study CT visual score was not able to demonstrate any significant difference of IPF abnormalities distribution on the basis of smoking habit. Conversely a greater progression of abnormalities was showed in heavy smokers and untreated patients.

B-0229 14:08

Volumetric texture analysis in the characterisation of interstitial lung diseases in lung transplant patients

F. Gentili, V. Nardone, D. Spina, D. Bennett, A. Fausto, P. Tini, P. Rottoli, L. Volterrani, M.A. Mazzei; *Siena/IT (francescogentili@gmail.com)*

Purpose: Diagnosing usual interstitial pneumonia (UIP) with chest CT is fundamental because of the new treatment options that could modify the prognosis of this disease; however, it still represents a challenge for radiologists. The aim of this work was to investigate the possibility of volume texture analysis (TA) in differentiating UIP from non-UIP fibrosis, comparing TA parameters with histological specimens.
Methods and Materials: We selected the pre-transplant chest CT examinations of 47 patients (35 males); eighteen of them (38.3%) suffered from UIP. The lung was segmented into three regions of interest (ROI), the apex (A-ROI), the middle (MD-ROI) and the lower lobe region (B-ROI), using the lung autosegmentation of the FocalPro software, Elekta ©. All the ROIs were analysed with LifeX Software © and TA parameters were extracted, including the grey level co-occurrence matrix feature (GLCM), neighbourhood grey-level dependence matrix (NGLDM), grey-level run length matrix (GLRLM), grey-level zone length matrix (GLZLM), sphericity and indices from the grey-level histogram. Univariate and multivariate analyses, with ROC curve calculation, between all these parameters and the pathological evidence of UIP/non-UIP fibrosis were performed.
Results: Only B-ROI TA parameters resulted significantly correlated with the diagnosis in univariate analysis (histogram kurtosis, p:0.016; GLCM-contrast, p:0.016; GLCM-dissimilarity, p:0.011; NGLDM-contrast, p:0.034; GLZLM-zp, p:0.042). The logistic regression analysis produced significant results for TA parameters B-ROI histogram skewness (p:0.011), GLCM-dissimilarity (p:0.005), LGRE (p:0.020) and A-ROI GLRLM-LRE (p:0.020), with an R^2 of 0,645 and an AUC of 0.897.
Conclusion: Volumetric TA seems to improve the differential diagnosis of pulmonary fibrosis.

B-0230 14:16

Utility of 3D computer-aided diagnosis system for pulmonary functional loss and treatment response assessments in connective tissue disease patients

Y. Ohno[1], A. Yaguchi[2], T. Okazaki[2], K. Aoyagi[3], S. Kaminaga[3], Y. Kishida[1], S. Seki[1], T. Yoshikawa[1], K. Sugimura[1]; [1]*Kobe/JP*, [2]*Kawasaki/JP*, [3]*Otawara/JP (yosirad@kobe-u.ac.jp)*

Purpose: To evaluate the capability of a 3D computer-aided diagnosis (CAD) system of thin-section CT for quantitative pulmonary functional loss and treatment response assessment in connective tissue disease (CTD) patients.
Methods and Materials: 37 consecutive CTD patients underwent thin-section CT and pulmonary function test as follow-up examinations. In this study, total 135 follow-up examinations were divided as following three groups at each time point: stable (n=103), acute exacerbation (n=16), and after treatment (n=16) phases. In this study, all CT data were analysed by our proprietary software, and percentages of following six volume extents to total lung volume were automatically calculated in each CTD patient: normal lung, GGO and reticulation, nodular, honeycombing, consolidation, and emphysema. To determine the capability of pulmonary functional loss assessments, step-wise regression analyses were performed. To evaluate the capability for treatment response assessment, each volume and pulmonary functional changes were compared among three groups by Tukey's HSD test.
Results: In the step-wise regression test, VC change was significantly affected by the following two factor changes: the first-step factor was GGO and reticulation, and the second-step factor was honey comb (r=0.39, p<0.05). On comparison of each volume change, stable and after treatment phase groups had significant differences with acute exacerbation phase group (normal lung, GGO and reticulation, honeycomb and consolidation: p<0.0001). In addition, consolidation volume change had significant difference between stable and after treatment phase groups (p=0.0002).
Conclusion: 3D CAD system for thin-section CT has a potential for pulmonary functional loss and treatment response assessments in CTD patients.

B-0231 14:24

Interstitial lung disease in systemic sclerosis: comparison between quantitative CT and visual-scoring system before and after therapy

G. Cicchetti[1], M. Occhipinti[2], M. Rucco[1], S. Bosello[1], A. Larici[1], L. Bonomo[1]; [1]*Rome/IT*, [2]*Florence/IT (cicchetti.giuseppe88@gmail.com)*

Purpose: To compare quantitative computed tomography (qCT) analysis with semiquantitative visual analysis for the evaluation of interstitial lung disease (ILD) in systemic sclerosis (SS). To evaluate the role of radiological scores during treatment follow-up.
Methods and Materials: 15 patients with ILD in SS were evaluated both clinically and radiologically with high-resolution computed tomography (HRCT) scans before and during treatment with immunosuppressive therapy. Semiquantitative evaluation was performed by 2 chest radiologists independently using Goh's visual-scoring system. Qualitative analysis was made using texture-analysis software CALIPER (Imbio, Minnesota), which can assess extent of 5 different patterns: normal, ground-glass, reticular, honeycombing, and hyperlucent. Results were compared with respiratory function tests (RFT).
Results: 30 HRCT scans were evaluated. For the semiquantitative analysis overall interobserver agreement between radiologists was good, whereas agreement between Goh's scoring system and CALIPER was fair for ground-glass and poor for reticular. The extent of ground-glass and reticular patterns were inversely correlated with RFT both with Goh's score and CALIPER, while the latter showed greater correlation at the analysis of Pearson's coefficient (P<0.001 for FVC and P=0.001 for DLCO). In particular, patients with FVC<79% and DLCO<50% showed significantly greater extent of each pattern of disease for both scores (P<0.05). ROC curve analysis did not identify any cutoff of radiological involvement extent to predict functional deterioration.
Conclusion: Both scores showed significant correlation between the extent of ILD and RFT. Despite the fair agreement with Goh's score, CALIPER showed good performance in assessing disease extent and a greater correlation with RFT than Goh's score.

B-0232 14:32

Three dimensional structures of alveoli and alveolar ducts on magnified 3D print model based on micro CT of the lung specimen

H. Natori[1], H. Takabatake[1], M. Mori[1], H. Homma[1], M. Oda[2], K. Mori[2], H. Koba[1], H. Takahashi[1]; [1]*Sapporo/JP*, [2]*Nagoya/JP (hnatori@sapmed.ac.jp)*

Purpose: Virtual microscopic images of the peripheral lung specimen by micro CT disclosed structures of the alveolar duct and alveolus. However, fine 3D structures of the alveoli and alveolar ducts have not been reported. Author reported those structures in fine visible form at a glance by magnified 3D print model.
Methods and Materials: Inflated fixed lung specimen was prepared by Heitzman's method. Size of 5 mm cubic sample was used. FOV of micro CT was 5 or 10 mm in diameter. Data were processed by the original application named as micro-NewVES and NewVES system for 3D vision and virtual endoscopy, created by co-author KM. Magnified 3D model was printed from micro CT data. Non-destructive analyses of internal structures were performed with virtual image of the magnified print model by high resolution CT for clinical use.
Results: Virtual micro endoscopic observation disclosed the orifice of the respiratory bronchiole, and then the alveolar duct was appeared. Magnified model and its virtual images disclosed structures of the alveolar ducts. The alveolar duct was constructed circular arrangement of 6 alveoli as one unit. Several units were successively connected one after another. At the dead end of the alveolar duct, there is one alveolus in the center that surrounded by 6 alveoli were found.
Conclusion: Magnified 3D model and virtual endoscopy of the model give us easy to understand complicated structures of peripheral lung at a glance. This method is useful to establish basics for image analysis of COPD and many diseases with alveolar involvement.

B-0233 14:40

Quantitative CT analysis in COPD: do coexisting fibrotic changes influence pulmonary function in patients with advanced emphysema?

F.W. Feldhaus[1], D. Theilig[1], R.-H. Huebner[1], J. Kuhnigk[2], F. Doellinger[1]; [1]*Berlin/DE*, [2]*Bremen/DE (felix.feldhaus@charite.de)*

Purpose: Aim of this retrospective study was to find out if there is significant correlation of fibrotic changes with pulmonary function tests (FEV1) in patients with severe pulmonary emphysema (GOLD 3-4).
Methods and Materials: 86 patients with pulmonary emphysema underwent CT followed by pulmonary function tests. All CT-scans were performed with identical scanning parameters. Quantitative analysis of CT-data was performed with MeVisPULMO 3D v3.42 (Fraunhofer MEVIS, Bremen, Germany) to detect low (LAV) and high (HAV) attenuation volumes, defined by a threshold (LAV: <-950HU; HAV: >-700HU). HAV was considered the measurable correlate of fibrotic changes of lung tissue. HAV-extent was classified in three groups (<7%, 7-10%, >10% of lung volume). Peripheral lung volumes within a subpleural space of 2cm width were considered as the lungs "peel". In multivariate regression-analysis results were correlated with FEV1 and LAV.
Results: There was no significant correlation of HAV and FEV1 compared with LAV. Even when more than 10% of all lung voxels accounted for HAV, LAV showed a significant higher negative correlation with FEV1 (r= -.309, R^2=.096, p=.003) than HAV (no correlation, p=.786). The highest decrease of FEV1 was registered in expiration-CT and core volumes (r= -.377, p<.001 vs. HAV with p=.376). Neither in in-/expiration series nor in core-/peel-volumes HAV showed a significant correlation with FEV1.
Conclusion: Only emphysematous changes have a significant influence on FEV1 whilst coexisting fibrotic changes do not. In contrast to CPFE (chronic pulmonary fibrosis and emphysema) emphysema-score seems to show best correlation with lung function in COPD.

B-0234 14:48

CT abnormalities in never-smoking HIV patients

R. Scaglioni, G. Besutti, G. Ligabue, A. Santoro, S. Zona, A. Malagoli, G. Guaraldi, P. Torricelli; *Modena/IT (riccardo.scaglioni@hotmail.it)*

Purpose: To assess the prevalence and risk factors for CT signs of chronic lung disease in a large cohort of never-smoking HIV-infected patients.
Methods and Materials: 329 never-smoking HIV-infected patients (49.6±8.9 years, 73.9% men) underwent ECG-gated chest CT scan for the evaluation of coronary artery calcium score (CACs) and CT slices at the level of L4-L5 for the assessment of subcutaneous and visceral adipose tissue (SAT-VAT). CT signs of chronic lung disease (emphysema, respiratory bronchiolitis (RB), bronchiectasis, bronchial wall thickening, fibrosis and non-calcified nodules) were collected. Lung emphysema was graded with a semi-quantitative visual score (0-4 for each lobe). Epicardial adipose tissue (EAT) was calculated in a subset of 153 patients. Univariable and multivariable logistic regression analyses were performed to identify factors independently associated with the presence of emphysema.

Results: Emphysema was found in 52 patients (15.6%, 13 patients with score>4), RB in 39 (11.7%), bronchiectasis in 52 (15.8%) and nodules in 33 (10%). Univariable analysis showed significant associations between the presence of emphysema and: male sex (p=0.09), age (p<0.01), BMI (p=0.05), Framingham risk score (p<0.01), CACs (p<0.01), VAT (p<0.01), and EAT (p<0.01). No significant association was found with HIV-related factors and inflammatory markers. In a multivariable model, significant predictors of emphysema were: age (OR=1.098; p=0.01), and EAT (OR=1.015; p=0.03).
Conclusion: CT signs of chronic lung diseases are common in never-smoking HIV patients. Emphysema was associated with epicardial and visceral adiposity, but not with HIV-related variables, underlying a common pathogenetic mechanism linking lung CT abnormalities and ectopic fat accumulation.

B-0235 14:56

Xenon-enhanced ADCT: utility for functional and morphological assessments of smokers as compared with ventilation SPECT/CT

S. Seki[1], Y. Ohno[1], Y. Kishida[1], T. Yoshikawa[1], Y. Fujisawa[2], N. Sugihara[2], E. Suehiro[1], T. Sekitani[1], K. Sugimura[1]; [1]*Kobe/JP*, [2]*Otawara/JP*
(yosirad@kobe-u.ac.jp)

Purpose: To prospectively and directly compare the utility of xenon-contrast enhanced area-detector CT (Xe-ADCT) for pulmonary functional and disease severity assessments in smokers, when compared with ventilation SPECT/CT.
Methods and Materials: 46 consecutive smokers underwent prospective unenhanced and xenon-enhanced ADCTs, krypton ventilation SPECT/CT and pulmonary function tests. Xe-ADCT was generated from unenhanced and xenon-enhanced ADCT. Then, all smokers were divided into 4 groups as follows: 'Non-COPD', 'Mild COPD', 'Moderate COPD' and 'Severe or Very Severe COPD' groups. For each method, regional ventilation was assessed by 10-point scoring system on a per-lobe basis. Then, ventilated lung volume (VLV) on each method, functional lung volume (FLV) and wall area percent (WA%) in each subject were calculated according to past literatures. To evaluate the capability of each index for pulmonary functional loss assessment, all indexes were correlated with $\%FEV_1$ by step-wise regression analyses. To compare each index among all groups, Tukey's HSD test were performed.
Results: In the step-wise regression test, $\%FEV_1$ (r=0.62, p<0.001) was significantly affected by the following three factors: the first-step factor, VLV on Xe-ADCT; the second-step factor, WA%; the third-step factor, FLV. All indexes of 'Non-COPD' and 'Mild COPD' groups had significant difference with those of 'Severe or Very Severe COPD' groups (p<0.05), and all indexes except VLV on SPECT/CT had significant difference between 'Moderate COPD' and 'Severe or Very Severe COPD' groups.
Conclusion: Xenon-enhanced ADCT had equal to or better capabilities for pulmonary functional and disease severity assessments in smokers as compared with ventilation SPECT/CT.

Quantitative CT analysis of pulmonary vessels using virtual gradationally peeled off lung in COPD patients: interrelation with emphysema, air trapping and pulmonary function

E. Lee, S. Lee, J. Seo, N. Kim, J. Bae, S. Lee, S. Oh, J. Lee, Y.-M. Oh;
Seoul/KR (eslee0214@gmail.com)

Purpose: To analyse quantitatively pulmonary vessel using virtual peeled off lung in COPD patients and interrelation with emphysema index (EI), air trapping index (ATI) and PFT.
Methods and Materials: 100 COPD patients (M:F=93:7; 65.2±0.8years) have non-contrast 3D inspiration/expiration CTs, PFT and DLco were enrolled. AView Lung software was used to analyse pulmonary vessel. Closed plane having an even distance (6mm~24mm, 3mm interval) from the fissure and surface regarding whole lung were automatically generated. Number of vessels per square centimeter, mean diameter of vessels, and percent of vessel area per surface were semi-automatically measured on all generated planes. EI (percentage of area HU≤-950), ATI (percentage of area subtracted HU≤60HU between inspiration CT and registered expiration CT), and mean of bronchiolar wall area percentage (WA%) were also measured. Correlations between parameters of vessels and EI, ATI, WA%, PFT, DLco were evaluated.
Results: All level of number of vessels per square centimeter and percent of vessel area per surface showed significant negative correlation with EI (r=-0.606~-0.811), ATI (r=-0.310~-0.423), RV (r=-0.331~-0.463) and positive correlation with WA% (r=0.264~0.340), and PFT parameters (r=0.243~0.552). They also showed significant positive correlation with DLco (r=0.241~0.443) except vessel area per surface on 6mm plane. Mean diameter of vessels showed significant negative correlation with EI, and ATI on 9~18mm level plane (r=-0.216~-0.370). All detailed results are showed in Table 1.
Conclusion: CT measured parameters of pulmonary vessels are related with CT measured emphysema, air trapping, airway wall thickness and clinical pulmonary functions.

B-0237 15:12

Cardiac remodelling in COPD: An effect of reduced preload or increased afterload?

J. Weir-McCall, A. Struthers, B. Lipworth, J. Houston; *Dundee/UK*
(jweirmccall@doctors.net.uk)

Purpose: The classic cardiac complication of those with chronic obstructive pulmonary disease (COPD) is that of cor pulmonale. However this has typically been described in those with end stage disease or based on echo measures which is known to be poor for right ventricular (RV) assessment and even worse in a COPD cohort. Thus the aim of the current study was to use cardiac MRI to assess cardiac remodelling in COPD.
Methods and Materials: 21 healthy volunteers (HV) free from cardiovascular disease and 60 patients with COPD were recruited. Those with COPD were screened with echocardiography, and those with silent left ventricular (LV) systolic dysfunction excluded. All patients underwent spirometry and cardiac MRI for mass and volume assessment on the same visit.
Results: With increasing severity of COPD both left and right ventricular end diastolic volumes (EDV) fell (LVEDV: 60±10ml in HV vs. 44±18ml in severe COPD, p=0.011; RVEDV 60±13 in HV vs. 42±16 in severe COPD, p=0.017) and as did stroke volumes (SV) (LVSV: 36±5ml in HV vs. 25±10ml in severe COPD, p=0.001; RVSV 37±6 in HV vs. 24±11 in severe COPD, p=0.001). Left ventricular mass (LVM) also fell with increasing severity of COPD (LVM: 41±7g in HV vs. 33±14g in severe COPD, p=0.024), while RV mass remained unchanged (p=0.24).
Conclusion: Increasing severity of COPD results in reduced cardiac volumes and mass, suggesting the predominant cause of cardiac remodelling in COPD is due to reduced preload rather than the classical cor pulmonale model of increased afterload.

B-0238 15:20

Pulmonary hypertension secondary to diffuse lung diseases: correlations between radiological findings and haemodynamic assessment

A. Poerio, A. Bruno, F. Ciccarese, V. Cosi, F. Ragusa, A. Conficoni, F. Niro, D. Attinà, M. Zompatori; *Bologna/IT (a.poerio@alice.it)*

Purpose: To evaluate the different correlations between radiological findings and haemodynamic parameters in a cohort of patients with pulmonary hypertension (PH) secondary to diffuse lung diseases (DLD) of different types and varying severity.
Methods and Materials: We retrospectively evaluated CT-pulmonary angiography (CTPA) and right heart catheterization (RHC) of 48 patients with PH secondary to DLD. Radiological assessment included: pattern of DLD (fibrosis, emphysema, CPFE); extension of disease (expressed as visual score: VS); radiological signs of PH. RHC values considered were: mean pressure of the main pulmonary artery (mPAP), pulmonary vascular resistance (PVR), pulmonary capillary wedge pressure (PCWP) and cardiac index (CI). We divided patients into 2 main groups based on VS (</≥40%) and into 3 sub-groups based on DLD pattern. Correlations between radiological and haemodynamic parameters among various groups were evaluated.
Results: In the group of patients with VS <40% we found a significant direct correlation between mPAP, RVP and the radiological signs of PH such as pulmonary trunk diameter (p: 0.04 and 0.02, respectively) and pulmonary trunk diameter to ascending aorta diameter ratio (p: 0.006), while in the group with VS ≥40% the significance was lost and even observed a trend to an inverse relation, especially in the CPFE sub-group, in which we found also a lower CI, predictive of worst prognosis.
Conclusion: Our results confirm the high potential of the CT pulmonary angiography in the assessment of PH secondary to DLD and highlight the usefulness of the visual score, expressed as percentage of total lung volume, to improve the sensitivity of imaging in the PH screening.

Comparison between contrast-enhanced CT (CECT) and contrast-enhanced ultrasound (CEUS) in patients with clinical suspicion of complicated acute pyelonephritis (c-APN)

C. Montalto, E. Raimondi, Z. Ferrante, M. Tilli, M. Giganti, G. Benea; *Ferrara/IT (edoardo.raimondi@unife.it)*

Purpose: To assess the value of contrast-enhanced ultrasonography (CEUS) in clinical suspicion of complicated acute pyelonephritis (c-APN), in terms of nature and extent of disease, compared with contrast-enhanced computed tomography (CECT) findings (reference standard).
Methods and Materials: From January 2016 to September 2016, 39 patients (33 women, 6 men; mean age 26 years, range 18-67) with clinical suspicion of complicated-APN, underwent both CEUS and CECT 72 hours after admission, performed in a blinded manner by two different operators. Prior informed consent, CEUS was performed evaluating both kidneys, after injection of 5 ml of US-contrast agent. CECT study (multislice 64-row scanner) was performed after injection of 100ml of iodinated contrast agent. All renal parenchymal changes were independently reported for both studies.
Results: At CECT 34/39 patients (87%) showed renal parenchymal changes suggestive for focal c-APN, confirmed in 33/34 (97%) at CEUS; the remaining case was false negative at CEUS (US anatomic limitation). 24/34 patients (70.5%) had unilateral and 4 /34 (11.7%) had bilateral focal APN. CECT showed 6/34 cases of renal abscesses, all confirmed at CEUS. In 5/39 cases there was no evidence of renal disease at CEUS or CT.
Conclusion: CEUS showed to be almost as equally accurate as CECT in patients with clinical suspicion of c-APN, allowing detection of renal parenchymal changes as focal APN and/or renal abscesses. Considering CECT-associated radiation and potential nephrotoxicity of iodine contrast media, in c-APN patients (frequently young women) CEUS should be considered as first-step imaging technique to depict the extension and entity of renal infection.

Detection and characterisation of urolithiasis using photon-counting-CT in a clinical setting

R.P. Marcus[1], J.G. Fletcher[2], T.J. Vrtiska[2], M.L. Wells[2], A.F. Halaweish[3], F.T. Enders[2], S. Leng[2], C.H. McCollough[2]; [1]*Tübingen/DE*, [2]*Rochester, MN/US*, [3]*Malvern, PA/US (roy.marcus@med.uni-tuebingen.de)*

Purpose: To compare the performance of an experimental photon-counting-detector CT (PCCT) with clinical dual-energy-CT (DECT) in detecting and characterising urolithiasis.
Methods and Materials: Non-contrast-enhanced DECT stone detection/characterisation exams were performed in thirty patients using a 2nd-generation dual-source-CT-system (SOMATOM Flash, Siemens) using 80/140Sn kVp or 100/140Sn kVp, depending on patient size. Subsequently, a similar exam was performed using the PCCT at 140 kV with energy thresholds at 25 and 75 keV, and CTDIvol matched between exams. 1 and 5 mm images were reconstructed using a D30 kernel. Two radiologists examined in a blinded fashion DECT mixed and low kV images, and PCCT low energy threshold (25-140 keV) and bin1 (25-75 keV) images. Confidence in stone presence was graded in consensus (1=definitely present, 2=probably present, 3=questionably present, 4=not seen). Stone characterisation was performed using commercial software (Syngo DE, Siemens) based on low- and high-kV-images for DECT and bin1 and bin2 images (25-75 and 75-140 keV) for PCCT.
Results: 160 stones (5.4±9.3 mm) were detected in total, with 91 stones ≤ 3mm. No difference in confidence for stone presence between DECT and PCCT was detected for 1mm images (p= 0.38-0.81). Stones were more likely to be definitely present with 1mm images compared to 5 mm images (p<.0001). Automatic stone characterisation was more successful in PCCT than DECT (112 vs. 87 stones), especially for small stones (45 vs.25). Agreement in stone composition between scanners (κ=.65) was substantial.
Conclusion: Detection confidence for stones was identical in both modalities. PCCT demonstrated improved stone characterisation results.

New radiologic classification of renal angiomyolipomas

B. Park, S. Song; *Seoul/KR (1436park@gmail.com)*

Purpose: To introduce a new radiologic classification of renal angiomyolipoma (AML).
Methods and Materials: Between 1995 and 2014, CT or MR images in 98 patients with histologically proven 98 AMLs were reviewed independently by a radiologist and a resident. The lesions were classified as (a) 53 fat-rich AML (≤ -10HU), (b) 22 fat-poor AML (> -10HU) with tumour-to-spleen ratio (TSR) <0.71 or signal intensity index (SII)>16.5%, and (c) 23 fat-invisible AML (>-10HU) with TSR≥0.71 and SII≤ 16.5%. Inter-reader agreement was assessed with a weighted kappa value. Fat-poor and fat-invisible AMLs were compared in terms of attenuation value, TSR, and SII using unpaired t-test.
Results: The weighted kappa value was 0.956 (95% confidence interval, 92.0 - 99.1%). When a region of interest (ROI) was placed within the most hypodense area on unenhanced CT or within the most signal-dropped area on chemical shift image, the mean attenuation values, TSRs, and SIIs of fat-poor versus fat-invisible AMLs were 19.5±8.1 HU versus 38.1±9.9 HU, 0.59±0.19 versus 0.96±0.01, and 43.7±16.9% versus -5.4±21.1%, respectively (p<0.0001). When a ROI was placed within the other area on CT or chemical shift images, 90.1% (48/53) of fat-rich AMLs were misclassified as fat-poor or fat-invisible AML and 50% (11/22) of fat-poor AMLs as fat-invisible AML.
Conclusion: The new radiologic classification of renal AML is feasible for clinical practice. ROI location is important in differentiating the types of AMLs.

B-0242 14:24

Two-point Dixon in the detection and evaluation of renal angiomyolipoma: does the fat-water fraction measurement have a contributing effect?

H. Demirtas, B. Değirmenci, A.O. Çelik, M. Kara, A.R. Aktaş, H.A. Ekşili, H. Orhan; *Isparta/TR (demhakan@yahoo.com)*

Purpose: The aim of this study was to compare the effectivity of 3D two-point Dixon sequence and in- and opposed-phase sequence in the detection of renal AML and in the detection of size and localisation of these lesions and also to evaluate interobserver differences.
Methods and Materials: The retrospective study included 35 patients who underwent renal mass MRI protocol that included Dixon sequences [in-phase (IP), opposed-phase (OP), water-only (WO), and fat-only (FO)]. The differences between sequences relating to tumour size and localisation were evaluated. The four sequences were compared in terms of lesion detection rate and interobserver differences were also evaluated.
Results: The lesion detection rates in the OP and FO sequences were 80% and 86% for Reader 1 and 91% and 96% for Reader 2, respectively. The rates in the WO and IP sequences were 66% and 74% for Reader 1 and 48% and 52% for Reader 2. The number of detected lesions smaller than 5mm was slightly higher in FO sequence. The evaluations indicated that small-size tumours were significantly more difficult to identify as compared to large-size tumours for both readers (Reader 1, p=0.039; Reader 2, p=0.047). The detectability of peripherally located lesions with regards to their localisation was significantly higher in the WO and IP sequences (Reader 1, p=0.014; Reader 2, p=0.004).
Conclusion: The OP and particularly the FO sequences are highly effective in the diagnosis of AML and centrally located lesions.The FO sequence can be useful in the detection of lesions smaller than 5mm in size.

B-0243 14:32

Characterisation of adrenal lesions with histogram analysis using unenhanced MRI

V. Romeo, R. Cuocolo, S. Dell'Aversana, M. Coppola, P. Mainenti, M. Imbriaco, S. Maurea, A. Brunetti; *Naples/IT (valeria.romeo@unina.it)*

Purpose: To investigate the role of quantitative histogram analysis applied to T1-weighted in-phase (IP), opposed-phase (OP) and T2-weighted sequences (T2w) in discriminating among lipid-rich adenomas (LRA), lipid-poor adenomas (LPA), and non-adenomas (NA).
Methods and Materials: Forty-five patients with unilateral adrenal lesions (18 LRA, 7 LPA, 20 NA) at MRI examination have been retrospectively enrolled. Each detected adrenal lesion was manually segmented with Itksnap through placement of a spherical ROI on IP, OP and T2w images. The ROIs were successively imported on a dedicated software (MITK) to calculate first-order histogram-derived statistics. Data were compared among LRA, LPA and NA lesions and differences were evaluated using Mann-Whitney tests. A p value ≤ 0.05 was considered statistically significant.
Results: Among the extrapolated parameters, entropy on T2w (e-T2w), standard deviation on T2w (sd-T2w), uniformity on T2w (u-T2w) and kurtosis on OP (k-OP) were significantly different between LRA and NA (p<0.05) and between LPA and NA (p < 0.05), while were not statistically different between LRA and LPA (p>0.05).

Conclusion: Several of the extrapolated parameters (mainly extracted from the T2w sequence) may play a role in the discrimination between adenomas (both LRA and LPA) and non-adenomas; however, the additional role of these parameters in characterizing adrenal lesions on standard unenhanced MRI protocol have to be investigated in a larger patient population to confirm our preliminary results.

B-0244 14:40

Quantitative ultrasound evaluation of cystic and solid tumours of the kidney: a fancy toy or an useful tool?

C. Bruno, A. Bucci, C. Dallaserra, R. Pozzi-Mucelli; *Verona/IT (costanza_bruno@libero.it)*

Purpose: To assess if ARFI can be a reliable technique in distinguish ccRCCS from other solid and fluid-containing small renal masses.
Methods and Materials: 50 small (less than 4 cm) renal masses (40 solid - 24/40 ccRCCs, 5/40 papillary RCCs, 4/40 chromophobe RCCs, 4 oncocytomas and 3 angiomyolipomas - and 10 cystic - 4 simple cysts, 1 MEST, 1 cystic nephroma, 1 mucinous tubular tumour, 1 tubulocystic tumour and 1 an Xp translocation RCC) were prospectively evaluated using US and ARFI. Each lesion was assigned an ARFI value obtained from the average of 12 measurements. Complex cysts were evaluated in the solid portion. All the solid masses underwent resection; among the 10 cystic lesions 4 were Bosniak 2, so were evaluated with follow-up, the other 6 underwent resection too.The difference existing between the two groups was evaluated by means of Student's t test. A cut off value was determined to distinguish between ccRCCs and other lesions and sensibility, specificity, PPV, NPV and accuracy were determined.
Results: ccRCCs are characterised by an higher ARFI value and - when compared with all the other lesions - the difference existing between the two groups was statistically significant (p<0.001). Considering a cut off value of 1.95 m/sec sensibility, specificity, PPV, NPV and accuracy were respectively 91%, 69.2%, 72.4%, 90% and 79.6%.
Conclusion: ccRCC is characterised by an higher ARFI value which can be used to distinguish it from other solid and fluid containing masses.

B-0245 14:48

Perfusion CT in the evaluation of renal cell carcinoma

S.S. Chauhan, R. Dixit, V. Chowdhury, N. Khurana; *New Delhi/IN (drshaan54@gmail.com)*

Purpose: The purpose of this study is to determine perfusion characteristics of renal cell carcinoma (RCC) using perfusion CT technique and compare them with histopathological findings.
Methods and Materials: 21 patients (18 clear cell, 2 papillary and 1 chromophobe subtype) of RCC underwent perfusion CT on a 128 slice MDCT scanner (Siemens Somatom Definition AS CT Scanner). A non-contrast scan of the upper abdomen was done to localize the region of interest (ROI) followed by dynamic CT acquisition of ROI. Perfusion parameters including blood flow (BF), blood volume (BV), permeability (PMB), mean transit time (MTT) and time to peak (TTP) were obtained from the tumour cross section (CS) and maximally enhancing area (MEA) of RCC and the contralateral renal cortex.
Results: Mean BF, BV and PMB were significantly reduced in both the tumour CS and MEA of RCC in comparison to contralateral renal cortex (p=0.00l). MTT was significantly increased both in tumour CS and MEA of RCC in comparison to contralateral renal cortex [(p=0.002) and (p=0.001) respectively]. TTP (sec) was significantly increased only in MEA of RCC in comparison to contralateral renal cortex (p=0.042). Mean BF and BV in the MEA were highest in clear cell RCC (88.83+/-49.74 ml/100ml/min and 19.64+/-10.10 ml/100ml) followed by papillary (49.74+/-7.94 ml/100ml/min and 10.48+/-2.26 ml/100ml) and lowest in chromophobe subtype (27.41 ml/100ml/min and 5.68 ml/100ml).
Conclusion: CT perfusion parameters show significant difference between the RCC and normal renal cortex and between various subtypes of RCC, thus can be used for preoperative subtype differentiation.

B-0246 14:56

Elastography point quantification and chronic renal diseases

E. Danse, C. Lenfant, M. Jadoul, F. Houssiau, S. Aydin, J. Cosyns, N. Demoulin, P. Trefois, N. Michoux; *Brussels/BE (etienne.danse@uclouvain.be)*

Purpose: Evaluation of the correlation between the renal cortex stiffness in chronic kidney disease (CKD) evaluated with elastography point quantification (ElastPQ) and the FIAT score of renal fibrosis in CKD.
Methods and Materials: 16 consecutive adults patients with CKD and 16 healthy volunteers underwent ElastPQ elastography. The elastographic measurements of the renal cortex were expressed with kPa values. 10 patients with CKD had a clinically indicated biopsy for which interstitial fibrosis was evaluated by the FIAT score. Correlation was evaluated between elasticity values and echographic (US), biological and histopathologic data for the patients comparison; US and biological results were used for the comparison of data between patients and volunteers.
Results: Renal cortical stiffness did not correlate with biological or US parameters. A significant correlation was observed between cortical stiffness and the FIAT score (r=0.7, p=0.0282). No significant difference were found between the renal cortical stiffness of the control group and the diseased group.
Conclusion: Renal cortical stiffness in CKD by ElastPQ was correlated with the FIAT score. A significant difference was observed between the grade 1 and 2 of the FIAT score with a thershold of 5.66kPa. This result offers pesrpectives in evaluation and detection of CKD with the possibility to reduce the number of biopsies.

B-0247 15:04

Evaluation of diffusion kurtosis imaging for detecting and grading the renal clear-cell carcinoma

Q. Feng; *Weifang/CN (fengqiang1975@163.com)*

Purpose: To investigate the detection of clear-cell renal cell carcinoma (CCRCC) by diffusion kurtosis imaging (DKI) and evaluate the association between DKI-derived parameters and pathologic factors.
Methods and Materials: In this study, 20 low-grade and 15 high-grade were performed. DKI with b values (0,500, 1000s/mm^2) and DWI data wtih b values (0,800s/mm^2) were acquired. In patients with histologically proven CCRCC, a representative region was determined on coronal T2WI. DKI parameters (D_{app} and K_{app}) and ADC values of the ROIs in tumour and contralateral areas were calculated. The receiver operating characteristic (ROC) were calculated for DKI parameters and ADC values. A subgroup analysis was performed to determine the aggressiveness of CCRCC using D_{app} and K_{app}.
Results: In the 35 patients, D_{app} was significantly lower in tumour compared with control regions (2.85±0.22 vs 2.93±0.27, P<0.05), and K_{app} was significantly higher (0.58±0.08 vs 0.51±0.06, P<0.05). D_{app} was significantly higher than standard ADC both in tumour regions and in controls (2.85±0.22 vs 2.72±0.24 and 2.93±0.27 vs 2.79±0.31, P<0.05). ROC revealed a significant difference between DKI and ADC for detection of CCRCC. Sensitivities ranged from 79% to 91% for DKI parameters; specificities ranged from 81% to 92%. Kurtosis was positively correlated with tumour histologic grade (r=0.83), diffusivity was negatively (r=-0.81), the significant difference were found for discrimination between high- and low-grade (P<0.05).
Conclusion: For detection and grading of CCRCC, DKI was better than standard ADC.

Four-dimension dynamic imaging by 640-slice multidetector CT for the diagnosis of urine flow related diseases

J. Guan, Y. Guo, H. Wang; *Guangzhou/CN (usefulkey0077@hotmail.com)*

Purpose: To explore the value of diagnosis on urine flow related diseases by applying of 640-slice MDCT four-dimension dynamic imaging.
Methods and Materials: Sixteen patients were clinically diagnosed with urine flow related diseases, and detail diagnostic information could not be provided by other routine imaging exam. Four-dimension dynamic CT imaging was performed for diagnosis by the 640-slice MDCT with a 160-mm detector, which was approved by the hospital ethics committee. According to the location of lesion, degree of hydronephrosis, status of bladder and so on, all cases received low dose CT scan with personalised scan protocols. Multi-planner reformation was performed for getting 4-dimension dynamic imaging.
Results: Four cases of slight urine reflux were confirmed. Four cases of stenosis of lower ureter were found (2 of moderate stenosis, and 2 of severe stenosis). The locations of ectopic ureter were accurately defined in five cases. The precise locations and sizes of fistula of fistulas were shown in three cases (1 of vesico-vaginal fistula, and 2 of vesico-rectal fistula). Compared with traditional cystography, 4-dimension dynamic CT imaging was a non-invasive examination.
Conclusion: Four-dimension dynamic imaging by the 640-slice MDCT is a new choice of imaging exam for urine flow related disease, and can directly and clearly show direction and route of urine flow, and provide detail and rich information for diagnosis.

3T multiparametric MRI in differentiating muscular-invasive and non muscular-invasive bladder cancer

M. Grompone; *Rome/IT (mdgrompone@libero.it)*

Purpose: The differentiation of muscular-invasive bladder cancer and non muscular-invasive bladder cancer is crucial for an effective treatment. Purpose of the study is to demonstrate the rule of 3T multiparametric MRI in differentiation and staging of muscular-invasive and non muscular-invasive bladder cancer.
Methods and Materials: 61 patients with suspected or confirmed bladder lesion underwent 3T multiparametric MRI exam. MRI protocol included T2W morphological sequences, dynamic sequences (PWI),b-500, b-800 and b-1000 diffusion sequences (DWI) and diffusion tensor imaging (DTI) with post-processing bladder wall reconstruction. MRI data were read in both qualitative (T2W, PWI, DWI and DTI) and quantitative (PWI, DWI and DTI) way. Endoscopic cystoscopy was performed for histological diagnosis of the lesion.
Results: The accuracy of mpMRI exam was 90%, 93%, 86% and 90% in T2W, PWI, DWI and DTI sequences respectively with the best performance combining and interpreting T2W, DWI and PWI sequences together. DTI helped to correctly categorize uncertain lesions and in cases of DWI and ADC interpretative doubt about bladder invasion.
Conclusion: 3T Multiparametric MRI can be considerd a valid tool in bladder cancer diagnostic pathway replacing diagnostic cystoscopy, that means just a therapeutical rule for interventional procedures.

RECIST 1.1, WHO and 3D CT-scan methods predict vocal cord remobilisation after induction chemotherapy in patients with T3 laryngeal squamous-cell carcinoma

G.C.T.E. Garcia[1], P. Gorphe[1], S. Ammari[1], C. Even[1], Y. Tao[1], C. Balleyguier[1], A. Varoquaux[2], F. Bidault[1]; [1]*Villejuif/FR*, [2]*Marseilles/FR (gabrielgarcia1988@gmail.com)*

Purpose: After induction chemotherapy (ICT) for head and neck squamous cell carcinomas (SCC) CT scan is used to assess tumour response (TR) but lacks rationalized measurement methods. In T3 laryngeal SCC, vocal cord remobilisation (VCR) is a major TR criterion. We compare the performances of RECIST 1.1, WHO and volumetric methods with CT-scan to predict remobilisation.
Methods and Materials: Contrast-enhanced cervical CT-scans were acquired before and during ICT from 43 patients treated for T3 laryngeal SCC with vocal cord fixation. Tumour size was assessed according to RECIST 1.1 (1D), WHO (2D) and volumetric (3D) methods. Tumour shrinkage after ICT was evaluated as predictor of VCR. Areas under the curve (AUC) of receiver operating characteristic curves were compared and sensitivity and specificity of optimal cutoffs were determined.
Results: AUCs were 0.763 (95%CI [0.615; 0.911]) for 1D, 0.779 (95%CI [0.63; 0.971]) for 2D and 0.763 (95%CI [0.623; 0.904]) for 3D evaluations with no significant difference (1D vs 2D p = 0.78; 2D vs 3D p = 0.66; 1D vs 3D p = 1). Optimal cutoffs were -29% (Se = 70.8%; Sp =68.4%), -47% (Se = 91.7%; Sp = 63.2%) and -64% (Se = 75%; Sp = 63.2%) for 1D, 2D and 3D evaluation, respectively.
Conclusion: RECIST 1.1, WHO or volumetric measurements with CT-scan equally predict, VCR after ICT in patient with T3 laryngeal SCC. Cutoff values were very close to these methods' usual thresholds, we could thus use them to assess TR when vocal cord fixation is absent.

B-0251 14:08

Correlation between locally advanced HPV positive oropharyngeal squamous cell carcinoma and quantitative MRI parameters

M. Leali, E. Tononcelli, E. Lleshaj, A. Grammatica, M. Ravanelli, D. Farina, R. Maroldi; *Brescia/IT (michela.leali@icloud.com)*

Purpose: to evaluate the association between quantitative MR parameters and HPV status in advanced oropharyngeal squamous cell carcinoma (OPSCC).
Methods and Materials: 24 patients with locally advanced OPSCC underwent pre-treatment MR. Histogram analysis was performed on TSE-T2, DWI and post-gadolinuim 3D-VIBE sequences before and after application of a Laplacian of Gaussian spatial scale filter (ssf) at the primary tumour site. Search of HPV DNA on biopsies was performed to evaluate HPV status. Mann-Whitney test was used to assess differences in quantitative MR parameters between HPV+ and HPV- groups.
Results: 10 patients were HPV-positive (41,7%). Mean ADC was significantly lower in HPV+ compared to HPV- patients (0.83 vs 1.04 x $10^{-3}mm^2/s$ respectively, p=0.015). Skewness measured on 3D-VIBE with 1mm-ssf was significantly higher in HPV+ compared to HPV- patients (p=0.03).
Conclusion: quantitative MR parameters, especially mean ADC, may reflect microstructural differences between HPV+ and HPV- OPSCC.

B-0252 14:16

DWI can distinguish between morphologically differentiated and undifferentiated thyroid carcinoma

S. Schob; *Leipzig/DE (stefan.schob@medizin.uni-leipzig.de)*

Purpose: Thyroid carcinomas represent the most frequent endocrine malignancies. Recent studies were able to distinguish malignant from benign nodules of the thyroid gland with diffusion weighted imaging (DWI). Although this differentiation is undoubtebly helpful, presurgical discrimination in between well differentiated and undifferentiated carcinomas would be crucial in order to define the optimal treatment algorithm. Therefore the aim of this study was to investigate if DWI is able to differentiate between differentiated and undifferentiated subtypes of thyroid carcinomas.
Methods and Materials: 14 patients with different types of thyroid carcinomas who received preoperative DWI using a RESOLVE sequence were included in our study. In all lesions ADCmin, ADCmean and ADCmax and D were estimated on basis of region of interest (ROI) measurements after coregistration with T1 weighted, postcontrast images. All tumours were resected and analysed histopathologically. Ki-67 index, p53 synthesis, cellularity, total and average nucleic areas were estimated using ImageJ version 1.48
Results: ANOVA revealed a statistically significant difference of ADCmean values between differentiated and undifferentiated thyroid carcinomas (p=0.022). Spearman-Rho calculation identified significant correlations between ADCmax and cell count (r=0.541, p=0.046) as well as between ADCmax and total nuclei area (r=0.605, p=0.022).
Conclusion: DWI can distinguish between differentiated and undifferentiated thyroid carcinomas.

B-0253 14:24

Prognostic significance of pre-treatment FDG PET-CT parameters in laryngeal and hypopharyngeal squamous cell carcinoma

S. Vaidyanathan[1], R. Prestwich[1], F. Slevin[1], G. McDermott[1], E. Ermis[2], P. Gopalan[1], A.F. Scarsbrook[1]; [1]*Leeds/UK*, [2]*Kahramanmaraş/TR (srivaidyanathan@gmail.com)*

Purpose: To evaluate the prognostic value of adaptive-threshold based metabolic tumour volume (MTV), maximum (SUV_{max}) and mean (SUV_{mean}) standardised uptake value and total lesional glycolysis (TLG) measured prior to radiotherapy on FDG PET-CT in patients with laryngeal and hypopharyngeal cancer.
Methods and Materials: 43 patients with locally advanced laryngeal or hypopharyngeal squamous cell carcinoma who underwent ^{18}F-FDG PET-CT before curative-intent (chemo)radiotherapy in a single centre (2009-2014) were retrospectively analysed. Imaging parameters including SUV_{max}, SUV_{mean}, MTV and TLG were calculated for both tumour and nodal disease using an adaptive thresholding method (Homburg algorithm). Univariate and multivariate analyses were used to identify clinico-pathological and imaging variables associated with progression-free survival (PFS) and overall survival (OS). Univariate analyses included the following variables: age, sex, T and N classifications, overall TNM stage, tumour size, nodal size, SUV_{max}, MTV, and TLG.
Results: The median SUV_{max}, MTV, and TLG were 11.1 (range, 0-53.9), 3.5 ml (2.0-42.9 ml), and 72.5 g (0-744.9 g) respectively. Univariate analyses showed that there were significant correlations between T stage (p = 0.013), primary tumour MTV (p = 0.031) and nodal TLG ([= 0.001) and overall survival. Multivariate analyses revealed that T stage, tumour MTV and nodal TLG were independent variables for PFS.

Conclusion: Pre-treatment values of MTV and TLG are independent prognostic factors in patients with laryngeal and hypopharyngeal tumours and may help predict subsequent patient outcome.

B-0254 14:32

Utility of T2-weighted magnetic resonance imaging, MR spectroscopy and diffusion-weighted imaging of thyroid to differentiate malignant from benign nodules

P. Yadav; *Pune/IN (yadavpratiksha@hotmail.com)*

Purpose: To evaluate the diagnostic performance of T2WI mean signal intensity combined with diffusion-weighted imaging and MR spectroscopy to differentiate thyroid carcinomas from benign thyroid nodules.
Methods and Materials: Study included 32 patients (12years to 67years) who had 41 solid thyroid nodules detected on high resolution ultrasonography. T2WI,T1WI & STIR sequences were acquired followed by DWI and MR spectroscopy. T2W mean signal intensity and ADC values of each thyroid nodule were calculated.MRS was done to observe the choline value. Histopathology was done in all the cases after MRI.
Results: Papillary carcinoma detected in 14 lesions,metastasis in 5 and lymphoma detected in one lesion ,5 detected thyroiditis and 7 lesions detected adenoma and 9 lesions confirmed colloid nodule on histopathology.T2W SI was lower in the thyroid carcinoma ranging 205-298 mean was 247.4 as compare to benign thyroid nodules ranging from 275-512, mean 391.72. Mean ADC values was 1.32+-38 x10^{-3} mm^2/s in malignant nodules and was 2.58+-53 x10^{-3} mm^2/s in benign nodules. ADC value was significantly lower in malignant nodules as compare to benign (p<0.001). MRS showed high choline value in the malignant nodules though choline was not raised in the benign nodules.Sensitivity to detect malignant lesion by DWI was 80% (95% CI 58.4-91.93),specificity 85.7%,(95%CI 65.36-95.02),PPV 84.2% and NPV 81.82%. Sensitivity by MRS was 75%(95%CI 53.13-88.8) and specificity 90.48%,(95% CI 71.09-97.35), PPV 88.24% and NPV 79.17%.
Conclusion: MRI thyroid is an efficient non-invasive imaging modality to differentiate thyroid carcinoma from benign nodules on the basis of MRI T2W SI, ADC values and MR spectroscopy.

B-0255 14:40

Is quantitative ultrasound elastography valuable in the assessment of cervical lymphadenopathy?

V. Selvadasan, A. Prakash, V. Chowdhury, A. Gulati, S. Jain, A. Garg; *New Delhi/IN (dr.vinayagamani@gmail.com)*

Purpose: Cervical lymphadenopathy frequently poses a diagnostic challenge as neither clinical nor imaging assessment can reliably differentiate between benign and malignant lymphadenopathy. Non-invasive differentiation between the two may help to reduce the number of FNAC or biopsy. The purpose of this study was to evaluate whether the new ARFI technique (Virtual Touch Quantification), in conjunction with greyscale sonography and colour Doppler, can help in the characterisation and differentiation of benign from malignant cervical lymphadenopathy.
Methods and Materials: Fifty adult patients with cervical lymphadenopathy were included in the study and sonoelastography of the enlarged nodes was done. ARFI (SWV) measurements in benign and malignant enlarged lymph nodes were compared using the Student *t* test and ROC curve was used to arrive at the Youden index , sensitivity, specificity, PPV, NPV and diagnostic accuracy.
Results: Sonographic patterns indicative of malignancy includes heterogenous echopattern, short axis/long axis ratio >0.5, absent echogenic fatty hilum and mixed vascular pattern. The sensitivity, specificity, PPV, NPV and accuracy in differentiation between the benign and malignant lymph nodes using ARFI elastography was 79.17%, 100% , 100%, 83.9% and 89.9% respectively. ROC curve analysis of SWVs for differentiation between the malignant and benign lymph nodes gave a cut-off value of 2.8m/s with an area under curve (AUC) of 0.892.
Conclusion: ARFI imaging technique provides quantitative information about the tissue stiffness of cervical lymph nodes which also complement sonography non-invasively and objectively in characterisation and differentiation of benign from malignant lymph nodes.

B-0256 14:48

Can qualitative and semi-quantitative ultrasound elastography contribute to the diagnosis of salivary gland tumours?

C.Z. Karaman, Y. Durum, A. Eryılmaz, F. Taşkın, E.H. Navaei; *Aydın/TR (yasemindurum@gmail.com)*

Purpose: The aim of this study was to investigate the contribution of qualitative and semi-quantitative strain sonoelastography in differential diagnosis of salivary gland tumours.
Methods and Materials: Fifty-seven patients (29 men and 28 women) with salivary gland mass, aged between 16 and 85 years (mean age 56,12±15) were enrolled in this prospective study. All masses were examined by qualitative and semi-quantitative strain elastography techniques. The most representative images were recorded to be evaluated according to a 4-scale scoring system. Score 1-2 were accepted to be benign and 3-4 malignant. The strain index of the mass in respect to surrounding parenchyma was measured.
Results: Fifty-three (%92.9) masses were located in the parotid gland, the rest in the submandibular gland (7.02%). Forty-seven (82.4%) masses were benign, and pleomorphic adenomas lesions were in the majority (44.6%). There were 10 malignant lesions (17.5%). Sensitivity, specificity, PPV and NPV were calculated for both qualitative scoring and strain index ratio. For qualitative assessment these values were 90%, 44,6%, 25,7%, 95,4%, respectively. Using the ROC analysis, sensitivity and specificity at the cutoff value of 2.44 for strain ratio were 70% and 100%, respectively (P=0.002). All the lesions with strain indices were malignant.
Conclusion: High sensitivity and negative predictive values for qualitative method may be better to recognise benign rather than malignant. High specificity of strain ratio at proper cutoff values may be helpful for verification of malignant tumours. Qualitative and semi-quantitative sonoelastography may be helpful in deciding the nature of salivary gland masses.

B-0257 14:56

Combination of diffusion weighted imaging and dynamic contrast-enhanced MRI improves differentiation of benign and malignant orbital masses

E.Y.L. Dai, A.T. Ahuja; *Hong Kong/HK (dai.eunice@gmail.com)*

Purpose: Diffusion weighted imaging (DWI) and dynamic contrast-enhanced MR imaging (DCE-MRI) allow assessment of lesion cellularity and vascularity respectively. We evaluated the combined use of DWI and time-signal intensity curve (TIC) analyses to differentiate benign from malignant orbital masses.
Methods and Materials: We retrospectively studied 54 patients with orbital masses who underwent MR imaging using DWI and DCE-MRI at either 1.5 or 3 Tesla. We calculated apparent diffusion coefficient (ADC) values and performed qualitative assessment of TIC curve patterns generated by DCE-MRI.
Results: 47 (87.0%) patients had benign orbital masses (4 benign tumours, 19 cavernous hemangiomas, 15 inflammatory lesions, 9 vascular malformations); while 7 (13.0%) patients had malignant orbital masses. All malignant masses were histologically proven while benignity was established by histology or clinical follow-up. Mean ADC values were significantly different for benign and malignant subgroups (ANOVA p=0.007). Benign masses had significantly higher ADC values compared with malignant masses (1.49±0.50 vs 0.97±0.45, p=0.01). Type of TIC curve was also significantly different amongst subgroups (p=0.04). 71.4% of benign masses had type 1 TIC pattern while none of the malignant lesions had type 1 pattern (p=0.01). Cavernous hemangiomas were predominantly associated with type I TIC pattern, and the predictive value of a type 1 TIC pattern for cavernous hemangioma was associated with high sensitivity (89.5%) and modest specificity (60.0%). In comparison, vascular malformations had heterogeneous TIC patterns.
Conclusion: Benign and malignant orbital masses have significantly different diffusion and perfusion characteristics and combination of ADC values and TIC pattern analysis improves their differentiation.

B-0258 15:04

Usefulness of microvascular ultrasonography in differentiation between pleomorphic adenoma and Warthin tumour of salivary glands

S. Chae, I. Ryoo, S. Suh, A. Park, M. Ku, H. Seol; *Seoul/KR (csyloo@naver.com)*

Purpose: Pleomorphic adenoma (PA) and Warthin tumour (WT) are the most common salivary gland tumours. It is important to differentiate between them because at least partial parotidectomy is necessary for PA, whereas enucleation is sufficient to WT. This study aimed to evaluate the usefulness of vascular pattern analysis using microvascular ultrasonography in differentiation of PA and WT of salivary glands.
Methods and Materials: Sixty-three patients with pathologically proven PA (n=39) and WT (n=24) were included. For all tumours, gray-scale, power-Doppler and microvascular ultrasonography (Superb-Microvascular Imaging) were performed. Differences between vascular patterns (internal vascularity and vascular distribution) on power-Doppler and microvascular ultrasonography and other sonographic features (size, shape, echogenicity, border, cystic change and heterogeneity) on gray-scale ultrasonography for PA and WT were evaluated. Comparison of diagnostic performance of gray-scale with power-Doppler ultrasonography and gray-scale with microvascular ultrasonography was performed. The level of inter-observer agreement of two reviewers in diagnosing tumours was evaluated.
Results: No sonographic features on gray-scale ultrasonography showed significant difference between two tumours. Internal vascularity and vascular distributions on power-Doppler (p=0.002 and 0.008, respectively) and microvascular ultrasonography (all p<0.0001) were significantly different. Diagnostic accuracy of gray-scale with microvascular ultrasonography (79.4%) is higher than that of gray-scale with power-Doppler ultrasonography (73.0%).

This difference was significant according to McNemar test (p=0.004). Inter-observer agreement was excellent in diagnosing tumours on both gray-scale with power-Doppler ultrasonography(κ=0.83) and gray-scale with microvascular ultrasonography(κ=0.94).
Conclusion: Vascular pattern analysis using microvascular ultrasonography with other sonographic features is helpful in differentiation between PA and WT in salivary glands.

B-0259 15:12

Thyroid nodules: utility of ultrasound combined to cytopuncture results in diagnosing malignant nodules that must be biopsied
G. Berrada, N. El Benna, O. Amriss, N. Moussali; *Casablanca/MA (berradaghita1988@gmail.com)*

Purpose: To highlight the high utility and accuracy of the ultrasound-guided cytopuncture of the suspect thyroid nodules detected by ultrasonography in assessing malignancy risk and selecting patients for surgery.
Methods and Materials: 19 patients were eligible to participate in a prospective study from March to June, 2016. The mean age of our patients was 51 years old (range, 29-65). It was about 17 women and 2 men. B-scan Ultrasonography, color Doppler imaging and pulsed method was performed using a linear high frequency probe (5-18MHz) (HITACHI). The cytopuncture was performed using 22-gauge fine needle.
Results: Using the risk stratification system for thyroid nodules TIRADS (Thyroid Imagind Reporting And Data System),we found 7 TIRADS "category 3" nodules (36,85%), 7 TIRADS "category 4a" nodules (36,85%) and 5 TIRADS "category 4b" nodules (26,3%). The cytologic results revealed 1 patient with benign cytology (5,27%), 6 with suspect nuclear atypia (31,58%), 5 with cytologic atypia that needs a checking (26,32%), 7 with hypocellular material and hematic cytology (36,85%).
Conclusion: The ultrasonography is the first line examination to select suspect thyroid nodules but the fine-needle cytopuncture of these nodules is the most efficient examination to assess malignancy risk to select the nodules that must be confirmed by tissue examination. Hence the utility of the duo ultrasonography / Ultrasound-guided cytopuncture.

B-0260 15:20

MRI-based treatment response assessment for head and neck tumours chemoradiotherapy
N. Plakhotina, D. Kuplevatskaya, A. Smirnova, M. Anishkin, A. Mikhailov; *St. Petersburg/RU (mikhail.a.cherkashin@gmail.com)*

Purpose: To create and implement MRI-based treatment response assessment algorithm in head and neck tumours after chemoradiotherapy (CRT).
Methods and Materials: Study involved 37 patients (age 41-76 years). 1.5T scanner was used. Sagittal T2, T1 WI, axial T1 WI with FS with large-field scanning were used, axial T2 STIR WI and sagittal or coronal T2 STIR WI were added depending on tumour localisation. Axial DWI and ADC maps were calculated. Post-contrast T1 WI sequences with FS were performed in 3 planes. Slice thickness 1-3 mm. MR examinations were performed before CRT and each 3 months after. For local failure confirmation, PET/CT was performed in 7 cases.
Results: In 37.8% (14 patients) early postradiation changes were detected. DWI helped to distinguish between tumour fragments with high cellularity and oedema and to trace increasing of ADC as sign of tumour regression. If area of pathological changes did not extend beyond area of radiation exposure, such changes were regarded postradiation alterations. Increasing postradiation necrosis was observed on average up to 8 months, with later swelling decreasing. Signs of clinically significant postradiation necrosis were not detected in our studies. In 16 patients tumour regression signs were detected. In 4 patients tumour progression was detected. All cases were confirmed by PET/CT.
Conclusion: Reactions of head and neck tumours after CRT characterised by heterogeneity. Most MR characteristics of tumour progression and postradiation changes are similar. Standard MRI is not enough to differentiate them, it is necessary to perform DWI and compare with PET/CT.

B-0261 15:28

Accuracy of diffusion-weighted imaging and dynamic contrast-enhanced MRI for differentiating benign from malignant non-cystic lesions in floor of the mouth
Y. Yuan, X. Tao; *Shanghai/CN (yuany83@163.com)*

Purpose: The aim was to evaluate the potential use of diffusion-weighted imaging (DWI) and dynamic contrast-enhanced MRI (DCE-MRI) in differentiating benign from malignant lesions in floor of the mouth (FOM).
Methods and Materials: A retrospective review was conducted of patients with pathologically confirmed non-cystic FOM lesions between January 2010 and December 2014. The apparent diffusion coefficient (ADC) and time-signal intensity curve (TIC) pattern were assessed. Receiver operating characteristic (ROC) and logistic regression analyses were performed to evaluate their differential value and association with malignancy.
Results: Significant differences were detected between benign and malignant lesions in ADC value and TIC pattern (p=0.015 and p<0.001). The areas under the curve (AUCs) for ADC and TIC pattern were 0.754 and 0.704, respectively. The joint association of ADC and TIC with malignancy was most prominent in lesions with both ADC≤1.23×10^{-3} mm^2/s and plateau/wash-out TIC pattern. The AUC of combined use of ADC value and TIC pattern was 0.820 (best sensitivity: 98.3%; best specificity: 88.9%).
Conclusion: Our results suggested that DWI and DCE-MRI contribute to differential diagnosis of non-cystic MOF lesions, especially when used in combination. Additional larger studies are warranted to confirm our findings.

Evaluation of CAD-RADS in coronary CTA: man vs machine
B. Szilveszter, M. Kolossváry, J. Karády, Z. Bagyura, M. Károlyi, A. Panajotu, Á. Jermendy, B. Merkely, P. Maurovich-Horvat; *Budapest/HU (szilveszter.balint@gmail.com)*

Purpose: The Coronary Artery Disease - Reporting and Data System (CAD-RADS) has been recently introduced to facilitate interdisciplinary communication of coronary CT angiography (CTA) results. The accuracy of readers to determine CAD-RADS has not been tested. Our aim was to assess readers' performance ("Man") using an automated structured reporting software ("Machine").
Methods and Materials: We prospectively analysed the reports of 149 patients who underwent coronary CTA. The scans were read by four expert readers with 2-6 years' experience using a structured reporting platform blinded to the automated CAD-RADS results. The readers recorded the CAD-RADS stenosis categories (0,1,2,3,4A,4B,5) and modifiers (V,N,S,G). The reporting platform ,,machine" automatically determined the CAD-RADS classification, which was validated previously and applied as the reference standard. We compared reader's and the machine's performance using Cohen's kappa.
Results: The agreement in stenosis categories was 93.3%, kappa:0.80. Whereas the agreement in modifiers was only 85.9%, kappa:0.73. Stenosis categories: 0: 18.1% vs 16.8%, 1: 31.5% vs 24.2%, 2: 19.5% vs 24.8%, 3: 9.4% vs 12.1%, 4A: 6.0% vs 8.7%, 4B: 0.0% vs 0.7% and 5: 5.4% vs 5.4%, reader vs machine, respectively. Modifiers: N: 10.1% vs. 7.4%, V: 9.4% vs 17.5%, N: 10.7% vs 12.1%, G: 2.7% vs 3.4%, S:4.7% vs 8.7%, readers vs machine, respectively.
Conclusion: Despite the fact that automated CAD-RADS classification uses data filled in by the readers it performs better than the clinical readers by preventing human errors and inattention. Structured reporting platforms with automated score calculations might improve data quality and support clinical decision making.

A new computer-aided decision (CAD) system based on artificial neural networks for detecting breast lesions on MRI
M. Telegrafo, V. Bevilacqua, S. De Ceglie, A. Stabile Ianora, G. Angelelli, M. Moschetta; *Bari/IT (mikitele@hotmail.it)*

Purpose: To evaluate the role of a computer-aided decision (CAD) system based on medical imaging for detecting regions of interest (ROI) including breast lesions on breast MRI, having contrast-enhanced MR and hystological findings as the reference standard.
Methods and Materials: 20 patients underwent MR examination on a 1.5T device with a diagnostic protocol including morphological (T2-TSE, STIR) and dynamic (THRIVE) sequences. The overall number of the obtained slices from MR examinations was 3735. An innovative preliminary step for segmenting

ROIs was used. Significant features were extracted from ROIs in order to obtain artificial neural networks (ANNs) architecture-based on error back propagation training algorithm. CAD sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and diagnostic accuracy for detecting ROIs including breast lesions on breast MRI were calculated.
Results: 192/3735 slices were considered as positive basing on the proposed CAD system while the remaining 3543/3735 were considered as negative. By comparing the obtained results with the reference standard, 102 false positive and 4 false negative slices were found. Sensitivity, specificity, PPV, NPV and diagnostic accuracy for the proposed CAD system were respectively of 96%, 97%, 47%, 100% and 97%.
Conclusion: The high negative predictive value and diagnostic accuracy of the proposed CAD System allows to select ROIs on breast MRI excluding areas which do not require further assessment.

B-0264 14:25

Why big image analytics is essential for imaging biobanks: an osteoporosis radiomics study

K.S. Mader[1], T.J. Re[2], J. Cyriac[2], B. Stieltjes[2]; [1]*Zurich/CH*, [2]*Basle/CH (kevinmader@4quant.com)*

Purpose: Imaging biobanks are becoming increasingly popular and active efforts from a number of different institutions in Germany, the UK, and US are making significant progress in collecting, storing, and organising large sets of image data. These large cohorts of data contain very diverse data from different sources, with different resolutions, and quality which makes large-scale analysis challenging. In this study, we aim to develop large-scale tools for processing and extracting meaningful bone information and statistics from a heterogenous set of CT data collected for other purposes.
Methods and Materials: The training and validation data are created by a trained radiologist that manually contoured all of the bone regions in 179 images from 60 different patients. These segmentations were augmented by adding noise and deformations and were then used to train a multi-layered convolutional neural network (CNN) until both the training and validation had above 95%.
Results: Our tools link the PACS directly to a computing cluster and allow the analysis to be run on any CT dataset immediately and scales linearly to 133,000 patients per hour. The results were very robust against noise, contrast, different body regions, energy, and dose settings. Compared to state of the art threshold and morphology approaches, it had 1000 fewer misclassified pixels at TPR of 99%.
Conclusion: The study presents the basis for conducting large scale studies to extract meaningful quantitative information from imaging biobanks. To analyse 80M images, these algorithms could be run in 10 days on a cluster (60 nodes).

Fully-automated mean bone density calculation on 1,000,000 CT scans: groundwork for opportunistic osteoporosis screening

T.J. Re, A.W. Sauder, E.M. Merkle, B. Stieltjes; *Basle/CH (tomjre@gmail.com)*

Purpose: Osteoporosis is estimated to causes more than 8.9 million fractures annually worldwide. Risk assessment of osteoporotic fracture currently relies on dual-energy x-ray absorptionmetry measurement of bone mineral density. We evaluate the possibility of utilizing CT data already present in our PACS for opportunistic screening of osteoporotic fracture risk.
Methods and Materials: We developed a software package, named “PACS Crawler”, for identifying, downloading, and post-processing CT images from the PACS. It was used to automatically identify all CT series performed between the years of 2010 to 2015 and currently stored in the PACS. It then randomly choose 1,000,000 samples and all samples were automatically post-processed to calculate a mean bone density and standard deviation from density range and shape-based bone segmentation.
Results: A total of approximately two million (1,903,715) CT series were identified in the PACS in the selected six-year period from which 1,000,000 samples were randomly selected. Fitted trend lines were calculated as f(x)= 245.5x-0.278 with R2=0.16 for females and f(x)= 219.0x-0.208 with R2=0.30 for males. Thus, as expected, bone density decrease over age was found to be more pronounced in women.
Conclusion: Automated bone density extraction from CT data using the developed pipeline is feasible and delivers plausible results. Future studies will be performed to evaluate the value of these measurement considering fracture risk prediction.

B-0266 14:41

Automatic vertebrae localisation in arbitrary field-of-view spine CT using decision forests

A. Jiménez-Pastor, E. Tomás-González, Á. Alberich-Bayarri, D. García-Juan, F. García-Castro, L. Martí-Bonmatí; *Valencia/ES*

Purpose: Diagnosis of spine abnormalities, vertebrae deterioration and bone characterisation from CT scans is a frequent task of radiologists. Our goal was to propose an algorithm based on supervised classification forests to automatically locate, identify and characterise vertebrae in spine CT scans.
Methods and Materials: The artificial intelligence (AI) technique used in this project was decision forests, based on supervised learning. For each voxel, hundreds of intensity-based features and their location were used as inputs and their corresponding label as output. These labels were: C1-C7, T1-T12, L1-L5, S1, B (vertebrae and background). The first step consisted on dataset preparation for training the forest algorithm. To build the input data, a total of 200 spine CT scans with arbitrary field of views were used, including healthy and pathological studies. The scans were manually labelled by selecting vertebrae centroids. To determine which label corresponded to each voxel, first of all we calculated the probability of each voxel to be part of each vertebra. Once the probabilities map was obtained, the label matrix was calculated. Finally, we trained our decision forest and then we tested it using new spine scans.
Results: The decision forest created to automatically determine vertebrae locations from new CT datasets was tested against 20 new cases with a mean performance of 95% correct classification of the voxels of a vertebra.
Conclusion: Automatic localisation and identification of vertebral bodies can be addressed with excellent results by all methods to improve diagnosis workflow and characterise bone structure.

B-0267 14:49

Quantitative CT metrics outperform pulmonary function testing for diagnosis of bronchiolitis obliterans syndrome after lung transplantation

E.J.M. Barbosa Jr.[1], H. Shou[1], S. Simpson[1], N. Tustison[2], J. Gee[1], J. Lee[1]; [1]*Philadelphia, PA/US*, [2]*Charlottesville, VA/US (eduardo.mortani@gmail.com)*

Purpose: Chronic lung allograft dysfunction after lung transplantation (LTx) manifests as a sustained decline in FEV1, indicative of bronchiolitis obliterans syndrome (BOS). Our hypothesis is that quantitative CT (QCT) metrics may be superior to PFTs and semi-quantitative image scores (SQS) to diagnose BOS.
Methods and Materials: Paired inspiratory-expiratory CT scans and PFTs of 178 LTx patients were analysed retrospectively, and separated into BOS (79) and non-BOS (99) cohorts. SQS were assessed by 2 radiologists and graded from 0-3 for features including mosaic attenuation and bronchiectasis. PFTs included FEV1 and FVC. QCT included lung volumes and air trapping volumes, by lobe. Multivariate regression modelling was performed using logistic and principal component analysis.
Results: Multivariate logistic regression using QCT metrics outperformed models using SQS or PFTs (area under the ROC curve of 0.95, 0.64, 0.80; respectively), to distinguish BOS from non-BOS LTx patients. Principal component regression of normalised variables determined that the first 3 components captured 79% of the variability of data, and the first two components heavily weighted a linear combination of QCT metrics in lieu of PFTs or SQS to predict BOS status.
Conclusion: While no single QCT metric was sufficient to determine BOS status, the constellation of QCT metrics dominate both multivariate logistic and principal component regression and are superior to PFTs and SQS to predict BOS status. This suggests that latent information on paired volumetric CT may be useful for early diagnosis of BOS in LTx patients, via computation of QCT metrics and multivariate modelling.

B-0268 14:57

Semi-automatic software for time-efficient CT-based quantification of abdominal adipose tissue

A. Schaudinn, N. Linder, A. Hudak, R. Stange, N. Garnov, G. Stocker, U. Hacker, T. Kahn, H. Busse; *Leipzig/DE (Alexander.Schaudinn@medizin.uni-leipzig.de)*

Purpose: Quantification of visceral and subcutaneous adipose tissue (VAT, SAT) based on CT-images is gaining importance in risk assessment in patients with metabolic disease or cancer, or prior to abdominal surgery. The aim of this study was to present a custom-made tool (*MatLab*-tool) for semi-automatic AT quantification.
Methods and Materials: Twenty normal to overweight patients (14 male, 6 female, mean BMI: 29.4 kg/m²) underwent IRB-approved abdominal CT (Somatom Sensation 64, Siemens, slice thickness 5 mm). Total volumes of VAT (V_{VAT}) and abdominal SAT (V_{SAT}) (diaphragm to pelvic floor) were determined with MatLab-tool using supervised automatic segmentation (under MatLab, MathWorks). Default AT-range was set between -190 and -30 HU. Analyses were repeated with a common commercial tool (SliceOmatic,

TomoVision). Agreement was determined by coefficients of determination (R^2) and standard deviations (SD) of the volume differences (Bland-Altman).
Results: Mean volumes were V_{VAT}=5.6L and V_{SAT}=8.6L. Processing involved an average of 83 slices and took a mean time of 15min (MatLab-tool) and 41min (SliceOmatic) per patient. Coefficient R^2 was 0.99 in both compartments while bias and SD (SD%) were 108ml and 73ml (1.2%) for V_{VAT} and -221ml and 165ml (1.9%) for V_{SAT}.
Conclusion: The presented tool provides a reliable and time-efficient option for CT quantification of adipose tissue, with an average time-saving of 26 minutes for each patient compared to commercial tools.

B-0269 15:05

Using 3D image features for the prediction of survival in patients after liver transplantation

D. Pinto dos Santos, M. Wand, S. Brodehl, C. Li, R. Klöckner, T.C. Hadler, M. Sprinzl, E. Schömer, P. Mildenberger; *Mainz/DE (pintodos@uni-mainz.de)*

Purpose: To explore whether automated extraction of 3D imaging features from CT scans and machine learning allow for the prediction of survival in patients with liver cirrhosis undergoing liver transplantation.
Methods and Materials: A total of 313 patients undergoing liver transplantation for final stage liver cirrhosis between 1989 and 2015 were included in this study. Clinical data, such as transplantation date, patient characteristics and survival were retrieved from the patient's records. Relevant imaging studies (i.e. CT scans of the abdomen) were retrieved from the PACS. An algorithm was developed that applied a linear max-margin classifier (SVM) to a bag-of-visual-words descriptor based on histograms of oriented 3D gradients. A pipeline was then designed where CT image data was processed through this algorithm. Results were validated on a separate randomised test dataset. Both, training and validation set were randomly sampled such that an equal number of positive and negative cases were present. Visual features identified by the algorithm could then be visualized on the respective CT data to allow for anatomical correlation.
Results: The training process took a few hours of computation time and was run on a standard workstation using the training dataset. Thereafter, the classification process based on the trained model could be performed within a few seconds per scan using the testing dataset. With this setup we achieved a prediction-accuracy of around 80% on the validation dataset.
Conclusion: Low-level 3D image feature statistics in CT scans can potentially help identifying patients that have a longer survival after liver transplantation.

Machine learning in whole-body oncology: fully automatic, multi-organ segmentation in whole body-MRI, using classification forests and convolutional neural networks

I. Lavdas, B. Glocker, D. Rueckert, H. Mair, A. Sandhu, E. Aboagye, A.G. Rockall; *London/UK (a.rockall@imperial.ac.uk)*

Purpose: As part of a programme to develop automatic tumour detection methodology for whole-body MRI, we initially developed and compared two algorithms for automatic, multi-organ segmentation in healthy volunteers.
Methods and Materials: Algorithm A was based on 'classification forests' and algorithm B on 'convolutional neural networks'. Healthy volunteers were scanned with multi-parametric whole-body MRI at 1.5T. MRI data were used as input data to the algorithms, while training was based on manual annotations by clinical experts. 5-fold cross-validation experiments were run on 34 subjects. We report the Dice overlap coefficient between the manual and automatic segmentations. Performance between the two algorithms was compared with a Mann Whitney U test.
Results: Both methods facilitated simultaneous multi-organ segmentation. The algorithms were efficiently trained using a relatively small number of data, an important consideration in the clinical setting. The mean Dice coefficient (±SD) for algorithms A/B, was: right and left lung: 0.92±0.02/0.94±0.01, liver: 0.90±0.02/0.91±0.04, gallbladder: 0.38±0.25/0.25±0.22, right kidney: 0.79±0.06/0.85±0.05, left kidney: 0.73±0.13/0.74±0.17, spleen: 0.67±0.15/0.72±0.11, pancreas: 0.55±0.11/0.54±0.13, bladder: 0.74±0.18/0.70±0.22, spine: 0.83±0.03/0.86±0.05, pelvic bones: 0.74±0.05/0.78±0.05. Algorithm B returned significantly higher Dice coefficient than algorithm A ($P<0.05$) for both lungs, the liver and the spinal/pelvic bones.
Conclusion: We report two robust algorithms for automatic multi-organ segmentation in whole-body MRI with good agreement to manual segmentations performed by clinical experts. Algorithm B outperforms algorithm A in terms of Dice coefficient for a number of structures, but with the penalty of training complexity/time. The methods are currently being optimised for automatic tumour lesion detection.

B-0271 15:21

Fully automated segmentation of rectal carcinomas using supervised learning techniques with expert-reader input

S. Trebeschi[1], J.J.M. van Griethuysen[1], H.J.W.L. Aerts[2], D.M.J. Lambregts[1], M.J. Lahaye[1], F.C.H. Bakers[3], N.H.G.M. Peters[4], M. Verheij[1], R.G.H. Beets-Tan[1]; [1]*Amsterdam/NL*, [2]*Boston, MA/US*, [3]*Maastricht/NL*, [4]*Heerlen/NL (j.v.griethuysen@nki.nl)*

Purpose: To perform fully automated segmentation of locally advanced rectal carcinomas (LARCs) via a supervised learning technique (SLT) trained and validated using delineations performed by expert-readers.
Methods and Materials: We selected the MRI scans (1.5T, T2-weighted and b1000 DWI) of 140 LARC-patients. Manual whole tumour volume delineation, performed by an expert radiologist (on b1000 DWI, was used as the standard reference). From each image, 500 pixels within the tumour and 500 pixels outside the tumour were randomly sampled. For each pixel, we extracted the surrounding patch of 25x25 in all MRI sequences. By fitting the resulting three patches as color channels, we could build a multiparametric representation of the image. The architecture consisted of three convolutional layers. A fully connected layer of 256 neurons was placed between the convolutional layers and the output layer. From each patient, 1000 patches were extracted. Both classes were balanced due to randomised sampling procedure. Patients were randomly and equally divided between training and testing.
Results: The algorithm was trained until it reached a stable condition. The trained algorithm was then applied on the test set, reaching an AUC of 0.94 based on the probability of being tumour for each pixel.
Conclusion: Automatic segmentation using an SLT is able to reproduce manual expert segmentations with an AUC of >0.90, suggesting that it can be a time-efficient solution to help delineation in daily practice.

Detection of single-phase CTA-occult vessel occlusions by CT perfusion post-processing predicts favorable response to IV thrombolysis in acute ischaemic stroke

W.G. Kunz, M.P. Fabritius, C. Höhne, L. Havla, M.F. Reiser, W.H. Sommer, K.M. Thierfelder; *Munich/DE (kolja.thierfelder@med.lmu.de)*

Purpose: To study the predictive value of single-phase CTA (spCTA)-occult occlusions detected using CT perfusion-based wavelet-transformed angiography (waveletCTA) on morphologic and clinical response to IV thrombolysis (IVT) in acute ischaemic stroke.
Methods and Materials: Patients were selected from a cohort of 1351 consecutive subjects who underwent multiparametric CT including whole-brain CT perfusion. Inclusion criteria were: (1) significant cerebral blood flow (CBF) deficit, (2) absence of spCTA occlusion, and (3) follow-up confirmed infarction. waveletCTA defines angiographic signal by voxel-based fitting of time attenuation curves to generic contrast bolus curves. waveletCTA was analysed by two blinded readers. Morphologic outcome was defined as final infarction volume divided by CBF deficit volume, of which smaller values were considered favorable. Favorable clinical outcome was defined as decrease in modified Rankin scale (mRS) score of ≥1 from admission to discharge (ΔmRS) and a decrease of National Institutes of Health Stroke Scale (NIHSS) score of ≥3 from admission to 24 hours (ΔNIHSS). Linear and logistic regression analyses were performed to identify independent associations.
Results: Among all included patients (N=106) with negative spCTA, 50 patients (47%) showed an occlusion on waveletCTA. In patients treated with IVT (N=50), regression analyses showed that the presence of a waveletCTA-detected occlusion was an independent predictor of a favorable morphologic outcome (beta=-0.524, p=0.015) and favorable clinical outcome (ΔmRS: OR=9.018, p=0.047; ΔNIHSS: OR=5.810, p=0.024), while it failed to predict outcome in patients who did not receive IVT (N=56; all p>0.05).
Conclusion: Detection of spCTA-occult vessel occlusions using waveletCTA independently predicts favorable response to IVT.

B-0273 14:08

Crossed cerebellar diaschisis in acute ischaemic stroke: impact on morphologic outcome, functional outcome and stroke-related complications

W.G. Kunz, W.H. Sommer, M.P. Fabritius, F. Schuler, M.F. Reiser, K.M. Thierfelder; *Munich/DE (wolfgang.kunz@med.lmu.de)*

Purpose: Crossed cerebellar diaschisis (CCD) is the phenomenon of hypoperfusion of the contralateral cerebellar hemisphere caused by dysfunction of related supratentorial regions. We analysed the clinical relevance of CCD in acute ischaemic stroke as assessed by whole-brain CT perfusion (WB-CTP).
Methods and Materials: Subjects with follow-up confirmed stroke caused by a vessel occlusion of the anterior circulation were selected from a cohort of 1644 consecutive patients who underwent multiparametric CT including WB-CTP. Two blinded and experienced readers evaluated the posterior fossa in terms of CCD presence (CCD+) or absence (CCD-). Final infarction volumes (FIV), modified Rankin scale (mRS) scores at discharge and at 90 days as well as the occurrence of stroke-related complications served as outcome indicators. Linear and logistic regression analyses were performed to determine the association of CCD occurrence with these indicators.
Results: In total, 156 patients matched the inclusion criteria, encompassing 102 patients (65.4%) categorised as CCD- and 54 (34.6%) as CCD+. In linear and logistic regression analyses, no significant association between CCD and FIV (β=-0.440, p=0.972), discharge mRS≤2 (OR=1.897, p=0.320), or 90-day mRS≤2 (OR=0.531, p=0.492) were detected. CCD+ patients had larger supratentorial cerebral blood flow deficits compared to CCD-patients (median: 164ml vs 115 ml; p=0.001). In logistic regression analyses of complications, the occurrence of CCD was associated with parenchymal haematoma formation (OR=4.793, p=0.035).
Conclusion: CCD is a frequent WB-CTP imaging finding in acute anterior circulation stroke. CCD was associated with parenchymal haematoma formation but did not prove to significantly influence either morphologic or functional outcome.

B-0274 14:16

Quantitative assessment of hyperacute cerebral infarction with intravoxel incoherent motion MR imaging: initial experience in a canine stroke model

S. Lu, Q. Gao, X. Xu, X. Liu, H. Shi, S. Liu; *Nanjing/CN (lushan1118@163.com)*

Purpose: To evaluate the feasibility of intravoxel incoherent motion (IVIM) for the measurement of diffusion and perfusion parameters in hyperacute stroke.
Methods and Materials: An embolic ischaemic model was established with an autologous thrombus in 20 beagles. IVIM imaging was performed on a 3.0 T platform at 4.5 h and 6 h after embolisation. Ten b values from 0 to 900s/mm^2 were fitted with a biexponential model to extract perfusion fraction f, diffusion coefficient D, and pseudo-diffusion coefficient D*. Additionally, the apparent diffusion coefficient (ADC) was calculated using the mono-exponential model with the maximum b value. Statistical analysis was performed using the pairwise Student's t-test and Pearson's correlation test.
Results: A significant decrease in f and D was observed in the ischaemic area compared to that in the contralateral side at 4.5h (p=0.001 and p=0.000) and 6h (both p=0.000) after embolisation. No significant difference was observed in D* between the two sides at either time point. f in the stroke area at 6h was significantly lower than that at 4.5h (p = 0.016). A significantly positive correlation was detected between ADC and D in both stroke and contralateral sides at 4.5h and 6h (both p=0.000). Significant correlation between ADC and f was observed in the contralateral side at 4.5h and 6h (p=0.019 and 0.026).
Conclusion: IVIM imaging could simultaneously evaluate the diffusion and microvascular perfusion characteristics in hyperacute stroke.

B-0275 14:24

Automated assessment of early ischaemic damage on CT scans: as good as an expert?

C. Goncalves[1], S. Bowman[1], S. Liyanage[1], R. OrathPrabakaran[1], S. Shah[1], S. Gerry[2], P. Harman[1], P. Guyler[1]; [1]*Southend-on-Sea/UK*, [2]*Oxford/UK*

Purpose: The ASPECTS (Alberta stroke program early CT score) is an established 10-point quantitative topographic score to assess early ischaemic changes on unenhanced CT. Recently, a software (e-ASPECTS, Brainomix Ltd.) has become available for automated scoring of ASPECTS regions and ischaemic damage.
Methods and Materials: 2640 (132 patients x 20 regions) ASPECTS regions were scored by 3 neuroradiologists (NRAD). The ground truth was determined by a corelab with access to follow-up scans (24h CT +_ DWI, CT Perfusion). Sensitivity, specificity and accuracy (SSA) for region-based and score-based analysis, ROC curves, Bland-Altman plots and Matthews correlation coefficients (MCC) relative to the ground truth were calculated and comparisons were made between NRADs and different pre-specified e-ASPECTS operating points. The non-inferiority margin was set to 10% for both sensitivity and specificity on region-based analysis.
Results: Mean time from symptoms onset to baseline CT was 146+/-124 min and median NIHSS was 11 (6-17 interquartile range (IQR)). Median ASPECTS for ground truth on follow-up imaging was 8 (6.5-9 IQR). In the region-based analysis, two e-ASPECTS operating points (SSA of 44%, 93%, 87% and 44%, 91%, 85%) were statistically non-inferior to all three NRADs (all p values <0.003). Both MCCs for e-ASPECTS were higher (0.36 and 0.34) than those of all NRADs (0.32. 0.31 and 0.3).
Conclusion: e-ASPECTS was non-inferior to three neuroradiologists in scoring ASPECTS on unenhanced CTs of acute stroke patients.

B-0276 14:32

MRI stroke protocol: one-stop shop in setting of acute infarct with multiple comorbids

F. Mubarak; *Karachi/PK (fatima.mubarak@aku.edu)*

Purpose: Purpose of our study is to predict progression of infarct size as depicted by venous congestion on susceptibilty weighted imaging (SWI).
Methods and Materials: We retrospectively enrolled all diagnosed cases of stroke from January, 2013 to December, 2015.We included only thirty patients since we had stringent incluion and exclusion criterias. Inculsion criteria were: 1. acute infarct on diffusion weighted imaging (DWI) in MCA, ACA or ICA territory. 2. stroke protocol performed including DWI and SWI on first day and repeat DWI with in three days.Exclusion criteria were: 1. tissue plasmineogen activator (TPA) given.2. Haemorrhagic infarction on initial presentation. 3. Watershd infarcts.Patients were imaged on 1.5T Siemens and 3T Toshiba machines.Venous congestion was defined as numerous and larger veins with greater hypointensity comapred with contralateral hemisphere.We used (ASPECTS) scoring system to estimate infarct size.Degree of venous congestion was graded as none, moderate and extensive on the basis of ASPECTS scoring.SPSS 21 version was used for analysis.The venous congestion grading was used to predict infarct growth.
Results: There was interval increase in ASPECT score on DWI in 15 patients with moderate degree of vascular congestion on SWI. The extent of venous congestion was significantly correlated with infarct growth (P<0.001). In 2 patients there was development of haemorrhage with stable size of infarct. In 13 patients there was no vascular congestion and no increase in size of infarct.
Conclusion: Venous congestion seen in infarcted territory is related to poor prognosis and this can be reliably used as a surrogate marker of oxygen extraction in penumbra.

B-0277 14:40

Intraluminal thrombus detection in patients with acute ischaemic stroke using three-dimensional black blood contrast-enhanced MRI: comparison on SWI

W. Jang, H.-S. Kwak, G.-H. Chung; *Jeonju/KR (weon0315@gmail.com)*

Purpose: To evaluate the accuracy of three dimensional black blood contrast-enhanced MR imaging in the detection of intra-arterial thrombus in patients with acute ischemic stroke
Methods and Materials: 47 patients with acute ischemic stroke involving anterior circulation underwent MR imaging within 6 hours of clinical onset. MR examination included SWI, DWI, PWI, TOF MR angiography, and three dimensional black blood contrast-enhanced T1-weighted imaging. Cerebral angiography for thrombectomy was used as the reference standard to establish the diagnosis of occlusion of intracranial artery. Two neuroradiologists interpreted three data sets as blinded study: 1, DWI + 3D BB contrast-enhanced MR imaging; 2, DWI + SWI; 3, DWI + 3D BB contrast-enhanced MR imaging + SWI. The diagnostic accuracy of both methods was evaluated using ROC analysis.
Results: For both observers, the Az values of the data 1 and 3 set included 3D BB contrast-enhanced MR imaging was significantly higher than that of the data 2 set included only SWI(observer 1; 0.978 vs. 0.915; p = .002, observer 2; 0.977 vs. 0.904; p = .000). The sensitivity of the data 1 set included 3D BB contrast-enhanced MR imaging was significantly higher than that of the data 2 set included SWI (observer 1; 95.7 vs. 83.0, p = .004 observer 2; 95.7 vs. 80.9; p = .009). The k-value of all data set was excellent (0.861).
Conclusion: Detection of intra-arterial thrombus using 3D BB contrast-enhanced MR imaging provides accurate detection of thrombus in patients with acute ischemic stroke.

B-0278 14:48

Site and rate of arterial occlusive disease in acute ischaemic stroke: a CT-angiography study of 50'807 cervico-cerebral arterial segments

D.C. Rotzinger, P.J. Mosimann, R.A. Meuli, P. Maeder, P. Michel; *Lausanne/CH (david.rotzinger@chuv.ch)*

Purpose: CT angiography (CTA) can rapidly and accurately depict arterial abnormalities in acute ischaemic stroke (AIS) patients. Our purpose was to determine the pattern of significant stenoses and occlusions at Admission based on CTA in a representative AIS population.
Methods and Materials: Data from consecutive AIS patients admitted to a single centre (CHUV) between 2003 and 2012 were prospectively collected in the Acute Stroke Registry and Analysis of Lausanne (*ASTRAL*) database. All patients with a good quality CTA within 24 hours from symptom onset were selected. All intracranial and cervical arterial stenoses ≥50% or occlusions were registered and classified according to 31 pre-specified segments per patient.
Results: Among 2'209 patients (42.6% females, median age 71 years), 1'177 (53.3%) had significant arterial CTA anomalies. Among the 50'807 examined arterial segments, 2'259 were abnormal: 1'851 (82%) were within the ischaemic territory, whereas 408 (18%) were considered asymptomatic. The arteries most frequently affected by symptomatic anomalies were the proximal MCA (20.1% of all segments), followed by the cervical ICA (16.7%) and the distal MCA (12.1%). In AIS patients imaged by CTA within 6 hours of onset, 40.7% had occlusions potentially amenable to endovascular therapy.
Conclusion: This study shows that CTA obtained within 6h of symptom onset can depict large, proximal segmental arterial occlusive disease amenable to endovascular therapy in more than 40% of AIS patients. The annual case load of CTAs performed in AIS patients may therefore serve to estimate how many acute endovascular treatments can be expected per stroke center or region.

B-0279 14:56

The application of Alberta Stroke Program Early CT Score (ASPECTS) to acute ischaemic stroke initial CT brain imaging and haemorrhagic transformation rates

M. Hanley, T. Tarmey, L. Morrison, C. Judge, M. Costello, K. Donlon, P.A. McCarthy, R. Ó'Caoimh; *Galway/IE (marionhanley98@gmail.com)*

Purpose: Predicting Haemorrhagic transformation (HT) in patients with acute ischaemic stroke often proves difficult, and the implications of this extends to clinical decisions such as the timing of reinstating anticoagulation therapy.
Methods and Materials: Data was collected from a single centre, University Hospital Galway (UHG). Patients were identified using a database of stroke patients presenting to UHG over a two year period. The initial CT brain images were reviewed, ASPECTS applied and high risk HT features were identified. Repeat CT brain images prior to initiating anticoagulation were then reviewed for HT.
Results: 150 patients were identified as having ischaemic stroke and atrial fibrillation. The average age was 77 years (33-100), 106 (70.9%) were male. 95 (61.3%) infarcts were not identified on initial CT brain imaging. 30 (20%) were small infarctions, 20 (66.7%) were medium, and 5 (3.33%) were large posterior infarctions. ASPECTS was applied to 68 (45.3%) initial CT brain images; average ASPECTS was 8.5 with 4.5% (15) having an ASPECTS of less than or equal to 7. Of these, 30% (5) were associated with haemorrhagic transformation, accounting for 4.8% HT overall. 105 (70%) initial CT images showed one or more high risk radiological features for HT.
Conclusion: ASPECTS and other high risk radiological features are important predictors of haemorrhagic transformation in the acute ischaemic stroke setting and greater weight should be emphasised on these features when making clinical decisions, such as, the timing of introducing or reinstating anticoagulation.

B-0280 15:04

Intracranial arterial calcification in black Africans with acute ischaemic stroke

R.B. Olatunji, A.J. Adekanmi, A.O. Ogunseyinde; *Ibadan/NG (richard_olat@yahoo.com)*

Purpose: Intracranial arterial calcification (IAC), a recognised marker of atherosclerosis on cranial computed tomography (CT), is an independent risk factor for ischaemic stroke. This study aimed to determine the prevalence, distribution, severity and associations of IAC in adults with acute ischaemic stroke at the University College Hospital, Ibadan, Nigeria.
Methods and Materials: Cranial CT images of 130 consecutive adults who presented with acute ischaemic stroke were acquired on a 64-slice multi-detector Toshiba Aquilion scanner and evaluated for IAC in bone window on Vitrea software using a semi-quantitative scoring method for extent, thickness and length of calcifications in the large intracranial arteries. Association of IAC with clinical and laboratory data was determined by statistical analysis at $p<0.05$.
Results: There were 71 male (54.6%) and 59 female (45.4%) patients with mean age of 63.0±13.2 years. IAC was found in 121 patients (93.1%), predominantly in the carotid siphon (86.1%) followed by the intracranial vertebral arteries (9.3%), middle cerebral arteries (2.4%), basilar artery (1.2%) and the anterior cerebral arteries (1%). Severity of the burden of IAC ranged from mild (17.4%), moderate (52.1%) to severe (30.6%). IAC was associated with age (p=0.003), diastolic blood pressure (p=0.03) diabetes mellitus (p=0.02) and elevated serum low-density lipoprotein (p=0.04) but not with sex (p=0.35).
Conclusion: The burden of intracranial arterial calcifications is high among black African patients with acute ischaemic stroke and preferentially involves proximal inflow arteries. Therefore, the role of large vessel atherosclerosis in ischaemic stroke in black Africans should be explored in future multicentre, multimodality studies.

B-0281 15:12

Haemodynamic disturbances in CT perfusion (CTP) for infarct core volume prediction during acute Ischaemic stroke (AIS) in large vessel multiple occlusion

E. Puglielli, R. Lattanzi, G. Esposito, V. Di Egidio; *Teramo/IT (edopug@hotmail.com)*

Purpose: To evaluate the impact of haemodynamic disturbances due to multiple intra- and/or extracranial vessel occlusions upon automated CT perfusion analysis tool during AIS.
Methods and Materials: We review our database retrospectively (876 pts) for all cases of endovascular treatment of AIS (from April 2009 to September 2016), with anterior circulation occlusion, baseline CTP and full recanalisation (mTICI III) (114pts). The infarct core was accurately measured using automated normalised, threshold and voxel-wise analysis in real time with CTP and time to peak enhancement TTP, mean transit time MTT, and cerebral blood volume CBV.
Results: CT angiography can well define the occlusion site, depict arterial state, grade collateral blood flow, and characterise atherosclerotic status. Comparison between multiple 68.4% (78/114) and non-multiple 31.5% (36/114) occlusion groups revealed similar baseline ischaemic core (21±19 vs 18±24cm^3; p=0.8), MTT>6s (175±105 vs 156±115cm^3; p=0.6), MTT>10s (92±84 vs 95±91cm^3; p=0.9) and final infarct volumes (44±46 vs 36±41cm^3; p=0.5). The mean difference between estimated core and final infarct volume was similar between patients with and those without multiple occlusion (23±43 vs 16±13 cm^3; p=0.5).
Conclusion: Automated CTP imaging is not significantly influenced by presence of intra- or extracranial carotid steno-occlusive disease in large vessel AIS and thus may be useful to select patients who will benefit from endovascular reperfusion therapy.

B-0282 15:20

Correlation between iodine extravasation after mechanical revascularisation in acute ischaemic cerebrovascular stroke and haemorrhage development

M. Bonatti[1], F. Lombardo[1], A. Comai[1], G.A. Zamboni[2], G. Bonatti[1]; [1]*Bolzano/IT*, [2]*Verona/IT (matteobonatti@hotmail.com)*

Purpose: To correlate iodine extravasation presence, distribution and concentration after mechanical revascularisation in acute ischemic cerebrovascular stoke with subsequent haemorrhage development.
Methods and Materials: We included in our IRB-approved retrospective study 9 consecutive patients who developed intracranial haemorrhage after mechanical revascularisation for ischemic stroke (group A) and 21 controls who didn't develop it (group B). All patients underwent post-procedural dual-energy CT of the brain. Iodine presence, distribution pattern (deep white matter (DWM), cortical or both) and maximum concentration (mgI/ml) were evaluated by means of a commercially available software.
Results: Iodine extravasation was present in 9/9 patients in group A and in 13/21 patients in group B (p>0.05). In group A, 4/9 patients presented DWM iodine distribution, 1/9 patients cortical distribution and 4/9 patients both. In group B, 4/13 patients presented DWM iodine distribution, 0/13 patients cortical distribution and 9/13 patients both. None of the distribution patterns was significantly associated with haemorrhage development. Mean maximum iodine concentration was 7.5±3.7 mgI/ml in group A (range 1.4 - 27.7 mgI/ml) and 1.3±0.3 mgI/ml in group B (range 0 - 4.2 mgI/ml) (p=0.0145). According to ROC analysis, a cut-off value of 1.3 mgI/ml had 100% sensitivity and 57% specificity for detecting patients who will develop haemorrhage.
Conclusion: Post-procedural intracerebral iodine extravasation with maximum concentration equal or greater than 1.3 mgI/ml can identify patients at higher risk of post-procedural haemorrhage development with excellent sensitivity and good specificity.

MDCT assessment of esophageal perforations in the emergency setting

C. Liguori, A. Pinto, G. Ponticiello, C. Stavolo, S. Nicotra, L. Romano;
Naples/IT (carlo.liguori@gmail.com)

Purpose: To investigate how accurately MDCT can diagnose the level of upper GI tract perforation especially assessing site and entity of esophageal leakages.
Methods and Materials: MDCT studies in 55 patients with surgically confirmed esophageal perforation were retrospectively evaluated. MDCT scans were obtained with 64-detector CT; submillimetre axial images and multiplanar reconstruction (MPR) images were generated for all patients. Intravenous contrast enhancement was performed in all patients and in 35 oral contrast was also administered. Two experienced radiologists reviewed the images for direct findings (free air, ruptured esophageal wall, oral contrast leak) and indirect findings (inflammatory changes, fluid collection, focal thickening of the GI tract wall) and attempted to identify the perforation site in each patient.
Results: Free air was seen in more than 95% of the patients with perforation at sites; rupture of the esophageal wall was directly visualised in 32%; oral contrast leakage was appreciated in 90%. Indirect signs: wall thickening and periesophageal inflammatory changes were present in 95% of cases, fluid collections in 87%. The perforation site was correctly diagnosed in 90% of the patients when the radiologists referred to both direct and indirect findings.
Conclusion: MDCT is a robust technique for esophageal perforation identification. Intravenous contrast and oral contrast administration are key factor for a confident diagnosis.

B-0284 14:08

Application of model-based iterative reconstruction algorithm in CT pulmonary angiography in emergency setting: dose reduction and image quality

L. Riva, D. Ippolito, C.R.G.L. Talei Franzesi, A. De Vito, C. Cangiotti, S. Sironi;
Monza/IT (luca.riva89@gmail.com)

Purpose: To compare radiation dose and image quality of low-dose CT pulmonary angiography with new model-based iterative reconstruction protocol (IMR), with a standard CTPA, in patients with suspect of pulmonary embolism (PE).
Methods and Materials: A total of 87 patients investigated for PE were enrolled in our study.The study group was evaluated using a new 256-MDCT (iCT elite,Philips) with low-kV (100 kV; automated tube-current modulation), low volume of CM and IMR algorithm to reconstruct raw data. Control group underwent standard CTPA study on 16-MDCT scanner, with the same volume of CM (120 kV; 150-250 mAs; FBP reconstruction). Two radiologists performed quantitative evaluation measuring vessels contrast enhancement and calculating SNR and CNR. A 4-point scale was used to perform the qualitative evaluation. Radiation dose exposure data was recorded as DLP, CTDIvol and ED.
Results: The intra-vessel density was higher in study group than in control group, while background noise was significantly lower ($p<0.05$) in study group than the control one. The SNR and CNR of the low-kV MBIR-CTPA were better than standard FBP-CTPA ($p<0.05$). DLP, CDTIvol and ED in study group were significantly lower than those in control group ($p<0,05$), with a 34% reduction in CTDIvol and 25% reduction in ED for study group, having SNR and CNR higher than those of standard FBP-CTPA. Moreover, the overall image quality rating score was higher for MBIR-CTPA than FBP-CTPA both for the two readers ($p<0.05$; C.Alpha=0.91).
Conclusion: Low-kV setting combined with MBIR can improve the diagnostic image quality of CTPA in pulmonary embolism, compared to a standard CTPA reconstructed with FBP, allowing to reduce the radiation dose to patients.

B-0285 14:16

Use of whole-body CT to detect patterns of CPR-related injuries after sudden cardiac arrest

A. Perez-Girbes[1], G.M. Dunham[2], F. Bolster[3], K. Sheehan[2], K.F. Linnau[2];
[1]*Valencia/ES*, [2]*Seattle, WA/US*, [3]*Dublin/IE (perez_alegir@gva.es)*

Purpose: Patients with Sudden Cardiac Arrest (SCA) commonly undergo cardiopulmonary resuscitation (CPR) in order to maintain, and ultimately restore return of spontaneous circulation (ROSC). CPR related injuries are common and may be detectable with whole-body computed tomography (WBCT). We have recently implemented a dedicated SCA- WBCT protocol to evaluate SCA patients with ROSC post-CPR. The aim of this study is to evaluate the number and pattern of CPR-related injuries in ROSC patients with SCA-WBCT.
Methods and Materials: Single-centre retrospective review of 39 patients (13 female; 26 male, mean age 51.8 yrs) with non-traumatic, out-of-hospital SCA and ROSC and evaluation with dedicated SCA-WBCT over a 10 month period (January to September 2016). SCA-WBCT-protocol includes non-enhanced head CT, ECG-gated CTA chest, and portal-venous CT abdomen and pelvis. Medical records were reviewed for demographic, CPR-related, and patient outcome data. Two radiologists reviewed all SCA-WBCTS by consensus.
Results: In-hospital mortality was 46%. Chest injuries were most common on WBCT: 84.6% (33) subjects had rib fractures (mean of 8.5 fractures/subject); 30.8% (12) sternal fractures; 12.8% (5) mediastinal haematoma; 10.3% (4) pneumothorax; 7.7% (3) pneumomediastinum and 2.6% haemothorax (1). Three subjects (7.7%) had abdominal injuries on WBCT, including one hepatic laceration with active haemorrhage."
Conclusion: CPR-related injuries on WBCT after ROSC are common, with serial rib fractures detected most commonly. An unexpectedly high rate of abdominal injuries was detected on SCA-WBCT. Radiologists need to be attuned to the spectrum of CPR-related injuries in WBCT, including abdominal injuries.

B-0286 14:24

Role of high-frequency ultrasound in ocular emergencies

S.S. Sachar; *Bareiily/IN (drsacharsaurabh@gmail.com)*

Purpose: To examine the effectiveness and accuracy of HFUSG for evaluation of acute ocular pathologies in emergency. 5% cases presenting to casualties are ocular emergencies and their evaluation can be limited by lack of specialised equipment, training, and ophthalmologic backup. Investigations such as CT, MRI, etc. are time-consuming, costly and may be unavailable. However, with the advent of HFUSG, many acute ocular pathologies, e.g. orbital trauma, rupture, retinal detachment (RD) central retinal artery or vein occlusion can be safely and non-invasively diagnosed at the bedside.
Methods and Materials: Prospective study was carried out in the casualty of teaching institutes named above during 06 months in which 44 patients were assessed who had acute ocular related complaints. A 10MHz linear array transducer with Doppler was used.
Results: Out of 44, 28 (64 %) were found to have serious acute ocular pathologies other than soft tissue swelling, including globe rupture, RD, vitreous haemorrhage, etc.
Conclusion: Acute ocular pathologies resulting from conditions such as trauma can be accurately and quickly diagnosed at the bedside itself by HFUSG resulting in immediate and correct therapeutic Intervention and lower costs for patients and must form an integral part of diagnostic protocol.

B-0287 14:32

Low-dose abdominal CT using pure iterative reconstruction in patients presenting to the emergency department with acute abdominal symptoms

F. Molony, M. Tomey, D. Ryan, K. James, T. Grey, N. Moore, M. Murphy, O. O'Connor, M. Maher; *Cork/IE (karl.m.james@gmail.com)*

Purpose: To evaluate the diagnostic ability of low-dose abdominopelvic CT using pure MBIR to accurately diagnose non-trauma patients presenting acutely with abdominal symptoms.
Methods and Materials: 57 patients were scanned using a split dose technique whereby 80-90% of the standard CT effective dose (ED) was used to generate a control study (CD) and was immediately followed by a low-dose CT (LD) using the remaining 10-20% of the standard ED CT dose. Dose measurements from both scans were obtained. Blinded reads by 2 experienced radiologists performed objective and subjective measures of image quality from both datasets and the ability to identify pathology and reach a diagnosis was compared between the two study types.
Results: The ED was significantly lower in the LD group by an average factor of 3 ($p<0.0001$). The LD CT study had significantly increased subjective image noise and poorer contrast and diagnostic resolution ($p<0.0001$). 28 of the 57 studies had an identifiable pathology and the low dose study was able to correctly identify this pathology in all but one of the abnormal studies. There

were 5 cases where there was discrepancy in the detail of the pathology (e.g. acute appendicitis vs. perforated appendicitis). The positive predictive value and negative predictive value of the LD compared with the CD studies were 96.4% (95% CI: 81.7%-99.9%) and 96.6% (95% CI 82.2%-99.9%) respectively.
Conclusion: Although more difficult to interpret, LD CT with MBIR provides diagnostic images in patients presenting with acute abdominal pain while imparting a significantly lower patient dose.

B-0288 14:40

Dengue fever: markers on ultrasound predicting prolonged hospital stay and complications

P. Khokhani, K. Dhamecha, H. Shah; *Anand/IN (khokhani1988@gmail.com)*

Purpose: Dengue fever during epidemics assumes very high hospital admissions. However these patients receive supporting management, our purpose of study was to elaborate the USG findings in general and grave findings in particular, concerned with prolonged hospital stay and complications.
Methods and Materials: The study was performed during peak epidemic between months of June to September 2016. Inclusive criteria are serologically and biochemically positive indoor patients. Informed consent of the patients and referring physician was taken. The ethical committee approval was obtained. The patients were subjected to USG of abdomen and chest with routine protocol. Machine used was Mind-Ray DC7, probes 3-5MHZ and 8-12MHZ.
Results: The findings of dengue positive patients were classified as general and in particular (which we focussed upon in study). Study comprised of 100 inward patients referred for USG. General findings comprised of: hepatomegaly (90%), splenomegaly (60%), gallbladder wall oedema (95%), clear ascites (90%). In particular findings to be focussed upon are: septated perinephric fluid (20%) and particulate ascites and periportal oedema (25%). In particular findings were associated with a platelet count of <20,000/mm3 and prolongation of hospital stay (>7 days) as compared to their counterparts having general findings. Here, the chi-square test of relevance showed $p<0.05$.
Conclusion: We conclude from this study, during dengue epidemic the findings on USG of septated perinephric fluid and particulate ascite with periportal oedema represents significant platelet loss, patient debility and prolongation of hospital stay.

B-0289 14:48

CT findings in impending rupture of atherosclerotic abdominal aortic aneurysms: a case control study

M. Giannotta, M. Piolanti, E. Pisano, L. Rignanese, F. Magnoni, A. Pilato, M. Zompatori, M. Imbriani; *Bologna/IT (marica.giannotta@studio.unibo.it)*

Purpose: Patients with impending rupture of atherosclerotic Abdominal Aortic Aneurysm (AAA) usually present with abdominal or back pain, that may mimic several abdominal emergencies. Prompt recognition of impending rupture is mandatory, since rupture is a life-threatening emergency. The purpose of this study is to value whether CT may correctly identify the presence of an impending rupture.
Methods and Materials: We retrospectively assessed CT findings in two groups of patients: 22 patients with impending rupture (symptomatic AAA without retroperitoneal haemorrhage at CT) and 27 patients with asymptomatic AAA (electively studied with CT). The groups were matched for size, age and sex. Presence of blebs, hyper-attenuating crescents, linear thrombus dissections, draped aorta sign, peri-aortic stranding and vertebral scalloping were blindly assessed by 2 experienced radiologists. The study was approved by the Institutional Review Board.
Results: No sign showed acceptable sensitivity for the diagnosis of impending rupture. Several signs showed high specificity with a satisfactory positive predictive value (PPV): draping aorta sign (specificity 96%, PPV 66%), hyper-attenuating crescents of the aortic wall (specificity 96%, PPV 80%), linear dissections of the thrombus (specificity 96%, PPV 80%) and peri-aortic stranding (specificity 100%, PPV 100%).
Conclusion: Various signs have been associated with AAA impending rupture in literature, although their reliability have never been assessed. Our results point out that no sign is sufficiently sensitive or has acceptable negative predictive value. Contrarily, there are some findings which have good specificity and PPV, that have to be taken in account when assessing AAAs.

B-0290 14:56

MDCT signs accuracy in detection of acute perforated appendicitis

M. Porta, C. Liguori, S. Daniele, T. Cinque, C. D'errico, L. Romano; *Naples/IT (m.elenaporta@gmail.com)*

Purpose: Presence of perforated appendicitis significantly increases morbidity, mortality and the risk of complications after surgical period. The aim of this study is to evaluate MDCT accuracy in detecting perforated appendicitis signs in the preoperative setting.
Methods and Materials: From January 2013 to August 2016, retrospective study included 73 patients (mean age 37.5y; 16y-68y) admitted to the emergency department with clinical suspicious of acute appendicitis. Intravenous contrast media was administered. Two Radiologists with 10- and 15-year experience in emergency imaging classified the six most frequent signs of perforated appendicitis as follow: 1) enlarged lumen calibre >6 mm (aspecific sign); 2) enhancing defect foci of the wall; 3) abscess presence; 4) phlegmon presence; 5) extraluminal air (also divided into 2-groups based on an anterior-posterior abdomen-Visceral Diameter -aVD- in axial plane); 6) extraluminal appendicolith. Perforated appendicitis imaging findings were compared with final pathology/clinical proven as standard of reference.
Results: 11 patients were excluded because of artefacts and/or no-appendicitis diagnosis. 62 (85%) had pathologically/clinical proven perforated appendicitis. Six individual CT signs sensitivity and specificity were respectively determined for each patient: 1(100%, 100%); 2(95%, 97%); 3(29%, 98%); 4(45%, 95%); 5(60%, 90%); 6(40%, 99%). Extraluminal air sign sensibility was also divided for aVD less(20%) or more(65%) than 15cm.
Conclusion: MDCT is a high sensitive/specific technique in setting of acute perforated appendicitis; enhancing defect foci of the wall and abscess presence showed the statistically most significant association with perforated appendicitis. Extraluminal air sign showed lower sensitivity in subjects with <15cm aVD.

B-0291 15:04

Interobserver variability in detection of acute abdominal bleeding with CT

J. Rabczak, M. Powerski, M. Pech, S. Penzlin, S. Neumann, R. Damm, B. Friebe, P. Schindler, S. Titz; *Magdeburg/DE (joanna.rabczak@med.ovgu.de)*

Purpose: Acute intra-abdominal bleeding is a common emergency indication to CT-angiography in daily routine as well as during off-hours. It is a sensitive and fast first-line modality not only to diagnose an active bleeding but also to plan the subsequent therapy. The main purpose was to evaluate accuracy of a radiologist in detection of active bleeding in abdomen with angiography as reference standard according to different level of experience of a proband.
Methods and Materials: Eight radiologists were assigned to three groups: with no practical clinical knowledge, in the fourth and fifth year of residency and a group of specialists with experience in interventions. Any of them reviewed independently CTA of 50 patient's abdomen. For each patient, a potential bleeding status was scored as positive, possible, uncertain, dubious or negative. The results of each group were analysed by the receiver operating characteristic curve analysis with consecutive assessment of interobserver agreement.
Results: The sensitivity for the youngest group was 77.3%, for the middle-experienced 80.6 % and for the group of interventionists 83.8%, the specificity subsequently 62%, 82.7% and 91%. The rate of ROC AUC was analogically 0.786, 0.842 and 0.905. Kappa analysis showed good agreement between the two more experienced groups, fair agreement between the novices and interventionists and poor agreement between the novices and the intermediate group.
Conclusion: The study shows some disparities between radiologist's interpretation that vary from personal experience and abilities which may significantly influence the outcomes of patients care.

B-0292 15:12

To die or die hard? Plain radiography for acute non-traumatic abdominal pain presenting to the emergency department

M.E. Abd El Bagi, B. Almutairi, S. Alsolamy, S. Alrashidi, I. Alrashidi, N. Ashraf, M. Reutener, A. Mohammed, N. Alrasheed; *Riyadh/SA (drm_bagi@hotmail.com)*

Purpose: To evaluate the utilisation of plain abdominal radio-graphs (PAR's) for imaging of acute non-traumatic abdominal pain (ANTAP) presenting to the emergency department(ED) in the era of low dose CT.
Methods and Materials: This is a retrospective study conducted at the ED of an 800 bed tertiary care hospital during the period from 01.06.2014 to 30.06.2014. The records of all adults who underwent PAR's due to ANTAP were reviewed. Trauma, gynecologic and paediatric cases were excluded.
Results: 756 patients were referred for PAR's due to ANTAP. 379(49.6%) of those were males, and 385(50.4%) were females. Age range was 15 to 92 years. Mean age was 46 years. Commonest presentation was unclassified abdominal pain in 679 (89.8%). PAR's were the only requested procedure for the vast majority of cases 594(78.57%). In 103(13.6%) conventional dose contrasted CT was added and in 33(4.3%) low dose CT was added. Abdominal ultrasound (US) was added in 52(6.8%). MRI was added for only one patient. When both PAR's and CT were used, there was a poor diagnostic congruence of 50% in cases of nonspecific pain, 43% in cases with non-significant findings and only 35.7% in abnormal cases.

Conclusion: Although of lower sensitivity, PAR's are still commonly used as a one stop shop for ANTAP presenting to the ED despite CT availability. When both CT and PAR's were used, there was a poor congruence of findings due to higher CT sensitivity but at a higher radiation dose. However, the new ultra-low- dose CT may soon replace PAR's.

B-0293 15:20

Suspicion of acute appendicitis in adults: the value of ultrasound

G. Benedetto, A. Llavata Solaz, M. Ferrer Puchol; *Alzira/ES*

Purpose: To evaluate the accuracy of ultrasonography for the diagnosis of acute apendicitis (AA) in adult patients, to calculate the negative apendicectomy rate (NAR) in operated patients and to identify statistically significant signs and symptoms of acute appendicitis.
Methods and Materials: In this prospective study, every ultrasound requested in a one-year period from the emergency department for adult patients (age 15 years and older) with pain in the right iliac fossa (RIF) was registered upon completion. Clinical symptoms, signs and ultrasound findings were recorded and a presumptive diagnosis was formulated in the report (normal, non-visible appendix and no indirect signs, non-conclusive, probable appendicitis, appendicitis). Optimal sample size was calculated and statistical analysis of the data was performed by means of the software Stata14 (descriptive analysis, t-test, Chi-square, Roc curve and diagnostic tests) and compared with the final post-surgical pathological findings.
Results: We studied 139 patients (45% men, 55% women), mean age: 33 (15-84). Statistically significant clinical signs and symptoms were RIF pain, fever, leukocytosis and left shift. Significant US findings were visible appendix, non-compressibility, echogenic fat, appendicolith and free fluid. NAR: 0%. Mean appendiceal diameter without AA: 5mm (5.53-6.58 with 95% CI), with AA: 9mm (7.84-9.15 with 95% CI). AUC of the ROC curve (with a 50% prevalence in our population for the categories of certain and probable AA with 95% CI): 0.935. Sensibility: 94.3%, specificity: 92.8%, PPV: 93%, NPV: 94%.
Conclusion: The ultrasonography yields excellent results and makes the correct diagnosis in case of suspected AA in adults.

Spondyloarthropathy (SpA): is sacroiliac (SI) joint imaging sufficient?

S. Gupta, J.P. Singh; *Gurgaon/IN (drsaurabhjmu@gmail.com)*

Purpose: To assess the utility of including sagittal STIR sequence of dorsolumbar spine and coronal STIR/PD fat saturated sequence through both hips, to routine SI joint MR imaging protocol, in patients clinically suspected to have SpA.
Methods and Materials: Observational study was conducted between February 2013 and October 2016 on clinically suspected SpA patients referred to our department for imaging. The images obtained using this new SI joint protocol were evaluated for findings suggesting SpA diagnosis as per the Assessment of SpondyloArthritis international Society criteria. Other differentials in symptomatic patients without radiologic SpA were also evaluated.
Results: Of the 308 patients (225M; 83F), 192 had features confirming the diagnosis of SpA and 116 had no radiological manifestations of SpA (29 were normal and 87 had other findings to suggest clinical symptoms e.g. degenerative spondyloarthropathy, Pott's spine, skeletal metastases, early AVN of hip, cysticercus, iliofemoral impingement etc.). 18/192 patients had normal SI joints but other findings to suggest diagnosis of SpA, e.g. romanus lesions, costovertebritis/costotransversitis, pubic symphysitis, inflammatory hip arthropathy, enthesitis, iliofemoral/trochanteric bursitis. 27/49 patients with chronic sacroilitis had disease activity in spine/hip.
Conclusion: Inclusion of sections through dorsolumbar spine and both hips to routine SI joint protocol, helped identify: (a) early disease in 18 patients, who had normal SI joints and may have otherwise been missed with routine SI joint imaging protocol, (b) additional findings in SpA related sacroiliitis, (c) disease activity in chronic sacroilitis and (d) other causes of low back pain, and thus helped in further patient management.

B-0295 14:17

Presence of bone marrow edema on MRI of the sacroiliac joints is predictive of subsequent (5 years) radiographic progression in early onset non-radiographic axial spondyloarthritis

A. Feydy, M. Dougados, A. Sepriano, R. Landewe, C. Dermattei, A. Molto, M. de Hooge, V. Navarro, M. Reijnierse; *Paris/FR (antoine.feydy@aphp.fr)*

Purpose: The aim of this study was to evaluate the rate of radiographic progression and its predisposing factors after a 5 years follow-up period in patients with recent onset axial SpA.
Methods and Materials: Patients: Recent onset (<3 years) axial SpA enrolled in the Cohort DESIR. Outcome measure: Radiographic SIJ status according to the mNY criteria after 5 years follow-up. Reading of the SIJ-X-Rays: 3 trained readers unaware of the chronology of baseline, 2-year and 5-year films and of the clinical and other imaging data.
Results: Of the 708 patients enrolled in the cohort 482 (68.1%) completed the 5 years follow-up. Complete x-ray data was available in 379 patients. 326/ 379 patients were mNY negative at baseline and 23 (7.1%) of these were found positive at year 5. Conversely, 53/379 patients were mNY positive at baseline and 5 (5.7%) were found negative at year 5 (net progression of 1.4%). BME on MRI-SIJ was found in 15 (71.4%) of the patients who switched from mNY-negative at baseline to mNY-positive at year 5 and only in 51 (16.8%) patients who remained mNY-negative throughout the 5 years follow-up period. In the multivariable analysis, presence of BME on MRI was the strongest predictor of radiographic progression (OR=4.85 [95% CI: 2.95-7.97]).
Conclusion: These data suggest that 5-year radiographic progression in SIJ of patients with early onset SpA is modest and demonstrate that a positive MRI of the SIJ (presence of BME) is the strongest predictor of radiographic progression in the SIJ of these patients.

B-0296 14:25

Whole spine MRI findings in SAPHO syndrome

W. Xu, C. Li, X. Shao, X. Zhao, W. Zhang; *Beijing/CN (xuwr0122@163.com)*

Purpose: To systematically document the whole spine MRI findings in a large cohort of synovitis-acne-pustulosis-hyperostosis-osteitis (SAPHO) syndrome.
Methods and Materials: 38 SAPHO patients (26 female, 46.3±9.3 years) were perspectively enrolled. MRI examinations of the whole spine were performed with standardised protocols. All the images were evaluated in a blinded manner, and discrepancies were reached in consensus after discussion.
Results: A total of 310 vertebrae were involved in 35 SAPHO patients. All the 35 patients had a multiple-vertebra involvement pattern (median: 7, range: 2-24), with a predilection on lumbosacral spine. 80.3%(249/310) affected vertebrae were continuously involved, while 19.7%(61/310) were separately involved. For the 310 affected vertebrae, a total of 567 lesions were observed. 35.8%(203/567) of the lesions were confined to vertebral corners, while 64.2% (364/567) also implicated adjacent endplate. Abnormal signal intensity (SI) of a mixture of bone marrow edema (BME) and fat deposition was found in 49.2%(279/567) lesions, while abnormal SI of solely BME or fat deposition was observed in 13.9%(79/567) and 36.9%(209/567) lesions, respectively. Cortical bone erosion was found in 50.6% (287/567) lesions. Vertebral collapse and bony bridge were observed in 0.6%(2/310) and 6.8%(21/310) affected vertebrae. Adjacent disk space was narrowed in 37.4%(116/310) affected vertebrae, but only 6.8%(21/310) were accompanied by hyperintensity on T2-weighted images. 1.3%(4/310) apophyseal joints were observed with hyperintensity on T2-weighted images. Thickening of anterior longitudinal ligaments was observed in 7.1%(22/310) affected vertebrae.
Conclusion: Imaging features of spinal disorders in SAPHO syndrome may facilitate better understanding of this rare disease and avoid misdiagnoses.

B-0297 14:33

Initial experience with dual-phase hybrid ^{18}F-Fluoride PET/MRI in patients with ankylosing spondylitis

L.M. Sawicki[1], S. Lütje[2], X. Baraliakos[3], J. Kirchner[1], V. Ruhlmann[2], H.H. Quick[2], L. Umutlu[2], G. Antoch[1], C. Buchbender[1]; [1]*Düsseldorf/DE*, [2]*Essen/DE*, [3]*Herne/DE (Linomorris.sawicki@med.uni-duesseldorf.de)*

Purpose: Increased ^{18}F-F uptake during blood-pool phase PET represents regional hyperaemia, while indicating osteoblastic activity during mineralisation phase PET. This study aimed to assess the feasibility of dual-phase ^{18}F-F PET/MRI of the sacroiliac joints (SIJ) in ankylosing spondylitis (AS) and find an association between regional hyperaemia and osteoblastic activity in different AS lesions.
Methods and Materials: Thirteen patients underwent dual-phase ^{18}F-F PET/MRI. Blood-pool phase PET was acquired 6 and mineralisation phase PET 40 min after ^{18}F-F injection. We analysed PET image quality (DIQ) and co-registration of blood-pool and mineralisation phase ^{18}F-F PET/MRI. SIJ quadrants (SQ) were assessed for presence of bone marrow oedema (BME), erosion, fatty deposits (FD), sclerosis, or ankylosis on MRI and focal ^{18}F-F uptake on PET.

Results: DIQ of both ^{18}F-F PET datasets was high, albeit DIQ of mineralisation phase PET was better than that of blood-pool phase PET (p<0.001). Image co-registration was equally good. BME alone was associated with focal ^{18}F-F uptake in 90.9% SQ on mineralisation phase and 63.6% SQ on blood-pool phase. FD, erosion, sclerosis, ankylosis were not associated with focal ^{18}F-F uptake on blood-pool or mineralisation phase. SQ with BME had a significantly higher (p<0.001) percentage of focal ^{18}F-F uptake on blood-pool phase (47.7% SQ) and mineralisation phase (86.4 % SQ) than SQ showing AS lesions without BME (6.7% and 11.7% SQ, respectively).
Conclusion: Dual-phase ^{18}F-F PET/MRI of SIJ is feasible with high image quality. Inflammatory AS lesions presenting with BME rather than structural changes are associated with regional hyperaemia and osteoblastic activity.

B-0298 14:41

Monitoring of tocilizumab treatment in patients with rheumatoid arthritis using selected imaging techniques

M. Dura[1], P. Zuchowski[1], S. Jeka[1], M. Waszczak-Jeka[2], E. Sokolska[1], T. Barczynska[1], M. Wegierska[1]; [1]*Bydgoszcz/PL*, [2]*Warsaw/PL (martadura83@gmail.com)*

Purpose: The aim of the study was to assess the usefulness of imaging techniques vs. disease activity score (DAS28) for therapy monitoring in patients with rheumatoid arthritis (RA).
Methods and Materials: The study included 24 RA patients (mean (SD) age 53 (12) years; disease duration 9.8 (8.5) years; 88% anti-CCP positive, 96% rheumatoid factor positive). At baseline, 17 patients had high disease activity (DAS28 > 5.1), and 7 patients had moderate disease activity (3.2 < DAS28 ≤ 5.1). All patients received tocilizumab for a year. Hand x-ray and MRI scans, power Doppler ultrasound (PDUS) of the metacarpophalangeal joints (MCP) as well as DAS28 measurement were performed at enrolment and completion of the study. At month 6 of the study, PDUS was performed and DAS28 was calculated. PDUS (semiquantitative scoring (0-3)) scans were performed by one rheumatologist. X-ray and MRI scans were interpreted by one radiologist.
Results: At month 6, remission (DAS28 ≤ 2.6) was observed in 15 (63%) patients, and the absence of synovitis was confirmed by PDUS in 16 (67%) patients. At month 12, remission (DAS28 ≤ 2.6) was observed in 24 (100%) patients; the absence of synovitis was confirmed in 19 (79%) patients by PDUS and in 17 (71%) patients by MRI. All patients showed no radiographic progression.
Conclusion: PDUS and MRI allow for detection of subclinical lesions, which are not identified by DAS28. The use of imaging techniques may prevent premature treatment modification in patients with remission as evidenced by DAS28.

B-0299 14:49

Ultrasound superb microvascular imaging in the evaluation of synovial vascularity: a preliminary study

S. Gitto[1], D. Orlandi[2], A. Corazza[1], E. Silvestri[2], M.A. Cimmino[2], L.M. Sconfienza[1]; [1]*Milan/IT*, [2]*Genoa/IT (sal.gitto@gmail.com)*

Purpose: Superb microvascular imaging (SMI) is an advanced flow-detection ultrasound (US)-based modality able to detect very low-flow vessels with high detail and definition. Our aim was to evaluate the use of SMI in patients with early rheumatoid arthritis (RA) and RA under treatment with rituximab also comparing the diagnostic performance of SMI with that of power Doppler (PDI) and B-mode US.
Methods and Materials: 30 patients (18 women, mean age 45±11 years) affected by RA with remission-to-moderate disease activity were examined. Ulnar recess, metacarpophalangeal I-to-V and proximal interphalangeal II-to-V joints of both hands were evaluated using a high-end US system equipped with a 7-18MHz broadband linear-array transducer, PDI and SMI module. From each US examination, short video clips showing B-mode US, PDI and SMI of synovial vascularity were registered and exported for image analysis. Two radiologists reviewed video clips registered for all patients evaluating synovial vascularity intensity with a semi-quantitative scoring system.
Results: SMI demonstrated the presence of synovial vessel signals in a significantly higher number of patients than PDI (P=0.02). Inter-observer agreement for B-mode US, PDI and SMI semiquantitative scoring was moderate (k=0.59), almost perfect (k=0.87) and almost perfect (k=0.82), respectively.
Conclusion: SMI detects more vessels than B-mode US and PDI in assessing synovial abnormalities in RA patients. This may allow for early diagnosis of synovial inflammation as well as monitoring its dynamic changes under therapy.

B-0300 14:57

MRI grading of cartilaginous tumours: comparison of texture analysis with visual MRI analysis

B. Fritz, D.A. Müller, R. Sutter, M.C. Wurnig, M. Wagner, C.W. Pfirrmann, M.A. Fischer; *Zurich/CH (benjamin.fritz@balgrist.ch)*

Purpose: To assess diagnostic accuracy and inter-reader agreement of MRI texture analysis (TA) for grading of cartilaginous neoplasms of bone in comparison to visual MRI analysis.
Methods and Materials: MRI of 101 cartilaginous neoplasms (grade 0-4) were retrospectively included. T1w-, T2w-, STIR- and contrast-enhanced T1w fs-images were analysed qualitatively and quantitatively by four independent musculoskeletal radiologists. Qualitative visual MR-features (N=14) included tumour morphology as well as cortical bone, bone marrow and soft tissue abnormalities, whereas quantitative TA-parameters (N=19) included grey-level histogram, co-occurrence and run-length-matrix features. Inter-reader reliability, univariate, multivariate and ROC analysis were performed for MR- and TA-parameters separately and for combined models to determine independent predictors and diagnostic accuracy for grading of cartilaginous lesions.
Results: Mean inter-reader agreement of visual MR- and TA-features were 0.49 (range: 0.08-0.82) and 0.81 (range: 0.34-0.99) respectively. Diagnostic accuracies for differentiation of benign vs. malignant as well as for benign vs. low-grade cartilaginous lesions were 92.6% and 95.1% using a combined model of visual MR- and TA-predictors, 89.5% and 78.7% using visual MR-predictors, and 87.2% and 86.9% using TA-predictors exclusively. For differentiation of low-grade vs. high-grade chondrosarcoma no significant independent TA-predictors existed, whereas a model containing visual MR-predictors exclusively had a diagnostic accuracy of 87.4%.
Conclusion: TA showed substantial higher inter-reader reliability compared to visual MRI analysis. A model combining visual MR- and TA-features showed a higher diagnostic accuracy for differentiation of benign vs. malignant as well as for benign vs. low-grade cartilaginous lesions compared to models using exclusively visual MR- or TA-predictors.

B-0301 15:05

Use of shear wave elastography to differentiate benign and malignant fatty soft tissues tumours

N. Regnard, S. Charlon, A. Buisson, A. Feydy, J. Drape, R. Campagna; *Paris/FR (nregnard@yahoo.fr)*

Purpose: It is not easy to discriminate, thanks to imaging, benign lipomas and atypic lipomatous tumours (ALT). The objective was to discriminate benign and malignant fatty soft tissues tumours with shear wave elastography.
Methods and Materials: All patients were included consecutively and prospectively in our institution. The multidisciplinary staff decided a biopsy under ultrasonography guidance. All patients had ultrasonography with shear wave elastography mode (Toshiba Aplio 500). We selected fatty lesions. We assessed the size of the tumour, the elasticity (value and ratio under subcutaneous fat), and the histology of the tumour. We compared the group with benign soft tissue tumours (lipomas) and malignant tumours (Atypic lipomatous tumours).
Results: 33 tumours were included (24 lipomas and 9 ALT). The mean age was 51.8 (+/- 15) in the benign group and 61.3 (+/- 15.1) in the malignant group (p=0.13) . The greater sizes were 82.2 mm (+/- 51) in the benign group vs 164 mm (+/- 89.2) in the malignant group (p= 0.03). The average volumes were 336.3 cc in the benign group vs 1463.3 cc in the malignant group (p=0.08). The average ratio between elasticity of the tumour and subcutaneous fat was 0.95 in malignant lesions vs 0.57 in benign lesion (p=0.05). The sensitivity and the specificity of this ratio to discriminate benign and malignant lesions were 77.8% and 75% with Area Under the Curve of 0.750 (p=0.01) with a threshold superior to 0.68.
Conclusion: We can discriminate benign and malignant fatty soft tissue tumours with shear wave elastography.

B-0302 15:13

PETMR evaluation of the relationship between metabolic activity on PET and cell-density on DWI for bone metastases

C. Giraudo, M. Weber, M. Hartenbach, P.A.T. Baltzer, M. Mayerhoefer; *Vienna/AT (chiara.giraudo@meduniwien.ac.at)*

Purpose: To assess the diagnostic performance of PETMR and DWI for bone metastases and evaluate whether, metabolic activity, on PET, and cell-density, on diffusion-weighted MRI, correlate in bone metastases.
Methods and Materials: Patients with histological proven cancer undergoing a PETMR (fully integrated system) for staging or restaging, with whole-body-DWI implementing the protocol, were evaluated. PETMR was rated positive when at least one hypointense lesion on T1w with high, non-inflammatory, uptake on PET (i.e., FDG, PSMA, Dotanoc) was shown.DWI was separately evaluated.PETMR and PETMR-DWI agreement (k) with the reference standard

(i.e., histology and/or follow-up/previous examination) was assessed.The relationship between bone metastases' metabolic activity (SUVmax, SUVmean) and cell-density (ADCmin, ADCmean) was investigated (Spearman correlation coefficient).
Results: One-hundred-three patients were evaluated (70 males; mean age±SD 58.29±16.76 years; 47 staging and 56 restaging). Sixty-four patients had lymphoma, 23 prostate cancer, six melanoma, two breast-, three gastrointestinal cancer, soft tissue sarcoma, bladder, ovarian, thyroid and neuroendocrine tumour one patient each. Thirty-four patients were correctly rated as positive at PETMR and 33 at PETMR-DWI. PETMR and PETMR-DWI showed a high agreement with the reference standard (k=.915 and k=.852, respectively). SUVmax, SUVmean, ADCmin and ADCmean, mean±SD values, were 12.62±10.50, 5.82±5.58, 629±238.37 and 895.52±278. No correlation emerged between SUVmax and ADCmin (r=.013; p=.941) and between SUVmean and ADCmean (r=-0.001; p=.996) neither, separately, at staging (r=.289, p=.296; r=.475, p=.074) or restaging (r=-.023, p=.925; r=-.293, p=.211).
Conclusion: PETMR and DWI demonstrated a high diagnostic performance for bone metastases.SUV and ADC seem to be independent imaging biomarkers for bone metastases, but further studies focused on cancer type and PET tracer, are necessary to fully assess this evidence.

Patient dose evaluation for whole-body skeletal CT using 100Sn filter for spectral shaping at 100kV in multiple myeloma
M. Meyer, N. Vogler, H. Haubenreisser, M.M. Ong, S.O. Schönberg, T. Henzler; *Mannheim/DE*

Purpose: To prospectively compare radiation dose parameters and image quality of an unenhanced whole-body CT protocol performed with 100kVp tube voltage in combination with a dedicated tin-filter (Sn-filter) for spectral shaping and a standard whole-body CT protocol performed with 120kVp tube voltage.
Methods and Materials: Twenty-five prospectively enrolled patients (18 men; median age 68 years) with proven multiple myeloma underwent a whole-body unenhanced 100kVp Sn-filter CT protocol. All scans were performed on a 3rd generation dual-source CT, using the following scan parameters: 100kVp tin filter, ref. mAs 280, 192 mm × 0.6 mm detector collimation, pitch 1.2. Each patient had undergone a previous CT whole-body standard protocol with 120 kVp within one year. Subjective and objective image quality was assessed in various anatomic regions and radiation dose was compared. Comparisons between the groups were analyzed with two-way ANOVA or Wilcoxon-Rank-Sum Test depending on the distribution of the data.
Results: All studies were rated as diagnostic. There was no significant difference between both protocols for subjective image quality (p>0.05). Objective image quality revealed significant higher attenuation values for the standard protocol, when compared to the 100 tin protocol for bone tissue, lung tissue and liver tissue (all p<0.05). Radiation dose was significantly less for the 100kVp tin protocol when compared to the standard protocol (mean dose-length-product 161±30 mGy*cm vs 1233±211 mGy*cm; p<0.0001).
Conclusion: 100 kVp spectral shaping whole-body CT by means of a tube-based tin-filter allows 88% dose reduction when compared to a standard 120 kVp.

Evaluation of a new x-ray imaging system based on Talbot-Lau interferometry: initial images of the knee joints of healthy volunteers
Y. Hara[1], J. Tanaka[1], M. Niitsu[1], Y. Hoshino[2]; [1]*Saitama/JP*, [2]*Hachioji/JP (jtanaka@saitama-med.ac.jp)*

Purpose: To evaluate the characteristics of images of the knee obtained in a hospital from normal volunteers using an x-ray interferometry system that does not require either a synchrotron or a microfocus x-ray tube, and instead uses a practical x-ray tube (Talbot-Lau interferometry).
Methods and Materials: The cartilage in the four knee joints of healthy volunteers was imaged using our test system via the differential phase image technique, and its visibility was evaluated. Adequate positioning of the knee joint was examined so that the x-ray beam could pass through the joint space properly, using a specially designed fixing device with a weight of 2-4kg. The average exposure time was 7 seconds and the maximum skin radiation dose was 8mGy. This trial was performed based on results using cadaveric knee joints and with the approval of the university ethics committee.
Results: In all case, the joint cartilage and part of the menisci were well depicted.
Conclusion: This new x-ray imaging system based on Talbot-Lau interferometry can be used to image the cartilage and menisci to some extent, but more quickly and inexpensively than with MRI. The thickness of the joint cartilage and menisci can be measured in these images. The potential of this technology for diagnostic applications should be explored further. We have already started to examine other joints, such as the hands and elbows, using this system, to advance the clinical application of this new device.

Chest imaging with x-ray dark-field radiography: first human body experience
A.A. Fingerle[1], K. Willer[2], L. Gromann[2], F. de Marco[2], T. Koehler[3], K. Rindt[3], K. Hellbach[1], F. Pfeiffer[2], P.B. Noël[1]; [1]*Munich/DE*, [2]*Garching/DE*, [3]*Hamburg/DE (alexander.fingerle@tum.de)*

Purpose: To evaluate the performance of an experimental x-ray dark-field radiography system for chest imaging in humans and to compare with conventional diagnostic imaging.
Methods and Materials: The study was institutional review board (IRB) approved. A single human body (52years, female, height: 173cm, weight: 84kg, chest circumference: 97cm) was imaged within 24 hours postmortem on the experimental x-ray dark-field system. In addition, the body was imaged on a clinical CT system to obtain a reference scan. The grating-based dark-field radiography setup was equipped with a set of three gratings to enable grating-based dark-field contrast x-ray imaging. The prototype operates at an acceleration voltage of up to 70kVp and with a field-of-view large enough for clinical chest x-ray (>35x35cm^2).
Results: It was feasible to extract x-ray dark-field signal of the whole human thorax, clearly demonstrating that human x-ray dark-field chest radiography is feasible. Lung tissue produced strong scattering, reflected in a pronounced x-ray dark-field signal. The ribcage and the backbone are less prominent than the lung but are also distinguishable. Finally, the soft tissue is not present in the dark-field radiography. The regions of the lungs affected by oedema, as verified by CT, showed less dark-field signal compared to healthy lung tissue.
Conclusion: Our results reveal the current status of translating dark-field imaging from a micro-scale (small-animal) to a macro-scale (patient). The performance of the experimental x-ray dark-field radiography setup offers, for the first time, obtaining multi-contrast chest x-ray images (attenuation and dark-field signal) from a human body.

Impact of aspiration on dark-field signal intensities in chest radiographs of living pigs

K. Hellbach[1], A. Bähr[2], P.B. Noël[1], S. Reu[1], A. Yaroshenko[3], T. Köhler[3], J. Mohr[4], M.F. Reiser[1], F. Pfeiffer[5]; [1]*Munich/DE*, [2]*Oberschleißheim/DE*, [3]*Hamburg/DE*, [4]*Eggenstein-Leopoldshafen/DE*, [5]*Garching/DE*
(katharina.hellbach@med.uni-muenchen.de)

Purpose: The purpose of this study was to assess the effect of aspiration on dark-field signal intensities in chest radiographs of living pigs.
Methods and Materials: Experiments were performed using 2.5 months old, wild-type German landrace pigs (n=5). Before image acquisition all animals were anesthetized, intubated, and mechanically ventilated. Pigs were imaged with an experimental grating-based large animal scanner to acquire x-ray transmission and dark-field radiographs in posterior-anterior (p.a.) and lateral direction under respiratory arrest. This was done prior to aspiration and 45 minutes after intrabronchial administration of 0.05M hydrochloric acid (HCl). Subsequently, pigs were sacrificed and their lungs were obtained for detailed histopathological analysis. ROIs were placed into the lungs to quantify signal intensities in dark-field and transmission images.
Results: When comparing the scans of the living pigs´ lungs prior to aspiration with the lung images after aspiration had been induced, a visible loss of dark-field signal intensity in the affected parts of the lungs was found.
Conclusion: We were able to show - for the first time - the impact of aspiration on the dark-field images of living large animals. Understanding the properties of this new imaging technique in the depiction of lung pathologies is an absolutely essential step towards transferring this experimental imaging method to a clinical setting.

A fully functional prototype for establishing electrochemotherapy in interstitial usage with drug application and a Q factor optimisation model

A. Ritter, J. Pfeffer, P. Isfort, M. Baumann, P. Bruners; *Aachen/DE*
(aritter@ukaachen.de)

Purpose: Irreversible electroporation (IRE) and electrochemotherapy (ECT) are two innovative electroporation-based minimally-invasive therapies for the treatment of cancer. Combining non-thermal properties of IRE with local application of chemotherapy, ECT is an established treatment modality for superficial malignancies of the skin. In ECT the induced nanopores facilitate the intracellular uptake of the chemotherapeutic agent. The application of ECT in solid organs has not yet been described, so we developed a prototype applicator for ECT in solid organs.
Methods and Materials: Computer simulations were used to design a needle-shaped applicator for percutaneous image-guided ECT in solid organs. To rate the criteria, a Q factor model with weighting coefficients has been developed to optimize the geometric and electric parameters dispassionately. In clinical application, the physician can adapt the 3D field distribution, i.e. the desired ablation zone to the patient individual situation.
Results: With the results of an electric field simulation processes we built up a fully functional needle-shaped prototype with a shaft diameter of 3.2 mm. The cylindrical applicator contains four expandable hollow electrodes in a semicircular configuration used both for interstitial injection of the chemotherapeutic agent as well as the creation of the electric field. First ex-vivo as well as in-vivo tests demonstrate promising results with excellent conformity of simulated and resulting ablation volumes.
Conclusion: Using the ECT prototype system promising results legitimate the next steps, i.e. broad animal studies, including the best strategy of chemotherapy application (intravenous, intra-arterial, interstitial). One of the main efficient advantages is one stich for five electrodes.

Multispectral magnetic particle imaging for real-time 3D MPI-guided treatment of a vessel stenosis

J. Salamon, M. Hofmann, C. Jung, M.G. Kaul, R. Reimer, A. vom Scheidt, G. Adam, T. Knopp, H. Ittrich; *Hamburg/DE (j.salamon@uke.de)*

Purpose: The aim was to establish a real-time multispectral (multicoloured) visualization of multiple MPI tracers and MRI/MPI-roadmapping for MPI-guided interventions on a vessel stenosis model. Since MPI visualizes the spatial distribution of superparamagnetic iron oxide particles (SPIOs) one challenge is the lack of anatomical background information. A multispectral blood pool agent or MRI/MPI road-mapping might overcome this problem.
Methods and Materials: A standard guide wire and balloon-catheter were labelled with a magnetic lacquer. A vessel phantom with a stenosis was either filled with saline or SPIOs (MM4). In vitro stenosis treatment was performed inflating the balloon either with MM4 or with saline. MPI data were acquired at a rate of 46 frames/s. For analysis of the magnetic lacquer marks electron microscopy and micro-computed tomography were performed.
Results: Real time multicolored visualization of the different tracers' distinct magnetic fingerprints at a rate of 6 frames/s as well as MRI/MPI-roadmapping using bimodal fiducial markers was feasible allowing MPI-guidance for PTA. The magnetic lacquer consisted of 10-20 nm thick iron plates with a size of 0.5 to 90µm (10.6 mg Fe/ml). Micro-CT showed a maximum lacquer thickness on the instruments of 80-100 µm allowing for coaxial use. Successful angioplasty was verified by MPI and MRI.
Conclusion: Multicoloured MPI allows for 3D real-time guidance of endovascular instruments and PTA. A combination of MPI/MRI for an anatomical road map in addition to multispectral interventions with a blood pool agent might emerge as a promising tool for radiation free interventions.

Impact of temporal resolution on quantitative renal perfusion MRI: assessment using a single contrast injection and a continuous golden angle radial sampling technique

J. Budjan[1], P. Riffel[1], R. Grimm[2], K. Block[3], F.G. Zoellner[1], S.O. Schönberg[1], U.I. Attenberger[1], D. Hausmann[1]; [1]*Mannheim/DE*, [2]*Erlangen/DE*, [3]*New York, NY/US*

Purpose: Dynamic contrast-enhanced (DCE) MRI is an established method for the quantitative assessment of renal perfusion. However, temporal resolution of DCE sequences varies in literature; there is no definite consensus on the minimal temporal resolution required for reliable quantitative perfusion assessment. Purpose of this study was the in-vivo evaluation of different temporal resolutions for quantitative renal DCE using a single contrast injection.
Methods and Materials: 22 patients (7 female; 58.7±21.2 years) underwent a prototypical fat-suppressed, contrast-enhanced, golden-angle radial stack-of-stars T1-weighted 3D spoiled gradient-echo examination (GRASP) for 3min during free breathing. Using this single acquisition, 4 datasets were retrospectively reconstructed for each patient with a temporal resolution of 9.7s, 5.9s, 3.6s and 1.3s, respectively. Renal plasma flow (rPF) was calculated for the entire renal volume using a voxel-by-voxel deconvolution approach on all datasets and manual kidney segmentation. rPF values were compared between the individual patients' datasets using paired t-testing and Blant-Altmann analyses.
Results: Using the datasets with the highest temporal resolution (1.3s), mean rPF was 216±93ml/100ml/min. The analysis of the lower temporal resolution datasets yielded similar values; no statistically significant differences between the groups were found (p>0.09 for all pairs).
Conclusion: DCE MRI for quantitative renal perfusion assessment performed with temporal resolutions between 1.3s and 9.7s results in comparable rPF values. An increase in temporal resolution does not seem to result in relevant changes of rPF parameters.

Novel high quantum efficiency photodiode for x-ray imaging

M.A. Juntunen, J. Heinonen, V. Vähänissi, P. Repo, A. Vaskuri, H. Savin; *Espoo/FI (mikko.juntunen@aalto.fi)*

Purpose: Performance of x-ray imaging using photodiodes with scintillators, for example computed tomography, is limited by radiation dose. Improving photodiode sensitivity helps reduce dose at given image quality or improve image quality at given dose. A novel high quantum efficiency photodiode applicaple to scintillator based imaging is introduced.
Methods and Materials: Present-day photodiodes notably suffer from optical losses, and generated charge carriers are often lost via recombination. Here we demonstrate a device characterized by very high external quantum efficiency. Instead of a conventional p-n junction, we use negatively charged alumina to form an inversion layer that generates a collecting junction. We enhance the collection efficiency further by nanostructuring the photodiode surface, forming black silicon, which dramatically reduces reflectance and allows for high response also at high incident angles. This enhances collection of diffuse light emitted by scintillators giving additional response improvement in comparison with planar photodiodes.
Results: External quantum efficiency of the sample diodes exceeds 96% over the wavelength range between 250 and 950 nm. Extremely low reflectance was measured up to 70 degrees incident angle. Signal from scintillator under x-ray beam was >20% higher than with similar size commercial planar photodiode.
Conclusion: Black Silicon photodiodes were shown to achieve very high optical quantum efficiency and to collect scintillator light signal far better than conventional planar diodes, giving possibility to improve performance of scintillator based x-ray imaging, like CT and SPECT, or to reduce radiation dose.
