MESENCHYMAL CELL TRANSPLANTATION

P0002 NATURAL KILLER CELLS MAY BE THE KEY FACTOR FOR THE AMELIORATION OF THE LIVER FIBROSIS AFTER MESENCHYMAL CELL TRANSPLANTATION

Introduction: Liver cirrhosis is associated with an imbalance between vasodilation and vasocostriction in the sinusoids. Therefore the investigation of the nitric oxide - cyclic guanosine monophosphate (NO-cGMP) pathway, a key regulator of vascular smooth muscle tone, is essential.

Aims & Methods: The rat model of thioacetamide (TAA) was used to induce liver fibrosis/cirrhosis and alterations of the NO-cGMP pathway and subsequent liver damage were assessed. 25 male Wistar rats were studied (11 untreated controls and 14 TAA treated animals [0.03 g TAA/100 ml drinking water for 16 weeks]). TAA dosage was adjusted weekly based on body weight changes. Hepatic gene expression of endothelial and inductive NO synthase (eNOS and iNOS), phosphodiesterase 5 (PDE5), soluble guanylate cyclase subunit a1 and b1 (sGCa1 and sGcb1) was determined by qRT-PCR. Serum cGMP concentrations were measured by ELISA using blood samples taken from the carotid artery. Likewise liver damage was assessed by liver chemistry (i.e. alanine- and aspartate-aminotransferase (ALT and ASAT), alkaline phosphatase (AP), albumin and bilirubin). The degree of fibrosis was estimated by histological criteria (i.e. Desmet scores). PDE5-expression was determined by immunohistochemistry. Kruksal-Wallis test was used for statistical analysis of group differences.

Results: 43% (6/14) of TAA-treated rats developed liver fibrosis (Desmet score of 1–3) while 57% (8/14) developed liver cirrhosis (Desmet score of 4). No major differences in ALT, ASAT, and AP serum concentrations were observed in either group. However, bilirubin was significantly elevated in TAA-treated rats, while albumin concentrations were significantly reduced. Gene expression analysis revealed significantly increased expression of eNOS (1.5fold), PDE5 (7.7fold) and sGcb1 (2.1fold) in fibrotic livers compared to controls. cGMP concentrations in fibrotic animals were slightly decreased (34%). Significantly increased expression of eNOS (2.26fold), PDE5 (11fold), sGCa1 (1.70fold) and sGcb1 (3fold) was observed in cirrhotic livers compared to controls, while cGMP concentrations were significantly decreased (40%). iNOS expression was only detected in fibrotic and cirrhotic livers, but absent in controls. Immunohistochemistry revealed markedly increased PDE5-expression in cirrotic livers, which was predominantly localized in hepatic stellate cells.

Conclusion: The analysis of the animal model of TAA-induced liver fibrosis/cirrhosis revealed alterations of the NO-cGMP pathway, characterized by increased PDE5-expression. These changes reinforce the hypothesis that sinusoids remain in a contractile state in cirrhotic livers, thereby contributing to increased PDE5-expression. The role of NO-cGMP pathway and subsequent liver damage was assessed. While, the role of NO-cGMP pathway in liver damage was assessed.

P0004 THE PROTECTIVE EFFECTS OF GROUP 3 INNATE LYMPHOCYTE CELLS ON HEPATITIS B VIRUS RELATED LIVER FIBROSIS COULD BE IMPAIRED BY TH17 CELLS

S. Wang, W. Ma, L. Cheng, W. Jiang
Gastroenterology, Zhongshan Hospital Fudan University, Shanghai/China

Contact E-mail Address: zhangtt246@sina.com

Introduction: Th17 cells have been proved to contribute to hepatitis B virus (HBV) related liver fibrosis. Group 3 innate lymphocyte cells (ILC3s), which have similar profiles of transcription factor and cytokines to that of Th17 cells, were also suggested to be involved in the progression of liver fibrosis.

Aims & Methods: The study was designed to explore the functions of ILC3s and the relationships between ILC3s and Th17 cells in liver fibrosis. Peripheral blood samples were collected from 60 patients with chronic hepatitis B (CHB), and 50 patients with HBV related liver cirrhosis (LC) as well as 30 healthy controls (HC). The percentages and cytokines secretion of ILC3s (Lin-CD127+CD117+CD274) and Th17 cells (CD4+IL-17+) were detected by flow cytometry. Peripheral blood mononuclear cells (PBMCs) and PBMCs without ILC3s cc-cultured with hepatic stellate cells (HSCs)-LX2 in contact and non-contact manners. Then Th17 cells, which were induced from naive CD4+ T cells in vitro, were transferred into Rag1-/- mice with carbon tetrachloride (CCL4) related liver fibrosis. In addition, ILC3s in Rag1-/- mice were depleted by injecting with anti-CD90.2 antibody.

Results: Compared with HC, the percentage of ILC3s increased in CHB group. The anti-inflammation cytokines secreted by ILC3s such as IL-22 increased, whereas pro-inflammation cytokines of ILC3s such as IL-17A, TNF-α, IFN-γ decreased in CHB patients. However, ILC3s decreased in LC patients with reduced cytokines secretion. Th17 cells frequencies significantly increased both in CHB and LC groups compared with HC. PBMCs without ILC3s, which were collected from CHB and LC patients, promoted the proliferation and activation of HSCs because of less IL-22 secretion. Similarly, compared with wild type mice, ILC3s in spleens and livers of C57BL/6 mice with liver fibrosis increased sequentially at time point of week 2 and week 4 following drug injection. Intriguingly, at week 6, ILC3s decreased compared with previous. However, Th17 cells increased gradually with CCL4 administration, even at week 6. Transferring Th17 cells into Rag1-/- mice with CCL4 related liver fibrosis made the ILC3s in spleens and livers decrease significantly, and the degree of mice liver fibrosis become more severe than control. Furthermore, ILC3s depletion correlated with reduced expression of IL-22 and more severe liver fibrosis. Transferring purified liver ILC3s into recipient mice resulted in liver inflammation and reverse liver fibrosis.

Conclusion: Our study has uncovered the protective role of ILC3s in liver fibrosis, which is through secretes IL-22 to reduce proliferation and activation of HSCs. However, the protective functions of ILC3s could be impaired by Th17 cells.

Introduction: Internal biliary drainage has been suggested better than external biliary drainage in alleviating the damage of intestinal mucosa barrier caused by obstructive jaundice; however, the relevant mechanism is not well understood.

Aims & Methods: We aimed to investigate the potential relationship between the expressions of bile acid receptor and TLR4/NO2 in intestinal mucosa and its influence on the intestinal mucosal barrier with obstructive jaundice. In this study, we mainly study the expression between FXR and TLR4, TGR5 and NO2. Sixty male adult Kunming mice were randomly assigned to four groups: SH (sham operation), OJ (obstructive jaundice), ID (internal drainage), ED (external drainage) (n = 15 in each group). On the 7th day from the first operation, the OJ and SH mice were executed and specimens of blood and ileal tissue of groups were collected. ED and ID were operated on day 8 for biliary drainage procedure. Blood was drawn from heart for liver function test. The terminal ileum specimen was collected for test of histology by haematoxylin-eosin staining. Western blot (WB) and real-time polymerase chain reaction (RT-PCR) were used to detect the expression of protein and mRNA of FXR, TGR5, TLR4 and NO2 in intestinal mucosa.

Results: We have successfully established the animal models. The histopathological examination revealed notable inflammatory infiltration and hyperplasia disruption at terminal ileum in OJ mice; significant alleviation of above injuries by ID while little improvement by ED. FXR-TLR4: After biliary obstruction, the expression of protein and mRNA of FXR were significantly increased, while the expression of protein and mRNA of TLR4 were significantly decreased compared with SH group’s (P < 0.001); after ED, compared with OJ group’s expression of protein of FXR was decreased while TLR4 were increased. The mRNA of both FXR and TLR4 were increased. After ID, the expression of protein and mRNA of FXR were significantly decreased compared with OJ group’s but were still higher than that in SH group and were significantly higher than ED group’s. And the expression of protein and mRNA of TLR4 were significantly increased compared with OJ group’s (P < 0.001), but were still lower than that in SH group and were still more than ED group’s. The trend of TLR4 expression was almost the same between vehicle group and no gavage group. After gavage with FXR agonist, the differences of TLR4 expression of four groups disappeared (P > 0.05). TGR5-NOD2: IHC and WB suggested that after OJ surgery, the protein expression of both TGR5 and NOD2 increased obviously compared to that of SH mice; then the level of TGR5 and NOD2 protein fell remarkably after ID surgery close to SH level while in ED group there was only a slightly reduction form OJ level and still with a high expression of TGR5 and NOD2 protein. Detection of RT-PCR found that TGR5 mRNA and NOD2 mRNA level in OJ group increased several times as that of the SH group; after ID surgery, the expression of TGR5 mRNA significantly reduced, NOD2 mRNA level also fell down significantly, but the effect was not observed in ED mice.

Conclusion: The expression of intestinal FXR and TLR4, TGR5 and NO2 could be one of the critical mechanism why internal drainage is better than external drainage in restore intestinal barrier function of obstructive jaundice mice.

Introduction: Alterations in the gut microbiota have been correlated to a wide variety of diseases, including liver diseases. Used as probiotics, several strains of Lactobacillus have been associated not only to modulation of intestinal tight junctions but also to amelioration of liver fibrosis. Common bile duct ligation (BDL) results in acute cholestatic injury and secondary biliary fibrosis, associated with early increased intestinal permeability and disturbed bile acid homeostasis. We have demonstrated that the oncocgenic microRNA-21 (miR-21) is upregulated in BDL mouse liver, mediating liver fibrosis. We aimed to investigate the role of miR-21 in the response of the small intestinal microbiota to BDL that may explain miR-21 effects in acute liver injury and fibrosis.

Aims & Methods: Three-month-old C57BL/6 wildtype (WT) and miR-21 whole body knockout (KO) mice were submitted to sham or BDL surgeries. After three days, the mice were sacrificed and small intestines in the littermate group were carefully removed and preserved. mRNA expression was analysed by qRT-PCR. Bacterial DNA was purified from the small intestinal lumen samples and analysed by next generation sequencing – metagenome analysis. Liver tissue and serum were also collected for biochemical analysis of hepatic damage and fibrosis.

Results: TNF-α and IL-1β mRNA levels increased in the small intestine of BDL mice compared with WT. TLR-4 and TGF-β expression was increased in both sham- and BDL-miR-21 KO mice which is in accordance with the higher LPS in blood plasma observed. Zona occludens (ZO-1) and occludin mRNA levels were decreased in WT mice after BDL. Strikingly, miR-21 KO reverted mRNA of tight junction proteins to control levels. BDL miR-21 KO mice showed decreased circulating levels of hepatic enzymes, concomitant with decreased fibrogenic gene expression in the liver, in comparison with WT mice, suggesting that miR-21 contributes to BDL-induced liver injury and fibrosis. Further, miR-21 KO not only show a decreased small intestine permeability through a ZO-1 and occludin pathway, as it is associated with development of beneficial strains of Lactobacillaceae that may also contribute to liver protection.

Conclusion: These data suggest that miR-21 depletion is associated with increased liver injury and fibrosis markers in the small intestine and better immune response to bacterial dysbiosis provoked by the BDL surgery, thus halting liver injury and promoting gut microbiota homeostasis. Akkermansia muciniphila is associated with different microbial communities. Akkermansia muciniphila can regulate immunologic and metabolic functions.

However, little is known about its effects on gut microbiota structure and function.

Aims & Methods: This study investigated the effect of A. muciniphila on immune-mediated hepatitis and potential underlying mechanisms. Twenty-two C57BL/6 mice were assigned to three groups (N = 7–8 per group) and continuously administered A. muciniphila Mox (ATTC BAA-835) for 14 days. Mouse feces were collected for gut microbiota analysis on the eleventh day, and acute hepatitis was induced by Concanavalin A (Con A, 15 mg/kg) injection through the tail vein. Samples (blood, liver, ileum, colon) were assayed for liver inflammation, systemic inflammation, and intestinal barrier function.

Results: We found that oral administration of A. muciniphila (Akk) decreased serum ALT and AST and alleviated liver histopathological damage induced by Con A. Serum levels of pro-inflammatory cytokines (IL-2, IFN-γ) were decreased, and serum levels of regulatory cytokines (IL-12p40, IFN-γ, IL-12p70, IL-10) were increased. Akk significantly decreased hepatic cell apoptosis; Bcl-2 expression increased, but Bax and DR5 decreased. Further investigation showed that Akk enhanced Ocludin and Tjp-1, two proteins related to strengthened intestinal barriers. Feecal 16s rRNA sequence analysis indicated that Akk increased microbial diversity and richness. The community structure of the Akk group clustered distinctly from that of the Control and Normal groups. Relative abundance of Firmicutes increased, and Bacteroidetes abundance decreased. Correlation analysis showed that injury-related factors (IL-12p40, IFN-γ, DR5) were negatively associated with specific genera (Ruminococcaceae_UCG-009, Lachnospiraceae_UCG-011, Akkermansia), which were enriched in mice pretreated with Akk.

Conclusion: Our results suggested that A. muciniphila Mox (ATTC BAA-835) had beneficial effects on immune-mediated liver injury by alleviating inflammation and hepatocellular death. These effects may be driven by the protective profile of the intestinal community induced by the bacteria. The results provide new perspectives on the immune function of gut microbiota in host diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: In this study, we investigated the mechanism of Sorafenib resistance in HCC cancer stem cells, and how ZBP-89 reduced drug resistance. The sensitivity of Huh7 and Hep3B parental and sphere-forming cells to Sorafenib was measured by MTT assay. We then examined the expression pattern of Notch1 and related factors (IL-12p40, IFN-γ) in human HCC tissue samples. The regulatory effects of ZBP-89 on CSC were evaluated using methods including colony formation, sphere formation, soft agar formation, and colony formation assay. Gene expression and protein interaction in stemness signaling pathways were analyzed.

Results: We found that sphere-forming HCC cells had significant higher resistance to Sorafenib, compared with their parental cells. The expression of Notch1 and EpCAM was increased along with the treatment of low dose of Sorafenib, suggesting that the activation of Notch1 pathway was associated with the drug resistance in liver CSC. Studies further indicated that ZBP-89 overexpression was able to improve the sensitivity of Sorafenib on sphere-forming HCC cells. Furthermore, we found that ZBP-89 expression was negatively correlated with CSC marker CD44 in human HCC tissues. In vitro study indicated that tumor sphere size was impaired upon transfection of ZBP-89, suggesting that ZBP-89 was involved in suppression of CSC phenotype. Detailed investigation against control cells showed that overexpression of ZBP-89 resulted in reduced expression of CSC markers EpCAM, CD133, Sox2 and c-myc at both mRNA and protein levels. In addition, the overexpression of ZBP-89 or silencing of Notch1 reduced the number of colonies formed by sphere-forming HCC cells, demonstrating opposite effects of these two proteins. Mechanistic studies revealed that ZBP-89 was able to repress the expression of Notch1 and reported that ZBP-89 overexpression was able to improve the sensitivity of Sorafenib on sphere-forming HCC cells. Furthermore, we found that ZBP-89 expression was negatively correlated with CSC marker CD44 in human HCC tissues. In vitro study indicated that tumor sphere size was impaired upon transfection of ZBP-89, suggesting that ZBP-89 was involved in suppression of CSC phenotype.

Conclusion: Sphere-forming HCC cells, which contained high levels of Notch1 and EpCAM, were resistant to Sorafenib. The overexpression of ZBP-89 was found to result in the loss of CSC phenotype and improve the sensitivity to Sorafenib in CSC through its interaction with activated Notch1. In conclusion, we believe that targeting ZBP-89 is likely to be a new therapeutic strategy to overcome Sorafenib resistance in HCC.
MOUSE MODELS OF NON-ALCOHOLIC FATTY LIVER DISEASE

Introduction: Non-alcoholic fatty liver disease (NAFLD) has become the most common liver disease worldwide, and is thought to be strongly associated with obesity, insulin resistance, obesity, and gut-driven endotoxin. Aims & Methods: This study was performed: 196 no steatosis; 90 liver steatosis. 251 patients with MS criteria and women (55.6%) presented MS: 135 patients with MS (49%); 141 without MS (51%). In 286 patients a MR study for the presence of liver steatosis was performed: 196 no steatosis; 90 liver steatosis. 251 patients with MS criteria and MR for steatosis: NMS group (128): no steatosis 103; steatosis 25; MS group (123): no steatosis 72, steatosis 51 (total: no steatosis 175, steatosis 76). When we study the presence of liver steatosis was more frequent in the MS group, the results obtained were statistically significant, p = 0.000. Conclusion: Nearly 50% of the patients referred for hyperferritinemia to the hospitals of our city had MS; the patients with MS had more frequently liver steatosis than the patients without MS. Disclosure of Interest: All authors have declared no conflicts of interest.

patients with HFE mutations and (transferrin saturation index (TSI) values
alone. But we did not have C282Y/C282Y patients in the series.

Aims & Methods: To study the relevance of HFE mutations and TSI in determining LIC for HF patients attending the outpatient clinic at 6 hospitals in the Basque country. Prospective study of 312 consecutive patients with HF. Group A: C282Y/C282Y, Group B: C282Y/H63D, Group C: H63D/H63D, and Group D: no predisposing mutations according to HFE mutations and TSI (Group A: no predisposing mutations (PM) for HH and TSI > 55 %; Group B: PM for HH: C282Y/C282Y; C282Y/H63D, H63D/H63D, and TSI > 45 %; Group C: no PM for HH and normal TSI;Group D: PM and normal TSI. In the Basque country, hereditary hemochromatosis (HH) predisposing mutations differ, with relevance of the H63D/H63D mutation. The LIC was measured by MRI.

Results: In all the patients LIC was measured; C282Y/C282Y 14 (4.49%); C282Y/H63D 10 (3.17%); wt/wt 98 (31.41%); C282Y/S65C 3 (1.02%); H63D/S65C 2 (0.64%); C282Y/wt 16 (5.13%); S65C/wt 10 (3.21%). LIC was obtained from all the patients by MR. Mean age: 53 ± 13.3, 272 men and 40 women. Group A: 35, Group B: 32 Group C: 160, Group D: 161. The mean LIC: group A: 72.71 ± 27.89, group B: 70.53 ± 56.87, group C: 35.23 ± 22.62, Group D: 42.67 ± 22.98. We compared the LIC mean values of the 4 groups (Bonferroni) with significant differences (p < 0.0001).

Conclusion: The LIC in different groups of patients referred for HF are significantly different with different predisposition to HH.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Approximately 25% of adult population in western countries have metabolic syndrome (MS). Hyperferritinemia (HF) is frequently present in patients with MS (dysmetabolic hyperferritinemia). There are some publications that suggest that HF is associated with a raised liver iron concentration (LIC) in these patients, but the doubts persist about this subject.

Aims & Methods: To study the LIC in patients referred for hyperferritinemia to six different hospitals in the Basque Country (multicenter study), Spain, and determine if there are differences between patients with or without metabolic syndrome. A prospective study of 312 consecutive patients with HF (> 200 µg/L men, > 300 µg/L women) was conducted from December 2010 to April 2013. The metabolic syndrome was defined by the presence of three of the following factors: waist circumference > 94 cm men, > 80 cm women; Triglycerides > 150 mg/dL or treatment for this dislipidemia; glucose 100 mg/dL or treatment for this dislipidemia; blood pressure > 130 mmHg/85 mmHg or treatment for arterial hypertension. LIC was measured by MRI.

Results: In 276 of 312 patients we have all the data to determine the MS presence: 115/240 men (48%) and 20/36 women (55.6%), 135 patients, presented in MS. In all 276 patients MRI for LIC determination (mean ± SD) was performed. (We have LIC data from (µmol/g) from the 276 patients.) The mean LIC was 30.83 ± 19.38 (women) and 38.84 ± 25.50 (men), with 37.66 ± 24.79 (CI 95%) 33, 44 to 41, 88 for all the MS group. In 141 patients MS was not diagnosed (NMS): 125/240 were men (52%), and 16/36 women (44.4%). The mean LIC was 34.88 ± 16.18 in women, and 44.48 ± 38.16 in men, with 43.39 ± 36.84(95%) 37, 32 to 49, 46 for all the NMS group. We compare the mean values of LIC from both groups (MS vs NMS) by Pearson’s Chi square test and Fisher’s exact test: no significant differences were seen (p = 0.12).

Conclusion: Patients with HF and MS (dysmetabolic hyperferritinemia) present a mean LIC near normal values and their values do not differ from those of patients with HF and without MS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: NASH is considered an important risk factor for liver fibrosis. Although literature data indicates that statins may be beneficial when given for NASH treatment, recent reports are controversial 1.

Aims & Methods: To evaluate if statins independently influence the evolution of fibrosis accompanying NASH using the scales of FibroMax. 120 patients with NASH and metabolic syndrome were followed-up for a period of 3 years. We excluded patients taking a series of drugs, with genetic metabolic disorders or impaired intestinal absorption (celiac disease) or alkoholics. Steatosis, fibrosis...
and NASH were quantified by using the FibroMax scales at baseline and after three years of treatment. Patients were randomized into two groups: the active group of 60 patients receiving low-dose hydrophilic statin (rosuvastatin 5 mg/day) and the witness group of 60 patients, matched by age, gender and sex, receiving placebo.

Results: 97% of subjects fulfilled the follow-up period. The FibroMax staging at baseline showed the following results in the active group: S1–29%, S2–41% and S3–30%; F1–50%, F2–30%, F3–13% and F4–7% of patients, respectively N1–31% and N2–69%. The staging according to FibroTest, SteatoTest and NashTest was similar in placebo group. After 2 years of low-dose hydrophilic statin, the mean ALT level from active group decreased from 72.22 IU/L to 32.80 IU/L, p < 0.05 (ss); in the witness group no significant ALT decrease was noticed (69.34 IU/L to 58.17 IU/L, p > 0.5). The FibroMax showed an increase in patients in active treatment, while in the witness group, there was no such increase in active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–27%, S1–46%, S2–25%, respectively S3–2% of patients, respectively F0–38%, F1–32%, F2–28%, F3–2%; F4–0% of patients. NASH patients showed positive evolution of liver histology in active group, compared with placebo (N0–36%, N1–40% respectively N2–26%, p > 0.001, ss). After adjusting for age, BMI, diabetes, LDL-cholesterol and triglyceride values, statin therapy showed a significant correlation with the steatosis, fibrosis and NASH stages improvement in the active group (r = 0.92, r = 0.87, respectively r = 0.93, p < 0.005, ss). Conclusion: While statins proved to be safe and efficient for the treatment of NASH in our series, larger cohort studies are needed to further demonstrate this potential positive effect on liver fibrosis.

Aims & Methods: We aimed to study the relationship between CRP and homocysteine (HC) levels with pathological changes in the liver, determined with the non-invasive bioprognostic test Steatoscreen in patients with AO. The study included 60 patients aged 18–59 years with joints with a waist circumference >80 cm for women, and >94 cm for men. All patients underwent a bioprognostic test Steatoscreen. Depending on the severity of the pathological changes in the liver, the Steatoscreen scale divided all the patients into 3 groups: steatosis, fibrosis and steato-fibrosis. Depending on the presence or absence of cytolysis syndrome, 2 subgroups were distinguished in each group: subgroups of non-alcoholic steatohepatitis (ALT values, AST above the norm more than 2 times), and steatosis. In all, the levels of CRP and HC were studied. Results: The levels of CRP and HC in patients with AO were higher than in non-obese NASH patients. The most severe levels of pathological changes in the liver on the Steatoscreen scale: r = 0.6. n < 0.001; r = 0.85 p < 0.0006 for CRP and HC, respectively.

Conclusion: NAFLD in patients with AO is characterized by the development of severe forms of metabolic diseases accompanied with liver fibrosis. This fact can influence the risk of developing the pathology of not only the liver, but also atherosclerosis and proves the need for a more thorough examination of patients with AO and NAFLD for the purpose of early detection and correction of existing metabolic disorders.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: Study of changes in the vascular wall of the common carotid artery (IMT CCA) and in patients with abdominal obesity (AO) and different forms of nonalcoholic fatty liver disease (NAFLD). The study included 60 patients with AO between the ages of 18 to 59 years (waist circumference >80 cm in women and >94 cm in men) and NAFLD, in the presence of clinical manifestations, provided written informed consent to participate in the study. All patients underwent an ultrasound examination of the abdominal cavity to determine the size of the liver and signs of steatosis. The level of severity of pathological changes in the liver tissue (fibrosis, steatosis and steatofibrosis) was assessed by non-invasive diagnostic method Steatoscreen. (Biopredictive laboratory, France). Measurement of the CCA IMT was performed according to standard procedures on the machine Voluson 730 Expert, equipped with a linear transducer phased array with a frequency of 7.5 MHz. The presence of early signs of atherosclerosis was defined as a local thickening of the IMT CCA more than 0.9 mm in any point of the carotid artery (CCA IMT max). Depending on the severity of the pathological changes in the liver, the Steatoscreen scale divided all the patients into 3 groups: steatosis, fibrosis and steatofibrosis. Depending on the presence or absence of cytolysis syndrome, 2 subgroups were distinguished in each group: subgroups of non-alcoholic steatohepatitis (ALT values, AST above the norm more than 2 times), and steatosis. In the future, the comparative and correlation analysis of the data was carried out. Results: Signs of early atherosclerosis, in the form of the IMT CCA, were detected in the majority of the patients (52%) and differed between the observed groups. The average thickness of the IMT CCA was significantly higher in patients with abdominal obesity and pathological changes in the liver in the form of severe steatofibrosis on the Steatoscreen scale than in groups of patients with less severe changes in hepatic tissue (0.83 mm for the steatosis group, 0.89 and 0.97 mm for fibrosis and steatofibrosis groups respectively, p < 0.001). At the same time, the maximum thickness of the IMT CCA was recorded in the group of patients with non-alcoholic steatohepatitis in the fibrosis group (1.14 mm, p = 0.002). In the process of regression analysis, a direct significantly relationship was found between the thickness of the carotid intima-media

P0019 INVESTIGATION OF THE RELATIONSHIP BETWEEN THE THICKNESS OF THE INTIMA-MEDIA COMPLEX OF COMMON CAROTID ARTERIES AND PATHOLOGICAL CHANGES IN THE LIVER IN PATIENTS WITH ABDOMINAL OBESITY AND NON-ALCOHOLIC FATTY LIVER DISEASE

Introduction: In the last decade, the notion of non-alcoholic fatty liver disease (NAFLD) has undergone noticeable changes. It is shown that in the liver with fatty hepatosis, insulin and glucose utilization is disrupted, conditions are created for the synthesis of atherogenic forms of cholesterol and triglycerides. This contributes to the development of violations of carbohydrate and lipid metabolism, the early appearance of atherosclerosis and associated cardiovascular complications. Thus, NAFLD can be considered as an independent, additional risk factor of atherosclerosis. Obviously, it is important to clarify the nature of the relationship between NAFLD and the early manifestations of atherosclerotic vascular wall lesions are relevant.

Aims & Methods: Study of changes in the vascular wall of the common carotid artery (IMT CCA) and in patients with abdominal obesity (AO) and different forms of nonalcoholic fatty liver disease (NAFLD). The study included 60 patients with AO between the ages of 18 to 59 years (waist circumference >80 cm in women and >94 cm in men) and NAFLD, in the presence of clinical manifestations, provided written informed consent to participate in the study. All patients underwent an ultrasound examination of the abdominal cavity to determine the size of the liver and signs of steatosis. The level of severity of pathological changes in the liver tissue (fibrosis, steatosis and steatofibrosis) was assessed by non-invasive diagnostic method Steatoscreen. (Biopredictive laboratory, France). Measurement of the CCA IMT was performed according to standard procedures on the machine Voluson 730 Expert, equipped with a linear transducer phased array with a frequency of 7.5 MHz. The presence of early signs of atherosclerosis was defined as a local thickening of the IMT CCA more than 0.9 mm in any point of the carotid artery (CCA IMT max). Depending on the severity of the pathological changes in the liver, the Steatoscreen scale divided all the patients into 3 groups: steatosis, fibrosis and steatofibrosis. Depending on the presence or absence of cytolysis syndrome, 2 subgroups were distinguished in each group: subgroups of non-alcoholic steatohepatitis (ALT values, AST above the norm more than 2 times), and steatosis. In the future, the comparative and correlation analysis of the data was carried out. Results: Signs of early atherosclerosis, in the form of the IMT CCA, were detected in the majority of the patients (52%) and differed between the observed groups. The average thickness of the IMT CCA was significantly higher in patients with abdominal obesity and pathological changes in the liver in the form of severe steatofibrosis on the Steatoscreen scale than in groups of patients with less severe changes in hepatic tissue (0.83 mm for the steatosis group, 0.89 and 0.97 mm for fibrosis and steatofibrosis groups respectively, p < 0.001). At the same time, the maximum thickness of the IMT CCA was recorded in the group of patients with non-alcoholic steatohepatitis in the fibrosis group (1.14 mm, p = 0.002). In the process of regression analysis, a direct significantly relationship was found between the thickness of the carotid intima-media
PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE MAY OVEREXPRESSION OF HEPASSOCIN IN DIABETIC METABOLIC SYNDROME.

Results: There was stastically significant increase in mean value of serum hepassocin on group 1 and IV on comparing with group II and group III. For group III there was stastically significant increase in mean value of serum hepassocin on comparing with other groups. There was a significant serum hepassocin up regulation in patients with type 2 diabetes and non alcoholic fatty liver disease patients (Group 1) even than non alcoholic fatty liver disease (Group 2).

Conclusion: The present study provides evidence that overexpression of HPS may aggravates NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Insulin resistance is the main pathogenic determinant of both NAFLD and diabetes, and it can facilitate triglyceride accumulation in the liver. Overexpression of hepassocin (HPS) increased hepatic lipid accumulation and NAFLD activity scores (NAS), whereas deletion of HPS improved high fat diet-induced hepatic steatosis and decreased NAS in mice.

Aims & Methods: The aim of this study was to explore the relationship between hepassocin and diabetic patients with or without NAFLD. The study included 90 patients that were divided into 4 groups: Group I: included 20 patients who were diagnosed as diabetes mellitus type 2, Group II: included 20 patients who were diagnosed as non alcoholic fatty liver disease, Group III: included 20 patients who were diagnosed as diabetes type 2 and non alcoholic fatty liver disease, Group IV (control group): included 20 healthy person who were matched in age and sex with patients group.

Results: There was stastically significant decrease in mean value of serum hepassocin of group I and IV on comparing with group II and group III. For group III there was stastically significant increase in mean value of serum hepassocin on comparing with other groups. There was a significant serum hepassocin up regulation in patients with type 2 diabetes and non alcoholic fatty liver disease patients (Group 1) mostly than diabetic patients (Group 1) and even than non alcoholic fatty liver disease (Group 2).

Conclusion: The present study provides evidence that overexpression of HPS may facilitate increased hepatic lipid accumulation with NAFLD and Type 2 Diabetes mellitus.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0022 DIAGNOSTIC ACCURACY OF SHEAR WAVE ULTRASOUND ELASTOGRAPHY FOR EARLY DETECTION OF NON ALCOHOLIC STEATOHEPATITIS AMONG PATIENTS WITH TYPE 2 DIABETES MELLITUS

A. Gameel1, E. M. Elhadyd1, A. A. Mousa1, M. M. Elrakhawy2
1Internal Medicine, Mansoura University, Mansoura/Egypt
2Department Of Gastroenterology, Peking University People’s Hospital, Beijing/China

Introduction: Non alcoholic fatty liver disease (NAFLD) is a broad term describing simple steatosis, non alcoholic steatohepatitis (NASH), NASH cirrhosis and NASH-induced hepatocellular carcinoma (1). Incidence increased in patients with type 2 DM. At a level of 8.45 kPa by shear wave elastography, we can differentiate simple steatosis from steatohepatitis (2). Different diagnostic modalities have great limitations in differentiating simple steatosis from steatohepatitis (3). Liver biopsy remains the gold standard for diagnosis of NASH, however, it is invasive with potential severe complications (4). Several ultrasound elastography techniques have been described including transient elastography, acoustic radiation force impulse elastography and shear wave elastography(5). Shear wave elastography shows a stepwise increase of liver stiffness as the severity of liver inflammation increases(6).

Aims & Methods: We aimed to evaluate the accuracy of shear wave ultrasound elastography in differentiating simple steatosis from steatohepatitis in patients with type 2 DM. This was a prospective study including 60 patients 30 males and 30 females who visited our outpatient clinic or inpatient department at Specialized Medical Hospital. These patients were diabetic aged more than 30 years old with ultrasound showing fatty liver. Significant alcohol consumption, drugs causing steatosis and hepatic diseases were excluded by history, laboratory investigations and liver biopsy. All patients underwent full detailed history, examination, laboratory investigations (complete blood count, liver functions, kidney functions, random blood sugar, lipid profile, serology for hepatitis B and C viruses). Shear wave elastography was performed to all patients and stiffness of the liver was measured from different areas in kilopascal (kPa) then average stiffness was calculated. Liver biopsy was done and histopathological examination by Hematoxin, Eosin and Masson Trichrome stains, then NAFLD activity score (NAS) was calculated.

Results: Correlation between results of stiffness by elastography and NAS by biopsy revealed that: There was a significant positive association between average stiffness by elastography and definitive NASH (NAS 5 and 6) in patients with type 2 DM. At a level of 8.45 kPa by shear wave elastography, we can differentiate simple steatosis from steatohepatitis (Area Under Curve 0.936, sensitivity 90%, specificity 90%, positive predictive value 81%, negative predictive value 49%).

Conclusion: Shear wave ultrasound elastography is a promising non invasive technique to differentiate simple steatosis from steatohepatitis in patients with type 2 DM.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Nonalcoholic fatty liver disease is a main cause of chronic liver disease worldwide. A quantitative, non-invasive assessment of hepatic steatosis is desirable. Throughout the path of ultrasound (US), attenuation by liver parenchyma is uneven. This is the basis of the controlled attenuation parameter (CAP). However, further accumulation of data is needed to assess the role of CAP in the diagnosis of steatosis. We investigated the diagnostic performance of B-mode image-guided ultrasound attenuation imaging and quantification for assessing hepatic steatosis by a liver biopsy (LB, reference standard). It was compared with the liver-to-spleen ratio (LS) (ratio) from computed tomography (CT) and CAP.

Aims & Methods: We prospectively analyzed 112 consecutive patients with chronic liver disease who underwent ultrasound attenuation imaging, CT, and liver biopsy. Ultrasound attenuation imaging was performed using the LOGIQ E9 scanner (GE Healthcare) with a CL-6-convex array probe (frequency, 4 MHz). We acquired a B-mode image of liver parenchyma. RF signals corresponding to the images were compensated by the reference signal previously measured using the reference phantom (known attenuation, 0.5 dB/cm/MHz). The attenuation coefficient (AC) was calculated from the signals’ decay slope. Steatosis, liver fibrosis, and necroinflammatory activity were staged and graded during pathological analysis. The steatosis grade was categorized as follows: S0, <38%; S1, 38–50%; S2, 51–72%; S3, >72%. The diagnostic performance of AC for steatosis prediction was assessed using area under the curve (AUC) analysis; it was compared with the L/S ratio or CAP. Univariate and multivariate regressions analyses were used to identify variables correlated with AC values.

Results: Patients (51% men; 42% non-alcoholic fatty liver disease, 58% had hepatitis C virus) had a median body mass index of 26.4 kg/m2. Median AC values for grades S0 (n = 38), S1 (n = 47), S2 (n = 18), and S3 (n = 9) were 0.49, 0.55, 0.66, and 0.72, respectively, demonstrating a stepwise increase with increasing steatosis severity (P < 0.0001). AC was significantly correlated with the steatosis percentage (r = 0.800, P < 0.0001), L/S ratio (r = −0.670, P < 0.0001), and CAP (r = 0.639, P < 0.0001). AUCs of AC vs. the LS ratio for identifying grades S1, ≥S2, and S3 were 0.919 vs. 0.856, 0.957 vs. 0.902, and 0.960 vs. 0.919, respectively, showing significantly better results than those for the L/S ratio and CAP. For the sensitivity and specificity of AC ≥58.5%, cut-off values were 0.53 dB/cm/MHz for ≥S1, 0.60 dB/cm/MHz for ≥S2, and 0.64 dB/cm/MHz for ≥S3. Steatosis was the only factor independently affecting AC values.

Conclusion: Ultrasonic attenuation imaging had a high diagnostic accuracy for detecting hepatic steatosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

detected in the TAA group compared with that in the control group. However, celecoxib significantly decreased the area of splenic white pulp by 37.6%. Besides, the portal pressure was measured by a transmural perfusion method. The enzyme-linked immunosorbent assay was performed to evaluate the expression of proinflammatory cytokines.

Conclusion: Our data provide novel evidence for the differential expression of miRNAs in ascites in patients with PCA and SBP. Evaluation of ascites-miRNAs may offer an alternative approach for diagnosis of peritoneal carcinomatosis and create an avenue for therapeutic application as well.
with that of the control group, demonstrating that PJK/AKT signal pathway was involved in the development of pathological angiogenesis. However, the treatment with celexobux strongly decreased the protein expression of VEGF, CD31, PJK3 and AKT in the spleen of cirrhotic rats.

**Conclusion:** The present study indicates that COX-2 contributes to splenomegaly by facilitating angiogenesis, fibrosis and inflammation in the spleen. Moreover, inhibition of COX-2 by celexobux could ameliorate portal hypertension and splenomegaly.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Spontaneous bacterial peritonitis (SBP) is a life-threatening complication in advancing liver cirrhosis. Translocation of intestinal bacteria or bacterial products from the gut to mesenteric lymph nodes is crucial for SBP, with *Escherichia coli* (E. coli), *Klebsiella pneumoniae* being the most common germs. Small intestinal bacterial overgrowth and a altered microbiota are so far known as risk factors for SBP. However, the exact mechanisms of bacterial translocation need to be identified as they are supposed to contribute to the development of early recognition systems and initiation of antibiotics.

**Aims & Methods:** With regard to the development of early recognition systems, pathomechanisms and signaling pathways of bacterial translocation in SBP were explored. These insights might lead to an initiation of antibiotics on time and reduced mortality in SBP.

Monolayers of human intestinal epithelial cell lines Caco-2 (p53 mutant) and HCT-116 (p53 wildtype) were cocultured with *E. coli* with different MOI (MOI 0, 1, 5 and 10) for 2 to 4 hours post confluence. Experiments with heat inactivated *E. coli* were performed as controls. Effects of microbial metabolic products were tested by using the supernatant of an overnight culture. qPCR and Western Blot analysis were performed to analyze changes in mRNA and protein levels of Occludin, E-cadherin and the p53 family including p53 and p73. Caco-2 cells displayed less reduction of Occludin and E-cadherin protein levels in comparison to HCT-116 cells, where significant decreases were observed. These effects might lead to an indication of antibiotics on time and reduced mortality in SBP.

**Conclusion:** By using an in vitro model, we demonstrate destabilizing effects of *E. coli* on intestinal cell junctions, p53 and p73. As far as these effects are dependent on incubation time, microbial concentration and living bacteria, these effects might represent the mechanism to protect the bacteria from intestinal immune responses and therefore to promote bacterial translocation in SBP.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Pathological bacterial translocation (BPT) in liver cirrhosis (LC) is the pathophysiological hallmark for spontaneous bacterial infections increasing mortality severely. Factors known to contribute to PBT in LC are among others an increased intestinal epithelial permeability.

**Aims & Methods:** Since mucus represents one of the major components of this barrier we hypothesize that: a) gut mucus is altered in LC and b) bile could be a modulator of its production. Two different models of experimental LC namely bile duct ligation (BDL) and the chronic treatment with carbon tetrachloride (CCl4) – as well as partial portal vein ligation (PPVL) and sham-operated mice were used. Finally the farnesoid X receptor (FXR) agonist obeticholic acid (OCA) par-tially restored GC loss in CCl4 treated animals (Control 0.63 GC/100µm of villus±0.08 vs Control OCA 0.65 GC/100µm of villus±0.07 vs CCl4 0.49 GC/100µm of villus±0.01 vs FEX-30.30 GC/100µm of villus±0.08). Moreover we have seen that farnesoid X receptor (FXR) agonist obeticholic acid (OCA) par-tially restored GC loss in CCl4 treated animals (Control 0.63 GC/100µm of villus±0.08 vs Control OCA 0.65 GC/100µm of villus±0.07 vs CCl4 0.49 GC/100µm of villus±0.01 vs FEX-30.30 GC/100µm of villus±0.08).

**Conclusion:** All these results suggest that a reduced bile production by the cirrhotic liver and not portal hypertension per se interfere in the goblet cell develop-ment and/or maturation. In addition, this effect can be, at least partially, be restored by the FXR agonist OCA. Our study opens the possibility, to a so far, unknown effect of bile salts in the intestinal epithelium development in the con-text of liver cirrhosis being a clear candidate for mucus layer regulation and hence protective effect against bacterial translocation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

2*University of Guadalajara, Guadalajara/Mexico*

**Contact E-mail Address:** edgarmendivill@live.com

**Introduction:** Liver fibrosis is an excessive accumulation of extracellular matrix (ECM) following a chronic liver injury. It is characterised by an increase in gene expression of proinflammatory molecules such as TGF-β1, IL-1β, IL-6 and TNF-α, as well as excess synthesis of ECM components such as COL-1. Capsaicin (CAP) is a pungent compound found in chili peppers which has shown anticarcinogenic, antiinflammatory and antifibrotic properties. Moreover, sulforaphane (SFN) is an isothiocyanate which is in cruciferous such as broccoli and it has exhibited an antioxidant effect in several in vitro and in vivo models.

**Aims & Methods:** The objective of this project was to evaluate the antifibrogenic and antiinflammatory effects of a daily supplementation with CAP and SFN in a rat model of liver fibrosis due to carbon tetrachloride (CCl4) intoxication. 35 male Wistar rats were included (n = 7/group); animals were administrated intra-peritoneally 5 times per week during 8 weeks with a mix of CCL4/minal (1/5: week 1, 1/4 week 2 and 1:3 week 3–8). Healthy and CCl4-fibrotic controls received only supplementation vehicle (Tween 2% in PBS). Treated groups receive SFN 5ug/kg, or CAP 2 mg/kg, or both supplements daily by oral gavage since the beginning of CCl4-intoxicacion regimen until sacrifice. Masson staining and PCR was performed in liver samples. Hepatic enzymes were ana-lysed in serum.

**Results:** Groups treated with CAP and SFN showed a decrease of ~30points in percentage of liver fibrosis according to Masson staining (p <0.05), hepatic function improve since ALT and AST serum levels diminish (p <0.01) also a lower gene expression of TGF-b1, Col-1, TNF-α, IL-1 β and IL-6 was detected in treated animals when compared with fibrotic controls (p <0.01). CCl4-induced fibrosis in this model of chronic-induced liver damage. These findings suggest that dietary sources of CAP and SFN might be included in dietetic guidelines for the preven-tion of liver fibrosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0033 DIAGNOSIS OF GASTRIC VARICES BY ENDOCOMIC ULTRASONOGRAPHY USING COLOR DOPPLER**

T. Sato

Gastroenterology, Sapporo Kosei Hospital Dept. of Gastroenterology, Sapporo/Japan

**Contact E-mail Address:** taka.sato@ja-hokkaidokouseirein.or.jp

**Introduction:** Gastric variceal bleeding is common complication, and it is associated with higher morbidity and mortality rates than hemorrhage from esopha-gal varices. Oesophagogastroduodenoscopy is usually the initial investigation in the portal hypertension for the purpose of the distinction between gastric varices and gastric folds. The aim of this study was to investigate endo-scopic color Doppler ultrasonography (ECDUS) findings of gastric varices.

**Aims & Methods:** Two hundred-fifteen patients with gastric varices were evalu-ated with ECDUS. To begin with, identification of gastric varices was performed with B-mode scanning and then, color flow mapping was done. On B-mode scanning, submucosal gastric varices, and para-gastric collateral veins were observed as hypoechoic vessels within gastric wall or in the tissue and spaces exterior to the adventitia of gastric wall. ECDUS provides a color display of blood flow and evaluates the flow pattern using fast Fourier transform (FFT) analysis. FFT analysis can indicate the flow pattern and calculate the velocity of blood flow. We monitored the color flow images of gastric varices, and para-gastric or peri-gastric collateral veins. Endoscopic findings of gastric varices were evaluated according to the grading system outlined in The General Rules for

**Results:** The color flow images of gastric varices and peri-gastric veins were delineated in all 215 patients with ECDUS. Evaluation of blood flow velocity in the 215 gastric varices revealed velocities of 7.7–35.7 cm/s (mean, 18.2 ± 6.0 cm/s). Mean velocity of large, coil-shaped (F3) type gastric varices was 23.7 ± 6.2 cm/s (n = 52), while the mean velocity of enlarged tortuous (F2) type gastric varices was 16.7 ± 5.0 cm/s (n = 163). The velocities of F3 type gastric varices were significantly higher than those of F2 type (p < 0.0001). Next, we evaluated the wall of submucosal gastric varices. Two hundred-fifteen of the gastric varices were 1.0–2.2 mm (1.6 ± 0.4 mm) in gastric wall thickness. Mean thickness of red color (RC) or erosion positive varices was 1.2 ± 0.2 mm (n = 42), while the mean thickness of RC or erosion negative varices was 1.7 ± 0.3 mm (n = 173). The thickness of RC or erosion positive varices was significantly thinner than that of the negative cases (p < 0.0001). Seven cases of the 215 patients had the current history of gastric variceal bleeding, and the other three cases had experienced variceal rupture on follow up (bleeding cases, n = 10), and mean thickness of these bleeding cases were 1.2 ± 0.2 mm.

**Conclusion:** ECDUS is a useful modality for the diagnosis of hemodynamics of gastric varices and may allow the stratification of patients into low, high risk for hemorrhage.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Liver cirrhosis and portal hypertension are associated with esophagogastric varices, gastric varices, small and large intestinal enteropathies.

**Aims & Methods:** We aimed to study the prevalence of colopathy and ileopathy in patients with portal hypertension secondary to liver cirrhosis. Chronic hepatitis C patients with portal hypertension secondary to liver cirrhosis were enrolled. Chronic hepatitis C patients admitted for variceal gastrointestinal bleeding. All patients were evaluated by upper endoscopy and colonoscopy for screening of portal hypertension complications. Esophageal varices were graded as small, moderate and big varices. Portal hypertensive gastropathy was classified as absent or present, and, if present, it was sub-classified as mild or severe. Coloscopy was done up to terminal ileum in all patients.

**Results:** Our study included sixty chronic hepatitis C patients with portal hypertension secondary to liver cirrhosis (53.33% females) their mean age (±SD) was 54.75 (±13.13) years. Child-Pugh class was A for 2 (3.34%), B for 33 (55.9%) and C for 24 (40.7%). 53 (88.3%) patients had esophageal varices (23 patients had small esophageal varices, 15 had moderate, and 8 had big varices, 2 post-banding ligation and 5 obliterated varices). Gastric varices were present in 3 patients (5%). Portal hypertensive gastropathy was noted in 43 patients (71.6 %) and was mild in 38 and severe in 5 patients. Coloscopy finding up to the terminal ileum revealed that portal hypertensive colopathy was present in 16 patients (26.7%). Portal hypertensive ileopathy was noted only in one case (1.7%). No colonic or ileal varices were noted.

**Conclusion:** Portal hypertensive colopathy but not ileopathy is common in Egyptians with liver cirrhosis. Ileal varices and ileopathy are not common in patients with cirrhosis and PHT.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0035 PREDICTIVE FACTORS FOR THE DEVELOPMENT OF ACUTE-ON-CHRONIC LIVER FAILURE IN PATIENTS WITH GASTROINTESTINAL BLEEDING**

C. Cojocariu1, S. Chiriac2, A. Trifan2, C. Stanciu3
1Gastroenterology, "Grigore T. Popa" University of Medicine and Pharmacy Iasi, Iasi/Romania
2Gastroenterology, "Grigore T. Popa" University of Medicine and Pharmacy, Iasi/Romania
3Institute of Gastroenterology and Hepatology, Iasi/Romania

**Contact E-mail Address:** stefanoenriciric@yahoo.com

**Introduction:** Acute-on-chronic liver failure (ACLF) is a specific clinical form of liver failure in patients with liver cirrhosis, referred as acute deterioration of liver function associated with an acute specific complication of liver cirrhosis. ACLF is defined by the presence of renal failure or 2 or more organ failures. In the European Association for the Study of the Liver-International Chronic Liver Failure consortium: 1) circulatory- need for vasopressor support; 2) renal- serum creatinine value ≥2 mg/dL; 3) cerebral- Grade III or IV hepatic encephalopathy; 4) respiratory- SpO2/FiO2 ≤214.

**Aims & Methods:** We aimed to identify predictive factors for ACLF development in cirrhotic patients admitted for variceal gastrointestinal bleeding. All patients with ACLF were consecutively enrolled in the Institute of Gastroenterology and Hepatology Iasi (consisting of 8 secondary hepatology centers) between June and December 2016 were evaluated for ACLF (we excluded from the study the patients presenting ACLF diagnosis criteria on admission). We compared cirrhosis patients who developed ACLF after 12 hours of admission with those who did not.

**Results:** 99 cirrhotic patients with gastrointestinal bleeding were evaluated. 48.5% of patients admitted with variceal bleeding developed ACLF. Demographic data were similar in patients with ACLF vs. no ACLF in age (54.2 ± 7.3), BMI (6 ± 9.5 years), male sex (54 vs. 45), and diabetes (56 vs. 43) and significant difference was found in alcohol consumption (72 vs. 27). In patients with ACLF, the grade 1 was the most frequent (56.3%); grade 2 (33.3%) and 3 (10.4%) of ACLF were more rare and no significant differences between the ACLF subgroups was observed. The patients with ACLF were more likely to be admitted with infections and alcohol consumption, when compared to patients without ACLF. Independent predictors for ACLF development included a high admission MELD (p < 0.05), presence of infection and alcohol abuse (p < 0.001), hospitalization in the last 6 months (p < 0.05). Inhospital and 30-day mortality were significantly higher in patients with ACLF (p < 0.0001).

**Conclusion:** Patients admitted with variceal bleeding, with alcohol consumption, high MELD on admission, previous admission in < 6 months are more likely to develop ACLF and need to be monitored closely for the development of ACLF.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Cirrhosis is characterized by both bleeding and thrombotic complications due to underlying procoagulative haemostatic imbalance [1]. Among thrombotic events, portal vein thrombosis (PVT) is the most common with annual incidence ranging between 4.6% and 12.8% [2, 3]. Demonstrated associated risk factors are severity of portal hypertension and slowed portal flow [4]. However, data regarding haemostasis in the portal venous system of cirrhotic patients is lacking.

**Aims & Methods:** To evaluate peripheral and portal venous haemocoagulative state in patients with cirrhosis in comparison with controls, through thrombin generation test (TGT), rotational-thrombelastometry (ROTEM) along with evaluation of endothelial dysfunction by quantification of circulating endothelial microparticles (MP). Correlate these results with activity levels of local pro and anticoagulant factors. Compare peripheral and portal venous districts in cirrhosis in terms of haemostatic balance. We consecutively evaluated adult patients with liver cirrhosis undergoing liver transplantation (LT) or transjugular intrahepatic portosystemic shunt (TIPS). Patients without liver disease awaiting liver surgery or deceased liver donors were enrolled as controls. The following laboratory tests were performed on citrated peripheral and portal venous blood samples: TGT with and without thrombomodulin (TM), ROTEM, dosage of main pro and anticoagulants factors activity and analysis of circulating endothelial MP.

**Results:** 25 cirrhotics (15 LT and 10 TIPS) and 6 controls (2 undergoing hepatic surgery or deceased liver donors were enrolled as controls. Peripheral blood in cirrhosis showed resistance to activation of PC-pathway at TGT (ETP with without TM 0.89 (0.78–0.92) vs 0.6 (0.3–0.74), p < 0.001), clofibrat stability at ROTEM (MCF-NATEM mm: 43.5 (36–51) vs 63 (53–69), p = 0.042), and significant increase of endothelial-MP (CD62EPM/L: 1391 (651–2301) vs 582 (380–1161), p = 0.046), indicative of higher endothelial damage compared to controls. Similar results were obtained comparing portal blood of cirrhotics and controls (ETP with/without TM 0.89 (0.78–0.92) vs 0.63 (0.33–0.75), p = 0.001; MCF-NATEM: 46 (39–51) vs 62 (49–66), p = 0.056; CD62EPM/L: 1606.5 (680–1885) vs 529.5 (266–781), p = 0.009). There was a significant correlation between diminished levels of PC, PS, AT, FII and either TGT or ROTEM parameters. Comparing portal and peripheral blood of cirrhotics, we detected endogenous heparinoids in portal (a-antigen NATEM 51 (46–57) vs
Aims & Methods: In this study 119 patients were included: 78% men with a mean age of 59 ± 13 years; 8% had hepatocellular carcinoma, and 45% had Child-Pugh C. The most frequent cirrhosis etiologies were alcoholic disease (60%) and HCV infection (12%). The precipitating factors, for the onset episode, more frequently detected were diuretic overdose (36%) and infection (31%). All patients were treated with standard therapy, with an adequate lactulose dose. The readmission rate after the first episode of HE was 72% (75% men). The estimated average time to relapse was 18 weeks. The most frequent causes of readmission were also diuretics overdose (31%) and infection (30%). The patients who were readmitted had a higher MELD score than patients without recurrent (13.9 vs. 11.6 points; p = 0.015). This association was verified in the multivariate analysis (OR = 1.1, p = 0.044).

Conclusion: In this cohort, there was a high rate of readmission for HE after the inaugural episode, which carries a great impact on individual health and high socio-economic costs. A higher MELD score was independently associated with a high probability of readmission for HE.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** The regulations for prescribing interferon-free treatment for patients infected with hepatitis C virus in Romania comprised only patients with F3/F4 fibrosis so the risk of hepatic decompensation and complications was higher compared to other cohorts. In previous interferon-based regimens, thrombocytopenia (<50,000) and hypoalbuminemia (<35 g/dl) was a contraindication for portal hypertension and its hepatic synthetic dysfunction, respectively, have been shown to reduce the likehood of sustained virological response and to increase the rates of serious adverse events.

**Aims & Methods:** The aim of this study was to evaluate the impact of thrombocytopenia and hypoalbuminemia on treatment outcome and disease complications. We included in this study 855 HCV-infected cirrhosis patients treated with ombitasvir/paritaprevir/r-dasabuvir/r-ribavirin for 12 weeks in 10 university hospitals in Romania. The following groups were studied: 151 patients (17.7%) with thrombocytopenia (<50,000/mm3) and 71 patients (8.3%) with both hypoalbuminemia and thrombocytopenia before initiating antiviral treatment. Safety (as AE in > 5% and SAE), efficacy (SVR4, SVR12) and complications were monitored. The prediction of mortality, even when excluding patients with in-hospital mortality was evaluated using Pearson’s correlation, multivariate analysis and Chi-Square test.

**Results:** Main patient characteristics were: 100% genotype 1, 82.5% median age of 66 (51.8-79) years, 54.7% high rate of previous interferon-based treatment (36.1%). End-of-treatment and sustained virological response rate were both >99% and there was no correlation with the presence of thrombocytopenia or hypoalbuminemia. The rate of adverse events in the whole cohort was 17.5% at 2 weeks reaching 18% at the end of treatment with only 0.8% severe adverse events with no statistical association with the presence of thrombocytopenia and hypoalbuminemia. The multivariate analysis showed significant association of thrombocytopenia (<10,000/mm3) with higher (>1) degree of oesophageal varices (p = 0.001), one of upper digestive hemorrhage during treatment (p = 0.011), and prior exposure to interferon based regimens (p = 0.025). Low albumin (<3.5 g/dl) also correlated with higher (>1) degree of oesophageal varices (p = 0.001) and onset of upper digestive hemorrhage during treatment (p = 0.002).

**Conclusion:** The efficacy and safety of the ombitasvir/paritaprevir/r-dasabuvir/r-ribavirin (as recommended by national regulations) was not different in cirrhotic patients with hypoalbuminemia and thrombocytopenia, but complications rate was higher so close follow-up and prophylactic measures should be recommended, especially if previously exposed to interferon containing regimens.

**Contact E-mail Address:** pdimaggio@norgine.com

**Introduction:** In the UK multicentre, retrospective, real-world study, IMPRESS, rifaximin-a (RFX) use in patients with hepatic encephalopathy (HE) significantly reduced hospitalisations and length of stay in the 6 and 12 months post-RFX initiation compared to the respective periods pre-RFX initiation. This post-hoc analysis of the IMPRESS data compared hospital resource use pre- and post-RFX initiation in 2 sub-groups of difficult-to-treat HE patients: those with advanced liver disease or current alcohol misuse.

**Aims & Methods:** Medical records of patients from 11 UK hospitals who were prescribed RFX for HE between July-2008 and May-2014 were retrospectively reviewed; details of demographic and clinical characteristics, and all-cause hospitalisations were collected in the 6 and 12 months pre- and post-RFX initiation. Patients with baseline MELD score ≥15 or not abstinent at the end of the study period were included in this analysis. Statistical significance of the mean change (standard error of the mean, SEM) was calculated using paired t-test or Wilcoxon test.

**Results:** Only patients alive at the end of the 6 and 12 months RFX-treatment periods were included: 114 and 102, respectively. Amongst these, 33/114 (29%, for the 6 months) and 26/102 (25%, for the 12 months) had baseline MELD ≥15; mean age, 63 years; 70% were male; 66% had alcohol-related liver disease; mean MELD 24. The mean (SEM) number of bed days/patient decreased from 25 (6.0) in the 6 months pre- to 15 (5.5) in the 6 months post-RFX initiation, and from 36 (9.5) in the 12 months pre- to 20 (7.7) in the 12 months post-RFX initiation (p value not significant). At 6 months post-RFX initiation, 15/114 (13%) patients were still actively drinking. At RFX initiation, mean age was 56 years; 73% were male, mean MELD was 19. Despite this, the mean (SEM) number of bed days/patient decreased from 36 (7.9) in the 6 months pre- to 15 (5.4) in the 6 months post-RFX initiation (p = 0.048), and the mean of hospitalisations/patient fell from 2.8 (0.8) to 1.2 (0.4) (t-test p = 0.059; Wilcoxon test p = 0.029). Too few patients with continued alcohol misuse were alive at 12 months to evaluate. Two patients reported adverse events, none serious.

**Conclusion:** In UK clinical practice, treatment with RFX for HE for 6 or 12 months suggested trends in reduced hospital length of stay in patients with advanced liver disease and those in continued alcohol misuse. However, larger studies are needed to strengthen these findings.

**P0042 BACTERIAL INFECTION IN PATIENTS WITH DECOMPENSATED CIRRHOSIS - A PREDICTOR OF LONG-TERM MORTALITY INDEPENDENT OF DISEASE SEVERITY**

**Gastroenterology, Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia/Portugal**

**Contact E-mail Address:** mafalda_em_p_sousa@hotmail.com

**Introduction:** Bacterial infections are common in cirrhotic patients and the pro-inflammatory response superimposed on the hemodynamic dysfunction of portal hypertension predisposes to the development of complications. Some authors suggest that the occurrence of infection should be considered a separate clinical stage, since it alters the natural history of cirrhosis.

**Aims & Methods:** Retrospective assessment of patients with cirrhosis hospitalized for first episode of decomposition between 2011-2015. The aim was to evaluate the prognostic significance of bacterial infections regardless of the severity of the underlying liver disease.

**Results:** Of the 547 patients (85% male, mean age 59 years, mean MELD 15, 72% alcoholic cirrhosis) were included with a total of 197 hospitalizations. Hospital admissions were more frequent due to variceal haemorrhage (42%) and encephalopathy (37%). The incidence of bacterial infection was 25%: 41% respiratory, 31% spontaneous bacterial peritonitis and 24% urinary. Of these, 51% were nosocomial and in 20% an infectious agent was isolated. The survival rates at 30 days, 3 months, 6 months and 1 year were 65%, 55%, 34% and 27% in patients with infection and 97%, 90%, 85% and 78% in those without infection (p < 0.001). In the multivariate analysis, survival was independently associated with MELD (hazard ratio (HR) 1.073, p = 0.048), and the mean of hospitalisations/patient fell from 2.8 (0.8) to 1.2 (0.4) (t-test p = 0.059; Wilcoxon test p = 0.029). Too few patients with continued alcohol misuse were alive at 12 months to evaluate. Two patients reported adverse events, none serious.

**Conclusion:** Patients with cirrhosis exposed to a bacterial infection are at increased risk of death. This risk remains in the long term when we exclude patients with in-hospital mortality and at 30 days and regardless of the severity of the underlying disease (MELD).

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0043 A PROPORTIONALLY GREATER ELEVATION IN LIVER TRANSPLANT CANDIDATE IN PATIENTS WITH NAFLD AND PORTAL VEIN THROMBOSIS

M. Basaranoglu
Gastroenterology, Buzmalem Vahid University, Istanbul/Turkey

Contact E-mail Address: metin_basaranoglu@yahoo.com

Introduction: NAFLD progresses to cirrhosis and its complications including hepatocellular carcinoma. It is possible that risk factors for NAFLD-associated cirrhosis may differ in Eastern countries where the disease is different from those in the West. Thus, we aimed to document the characteristics of patients with NAFLD-associated cirrhosis from Turkey, a European country sharing 97% of its borders with Asia. Relative to other European, the Turkish population exhibits a higher rate of obesity that may influence the rate to that in the Western population.

Aims & Methods: To characterize non-alcoholic fatty liver disease (NAFLD) presentation with esophageal varices. METHODS: We have kept the records of patients at our hepatology unit and affiliated liver center. Data were collected for all patients who were at the advanced stage of cirrhosis. A cohort of patients with esophageal varices from 2003 to 2014 was reviewed. Eligible patients were ≥18 years of age and have had esophageal varices diagnosed by upper gastrointestinal endoscopy examination. They had regular clinical follow-up and endoscopic examinations at this clinic. Efficacy data were based on the last evaluation. Transplanted cases were excluded.

Results: Primary end-point of the study was to use this cohort of patients with esophageal varices to evaluate the relationship between this disease and several etiologies, including NAFLD, hepatitis B, hepatitis C or other liver-related diseases. We included 308 patients with a mean age of 67.8 ± 12.0 years and 62% of these patients were men. In this study, each patient was evaluated for fundal varices, PVT, cirrhosis, HCC, and mortality. After the first evaluation, patients were divided into 4 groups: Those with hepatitis B, hepatitis C, NAFLD and others related to autoimmune hepatitis. Wilson Disease, primary biliary cirrhosis, etc.

Results: Risk factors and predictive model for the

P0044 RISK FACTORS AND PREDICTIVE MODEL FOR THE DEVELOPMENT AND DROUG RESPONSE TO Bacterial INFECTIONS AND THE IMPACT ON PROGNOSIS IN HOSPITALIZED DECOMPENSATED LIVER CIRRHOSIS PATIENTS

Introduction: Hepatitis C virus (HCV) diminishes health related quality of life (HRQOL). Currently, there is no published data on assessing of the impact of treatment of chronic hepatitis C with the new antiviral drugs in older-aged patients.

Aims & Methods: The aim is to study the effect of treatment of chronic hepatitis C with the new antiviral drugs in older-aged patients in HRQOL. About 132 patients with chronic hepatitis C (cirrhotic and non-cirrhotic) were enrolled in the study. Age of patients was sixty years old and older. All patients were treated with sofosbuvir/daclatasvir with or without ribavirin for three months. The HRQOL was assessed with sickness impact profile scoring (SIP) before start of treatment, at end of treatment and after three months of end of treatment.

Results: Old chronic hepatitis C patients who were treated achieved primary virological response (end of treatment) with percentage 100% and sustained virological response (SVR) (after 3 months of end of treatment) in about 96% of treated patients. Before treatment, patients with chronic hepatitis C had worse scores especially in work, sleep, rest and recreation and pastimes categories. After treatment, patients who received sofosbuvir/daclatasvir with or without ribavirin had significant improve in work, sleep, rest and recreation and pastimes categories with p-value 0.001. Numerical improvement was observed in total score, physical and psychosocial dimension scores. In patients with SVR, the most improvement was in work and psychosocial dimension scores. There was no significant difference in SIP between scores after end of treatment and after 3 months of end of treatment.

Conclusion: Treatment of chronic hepatitis C in old-aged patients had a significant improvement in HRQOL.

Disclose of Interest: All authors have declared no conflicts of interest.

**Contact E-mail Address:** daliaomran@kasralamy.edu.eg

**Introduction:** Accurate determination of the degree of hepatic-fibrosis is mandatory not only for the diagnosis and prognosis of disease, but also for deciding on the antiviral treatment. Indeed, many studies have been dedicated to the search of non-invasive fibrosis markers capable of providing an accurate information about hepatic fibrosis stage in patients with chronic hepatitis C (CHC). Direct and indirect markers of hepatic fibrosis are useful for prediction of liver cirrhosis but have limited accuracy for the diagnosis of significant fibrosis. Therefore, the development of more advanced scores combining both direct and indirect markers may improve their diagnostic accuracy.

**Aims & Methods:** This work is concerned with determining the levels of some fibrosis markers, which are directly involved in deposition and removal of extracellular matrix (ECM), together with other indirect fibrosis markers so as to construct a predictive score capable of identifying the presence of significant fibrosis with a high degree of accuracy. Then, we aimed to estimate its performance against that of the other simple noninvasive tests in chronic hepatitis C patients.

**Material and Methods:** A total of 148 Egyptian HCV patients were subjected to routine laboratory workup in addition to estimation of serum AFP, hyaluronic acid (HA), platelet-derived growth factor (PDGF), tissue inhibitor of metalloproteinase-1 (TIMP-1) and collagen IV. According to fibroscan, patients were classified into those with non-significant fibrosis (F<2) and significant fibrosis (F>2).

**Results:** Based on univariate analysis, ten variables were significantly higher in patients with significant fibrosis. Patients with F2-F4 had 2.08-fold, 2.14-fold, 1.80-fold and 1.90-fold increase in the concentrations of collagen IV, HA, PDGF and TIMP-1, respectively. Multivariate regression demonstrated that only age, AFP, PDGF, collagen IV and TIMP-1 retained significance. Therefore, a five-marker name score Egyptian (EGY) Fibro-mark (FM) was developed. A significant correlation was found between its candidate markers and liver fibrosis progression. AFP was found to have highest correlation (r=0.47, P<0.0001) followed by collagen IV (r=0.46, P<0.0001), age (r=0.43, P<0.0001), TIMP-1 (r=0.40, P<0.0001) and PDGF (r=0.40, P<0.0001). ROC curve was used to estimate and compare the diagnostic accuracy of these candidate variables. As a consequence, these markers were in a decreasing rank: AFP (AUC 0.79), collagen IV (AUC 0.78), age (AUC 0.70), TIMP-1 and PDGF (AUC 0.75). Additionally, Bivariate Spearman’s rank correlation coefficient between EGY-FM and its candidate markers was determined for estimating the impact of each marker on the predictive criteria. The diagnostic value of Egy FM was then assessed by ROC curve showing an AUC of 0.89 for diagnosing significant fibrosis at an optimal cut-off point of 4.05 with 77% sensitivity, 83% specificity and 79% efficiency. Next, the area under the ROC curve (AUC) was used in order to simulate and compare the performance characteristics of different non-invasive scores. The AUC was greatest for Fibro-mark (0.89), then BRC (0.83), followed by FRT and King’s score (0.82), APRI (0.80), Fibro-a (0.70) and finally FibroQ (0.63).

**Table 1:** The correlation of each score to hepatic fibrosis progression

**Conclusion:** Egy Fibro-mark (FM) score, a more sophisticated score combining ‘direct’ and ‘indirect’ markers, is a useful tool to improve the staging of liver fibrosis in CHC patients and seems more efficient than BRC, FRT, King’s score, APRI, Fibro-score and FibroQ in this group of Egyptian patients.

Recent studies have shown that treating CHCV genotype 4 patients with persistently normal liver enzymes in a real-world cohort from Egypt. SOF/DCV/C6 combination was the most effective among the studied regimens. RBV combination was the most effective among the studied regimens.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: The aim of this study was to determine the prevalence of HCV infection among household contacts of HCV seropositive index patients. We also aimed to compare HCV genotyping distribution in upper and lower Egypt. In this Multicentre hospital case control based study a total of 4894 Egyptian individuals were recruited to the hospitals from different Egyptian population in Upper & lower Egypt (mainly from Dakahlia, Cairo and Assuit governorates). The index HCV patients were 1106 cases whereas the families or close household contacts of these index cases were 3788 cases. Ideally family was selected on the basis of containing at least one positive HCV index, one positive HCV member and other one negative HCV member with no history of any liver complications or disorders first and second degree consanguinity, living and sharing usual life activity and having at least 15 years of exposure to the index case). The positive case (index or contact cases) in the family were selected with inclusion criteria of 1-HCV positive by PCR RNA> 6 months, 2-Adults (above 18 years) of both sexes 3-Any stage of HCV related liver diseases. While cases were diagnosed as spontaneously cleared the virus (SVC). The HCV prevalence among household contacts was 20.71% but when PCR HCV was performed only 17.83% were positive while 2.9% & 8.3% as shown in the following table.

cancer incidence following DAA therapy may include the rapid clearance of hepatitis C virus, reconstitution of the immune system, and reduction of cancer immunosurveillance [2]. These changes may in fact have an impact on the development of cancer in other organs.

**Aims & Methods:** We conducted a retrospective analysis to compare the cancer incidence in patients treated with IFN-free DAA therapy with those treated with IFN therapy. All patients who achieved sustained viral response following antiviral therapy between 1992 and 2016 in our hospital were investigated retrospectively. Patient records were examined to identify new cases of cancer, as determined by pathology or medical imaging, in organs other than the liver following antiviral therapy. The date of diagnosis was determined based on the records, and the cancer incidence was compared between patients treated with DAA therapy and those treated with IFN therapy using the Kaplan-Meier method. Propensity analysis. Patients with recurrent cancer were excluded from the analysis. Propensity score analysis followed by inverse probability of treatment weighting (IPTW) was used to correct for the effects of confounding factors.

**Results:** There was a significant difference in the age and sex of the patients treated with DAA therapy (n = 324, median age: 70, male: 41%) and those treated with IFN (n = 445, median age: 58, male: 60%). Median lengths of the observation period for the DAA and IFN groups were 1.3 and 6.2 years, respectively. There were 12 and 25 cases of cancer occurring in organs other than the liver in the DAA and IFN groups, respectively. These cancer cases occurred mostly in the gastrointestinal tract, followed by the urinary organs, hematopoietic organs, biliary tract/pancreas, lungs, and other, and the median periods from the start of the antiviral therapy to the time of diagnosis were 0.9 and 6.8 years in the DAA and IFN groups, respectively. Cumulative rates of cancer after 1 and 2 years were 3.0 and 5.0% for the DAA group, and 0.2 and 0.0% for the IFN group, respectively. The difference between the groups was significant (p = 0.02) based on Cox regression analysis using IPTW.

**Conclusion:** Because cancer detection in organs other than the liver can be challenging in management of hepatitis, some cases with cancer found after the treatment might have been diagnosable before the treatment, possibly leading to an overestimation of the incidence after the treatment. The number of newly diagnosed cancer cases was small in the present study, resulting in a low statistical power. Nevertheless, the cancer incidence in organs other than the liver was significantly higher in patients treated with DAA therapy than those treated with IFN therapy. This difference persisted after correcting for possible confounding factors by age and sex of the patients. Our findings suggest that patients need to be carefully examined after DAA therapy for the development of cancer in various organs, including but not limited to the liver.

**Introduction:** The shift from therapy with interferon to Direct antiviral agents (DAAs) has been a watershed for the management of HCV-related chronic liver diseases. In fact, treatment with second-generation DAAs cures the great majority of patients treated with HCV chronic infection, with the exception on genotype 3 cirrhotic patients.

**Aims & Methods:** The present report focuses on HCV genotype 3 cirrhotic patients treated with second-generation DAAs in order to identify which of the several treatment schedules recommended for genotype 3 would constitute the best option. Methods: 1. Twenty-four italian centers (ITAL-C consortium) were involved in this real-life study where HCV genotype 3 patients treated with DAAs. Eligible patients were >18 years old, noncirrhotic chronic HCV infection, either naive or treatment-experienced. In the analysis of any of the patients were excluded: infection with HCV genotypes other 3, active HCC on imaging, HIV and/or HBV co-infection, liver-transplant recipients, patients with an estimated glomerular filtration rate <30 ml/min. 2. With the intent to delineate treatment schedule with the new DAAs that would offer the higher chance of SVR to patients with HCV genotype 3, a systematic search of the literature data was implemented and the retrieved information was pooled and evaluated by a meta-analytical approach. Electronic, systematic review of the available evidence presented literature was performed via Medline from 2012 to 2016 by the following search keys: HCV Genotype 3 AND (DAA/OR (sofosbuvir) OR (daclatasvir) OR (ledipasvir) OR (Velpatasvir)).

**Results:** A total of 233 HCV genotype 3 patients were enrolled. In the entire population, the SVR rate was achieved by 205 subjects (88.0%). A successful treatment outcome was documented in 79.0% of patients treated with sofosbuvir in combination with RBV, in 92.0% of those who received sofosbuvir/ledipasvir or ledipasvir with or without RBV, and in all 7 patients treated with sofosbuvir/ledipasvir or without RBV. At the univariate analysis, baseline predictors of the SVR12 were gender (female patients being more responsive than males), BMI < 30 and the treatment schedule. Of relevance, age, stage of liver disease (advanced fibrosis or cirrhosis), RBV use, and treatment length were irrelevant to SVR12. At the stepwise logistic regression analysis, the only two factors independently associated with SVR12 were regimen containing sofosbuvir in combination with daclatasvir or ledipasvir (OR:4.25; 95%CI: 1.81-9.97; p = 0.001), and the BMI < 30 (OR: 2.64; 95%CI: 1.04-6.72; p = 0.041). The systematic review of literature provided data of 3311 patients from 17 full text article and two abstracts. The mean weighted SVR12 rate was 84.4%(CI:80.4–87.8); the rates varied from 79.0%(CI:70.9–85.3) with sofosbuvir/daclatasvir/ledipasvir, to 88.2%(CI:83.3–91.7) with sofosbuvir/daclatasvir. Conclusions: HCV genotype 3-infected patients, and in particular those progressed to cirrhosis, should be no more considered difficult-to-treat individuals, provided that an optimal therapeutic schedule is applied. Patients without cirrhosis should be treated with sofosbuvir and daclatasvir for 12 weeks. Patients with cirrhosis should be treated with sofosbuvir and daclatasvir for 24 weeks with or without RBV.

**Introduction:** The impact of the virological cure on the evolution of cirrhosis following treatment with direct-acting antiviral agents (DAAs) has been a watershed for the management of HCV-related chronic liver diseases. Recently, some papers reported an elevated incidence of recurrence of hepatocellular carcinoma (HCC) 1, 2 and others a possible rise on the de novo incidence of HCC in the first year after treatment with DAA 3, 4, but not others 5.

**Aims & Methods:** This is a prospective study of cirrhotic patients treated with DAA between February/2015 and January/2017, under HCC screening with ultrasound according to international guidelines. The main endpoint of the study was to determine the incidence of “de novo” and recurrent HCC. The second endpoint was to search for possible predictive factors associated with the occurrence of HCC. Statistical analysis performed on SPSS 24. Results: 106 cirrhosis (73% mean; 54.5±8.8 years), MLD 73±2.6, 60% with portal hypertension (n = 64) and 22% with decompensated cirrhosis (n = 23, 22 Child-Pugh B). Two patients with previous HCC, stage Barcelona Clinic Liver Classification (BCLC) A, invisible after loco-regional treatment. The sustained virological response at week 12 was 89.9% (71/79); 4 deaths, 1 relapse, 1 therapeutic failure and 2 losses to follow-up (FU). In 11±7 months of FU, we registered 1 case of HCC, 4 “de novo” and 1 recurrence, which corresponds to an incidence of 3.8% of “de novo” HCC (13% in decompensated cirrhosis). The BCLC staging was: 2 stage A, 2 stage B and the one with the recurrence was stage D. 8 A Child-Pugh B class (p = 0.004), low platelets level (p = 0.001) and hospitalization for decompensation (p = 0.005) were associated with the occurrence of HCC; the genotype did not have association. The mean time to HCC development was 7.5 months (2-14).
Aims & Methods: The regulation of miR-506 gene expression and its role in (InsP3R3), leading to cholestasis.

exchanger 2 (AE2) and type III inositol 1, 4, 5-trisphosphate receptor were transfected in human cholangiocytes (H69 cells) and the role of pro-cholangiocyte pathophysiology and immune activation was studied. Different centers were involved in liver transplantation for PBC patients.

Introduction: Salamanca, Salamanca/Spain

Results: Several pro-inflammatory cytokines were overexpressed in PBC liver biopsies [such as IL-8, IL-12, IL-17, IL-18 and TNFα] stimulated miR-506 promoter activity in human cholangiocytes, as revealed by luciferase reporter assays. Experimental overexpression of miR-506 in cholangiocytes dysregulated the cell proteomic profile (by mass spectrometry) affecting proteins involved in different biological processes including mitochondrial metabolism. In cholangiocytes, miR-506: (i) induced de-differentiation with downregulation of biliary and epithelial markers together with upregulation of mesenchymal and pro-inflammatory markers; (ii) increased oxidative and endoplasmic reticulum (ER) stress; (iii) induced DNA damage, and iv) sensitized to caspase-3-dependent apoptosis induced by cytotoxic bile acids. These events were also associated with impaired energy metabolism in mitochondria (proton leak and low ATP production) and PDC-E2 overexpression. Co-culture of miR-506 over expressing cholangiocytes with PBC immune cells induced activation and proliferation of PBC immunocytes.

Conclusion: Different pro-inflammatory cytokines enhance the expression of miR-506 in biliary epithelial cells. MiR-506 induces PBC-like features in cholangiocytes and promotes immune activation, representing a potential therapeutic target for PBC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Area under the curve and receiver operator characteristic (AUROC) compari-
sed the diagnostic accuracy of the eight methods. The interquartile range (IQR) and median of 10 SWE measurements using body mass index (BMI) and age were analysed using the Mann-Whitney U test.

Results: The study population consisted of 106 men and 94 women with a mean age of 65.1 ± 10.8 years and a median BMI of 25.4 kg/m². Fibrosis in F0/F1/F2/F3/F4 was F0/F1/F2/F3/F4 in 7/50/33/24/23 patients, respectively. The median SWE (median) of 10 measurements in patients with F0, F1, F2, F3, and F4 were 1.33, 1.57, 1.73, 1.95, 1.98, respectively. The median IQR/median was 0.21. Furthermore, we found that BMI (BMI ≥ 25) was related to significantly higher mean ADC values (P = 0.001) using b value 1000, there was a significant difference with higher mean ADC values of measurements taken. Our results suggest that 10 measurements are recom-

[51x77]d) respectively. In the cohort of obese (BMI ≥ 25) 0.24, < 25 0.20, p = 0.012) indicated significantly greater IQR/median.

There was no significant difference in the diagnostic accuracy between using the median or mean of three, five, and 10 measurements. The AUROCs to diagnose patients with severe fibrosis (F2) ranged from 0.77 (A) to 0.876 (H). AUROC increased based on the number of measurements. A signif-
cificant difference between 1 and 5 (p < 0.05), 1 and 10 (p < 0.01), 2 and 10 (p < 0.05) measurements was observed in pairwise comparison. Likewise, A significant difference between patients with severe fibrosis (F2) ranging from 0.821 (A) to 0.923 (G). A significant difference (p 0.05) was seen between one and 10 measurements. In the cohort of IQR/median < 0.3, the diagnostic accuracy of ≥F2 and ≥F3 ranged from 0.806 (A) to 0.877 (H), and from 0.832 (A) to 0.928 (H), respectively. In the cohort of obese (BMI ≥ 25) and old patients (age ≥ 65), the diagnostic accuracy of ≥F2 and ≥F3 ranged from 0.752 (A) to 0.862 (D), and from 0.735 (A) to 0.903 (H). Comparing the AUROC of one measurement, IQR/median < 0.3 showed greater AUROC than those of other co-
horts, however, the AUROCs of ten measurements were similar in each cohort.

Conclusion: No difference was found between reporting mean or median SWE measurements. The diagnostic performance of SWE increased with the number of measurements. Our results suggest that 10 measurements are recom-

mended to ensure the accuracy of SWE measurements in a practical setting.

Contact E-Mail Address: emara_2007@yahoo.com

Introduction: Percutaneous radiofrequency ablation (RFA) is a commonly used locoregional interventional procedure in treatment of hepatocellular carcinoma (HCC). There is growing evidence that apparent diffusion coefficient (ADC) value can be used in evaluating RFA therapeutic efficacy in treatment of HCC and thus represent a reliable predictor of local HCC recurrence after treatment.

Aims & Methods: We aimed to determine the therapeutic efficacy of RFA in patients with hepatocellular carcinomas using ADC value. A total of 52 patients with 58 HCCs were included, and were treated with RFA according to the guidelines. All lesions were evaluated by diffusion weighted imaging (DWI) and ADC value measurement before and after RFA treatment. DWI was obtained using axial a single-shot echoplanar imaging with two b-values (500, 1000 mm2/s) using 3 tesla MRI machine. Quantitative ADC maps were calculated using com-
mputer software and an image analysis. Diffusion weighted imaging (DWI) and magnetic resonance imaging (MRI) confirmed the HCC relied on triphasic CT and MRI, showing enhancement at the arterial phase of the therapeutic effect of RFA for treatment of patients with HCC and can be used as good non-contrast alternative to conventional imaging methods in post ablation follow-up.

2State Public Health Budget Institution ‘Scientific Research Institute - Ochapovsky Clinic’/Omsk, Russian Federation

Contact E-Mail Address: katrich1-a@yandex.ru

Introduction: To study the effect of NAFLD on the results of shear wave elastography (SWE) in patients with chronic diffuse liver disease.

Aims & Methods: We have performed outcome analysis in 100 patients with chronic diffuse liver disease who were treated from 2015 to 2016. There were 41 male patients (41%), and 59 female patients (59%), age Me (LQ-UQ) 49 (39– 56), minimal age was 18 years, maximal age was 77 years. All patients were found to have chronic diffuse hepatic diseases and were hospitalized for morphological studies. Healthy volunteers, patients with liver cirrhosis (F0–F4) and healthy volunteers (F0–F1) were enrolled. 65 healthy volunteers (HV) were also examined. SWE was blindly evaluated. After the end of the study, all authors received results.

Results: Based on the obtained morphological results, we have formed the fol-

lowing subgroups of patients: F0 – F31 people, F2–9: 15 and F4–45 patients. Given that patients with a degree of fibrosis on the scale METAVIR F0 and F1 do not require active conservative therapy, we combined the data of the group into one F0–F1. The obtained results of shear wave elastography are presented in the form of quantitative variables. Median stiffness with interquar-
tile range (25–75%): in groups: F0 – F1: 5, (4, 6–5, 6) kPa, F2–8, (5, 3–8, 9) kPa, F3 – 13, 5 (10–14, 8) kPa and F4 – 22, 0 (18, 2–28, 5) kPa. The parameters of liver stiffnessometry in the various groups were: for stage F0: 2.5 mm2/s with a statistically significant difference compared to the other stages (P ≤ 0.003). Using b value 500, the mean ADC value before treatment didn't change significantly (P = 0.003), 1 and 10 (0.16, 0.12, 0.28 mm2/s with a statistically significant difference (P ≤ 0.05), 1 and 10 (0.16, 0.12 mm2/s) and stage F1 (1.46, 1.73, 1.95, respectively). The median IQR/median was 0.21. Furthermore, we found that BMI (BMI ≥ 25) was related to significantly higher mean ADC values (P = 0.001) using b value 1000, there was a significant difference with higher mean ADC values of measurements taken. Our results suggest that 10 measurements are recom-

mended to ensure the accuracy of SWE measurements in a practical setting.

2Department of Internal Medicine I, J.W. Goethe-University Hospital, Frankfurt am Main/Germany
3Institute of Clinical Physiology, University of Milan, Milan/Italy

Contact E-Mail Address: benedetta.conti1@gmail.com

Introduction: The estimation of liver stiffness (LS) has recently been evaluating by new elastographic techniques, such as Shear Wave Elastography (SWE), with a wider applicability than transient elastography (1). No studies evaluated LS in patients with alcoholic liver diseases (ALD) by using the elastographic methods. Moreover, exploring the possibility to assess the elasticity of other tissues, few studies evaluated the pancreatic stiffness (PS) by using transabdominal elastography (2,3), observing that chronic pancreatitis and alcoholic etiology had higher PS values (2).

Aims & Methods: The present study aimed at assessing the feasibility and repro-
ducibility of SWE at measuring LS and PS in a cohort of patients with alcohol abuse and known to have chronic liver disease and PS was performed by a single operator. The comparison of stiffness values between patients and HV was performed. Interobserver agreement for SWE was assessed by intraclass correlation coefficient (ICC). The effect of clinical and imaging data was assessed by using logistic regression model, with PS or LS as dependent variable. P values <0.05 were considered statistically significant.

Results: LS and PS by SWE were obtained in all the patients and HV. No failure was observed. LS and PS were significantly higher in patients than in HV: 22.1 kPa (95% CI, 16.9–36.2) vs 5.7 kPa (95% CI 5.2–6.4) for LS and 15.4kPa (95% CI 12.2–19.9) vs 12.4kPa (95% CI 9.5–13.6) for PS, p < 0.001. ICC for LS was good: 0.64 (95%CI, 0.50–0.74). ICC for PS was fair to good: 0.40 (95%CI, 0.24–0.54)
0.21–0.57). At univariate analysis LS was associated with liver cirrhosis (p < 0.0001), steatosis (p = 0.0003), liver surface nodularity (p = 0.0003), active alcoholic consume (p = 0.015), alcohol consumption/day (p = 0.0134), diabetes (p = 0.0223). At multivariate analysis cirrhosis (p < 0.0001) and steatosis (p = 0.0073) were independently associated with LS. At both univariate and multivariate analysis, PS was significantly correlated only with liver cirrhosis (p = 0.0058).

Conclusion: The present is the first series assessing LS and PS in ALD patients by using SWE. The feasibility of the technique was excellent. The reproducibility was good for LS and for PS. SWE was a good predictor of liver fibrosis in the ALD cohort. Liver cirrhosis was the only independent variable correlating with PS, whose estimation could be useful to detect alcohol-related pancreatic damage in patients with severe ALD.

P0061 EXOSOMIC miR-224 REGULATED TUMOR INVASION AND MIGRATION THROUGH IL-6/STAT3 PATHWAY IN HEPATOCELLULAR CARCINOMA
F. An, D. Chen, Q. Zhan, M. Xia, X. Wu
Gastroenterology, Westui People’s Hospital Affiliated to Nanjing Medical University, Westui/China

Contact E-mail Address: wd18025@163.com

Introduction: In our previous studies, IL-6/STAT3 pathway play key role, but the precise underlying mechanism remains to be explored. It was found exosomes are the vesicles released by the tumor cells into tumor microenvironment, they are a powerful diagnostic tool due to relative stability and composition covering the whole range of cancer-related biomarkers including proteins, metabolites, DNA, DNA modifications, coding and non coding RNA. Thus, study the roles of exosomic miRNA-145 20.65

Aims & Methods: The expression of miR-224, IL-6, STAT3 and SMAD4 in carcinoma (HCC).

Results: The expression of miR-224 were significantly increased compared to the rest of the world due to the high incidence of chronic infection with hepatitis C virus (HCV). In Egypt, HCV infection is the leading cause of HCC which is usually diagnosed at late stages. Due to the absence of reliable and accurate biomarkers for early detection of liver cancer, circulating microRNAs have recently emerged as great candidates for early diagnosis of HCC. These small non-coding RNA molecules are responsible for regulating gene expression and RNA stability. Therefore, the aim of this study is to investigate the potential of liver-specific circulating microRNAs as an accurate non-invasive diagnostic tool for the early detection of HCC-induced HCC.

Aims & Methods: Seven main miRNAs (miR-125a, miR-139, miR-34a, miR-221, miR-16, miR-145 and miR-199a) were selected due to their expression patterns in HCC as well as their contribution to the development of hepatocarcinogenesis. A total of 165 patients were enrolled in this study, from which serum samples were collected and categorized into four main patient groups: 42 healthy controls, 42 hepatitis B (CHB), 42 hepatitis C (CHC) without cirrhosis, 45 CHC with cirrhosis (LC), 38 HCC with HCV patients, and 40 healthy controls. The expression profile of the seven miRNAs was analyzed using TaqMan real-time transcription-polymerase chain reaction. Additionally, the conventional markers for HCC (alpha fetoprotein (AFP) and des-g-carboxyprothrombin (DCP)) were measured using commercial kits.

Results: Serum levels of miR-125a, miR-139, miR-145 and miR-199a were significantly decreased (p < 0.01) in HCC than in the CHC and LC groups (Table 1). On the other hand, miR-16 and miR-34a were significantly increased (p < 0.01) in HCC patients compared to the normal group. However, no significant difference was shown in the expression of miR-16, miR-34a, and miR-221 between the CHC, LC, and HCC groups. As a single biomarker, miR-34a showed the highest sensitivity and specificity among all miRNAs investigated, followed by miR-221, miR-125a, miR-139, miR-145, and miR-199a.

**p < 0.01 significant increase than control; p < 0.01 significant decrease than CHC; **p < 0.01 significant decrease than CHC and HCC; p < 0.01 significant decrease than control; p < 0.01 significant decrease than CHC and LC; p < 0.01 significant decrease than CHC

Conclusion: These results indicate that measuring the expression levels of liver-specific circulating microRNAs can be used as a reliable diagnostic and prognostic tool for HCC. Our results demonstrated that the up-regulation of miR-16, miR-34a, and miR-221 can differentiate between normal individuals and patients with liver disease ranging from fibrosis, cirrhosis, and HCC. Meanwhile, the noticeable down-regulation of miR-125a, miR-139, miR-145 and miR-199a in the HCC patient group indicates that these microRNAs can differentiate HCC from CHC and LC.

Introduction: Primary hepatocellular carcinoma (HCC) is one of the most common malignancies all over the world. HCC is associated with poor prognosis. However, the mechanism of HCC initiation and development remains unclear. In our previous work, high-throughput microarray assay in collected clinical HCC samples followed by bioinformatic analysis suggested that Metallothionein IEG (MT1G) might be one of the key factors in HCC.

Aims & Methods: We detected the MT1G expression in paired HCC samples and HCC cell lines by RT-qPCR and Western blot. Then MSP (methylation specific PCR) and BGS ( Bisulfite genomic sequencing) were performed to evaluate methylation status of MT1G in HCC. The functional significance of MT1G in HCC was investigated by overexpression or knockdown in HCC cell lines. The effects of MT1G re-expression were also determined by flow cytometry.

Results: MT1G was inactivated in all (6/6) HCC cell lines tested, but was readily expressed in immortalized liver cell line LO2. The expression of MT1G was significantly decreased than control; **p < 0.01 significant increase than control; p < 0.01 significant decrease than CHC; **p < 0.01 significant decrease than CHC and HCC; p < 0.01 significant decrease than CHC and LC; p < 0.01 significant decrease than CHC
regulated in cancer tissues compared with the adjacent non-tumor tissues (R). The expression level of MTIG in the liver cancer tissue cells was closely correlated to the promotor hypermethylation status. The MTIG expression in silenced HCC cell lines could be restored by demethylation agent. We generated HCC cell lines overexpressed MTIG. Ectopic re-expression of MTIG by stable transfection in SMMC-7721 and Hep3B cells inhibited colony formation (P < 0.001), suppressed cell motility and invasiveness (P < 0.05), concomitant with up-regulation of E-cadherin; and down-regulation of PCNA, MMP2, MMP3 and Vimentin. The in vivo growth of HCC cells in nude mice was also markedly inhibited after stable expression of MTIG (P < 0.001). MTIG over-expression in HCC cells induced the cell apoptosis (P < 0.01).

Conclusion: Our results demonstrate that MTIG promoter methylation directly mediates the transcription down-regulation and commonly occurs in HCC. MTIG gene can act as a functional tumor suppressor in liver carcinogenesis by playing an important role in depression of cell proliferation, migration, invasion, and induction of cell apoptosis.

Introduction: Hepatocellular adenoma (HCA) and focal nodular hyperplasia (FNH) may be confused on medical imaging. Both tumours are not connected to the biliary tree, however only FNH accumulates bile salts, suggesting that expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of pro-apoptotic genes. Its aberrant expression in tumor turns its role as foe. Aims & Methods: Here, we analyze the role exerted by CUX1 during deacetylase inhibitors mediated cell death in liver cancer cells. CUX1, endoplasmatic reticulum (ER) stress and autophagy markers were analyzed by RT-qPCR in two liver cancer cell lines HepG2 and Hep3B. Protein level was measured by western blotting. Cells were transfected with siRNA for CUX1 and furthermore treated with deacetylase inhibitors with up-regulated caspase 8 and protein level of survivin, p53 and caspase 3. Results: CUX1 knock down caused a suppression of ER stress and autophagy markers BIP, CHOP, ATFS, ATF6, Beclin1, MAP1LC3B, UVRAG and TFEB after early time point (6 hours) in both cell lines. Prolonged transfection did not alter the expression of the above mentioned markers; BIP was the only one suppressed in HepG2 after 24 hours. Interestingly, the deacetylase inhibitors are able to promote CUX1 over-expression after 6 hours of treatment, whereas they showed to lose this ability after 24 hours. CUX1 knock-down reduced significantly its protein level after treatment with deacetylase inhibitors. CUX1 knock down counteracts the accumulation of BIP protein after 24 hours of treatment with deacetylase inhibitors. Thapsigargin induced BIP independently from CUX1.

Conclusion: ER stress and autophagy markers are under the control of CUX1. The cell death induced by deacetylase inhibitors is strictly connected with CUX1 expression and activity. Further studies are needed to clarify the exact mechanism exerted by CUX1 in this scenario.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: CUX1 (CUTL1) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of pro-apoptotic genes. Its aberrant expression in tumor turns its role as foe.

Aims & Methods: Here, we analyze CUX1 activity in TRAIL (Tumour necrosis factor related apoptosis inducing ligand) mediated cell death in liver cancer cells. CUX1 was knocked down in HepG2 and Hep3B cells. Cells were further treated for 48 hours with a strong ligand (superkiller) binding DR4 and DR5 (TRAIL death receptors). The cell death inducers were analyzed by FACS analysis. RT-qPCR was performed to detect the expression of apoptotic markers. Caspase activity was measured by luminescence. Apoptosis array was performed. Western blotting was performed for caspase 8 and FipL detection.

Results: Treatment with superkiller TRAIL, at 50 and 100ng/ml, caused cell death in HepG2 and Hep3B cells after 48h proven by an accumulation of 40% of sub-G1 events. CUX1 knock down caused a sensitization of liver cancer cells to TRAIL effect by increasing, significantly, the percentage of sub-G1 events (60% with 100ng/ml). CUX1 knock down did not change the expression of TP53, KRT18, CDCNK1A and CDCNK1B. Interestingly, silencing CUX1 increased the activity of caspase 3/7 after treatment with soluble TRAIL. The effect was neutralized by pan-caspase inhibitor zVAD. Apoptosis array evidenced an increased protein level of un-cleaved caspase 3 after CUX1 knock down. Caspase 8 uncleaved form was down-regulated at protein level after CUX1 knock down and treatment with TRAIL. Its cleaved forms were up-regulated. Flip decreased in favor of FlipS also.

Conclusion: CUX1 mediates the resistance of liver cancer cells to TRAIL signaling. Knock down of CUX1 restores the potential of TRAIL to trigger cell death.

Disclosure of Interest: All authors have declared no conflicts of interest.
The diagnosis of liver cancer depends on both screening with alpha-fetoprotein (AFP) and radiological imaging studies. Generally, normal levels of AFP are below 10 ng/ml but AFP greater than 200 ng/ml is suggestive of HCC. The sensitivity of AFP for liver cancer is about 67%; therefore a normal AFP does not exclude HCC. "Now another tumor marker, that together with AFP could improve the diagnostic utility of HCC."

Squamous cell carcinoma antigen (SCCA), a member of the high molecular weight family of serine protease inhibitors named serpins which are physiologically found in the granular layers of normal squamous epithelium but found to be typically expressed by neoplastic cells of epithelial origin in a number of different cancers for example cervical, lung, and head and neck cancers hence, it can be used as a clinical marker of these malignancies. [4] The structure of the serum ovalbumin revealed the archetype native serpin fold that typically have three β-sheets (termed A, B, and C) and eight or nine α-helices (hA-hI). Serpins also possess an exposed region termed the reactive centre loop (RCL) that includes the specificity determining region and forms the initial interaction with the target protease.

Recently much attention has been focused on the role of SCCA in HCV cirrhotic patients suggesting that high levels of SCCA can assess HCC development. [5] The aim of this study was to assess the serum level of squamous cell carcinoma antigen (SCCA) in cirrhotic chronic HCV patients with and without hepatocellular carcinoma in relation to alpha feto protein (AFP).

**Aims & Methods:** The aim of this study was to assess the serum level of squamous cell carcinoma antigen (SCCA) in cirrhotic chronic HCV patients with hepatocellular carcinoma in relation to alpha feto protein (AFP). These groups were from both sexes who are admitted to the inpatient ward and the outpatient clinic of Tropical Medicine Department, Faculty of Medicine, Alexandria University. This study was carried out on:

- Group A: 100 cases of hepatocellular carcinoma without interventions.
- Group B: same 100 cases of Group A before and 3 months after successful interventions.
- Group C: 100 cases of established cirrhosis.
- Group D: 100 cases with chronic hepatitis C virus infection without established cirrhosis.
- Group E: 100 healthy individuals as controls.

All patients in this study were subjected to: complete blood picture, liver biochemical profile, serum alanine aminotransferase (ALT), serum aspartate aminotransferase (AST), serum alkaline phosphatase, total and direct serum bilirubin, prothrombin time and activity, serum albumin blood urea nitrogen (BUN), serum creatinine. Fasting blood sugar. Serum alpha fetoprotein (AFP).

**Determination of squamous cell carcinoma antigen (SCCA):** Serum from selected patients and controls were used for estimation of SCC-Ag using CanAg SCC EIA. The CanAg SCC EIA is a solid phase, non-competitive immunoassay based on the direct sandwich technique. Calibrators and patient samples are incubated together with biotinylated Anti-SCC monoclonal antibody in Streptavidin coated microstrips. After washing buffered Substrate/Chromogen reagent (hydrogen peroxide and 3, 3’, 5, 5’ tetramethylbenzidine) is added to each well and an enzyme reaction in enzyme is allowed to proceed. During the enzyme reaction a blue colour will develop if antigen is present. The intensity of the colour is proportional to the amount of SCC present in the samples. The colour intensity is determined in a microplate spectrophotometer at 620 nm (or optionally at 405 nm after addition of Stop Solution). Calibration curves are constructed for each calibrator. The SCC concentrations of patient samples are the read from the calibration curve.

**Results:** Table 1 shows a statistical significant difference between different studied groups regarding alpha feto protein (P = 0.000).

**Conclusion:** In the present study patients with HCC either with or without therapeutic intervention have significantly higher level of AFP in comparison to chronic HCV, cirrhotic and control groups this is in agreement with Awadhallah et al.[6] who reported a statistically highly significant elevation in the serum AFP in HCC group when compared with control group. Moreover, the mean serum level of AFP in group A (HCC before intervention) was 263 ng/ml that decreased to 209.4 ng/ml in group B after therapeutic intervention and this agreed with Peng et al.[7] and Molinari et al.[8] Also, at AFP level of 200 ng/ml the sensitivity was 90%, while the specificity was 60%.

Our results showed that SCCA level ranged from 2.5-10 with a mean of 5.53 in HCC patients without interventions, 3.3-7.6 with a mean of 5.3 in patients with HCC with therapeutic interventions, 1.2-5.6 with a mean of 3.3 in cirrhotic group, 0.6-1.05 with a mean of 0.824 in chronic HCV group while healthy control group had much lower values ranging from 0.3-0.95 with a mean of 0.646. Thus, a highly significant increase in serum SCCA level in patients with HCC before and after therapeutic intervention when compared to cirrhotic, chronic HCV and control groups (p < 0.001). These results were in accordance with Hussein et al.[9] and El Ezaawy et al.[10] SCCA was also higher among patients with HCC before intervention compared to patients with HCC after intervention as found by Bin et al.[11]

**Table 3:** Correlation Between AFP and SCCA

Applying the ROC curves analysis showed the best cut-off value to differentiate HCC patients from cirrhotic patients was 3.2 ng/ml for SCCA yielded 80% sensitivity and 90% specificity. These results were in agreement with Trevisani et al.[12] Patients with HCC, in our study were none randomized selected as BCLC stage B (either one HCC lesion < 5 cm in size or 3 lesions < 3 cm) so no statistical correlation was done between serum AFP level and tumor size.

Our results showed a significant positive correlation between serum SCCA and AFP among patients with HCC before and after therapeutic intervention. Our data are in agreement with that of Hussein et al.[9] and El Ezaawy et al.[10] who detected that SCCA were positively significantly correlated with AFP level. When combined sensitivity of both markers was calculated in our study at the best-cutoff values (SCCA 3.2 ng/ml and AFP 200 ng/ml) sensitivity improved to 93%. Matching results were found by Gianluigi et al.[4]

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**

The overall survival rate of 80%, 66.7% vs 60%, 46.7% at 12 months and 30 months, respectively, was not statistically significant ($p = 0.098$) vs 73.3% and 80% ($p = 0.652$) for medium and large hepatomas during 30 months follow up were not statistically significant. The overall survival rates of 80%, 66.7% vs 60%, 46.7% at 12 and 30 months, respectively, was not statistically significant ($p = 0.390$). By multivariate analysis, BCLC stage (HR $= 3.904$, $p = 0.023$), MELD score (HR $= 1.220$, $p = 0.021$) and pre-treatment AST level (HR $= 1.028$, $p = 0.019$) were independent prognostic factors for overall survival.

Conclusion: Multiple bipolar RFA system can achieve high complete tumor necrosis rate and low complication rate and compared between medium and large hepatomas using Kaplan-Meier survival and the prognostic factors were using multivariate analysis.

Results: 30 patients were divided equally into two groups with 15 patients in each of medium and large hepatoma groups. 17 patients underwent artificial ascites (56.3%). The complete necrosis rate after ablation was 93.3% (14/15 patients) for either medium or large hepatomas. The local tumor progression rate and distant tumor recurrence rate of 40% and 60% ($p = 0.098$) vs 73.3% and 80% ($p = 0.652$) for medium and large hepatomas during 30 months follow up were not statistically significant. The overall survival rates of 80%, 66.7% vs 60%, 46.7% at 12 and 30 months, respectively, was not statistically significant ($p = 0.390$). By multivariate analysis, BCLC stage (HR $= 3.904$, $p = 0.023$), MELD score (HR $= 1.220$, $p = 0.021$) and pre-treatment AST level (HR $= 1.028$, $p = 0.019$) were independent prognostic factors for overall survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Introduction: Hepatocellular adenomas (HCA) are rare, benign tumors of pre- sumable epithelial origin, that occur predominantly, but not exclusively, in young women taking oral contraceptives (OC) or anabolic steroids. The Bordeaux adenoma tumor markers are a promising method of identifying the high-risk HCA of malignant transformation into hepatocellular carcinoma (HCC).

Aims & Methods: Aims: The authors propose to evaluate the demographics, etiology, clinical manifestations and prognosis of HCA.

We undertook retrospective analysis of patients with HCA, histologically confirmed (by guided biopsy or surgical resection), between 2008 and 2016, in a tertiary referral centre. When feasible, the subtype classification of HCA proposed by the Bordeaux group, was performed. Descriptive statistics, uni and multivariate analysis were performed using IBM SPSS Statistics 22, with p < 0.05 deemed to be statistically significant.

Results: In this study 27 patients were included, 2 man and 25 women, with a median age of 38 ± 11 years, followed for a mean time of 78 ± 36 weeks (lost follow-up in 7 cases). Three cases of hepatic adenomatosis were included. Forty-one percent of the women used OC and 38% of the patients had dyslipidemia. The mean size of the HCA was 70 ± 42 mm; 65% of the patients had abnormal liver tests at diagnosis, 46% were symptomatic and in 21% the diagnosis was performed due to ruptured HCA. Surgical resection was performed in 88% of the cases; complete resection was achieved in 75% of the cases. Of the 19 patients who performed abdominal-CT scan or abdominal-MRI before histological confirmation, only 50% had an imagiological diagnosis of HCA. In 12/44% cases, immunohistochemical analysis was performed. According to the Bordeaux classification of HCA, 8 (67%) cases were classified as inflammatory, 2 (17%) as HNF-la-mutated, 1 (8%) as β-catenin mutated and 1 (8%) as unclassified. During surgery, patient died due to hemorrhagic shock related with HCA rupture and in 2 (10%) was necessary surgical revision due to incomplete resection. There was no HCC cases diagnosed during the follow-up. The median size of the HCA that weren’t completely resected and also of those presenting with HCA rupture was significantly higher: (110 ± 55 mm [p = 0.035] and 105 vs 47 mm [p = 0.037], respectively). The 2 male patients had inflammatory HCA (p = 0.011).

Conclusion: In this cohort, HCA were prevalent in female taking OC and the inflammatory type HCA was the most common. In many cases, abdominal imaging is insufficient for a correct diagnosis, and biopsy specimen or surgical resection should be performed for a correct diagnosis. Lesion size was associated with the risk of rupture and incomplete surgical resection.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic ultrasound (EUS)-guided fine needle aspiration (EUS-FNA) is one of the alternative methods for tissue sampling of liver solid mass. However, the diagnostic efficacy using cytological analysis was limited.

Aims & Methods: In this study, we evaluated the feasibility and diagnostic accuracy of EUS-guided fine needle biopsy (EUS-FNB) for hepatic solid masses in patients with suspected malignancy. The EUS-FNB using 20G, 22G or 25G ProCore needle (PCN) was performed to evaluate the patient with solid liver mass. The primary outcome was the diagnostic accuracy of EUS-FNB for malignancy, and adequacy of the specimen for histology. The secondary outcomes were (1) the proportions of patients in whom immunohistochemical (IHC) stain was possible, and (2) compared diagnostic yield of FNB according to the needle size (40-50 mm, 51-60 mm and >60 mm).

Results: Forty-one patients (13 women; mean age, 67.9 ± 10.3 years [range, 46–86]) underwent evaluation with EUS and identified hepatic lesions ranging in size from 0.7 cm to 15 cm. EUS-FNB with 20G (n = 10), 22G (n = 24) or 25G PCN (n = 7) was performed (right lobe: n = 10, left lobe: n = 31). The median number of needle passes was 2 ± 3.0 (range, 1–5). Technical success rates for tissue acquisition were 97.6%, but both specimen adequacy for histology and available HCA (30%) was 92.6%. Three (7%) cases were non-diagnostic, and subsequently proved to be malignant; 2 by smear cytology and 1 after surgical resection. The diagnostic yield, sensitivity and specificity of EUS-FNB for the diagnosis of malignancy were 92.6%, 92.6% and 100%, respectively. The diagnostic yield in 20G, 22G or 25G PCN was significantly superior to the 25 G PCN (p = 0.045). There was one bleeding complication, but controlled with endoscopic hemostasis with endoclips.

Conclusion: EUS-FNB with core biopsy needle may be a safe and useful modality in the management of patients with hepatic solid mass. Moreover, 20G and 22G FNB may be adequate for liver biopsy.

P0073 COMPARISON OF METHODS TO ESTIMATE LIVER FUNCTION IN NEWLY-DIAGNOSED HEPATOCELLULAR CARCINOMA PATIENTS WITH ASCITES

Y. Ko
Internal Medicine, Samsung Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: bs2-32@hanmail.net

Introduction: Liver function is a key element in determining outcome of patients with hepatocellular carcinoma (HCC). For HCC with ascites, estimation of liver function is particularly important, as they have already decreased liver function.

Aims & Methods: We aimed to find out best method to predict outcome of HCC patients with ascites. A total of 437 newly-diagnosed HCC patients with ascites (mean age = 56.0 y, male = 74.8%, hepatitis B virus = 73.2%) were analysed. We compared Child-Pugh score, Model for End-stage Liver Disease (MELD) score, MELD-Na score, and the Albumin-bilirubin (ALBI) grade for overall survival.

Results: During a median 9.0 months of follow-up (range: 0.1-154.0), mortality was recorded in 275 out of 267 patients' (50.3%) patients. MELD showed highest c statistic in predicting one-year survival (0.76). Higher scores were associated with worse survival. Patients with MELD-Na < 13 or ALBI grade ≤ 1 showed significantly worse survival than those who did not (median survival: 13.3 vs. 24.0 months, p < 0.001). When patients were further stratified by nUCC stage and MELD-Na score, treatment was not associated with better outcome for nUCC stage IV patients with MELD-Na ≤ 12 (median survival: 22.2 vs. 18.8 months for treatment vs. best supportive care, p = 0.15), while treatment was associated with better outcome in other subgroups.

Conclusion: In HCC patients with ascites, treatment was associated with better survival, except for subgroup with advanced tumor with decreased liver function, independent of ascites. These results are not absolute contraindication for HCC treatment. For these patients, MELD-Na showed better performance than MELD, Child-Pugh score and ALBI score for predicting overall survival.

Introduction: The ideal serological marker in hepatocellular carcinoma (HCC) has not been identified yet since Alpha-fetoprotein (AFP) has unsatisfactory characteristics. Squamous Cell Carcinoma Antigen (SCCA) is expressed in tissue sample analysis of determined immunocomplexed with IgM (SCCA-IgM) has satisfactory diagnostic and prognostic performance.

Aims & Methods: Aim of our study was to evaluate, in HCC patients, the diagnostic and prognostic role of SCCA determination in tissue and in serum samples. SCCA-IgM levels were determined in 409 sera obtained from 196 HCC patients and 213 cirrhotics. SCCA tissue expression was analyzed in a subgroup of 62 patients with biopsy available at diagnosis. Sensitivity, specificity, correlation with clinical and tumor parameters, response to treatment and survival were evaluated.

Results: HCC patients had SCCA-IgM levels significantly higher than cirrhotics (P < 0.0001). Sensitivity, specificity, positive and negative predictive values were 76%, 52%, 60% and 78%, respectively. In comparison, sensitivity and specificity of Alpha-fetoprotein (AFP) and SCCA-IgM are 24% and 64%, respectively. SCCA-IgM levels were determined in 409 sera obtained from 196 HCC patients and 213 cirrhotics. SCCA tissue expression was analyzed in a subgroup of 62 patients with biopsy available at diagnosis. Sensitivity, specificity, correlation with clinical and tumor parameters, response to treatment and survival were evaluated.

In comparison, sensitivity and specificity of Alpha-fetoprotein (AFP) and SCCA-IgM are 24% and 64%, respectively. SCCA-IgM levels were determined in 409 sera obtained from 196 HCC patients and 213 cirrhotics. SCCA tissue expression was analyzed in a subgroup of 62 patients with biopsy available at diagnosis. Sensitivity, specificity, correlation with clinical and tumor parameters, response to treatment and survival were evaluated.

Introduction: The BCLC algorithm is the standard system for clinical management of HCC. Data on adherence to this therapeutic paradigm are scarce. The aim of this field-practice study is to provide a description of HCC patients in Southern Italy, to evaluate the adherence to BCLC guidelines and its impact on patients' survival.

Methods: We analyzed the region-wide Italian database of Progetto Epatocarcinoma Campania, which includes data of HCC patients, prospectively collected from January 2013 to December 2015 in 16 regional centers.

Results: Overall 1008 HCC patients were enrolled: 70.6% patients received therapy recommended by BCLC algorithm, while 29.4% underwent different treatment. Among patients who were treated in adherence to guidelines, a higher rate of diagnosis on surveillance programs, better liver function, lower rate of AFP > 200 ng/ml, more early stage and monofocal HCC, lower frequency of nodules > 5 cm, portal vein thrombosis and metastases were observed. The multivariable analysis showed that non-adherence to treatment guidelines was independently associated to the BCLC stage B, Child-Pugh classes B-C, and to the presence of neoplastic thrombosis and metastases. The mean overall survival in patients treated according to BCLC indications was 35.5months, while in patients managed differently was 31.9 months (p < 0.0001).

Conclusion: Adherence to BCLC algorithm in field-practice was high in early and end stage HCC patients, but it was poor in intermediate and advanced patients. This may be due to the wide heterogeneity of intermediate-stage patients, and to the limited use of sorafenib in advanced-stage patients. Strategies to improve treatment and stratification of HCC patients are required.

P0076 A QUESTIONNAIRE SURVEY ON QUALITY OF LIFE WITH ANXIETY AND DEPRESSION SELF-RATING IN PATIENTS OF LIVER CIRRHOSIS

Y. Zhang1, X. Li1, N. Cui2, Y. L. Liu1
1Dept. Of Gastroenterology, Peking University People's Hospital, Beijing/China
2Dept. Of Respiratory, Beijing Hospital of Chinese Traditional and Western Medicine, Beijing/China

Contact E-mail Address: medicalyuan@qq.com

Introduction: Liver cirrhosis is a great public health burden for Chinese health system. The most common cause are HBV, HCV, alcohol consumption and non-alcoholic fatty liver disease, etc. The quality of life of liver cirrhosis patients is impacted by the physical symptoms and psychological symptoms such as anxiety as depression.

Aims & Methods: We aimed to investigate the quality of life of patients with cirrhosis, as well as depression and anxiety. A questionnaire survey was carried out in 95 patients in our gastroenterology department, Peking University People's Hospital from May to August in 2016. The patients were divided into two groups, cirrhosis group and control group. The patients in cirrhosis group...
were diagnosed liver cirrhosis without complications. The control group included the digestive polyps patients without other diseases. The questionnaire included the World Health Organization Quality of Life (WHOQOL)-BREF, Self-rating Anxiety Scale (SAS) and Self-rating Depression Scale (SDS). The questionnaire scores of the two groups were analyzed.

Results: A total of 95 valid questionnaires were collected and divided into cirrhosis group (n = 40) and control group (n = 45). In the cirrhosis group, there were 22 males and 18 females, average age 57.97 ± 10.448 years. In the control group, there were 45 males, 23 males and 22 females, with an average age of 61.47 ± 13.081, showing no difference from cirrhosis group. WHOQOL includes four domains: physiological domain, psychological domain, social relationship domain, environment domain. The scores of liver cirrhosis group: physiological field (22.23 ± 3.312), psychological field (19.59 ± 3.925), social relationship field (9.64 ± 2.497), environment domain (26.23 ± 7.534) and control group (22.96 ± 3.275 in physiological field, 19.87 ± 3.152 in psychological field, 10.58 ± 2.061 in social relation field and 28.36 ± 5.091 in environmental field), they had no significant difference between the two groups (P > 0.05). The depression-sel- fnosis group (female 47.82%) was significantly higher (P = 0.034) than that of control group (42.61 ± 11.564). Meanwhile, there was no significant difference between the Self-rating Anxiety Scale scores of the cirrhosis group (38.46 ± 11.917) and control group (37.00 ± 12.521) (P > 0.05) (Table 1).

Conclusion: The quality of life and anxiety score in cirrhosis group had no sig- nificant difference from the control group, but the depression score was higher than that of the control group.

Contact E-mail Address: liya73@mail.ru

Introduction: Non-alcoholic fatty liver disease (NAFLD) is liver disease with histological signs of accumulation of cholesteryl excessive amount in hepatocyte in patients not consuming alcohol as a single cause (due to causes other than). The search for accessible, non-invasive and effective methods of screening for this pathology, allowing to detect NAFLD at early, potentially reversible stages of development is relevant. The purpose of the work was frequency estimation of the prevalence steatosis according to elastometry with controlled attenuation parameter (CAP%) among young people and associated with them specific body composition.

Aims & Methods: 59 volunteers (students of medical university) at the age of 19–28 years (the median age of 20.5) have participated in research. There were 22 (37.3%) men and 33 (62.7%) women among them without verified liver diseases. The survey was conducted in order to exclude or detect risk factors. Determining the body mass index (BMI), body composition, CAP% (CAP%) was used for the severity of steatosis. Moreover, there was the body electrical impedance analysis of body (BIA), evaluated: body mass index (BMI), body fat.

Results: The signs of violations of the structure of the liver were diagnosed in 15 people (25.4%). The signs of steatosis were found in 12 (20.3%) subjects. The symptoms of liver fibrosis were found in 7 (11.9%) people (E> 5, 8, 5KPa). At the same time the combination of liver fibrosis and steatosis was diagnosed in 4 (6.8%). After analyzing data of BIA it was revealed that body weight above normal in 25 (40, 3%) subjects, while body composition above normal values in 19 (33, 4%). Results of binary regression analysis showed that the chance of development of hepatic steatosis in case of excess adipose tissue increase 28 times (p = 0, 045), influence of BMI, gender, age was statistically insignificant.

Conclusions: Based on the obtained results, it can be concluded that there is high enough level of distribution of liver steatosis among young people. Transient elastography (TE) with controlled attenuation parameter (CAP%) is a fast, reliable, repeatable non-invasive method for the assessment of NAFLD. The development of hepatic steatosis among practically healthy young people was validly associated with the increase the amount of adipose tissue in the body. Confirmed the importance of evaluation of body composition and lack of information of using only BMI when evaluating the chances of development of NAFLD.

P0080 SALVAGE TECHNIQUE USING A MICRO GUIDEWIRE FOR DIFFICULT BILIARY CHOLANGIOPANCREATOGRAPHY
Ichinomiya Nishi Hospital Dept. of Gastroenterology, Ichinomiya/Japan

Contact E-mail Address: a-mori@anzu.or.jp

Introduction: Biliary cannulation is indispensable for therapeutic endoscopic retrograde cholangiopancreatography (ERCP) in patients having biliary disease. Selective biliary cannulation is often difficult due to anatomical constraints. Numerious techniques have been attempted to overcome such problems. Although a wire-guided selective cannulation technique into the bile duct is a useful approach, conventional guidewires (0.025 or 0.035 inch) are relatively rigid to pass through the long curved narrow distal segment (NDS) or malignant stricture and sometimes get flicked off the NDS in such cases. It may be better to use finer and more flexible guidewires. Hence, we developed a novel guidewire technique using a micro guidewire (GT wire; 0.016 inch, 300 cm, TERUMO, Japan) designed for super-selective angiography in difficult cases of selective biliary cannulation.

Aims & Methods: We aimed to assess usefulness of GTWt for salvage technique in biliary cannulation. We studied 240 consecutive ERCP-naive patients between August 2014 and February 2017. We have tried to perform GTWI to ERCP-difficult cases that was defined as patients of unsuccessful cannulation despite attempts over 15 min with conventional techniques including wire-guided cannulation, pre-balloon dilatation, pre-placement of guidewire (0.025 or 0.035 inch). Following the unsuccessful attempts, the guidewire was changed to GT wire and selective biliary cannulation was performed under fluoroscopic control. We assessed the number of patients who benefitted from GTWI and whether overall success rate of biliary cannulation in ERCP was improved.

Results: Among 240 ERCP-naive patients, 40 were ERCP-difficult cases (success rate with conventional technique: 200/240; 83%). Among 45 ERCP-difficult cases, GTWI was successful in 32 patients (success rate with GTWI: 32/40; 80%). Overall success rate of ERCP-naive patients improved from 80% to 93% with GTWI, for patients with malignant stricture and four patients with difficult front of papilla. Among eight patients who failed with GTWI, seven were successful performing precut papillotomy or endoscopic ultrasound-guided biliary drainage and one was interrupted because of developed serious condition.

Conclusion: GTWt as a salvage technique for unsuccessful selective biliary cannulation cases improves the success rate of ERCP, and could be attempted before performing a precut papillotomy, endoscopic ultrasound-guided techniques or other cumbersome procedures.

Introduction: Gallbladder stone (GBS) is a common gastrointestinal disease can progress to severe cholecystitis and is a strong risk factor for gallbladder cancer (GBC). Recently, clinical epidemiologic studies revealed that the alcohol consumption has a preventive effect for development of gallsone diseases.

Aims & Methods: To evaluate the relative risks of alcohol consumption for the gallstone stones disease development. Systematic searching was performed using MEDLINE, EMBASE and Cochrane library from January 1st, 1996, to December 31st, 2016 for studies assessed the relationship between alcohol consumption and gallstone development risk. The eligibility criteria included: 1) studies involving the patients with gallbladder stone with or without cholecystitis; 2) cohort or case-control studies investigated the association between alcohol consumption and gallstone disease development. Newcastle-Ottawa Scale was used to assess the methodologic quality of each studies. Data was obtained from each selected studies regarding: 1) baseline characteristics of the study (cohort, case-control); 2) number of participants; 3) participants’ clinical features; 4) country; 5) publication year; 6) Risk or odds ratio (OR) and 95% confidence intervals (95% CI). All studies were categorized into the following groups: 1) alcoholic groups (higher levels of alcohol consumption and risk of gallstone). The random effect model used was to estimate the pooled relative risks (RR) with 95% confidence intervals (CIs).

Results: Twenty-five cohort and case-control studies were included, and total 12, 581 cases with gallstone diseases among those 172, 599 controls. Alcohol consumption indicated a decreased risk of GSD development (Pooled RR = 0.84 [0.79–0.90], P < 0.001). Subgroup analyses according to the alcohol doses (g/d) confirmed a gradual risk-reduction effect on GSD compared to non-drinkers (Light: RR = 0.97 [0.94, 1.00], p = 0.864; Moderate: RR = 0.82 [0.79, 0.86], p = 0.777; Heavy: RR = 0.70 [0.62, 0.80], p < 0.01).

Disclosure of Interest: All authors have declared no conflicts of interest.

P0082 ALCOHOL CONSUMPTION CAN REDUCE THE RISK OF GALLSTONE DISEASE: A SYSTEMATIC REVIEW WITH DOSE-RESPONSE META-ANALYSIS OF CASE-CONTROL AND COHORT STUDIES

M. Kida, H. Yamauchi1, Y. Kawaguchi1, E. Miyata1, R. Hasegawa1, T. Kaneo1, K. Okuwaki1, T. Iwai1, H. Kikuchi1, H. Imazumi2, W. Koizumi2

Introduction: ERCP with short-type SBE in patients with surgically anatomy is not practicable with high success rate, except for cases with HJ without gastrectomy. After that, several studies with long enteroscope have reported that balloon enteroscopy-assisted ERCP (BEA-ERCP) is a safe and effective procedure with about 69–100% of reaching the blind end. However long type enteroscope allows to use limited number of ERCP devices because of its length 200 cm. Then Olympus Co. introduce the prototype of short single balloon enteroscope (SBE) with bigger channel 3.2 mm in diameter was developed. We will present its usefulness and limitation.

Aims & Methods: In order to investigate the usefulness and limitation of short-type SBE, we have performed totally 183 cases/302 procedures of ERCP with short-type SBE (associated with B-II (24 cases, 30 procedures), R-Y gastrectomy (RY; 94, 138), Hepatico-Jejunostomy without gastrectomy (HJ; 29, 58), and Child/Whipple (CW; 36, 76) from 2009 to 2016. We have investigated its rate of reaching blind end, time of procedure, success rate of therapeutic procedure, complications and its limitations.

Results: Using short type SBE, the rate of reaching blind end is B-II: 97% (29/30), R-Y: 91% (126/138), HJ: 72% (39/56), CW-93% (71/76), and 88% (totally). Success rate of therapeutic procedure in reached blind end cases, is B-II: 100% (27/27), R-Y: 96% (104/108), HJ: 94% (34/36), CW:100% (67/67), and 97% (232/238) totally. The average time of procedure is B-II: 38.6 min, R-Y: 47.2, HJ: 38.5, and CW-44.3, respectively. The reason of unreached cases in HJ without gastrectomy were either for symptomatic stent change only or conservative management. In 27 patients duct clearance was not achieved; 26% (7/27) underwent surgical management (CBD exploration/on table cholangiogram and CCX). The remaining 74% (20/27) patients were deemed unsuitable for invasive intervention and were either for symptomatic stent change only or conservative management.

Conclusion: The time period between duct clearance and CCX was longer than anticipated, especially in patients with mild acute pancreatitis as none of them underwent CCX during index admission or within 2 weeks of ERCP/duct clearance. Some patients re-presented with CBDs while awaiting CCX. We looked into potential causes of delay in CCX – delayed referral to surgery, long waiting time for elective CCX and patient choice. We propose to develop a local pathway for patients with CBDs and gallstones and institute a robust system for referring patients for CCX following duct clearance. This would help to minimize readmission and potential complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The aim of current study is to develop the multi-layer drug eluting membrane using ultrasonic spray coating method, which have uniform capacity of drug and be able to control the drug-release capacity. Methods: The drug eluting membrane was made using ultrasonic spray coating machine (MediCoat-23X). The membrane consists two kinds of coating material. One is silicone (MED-6604), that was used to basic structure of membrane and the other coating agent is polyurethane (tecophilic, tecothane, tecoflex and pellethane). The gemicitabine was used as antitumor drug, and coated to membrane by mixed form with polyurethane (gemicitabine, 250µg/ml; polyurethane, 500µg/ml). The thickness of membrane and the capacity of drug in membrane were measured at the proximal and distal end, and mid portion. The drug release capacity and duration was measured by using drug releasing test in vitro for 3 days. Results: The mean thickness of membrane was 50µm. The mean capacity of drug per unit area was 100 µg/cm², and the amount was constant in all tested area (Standard deviation, 5 µg/cm²). In drug release test, the capacity of releasing drug was different depended on the kinds of polyurethane. The total amount of released drug in 24 hours was 919 ug, 836 ug, 868 ug and 580 ug in tecophilic coating, tecothane coating, tecoflex coating, and pellethane coating. The total of released drug amount depended on polyurethane was described in table 1.

Table 1: The total of releasing drug amount in 72 hours

<table>
<thead>
<tr>
<th>Drug release amount</th>
<th>Gemicitabine (ug)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Coating Polymer</td>

Conclusion: The ultrasonic spray coating technique could be applied to make multi-layer drug eluting membrane with regular thickness. The membranes contained the uniform capacity of drug in all tested area. The releasing drug capacity is able to control by applying different kind of polyurethane.

1. Meredith C, Baird, P. Diagnostic yield of SurePath (SP) and conventional smear preparations (CSP) for brush cytology obtained from the common bile duct (CBD) in patients undergoing endoscopic retrograde cholangiopancreatography (ERCP). Gastroenterology, Vol 150, Issue 4, S516, 2016

P0087 ADVANCES IN CYTOLOGY FOR THE EARLY DIAGNOSIS OF PANCREATO-BILIARY MALIGNANCY

C. Meredith1, P. Irandoost1, P. Baird2
1Gastroenterology And Hepatology, Bankstown-Lidcombe Hospital, Bankstown/Australia/NSW
2Cytology, Lavery Pathology, Ryde/Australia/NSW

Contact E-mail Address: drmcreديث@gmail.com

Introduction: Liquid-based sample preparations for cytology have improved the cellular yield in pancreatic-biliary (PB) malignancy.1 The SurePath (SP) method-ology produces a pellet of concentrated cellular material which enables addi-tional slides for immunohistochemical (IHC) staining for tumour markers Ki67, p53 and CDX2. The presence of the mitosis-related marker, Ki67, in high con-centration in malignant cells with a specific diagnostic pattern adds a level of confidence in diagnosing malignancy using cytological preparations. The aim of this study was to assess Ki67 staining in biliary epithelium obtained from patients with bile duct obstruction.

Aims & Methods: Brushings were obtained from the common bile duct during endoscopic retrograde cholangiopancreatography (ERCP) in patients presenting with biliary obstruction. After collecting the sample, the brush was placed immediately into a SurePath vial and shaken vigorously for 24 hours to fix and suspend the cells. In cytopathology, the vial (with brush included) was agitated on a platform vortex for 10 minutes to shake the cells off the brush into the solution. The high cellular content enabled the preparation of multiple slides for H&E and these slides were reviewed independently by two senior cytopathologists.

Results: Thirty-four (34) consecutive patients with bile duct obstruction were included in the study. The cohort had a mean age of 70.2; 41% were female. Adenocarcinoma was identified in 19 (56%) and atypical/reactive cells in 9 (26%). Ki67 positive nuclei were present in 90-100% of the cells in malignant cell clusters, whereas sheets of normal cells had positive nuclei in less than 20% of cells. Atypical cells sheets had an intermediate percentage range.

Conclusion: SP is superior to conventional slide-based cytology preparations in the diagnosis of malignant bile duct structures. Advantages include ease of collect-ion, no requirement for a cytology technician, a sizable pellet of intact cells for the cytopathologist to examine and the ability to undertake IHC staining. Ki67 is a marker of cell division and cells stained with Ki67 are increased significantly in adenocarcinoma as confirmed by this study. The presence of a large number of cells stained with Ki67 as well as the pattern of intracellular staining adds a level of confidence for the cytopathologist to diagnose malignancy, particularly when there is no clinical or scan evidence of a tumour mass. Early diagnosis is the key for curative surgery and specific cell tumour markers and/or their pattern may impact significantly on the outcome.

**P0089** PROGNOSTIC VALUE OF EARLY CA19-9 RESPONSE DURING CHEMOTHERAPY IN PATIENTS WITH ADVANCED OR RECURRENT BILIARY TRACT CANCER

N. Takahara1, Y. Nakai1, K. Saito1, T. Nakamura1, T. Sato1, T. Takeda1, R. Uchino1, S. Mizano2, H. Kogure2, S. Matsubara1, M. Tada1, H. Isayama1, K. Koike1

1Dept. Of Gastroenterology, The University of Tokyo, Tokyo/Japan
2Dept. Of Gastroenterology, Juntendo University, Tokyo/Japan

**Abstract**

**Purpose:** The aim of this study was to investigate the failure and complication rate of the initial drainage procedure in patients with unresectable PHC.

**Methods:** Between January 2006 and March 2016, a total of 185 advanced or recurrent BTC patients receiving a first line systemic chemotherapy for at least two cycles were retrospectively studied. Serum CA 19-9 was measured at baseline (CA19-9_Pre) and after two cycles of chemotherapy, and patients were categorized into three groups based on CA19-9 response: CA19-9 decrease group (≥30% decrease), stable group (<30% decrease and ≥20% increase), and increase group (≥20% increase). The Cox proportional hazards model was used to analyze the prognostic factors for OS and PFS, using the landmark method.

**Results:** The primary tumors were located as follows: 68 (37%) in intrahepatic bile duct, 43 (23%) in extrahepatic bile duct, 64 (35%) in gallbladder and 10 (5%) in ampulla. As for chemotherapeutic regimen, single-agent or combination therapy was given in 49 (26%) or 136 (74%), respectively. After 2 cycles of chemotherapy, CA19-9 decrease was obtained in 77 (42%), stable in 56 (30%), and increase in 52 (28%). The median CA 19-9 levels at baseline and after two cycles were 264 IU/mL and 194 IU/mL, respectively. After 2 cycles of chemotherapy, CA19-9 decrease was obtained in 77 (42%), stable in 56 (30%), and increase in 52 (28%). The median CA 19-9 levels at baseline and after two cycles were 264 IU/mL and 194 IU/mL, respectively. After 2 cycles of chemotherapy, CA19-9 decrease was obtained in 77 (42%), stable in 56 (30%), and increase in 52 (28%).

**Conclusions:** The decrease in CA 19-9 response was prognostic both for OS and PFS in addition to CA19-9_Pre and performance status.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Aim & Methods: The objective of the study was to evaluate if the systematic use of percutaneous drainage or emergency cholecystectomy. Among the patients with MHBO who underwent endoscopic biliary drainage with self-expandable metal stents (SEMS) at our institution from March 2012 to March 2017. Unilateral metal stenting was performed in 15 patients (Uni group) and bilateral metal stenting was performed in 18 patients (Bi group). In the Uni group, we placed uncovered SEMS. In the Bi group, we placed cross-wired metal stents with the SIS technique. Technical success rates, complication rates, and stent patency were compared between the groups. Results: There were no significant differences between the Uni group and the Bi group in technical success rate (100% vs. 94%), complication rate (0% vs. 0%), stent occlusion rate (15% vs. 18%) or median stent patency period (102.5 days vs. 98 days). There was no significant difference in cumulative stent patency between the groups (p = 0.669).

Conclusion: Endoscopic bilateral SEMS placement of metal stents for palliative treatment of MHBO had a high technical success rate and low complication rate, similar to those of unilateral placement.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0093 UNILATERAL VERSUS BILATERAL STENT-IN-STENT PLACEMENT OF METAL STENTS FOR MALIGNANT HILAR BILIARY OBSTRUCTION

H. Toyonaga, Y. Taniguchi, T. Inokuma

Gastroenterology, Kobe City Medical Center General Hospital, Kobe/Japan

Contact E-mail Address: toyonaga.pc@gmail.com

Introduction: Endoscopic biliary stenting is widely accepted as effective palliation therapy for unresectable malignant hilar biliary obstruction (MHBO). Although draining more than 50% of liver volume is associated with better outcomes, it can occasionally be technically difficult. Aims & Methods: The aim of this study was to evaluate differences in technical feasibility and clinical efficacy between unilateral and bilateral stent-in-stent (SIS) placement of metal stents for MHBO. We retrospectively reviewed 23 consecutive patients with MHBO who underwent endoscopic biliary drainage with self-expandable metal stents (SEMS) at our institution from March 2012 to March 2017. Unilateral metal stenting was performed in 15 patients (Uni group) and bilateral metal stenting was performed in 18 patients (Bi group). In the Uni group, we placed uncovered SEMS. In the Bi group, we placed cross-wired metal stents with the SIS technique. Technical success rates, complication rates, and stent patency were compared between groups.

Results: There were no significant differences between the Uni group and the Bi group in technical success rate (100% vs. 94%), complication rate (0% vs. 0%), stent occlusion rate (15% vs. 18%) or median stent patency period (102.5 days vs. 98 days). There was no significant difference in cumulative stent patency between the groups (p = 0.669).

Conclusion: Endoscopic bilateral SEMS placement of metal stents for palliative treatment of MHBO had a high technical success rate and low complication rate, similar to those of unilateral placement.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0094 CLINICAL ASSESSMENT OF THE SAFETY AND EFFICACY OF A NOVEL BIODEGRADABLE STENT IN PATIENTS WITH BILIARY OBSTRUCTION: A PILOT STUDY

H. Othman1, N. Y. Yaacob2, E. J. Roslan1, R. Jarman1, Z. Mohamed2

Introduction: The commonest indication for biliary stent is for the treatment of obstructive jaundice and for the management of bile leak. The currently available stents are made of either plastic or metal alloy. The stents can be inserted endoscopically to provide internal drainage of the bile into the duodenum. Among the disadvantages of plastic stents are recurrences of jaundice due to biofilms formation, which require a repeat ERCP procedure to remove the stent before 3 months. We have embarked to study the safety and feasibility of a biodegradable stent for biliary stenting, which can treat biliary obstruction without the need to undergo a repeat endoscopic procedure to remove the stents.

Aims & Methods: This is a pilot study enrolling 30 subjects with symptomatic jaundice and pruritus caused by either benign or malignant biliary obstructions that were amenable to treatment by ERCP guided stenting. Primary objective was technical success and safety. Procedural and technical successes were assessed during the stenting procedure. Adverse events or complications were monitored throughout the studies. The secondary endpoints were clinical success, which was measured by a reduction of at least 20% of the initial serum bilirubin level at Day 7 post stenting. A self-assessment scale from 0 to 10 was used to assess quality of life before and after the stenting.

Results: 30 patients had the Biodegradable Biliary Stent (BBS) implanted. 18 patients (60%) were males, the mean age was 56.9 years. 26 patients (86.7%) had benign biliary duct disease and 4 (13.3%) patients had malignant condition.
P0096 THE IMPAIRED FUNCTION OF THE PLASMA MEMBRANE CA2+ PUMP RESULTS IN CA2+ OVERLOAD AND CELL DAMAGE IN CFR KNOCK OUT PANCREATIC DUCTAL CELLS

Introduction: The cystic fibrosis transmembrane conductance regulator (CFTR) has a major role in pancreatic ductal secretion and it's genetic defects damage the pancreas. It is known that intracellular Ca2+ homeostasis is disturbed in bronchial epithelial cells in cystic fibrosis (CF), but the connection of CFTR and the intracellular Ca2+ signaling has never been suggested in pancreatic damage in CF.

Aims & Methods: Our aim was to characterize the Ca2+ homeostasis of CFTR-deficient PDC. Wild type (WT) and CFTR knockout (KO) mouse pancreatic ductal and acinar cells and iPSC (induced pluripotent stem cell) derived human organoids from 2 CF patients and controls, human CF pancreatic cell line (CFPAC-1; ΔF508 mutant) were used for intracellular Ca2+ measurements. Mitochondrial membrane potential (ΔΨm) and mitochondrial morphology was assessed in isolated pancreatic ducts. Immunofluorescent staining and quantitative PCR measurements were performed to detect changes of mRNA and protein expressions.

Results: The plateau phase of the agonist-induced Ca2+ signal was elevated in CFTR-deficient PDC, which was caused by decreased function of the plasma membrane Ca2+ pump (PMCA). The functional inhibition of CFTR had no effect on the PMCA activity. Human CF organoids have shown decreased PMCA function compared to control while the 24h treatment of the CF organoids with VX-809 have restored the PMCA function to the control level. Similarly native CFPAC-1 cells and PDEC treated with siRNA to inhibit the expression of CFTR showed the same PMCA dysfunction. Viral transfection of CFPAC-1 with CFTR gene completely restored PMCA function. Sustained [Ca2+]i levels decreased ΔΨm and induced cytochrome c release in CFTR KO PDEC without significant alterations in mitochondrial morphology.

Conclusion: Dysfunction of PMCA leads to disturbed Ca2+ homeostasis in CFTR-deficient PDC and the consequent cellular Ca2+ overload impairs mitochondrial function contributing to the pancreatic damage in CF.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0097 EXPDF IMPACTS PANCREATIC DIFFERENTIATION OF HUMAN PLURIPOTENT STEM CELL DERIVED PANCREATIC ORGANOIDs

Introduction: Given their capability to differentiate to every cell type of the human body, human induced pluripotent stem cells (hiPSCs) provide a unique platform for translational and regenerative medicine. The generation of a pancreatic progenitor (PP) cells from pluripotent stem cells follows the sequential induction of virtually pure definitive endoderm (DE), foregut endoderm (GTE) and pancreatic endoderm (PE). We have recently reported the generation of a novel three-dimensional pancreatic organoid culture system that generates functional acinar-duodenal-like structures from pluripotent stem cells (Hohwieler et al., GUT, 2016).

Aims & Methods: In the current study we implemented this culture system to understand the role of exocrine differentiation and proliferation factor (ExpdF), a signalling molecule proposed to be involved pancreatic differentiation in zebrafish. CrisprCas9 technologies were used to ablate ExpdF in human embryonic stem cells, while a piggy bac engineering approach allowed us timed expression to study the role of both loss and gain of ExpdF function during pancreatic differentiation.

Results: First, a limited role of ExpdF was observed until the PE stage, while PP formation was strongly diminished. Moreover, a dramatically altered organoid morphology was observed in ExpdF knockout lines leading to mostly cystic structures. Phenotyping for duodenal and acinar lineage allowed to investigate these
changes in more detail and genome wide expression profiling helped us to under- 
stand the role of Expdf in more detail.

**Conclusion:** Thus, we report a novel signalling molecule playing a critical role 

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0098 MELATONIN METABOLITE; N1-ACETYL-N2-FORMYL-5-METHOXYKYNUMURAMINE STIMULATES PANCREATIC ENZYME SECRETION VIA CCK RELEASE. STUDY ON THE RATS

J.M. Jaworek

Dept. Of Medical Physiology, Jagiellonian University CM, Krakow/Poland

Contact E-mail Address: jalonta.jaworek@uj.edu.pl

Introduction: N-acetyl-N-formyl-5-methoxykynuramine (AFMK), melatonin metabolite was determined recently as a secretagogue in response to acute pancreatic overload against acute inflammation. AFMK significantly attenuated acute pancreatitis; however, its effect on pancreatic exocrine function has not been investigated yet.

Aims & Methods: 1. To investigate the effects of intraduodenal (i.d.) application of AFMK on pancreatic enzyme secretion under basal conditions and following the stimulation of this secretion with diversion of pancreatic-biliary juice (DPBJ) and to examine the role of CCK in this process. 2. To assess the effect of AFMK on CCK receptor in pancreatic acinar cell line AR42J. Material and methods: For in vivo study Wistar rats weighing 300 g were employed. Under pentobarbi- 
tane anesthesia the animals were surgically equipped with silicone catheters, inserted into pancreatic-biliary duct, and into duodenum. AFMK (5.10 mg/kg i.d.) was given to the rats under basal conditions or following stimulation of pancreatic secretion with DPBJ. Lorglumide, the CCK1 receptor antagonist (1 mg/kg i.d.) was administered 15 minutes prior to the application of AFMK. Samples of pancreatic-biliary juice were collected to measure the amylase outputs. The blood samples were taken for determination of CCK by ELISA kit. For in vitro study AR42J were incubated in presence of AFMK alone or in combination with CCK. The protein signal of CCK receptor was determined by Western blot.

Results: AFMK given i.d. produced the dose-dependent increases of pancreatic amylase secretions both; unstimulated, as well as that induced by DPBJ. The rises of pancreatic amylase outputs were accompanied by significant increase of CCK plasma levels. Administration of lorglumide, a CCK1 receptor blocker, comple- tely abolished the stimulation of pancreatic exocrine function induced by AFMK. This melatonin metabolite failed to affect protein signal for CCK recep- tor in AR42J cells.

Conclusion: The stimulatory effect of AFMK on pancreatic enzyme secretion in the rats is indirect and dependent on the release of CCK by this melatonin metabolite.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0099 INVESTIGATION OF THE FUNCTION OF TRPM2 IN MOUSE PANCREATIC ACINAR CELLS

J. Fanczal1, P. Biró1, T. Maday1, P. Hegyi1, J. Maleth1

Introduction: Aberrant intracellular Ca2+ signaling is the hallmark of acute pan- creatitis (AP) inducing mitochondrial damage, intraacellular digestive enzyme activ- ity of cells. Thus prevention of toxic cellular Ca2+ overload is a promising therapeutic target. The transient receptor potential metallastat 2 (TRMP2) is a non-selective cation channel that plays major role in oxidative stress induced cellular Ca2+ overload in different cell types. Although likely, its role in pancreatic acinar cells and the pathogenesis of AP was not investigated yet.

Aims & Methods: Our aim was to characterize the functional activity of TRPM2 in pancreatic acinar cells. In our experiments pancreatic acinar cells (PAC) were isolated from wild type (WT) and TRPM2 knockout (KO) mice with enzymatic digestion. The changes of the intracellular Ca2+ level was measured with high fluores- cent microscopy using FURA2-AM.

Results: The intracellular Ca2+ signals evoked by 100 mM carbachol were not different in WT and TRPM2 KO PAC. On the other hand, 1 mM H2O2 induced significantly higher intracellular Ca2+ elevation in WT PAC compared to the TRMP2 KO. In Ca2+ free extracellular solution the Ca2+ signal in response to 1 mM H2O2 was markedly reduced in WT PAC confirming that H2O2 activates dominantly intracellular Ca2+ influx.

Conclusion: Our result confirmed the functional activity of the TRPM2 channel in pancreatic acinar cells. In further investigations we aim to clarify the pathogenetic role of TRPM2 in AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0100 INVESTIGATION OF THE PANCREATIC DUCTAL ION SECRETION IN PANCREATIC DUCTAL ORGANOID CULTURES

Introduction: Pancreatic ductal fluid and HCO3− secretion are crucially impor- tant in the physiology and pathophysiology of the exocrine pancreas. However, the role of human pancreatic secretory processes is great challenge due to the limited access to human pancreatic ductal cells. The recently developed three- dimensional pancreatic organoid cultures (OC) may help to overcome this limit- ation. However, the ion secretory processes in pancreatic OC is not known.

Aims & Methods: Our aim was to characterize the ion transport processes in mouse pancreatic OC. Mouse pancreatic ductal fragments were isolated by enzymatic digestion. The isolated ducts were grown in Matrigel on 37°C for a week in OC media. Changes of the intracellular pH was measured to characterize the ion transporter activities of the epithelial cells in OC.

Results: Basolateral administration of 20 mM NH4Cl in standard HEPES or CO2/HCO3− buffered solution resulted in rapid intracellular alkalization, while the apical administration of NH4Cl induced rapid acidification followed by regeneration to the resting pH levels. The regeneration phase was inhibited by the removal of extracellular Na+ . The administration of 10 mM CFTRinh172, a selective inhibitor of cystic fibrosis transmembrane conduc- tance regulator decreased the regeneration from alkali load. Basolateral administration of 20 mM amiloride and 20 mM H2DIDS decreased the intracel- 

lular pH suggesting the activity of Na+/H+ exchanger and Na+/HCO3− cotrans- porter on the basolateral membrane.

Conclusion: The ion transport activities in mouse OC are similar to those observed in freshly isolated primary tissue. This suggest that OC will be suitable to study human ductal epithelial ion transport.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0101 INVESTIGATION OF THE ORA11 MEDIATED CA2+ ENTRY IN MOUSE PANCREATIC DUCTAL CELLS

Introduction: Acute pancreatitis (AP) is the most common inflammatory disorder in the gastrointestinal tract with an overall mortality of 20–30% in severe cases. The treatment of AP is not resolved yet, urging the identification of novel drug targets. Toxic cellular Ca2+ overload was highlighted as a key event in pancreatic acinar and ductal cells during the pathogenesis of AP. In addition, the inhibition of Orai in pancreatic acinar cells markedly decreased the Ca2+ toxicity and the severity of AP. However, We have no information regarding the role of Orai in pancreatic ductal physiopathology.

Aims & Methods: Wild type FVB/N mice were used for the isolation of pancreatic ductal fragments. The intracellular pH and Ca2+ level of the pancreatic ductal cells (PDC) were measured by microfluorimetry. The effect of selective Orai inhibitors provided by CalciMedica was evaluated.

Results: The tested compounds dose-dependently inhibited Ca2+ influx during the carbachol induced Ca2+ signal in PDC. Inhibition was complete at a con- centration of 10 μM (CM-B: 99.87%, CM-C: 95.29%). Next, endoplasmic reti- 
culum Ca2+ stores were depleted with cyclopiazonic acid and the inhibition of store-operated Ca2+ entry (SOCE) was investigated after the re-addition of extra- 
cellular Ca2+. Under those conditions CM-B and CM-C significantly, but not completely, decreased SOCE in PDC (55.96% and 55.03% respectively). The removal of extracellular Na+ to abolish activity of the Na+/Ca2+ exchanger had no effect on the inhibition of SOCE by CM-B or CM-C. We also showed that the inhibition of Orai has no effect on the basal secretion of HCO3− by PDC, which is the main physiological function of these cells.

Conclusion: We showed that Orai has a significant role in the Ca2+ signaling of PDC. In the next step we will evaluate the pathophysiological relevance of the channel.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0102 ACUTE PANCREATITIS OF UNKNOWN ORIGIN AND IDIOPATHIC JUVENILE PANCREATITIS IN SWEDEN

1Center For Digestive Diseases, Karolinska University Hospital, Stockholm/ Sweden
Respiratory failure 3.13(2.01–4.89)
Advanced age 2.64(1.78–3.93)

Introduction: Acute pancreatitis (AP) is among the most difficult diseases faced by gastroenterologists and surgeons. In some cases it is difficult to understand etiology of AP. Hereditary pancreatitis (HP) is an autosomal dominant genetic disorder characterized by recurrent attacks of acute pancreatitis.

Aims & Methods: We analyzed medical records of patients who were diagnosed with severe juvenile pancreatitis of unknown etiology (UEP) at the Center for Digestive Diseases at Karolinska University Hospital from January 2008 to December 2016.

Results: During the observation period, 44 patients (17 male and 27 female) were registered with the ICD code chronic or relapsing pancreatitis, and onset of symptoms before the age of twenty. At time of first visit, the mean age was 36.7±26.9 years, range 24–57. The average period between the occurrence of first symptoms and diagnosis was 14.0 years (range 1–39 years). All patients (100%) clinically presented with recurrent acute pancreatitis. There were 28 (63.7%) patients with genetic mutations. Five out of 28 genetic positive patients (17.9%) had a definitive diagnosis of genetic etiology of pancreatitis. Seven out of 28 genetic positive patients (25%) had complications: in five patients endoscopic treatment due to pancreatic duct stenosis was performed; one patient had pancreatic and bile duct stenosis and one patient (female, age 28, CFTR heterozygous mutation) a pancreatic tumor (mucinous cystadenoma with high dysplasia that was successfully surgically treated with excision). One patient died due to non-pancreatic related disease (kidney cancer). None of the patients reported alcohol overconsumption. Four out of 28 genetic positive patients (14.3%) were active smokers. Fecal elastase-1 (FE-1) was tested in 28 (63.6%) patients: 16 (57.1%) in genetic positive and 12 (75%) in genetic negative group of patients. Pancreatic exocrine insufficiency (PEI) was found in 5 out of 12 (41.7%) of genetic negative patients and in 5 out of 16 (31.2%) genetic positive patients. Average age at onset of PEI was 38 years (range 27–53). Diabetes mellitus (DM) was diagnosed in one patient in group with genetic alterations and 2 patients in group without genetic alterations.

Conclusion: We found high proportion of genetic alterations in patients with juvenile pancreatitis and PUE. In patients in whom pancreatitis remains unexplained after excluding of the most often etiologies and presence of genetic alteration, hereditary pancreatitis seems as reasonable explanation even in patients with other genes than PRSS1. Routine follow-up of patients with regular testing on pancreatic exocrine insufficiency and diabetes mellitus and pancreatic cancer surveillance is necessary.

Disclosure of Interest: All authors have declared no conflicts of interest.

Disclosure of Interest: All authors have declared no conflicts of interest.
and their evolution after 24 h were evaluated. Accuracy was measured using different methods or operating characteristic (ROC) analyses.

Results: Of the 817 eligible patients, 118 were excluded, most for a previous episode before admission. We analyzed 699 patients with a median age of 57.5 years (IQR: 45.1–72.7), 57.4% males. Most frequent comorbidities were: diabetes (18%), hypertension (16.6%), and COPD (7.7%). Median length of stay was 7 (5–10) days. Most common causes were: biliary (53.9%), idiopathic (21.8%) and alcoholic pancreatitis (14.3%). A CT scan was performed in 56.1% identifying local complications in 36.2% of them, acute fluid collections in 16.8%. There were 42 (6.6%) severe and 196 (28%) moderately severe cases. Overall mortality was 2.4% (1.5–3.9%), 35.7% (23.0–58.7%) among severe cases. BUN at admission AUC: 0.88 [0.85–0.90], aBISAP score [AUC: 0.88 [0.85–0.90] and APACHE II [AUC: 0.87 [0.84–0.89]] had a high overall ability in predicting death. APACHE II resulted in the highest sensitivity, 100% (81.6–100%), while the BISAP score presented the highest specificity, 93.1% (90.6–94.8%). BUN at admission [AUC: 0.89 (0.86–0.91)] and the aBISAP score [AUC: 0.87 (0.84–0.89)] also presented the best predictive potential. The BISAP score obtained the highest correlation coefficient (94.2% (92.2–95.8%), although with a low PPV, 32.1% (21.4–45.2%). On the other hand, diagnostic accuracy for mild AP was poor, as all predictors presented an AUC < 0.7. The aHAPS score reached the highest specificity, 87.8% (83.9–91.4%), but presented a very poor sensitivity (28.9% [24.3–33.9%]).

Conclusion: The revised Atlanta classification accurately identifies those patients at higher risk of death. Among the available predictors of severity, BISAP and BUN at admission presented an excellent performance, with an AUC of nearly 0.9. New scores are needed to predict a mild course, as none of the available indexes presented an AUC > 0.7.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The severity of acute pancreatitis varies widely, from a mild self-limited disease to one with a severe clinical course complicated by multiple organ dysfunction syndrome.1 No pharmacologic treatment for acute pancreatitis has shown to improve the prognosis of patients with severe acute pancreatitis, while the quality of supportive care including early fluid resuscitation is critically important.2 Fluid resuscitation maintains adequate intravascular volume by compensating for fluid shifts to the third space.3 However, there is a lack of consensus regarding the details of optimal fluid administration such as the type of fluid, infusion rate and volume of administration, and the physiologic goals of fluid resuscitation.4

Aims & Methods: The aim of this study is to evaluate the association between the administered fluid volumes during the first 24 hours and pancreatitis severity in patients with severe acute pancreatitis. We conducted a secondary analysis of data from a multi-centre retrospective study of patients with severe acute pancreatitis in Japan, which was registered with the University Hospital Medical Information Network Clinical Trials Registry (Registry number 00012220) and approved by the Institutional Review Board or the Medical Ethics Committee at each institution.5 The diagnosis of severe acute pancreatitis was based on criteria of the Japanese Ministry of Health, Labour and Welfare (Japanese Severity Score).1 Patients classified in the fluid ≥6000 ml group had significantly higher mortality than those in the fluid <6000 ml group. There were no significant differences between the two groups and clinical outcomes using multivariable logistic regression analysis. The primary outcome was in-hospital mortality. As a sensitivity analysis, we conducted an identical analysis for patients with severe acute pancreatitis diagnosed according to the revised Atlanta classification.7

Results: We analysed 1097 patients, and the mean fluid volume administered was 5618±3018 ml (mean±standard deviation), with 708 and 389 patients stratified into the fluid <6000 ml and fluid ≥6000 ml groups, respectively. Overall in-hospital mortality was 12.3%. The fluid ≥6000 ml group had significantly higher mortality than the fluid <6000 ml group (15.9% vs. 10.3%, p < 0.05). However, in multivariable logistic regression analysis, conversely fluid ≥6000 ml within the first 24 hours was significantly associated with reduced mortality (OR 0.58, 95%CI 0.34–0.98). We performed subgroup analyses for patients diagnosed with severe acute pancreatitis based on the revised Atlanta classification.7 One thousand-seven patients were classified in the fluid <6000 ml group, and 201 patients classified in the fluid ≥6000 ml group. There were no significant differences between the two groups with regard to in-hospital mortality (fluid <6000 ml: 35.3% vs. fluid ≥6000 ml: 28.4%, p = 0.18). In multivariable logistic regression analysis, administration of fluid ≥6000 ml within the first 24 hours was associated with significantly less mortality (OR 0.56, 95%CI 0.32–0.98).

Conclusion: In patients with severe acute pancreatitis, administration of fluid ≥6000 ml within the first 24 hours is associated with decreased mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is increasingly used for therapeutic management of various biliary and pancreatic diseases\(^1\). However, ERCP is not a procedure without morbidity\(^2\). Post-ERCP pancreatitis (PEP) remains the most common and serious complication after ERCP\(^3\).

Aims & Methods: To detect risk factors for post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) and investigate the predictors of its severity. This is a prospective cohort study of all patients who underwent ERCP. Pre-ERCP data, intraoperative data, and post-ERCP data were collected.

Results: The study population consisted of 996 patients. Their mean age at presentation was 56.42 (±14.72) years, and there were 454 male and 442 female patients. Overall, PEP occurred in 102 (10.2%) patients of the study population; 38% (84.7%) of cases were of mild to moderate degree, while severe pancreatitis occurred in 22 (21.6%) patients. No hospital mortality was reported for any of the PEP patients during the study duration. Age less than 35 years (P = 0.001, OR = 0.305), narrow common bile duct (CBD) diameter (P = 0.0001) and increased number of pancreatic cannulations (P = 0.0001) were independent risk factors for the occurrence of PEP. Patients with these risk factors are candidates for prophylactic and preventive measures against PEP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The Cotton criteria (1) and the revised Atlanta classification (2) are advocated to define post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) severity (3). Whereas Cotton puts the emphasis on length of hospitalisation, Atlanta focuses on the presence of local (necrosis) and systemic (organ failure) complications. The number of hospitalization days may not be a proper representation of PEP severity, because it is influenced by other diagnoses such as ERCP complications and comorbidity. The goal of this retrospective cohort study is to compare the Cotton and Atlanta criteria for the severity of PEP.

Aims & Methods: All ERCP procedures from a Dutch university medical centre and a teaching hospital between 2012 and November 2016 were checked retrospectively for patients with PEP. Patients were eligible if they met the Cotton criteria or Atlanta criteria for acute pancreatitis. All records were checked up to 48 hours after ERCP to capture delayed PEP. Patients were excluded if they had acute pancreatitis prior to ERCP or had chronic pancreatitis. In the primary analysis, mild/moderate and severe PEP were compared between Cotton and Atlanta with Fischer's exact test. Atlanta was regarded as the golden standard. Secondarily, we compared the sensitivity and specificity of both definitions for mortality.

Results: Out of a total 2156 ERCPs, 66 patients (3%) had PEP. Two patients died 16 days after ERCP due to documented mesenteric ischemia during the early phase (<8 days) and 3/10 patients during the late phase (>8 days). IPN was present in 62 patients (43%), all requiring an intervention (i.e. radiological, endoscopic, and/or surgical). 35% of patients (22/62) had only one modality (drainage/anticoagulant or transgastric) and did not require necrosectomy. For 30 patients (48%), additional necrosectomy was needed because of lack of improvement after drainage alone. 10 patients (17%) had only necrosectomy without prior drainage procedure. Complications such as hemorrhage and perforation of visceral organ occurred more frequently in the IPN group (14.5% vs 14.4%, p<0.001 and 5% vs 8.5%, p=0.02 respectively). The late phase mortality (>8 days) was significantly higher in the IPN group (14.5% vs 14.4%, p<0.01). In multivariate analysis factors associated with IPN were number of OF and postrevascular mesenteric venous thrombosis (table 1). 39 patients (68%) received anticoagulants with a median time of 6 [3-6] months and among them, 25 patients developed cauvermanea, irrespective of whether or not they receive systemic anticoagulants.

Conclusion: In conclusion, this study performed in routine practice conditions showed that IPN occurs in almost half of patients hospitalized in ICU for severe AP, and is associated with increased mortality and complications rates. Overall mortality was 17.6%, and factors associated with mortality were a high BMI, CTSI and persistent OF. Those results are consistent with previous studies1, 2, but we reported a high rate of mesenteric ischemia (7/26 patients deceased) while this complication is occasionally described. IPN patients required an intervention for drainage of infected tissue removal, which was performed using minimally invasive techniques in the vast majority of cases, with no complication or severe side effect. 35% of patients were treated with drainage alone without any additional necrosectomy. Finally, PSMT and early OF appeared to be associated with risk of developing an IPN but anticoagulation for PSMT did not protect for cauvermanea occurrence and can expose to intestinal bleeding. Our results also suggest that the optimal and early management of OF and detection of PVSMT might prevent IPN and/or its complications. Such hypothesis will need to be tested in large multicentre prospective studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute pancreatitis (AP) is a common but potentially lethal pathology due to the multiplicity and severity of its complications. Infected pancreatic necrosis (IPN) occurs in 30% of patients with necrotizing AP and is associated with an increase in mortality ranging from 15% to 39%. While interventional drainage and/or removal of the infected tissue remain the mainstay of therapy of IPN, important progress have been achieved over the last decade and minimally-invasive treatments have been developed. The aim of this study was to identify factors associated with IPN and to describe outcomes and mortality.

Aims & Methods: This was a retrospective study of collected data from all patients admitted in Intensive Care Unit (ICU) in a single centre from 2012 to 2015 for a severe AP. Baseline characteristics of the overall population were expressed as frequencies (percentages) for categorical variables, as mean ± standard deviation (SD) for continuous data. For the analysis of mortality, multivariate analysis with Cox proportional hazards regression modeling was used to identify independent predictors. Association between IPN and patients' characteristics at baseline was evaluated using logistic regression.

Results: In total, 148 patients were included in this study. Overall mortality was 17%. Body mass Index, computed Tomography Severity Index (CTSI) ans persistent (>48H) organ failure (OF) were independently associated with overall mortality. Of the 16 patients died during the early phase (<8 days) and 3/10 patients during the late phase (>8 days). IPN was present in 62 patients (43%), all requiring an intervention (i.e. radiological, endoscopic, and/or surgical). 35% of patients (22/62) had only one modality of drainage (anticoagulant or transgastric) and did not require necrosectomy. For 30 patients (48%), additional necrosectomy was needed because of lack of improvement after drainage alone. 10 patients (17%) had only necrosectomy without prior drainage procedure. Complications such as hemorrhage and perforation of visceral organ occurred more frequently in the IPN group (14.5% vs 14.4%, p<0.001 and 5% vs 8.5%, p=0.02 respectively). The late phase mortality (>8 days) was significantly higher in the IPN group (14.5% vs 14.4%, p<0.01). In multivariate analysis factors associated with IPN were number of OF and postrevascular mesenteric venous thrombosis (table 1): 39 patients (68%) received anticoagulants with a median time of 6 [3–6] months and among them, 25 patients developed cauvermanea, irrespective of whether or not they receive systemic anticoagulants.

P0114 EARLY PREDICTORS AND OUTCOMES OF FLUID SEQUESTRATION IN ACUTE PANCREATITIS

S. Goyal
Gastroenterology, Banaras Hindu University, V.FARASAI/India

Contact E-mail Address: drsundheepgoyal@gmail.com

Introduction: Although it is well known that some patients with AP have an increased need for fluid therapy, it is not clear who should get fluids aggressively. Changes in hematocrit, BUN and serum creatinine, has been documented to limit fluid sequestration. In this prospective cohort study 300 consecutive patients of acute pancreatitis were included. Fluid sequestration was calculated by adding the total amount of fluid administered and subtracting the total amount of fluid lost in the first 48 hours of hospitalization. Local complications were defined...
Pancreatic guidewire is a potential candidate for prophylactic pancreatic stent to prevent post-ERCP pancreatitis: a matched propensity analysis

Gastroenterology and Hepatology, Toyonaka Municipal Hospital, Toyonaka, Japan

Contact E-mail Address: hayashishiri1976@yahoo.co.jp

Introduction: Post-ERCP pancreatitis (PEP), that can potentially result in procedure-related death is still great concern in pancreatic-biliary endoscopists because it may be a potentially preventable complication but it is difficult to prevent. Among reported prophylactic procedures for PEP, placement of prophylactic pancreatic stent (PPS) is known as a promising one to decrease the risk of PEP in high-risk patients. It is, however, still unclear what high-risk patient is a good candidate for PPS. We have previously reported the two predictive factors for PEP; the cannulation time longer than 13 min and 2-hour amylase level over 264 IU/L (World J Gastrointest Endosc 2016; 8: 777–784). In the present study, we evaluated if PPS for PEP was useful in high-risk patients with using the propensity score matching method.

Aims & Methods: This is a retrospective single center cohort study of consecutive patients that underwent ERCP from January 2010 to December 2015. A total of 2298 patients (average age 73 ± 11, female 42.2%) were enrolled. Of them, 174 cases with the following conditions were excluded: 1) gallstone pancreatitis, 2) unreachable to papilla, 3) missing data of procedure time or serum amylase levels. Finally, 2124 cases were analyzed. Overall, 86 of 2124 cases developed PEP (3.96%). PEP in high-risk patients with the cannulation time longer than 15 min were revealed as significant high-risk factor of PEP using a univariate analysis. There were a total of 216 patients with above two risk factors (HR group). Of them, 30 patients developed PEP (13.9%). Using logistic regression, propensity scores were used to prevent selection bias between with and without PPS. The covariates entered in the propensity model were age, gender, native papilla, endoscopic biliary stent, endoscopic metallic stent, pancreatic guidewire, pancreatic injection, endoscopic sphincterotomy, precut, endoscopic papillary balloon dilatation, pancreatic guidewire without duct brush. Subsequently, 1-to-1 matched PPS and non-PPS group (each N = 64) were extracted from the cohort using the closest matching score.

Results: After matching, mean propensity matching score in PPS and non-PPS group were 0.46 ± 0.2 and 0.46 ± 0.2 respectively. There were 62 female (48.4%) with a mean age of 71 in each group. A total of 17 patients with HR developed PEP (13.2%). The PEP rate in PPS group was significantly lower than in non-PEP group (6.3% vs 20.0%; p = 0.019). Mean post-ERCP 2 h amylase levels were 191 IU/L (106–359) in PPS group than non-PPS group (196 IU/L (90–411); p = 0.002).

Conclusion: Using a propensity analysis revealed that PPS significantly reduce the risk of developing PEP in high-risk patients with longer cannulation time and pancreatic guidewire. Consequently, we considered patients with above two risk factors be a good candidate for PPS.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0115 LONGER CANNULATION TIME AND Pancreatic PAP Pancreatitis: A MATCHED PROPENSITY ANALYSIS

Gastroenterology and Hepatology, Toyonaka Municipal Hospital, Toyonaka, Japan

Contact E-mail Address: hayashishiri1976@yahoo.co.jp

Introduction: Post-ERCP pancreatitis (PEP), that can potentially result in procedure-related death is still great concern in pancreatic-biliary endoscopists because it may be a potentially preventable complication but it is difficult to prevent. Among reported prophylactic procedures for PEP, placement of prophylactic pancreatic stent (PPS) is known as a promising one to decrease the risk of PEP in high-risk patients. were good. Case B: 29 y/o female. Alcoholic chronic pancreatitis, pancreatic duct, stones were removed easily. This is our first case of EPDBD. In our hospital, stones were removed by basket catheter and severe pain continued, so EPDBD was done. Pancreatic calculi (PC) are a sequelae of chronic pancreatitis (CP) – ITS USEFULNESS AND SAFETY

Introduction: We started our original EPDBD (endoscopic pancreatic duct balloon dilatation) therapy for pancreatic diseases in 1996. In these 22 cases, 698 cases were treated by this method. We would like to show its usefulness and safety.

Aims & Methods: The balloon (6 mm diameter, 15 mm long -Boston Scientific) was inflated in the stenotic portion of the pancreatic duct at 6 atm. pressure for 1 minute several times. Then stone removal or EPS (endoscopic pancreatic stenting) was evaluated: the stone free rate and stone relapse rate in 586 pancreatic stone cases treated by EPDBD 2. The prognoses of 114 EPS-successful pseudocyst cases treated by EPDBD 3. The prognoses of 16 EPS-successful divi

Results: The purpose of EPDBD therapy for pancreatic stone was to use endoscopic procedures in the pancreatic duct and stone removal, and to reduce stone relapse rates. 508 cases of pancreatic stone were treated by EPDBD. They consisted of 90 cases treated by endoscopic sphincterotomy, stone extraction, and minor papillotomy (28), and 478 cases treated by ESWL + endoscopic method (via major papilla 381, minor papilla 97). After EPDBD therapy, the stone free rate was 75.3%, the pain free rate 97.1%. The stone relapse rate was 5.7% - this is a much lower result compared to other reports. We think that EPDBD contributes to this good result. Complications of EPDBD therapy were only minor bleeding from orifice at the therapy and mild pancreatitis after therapy for several days. Case A: 22 y/o male. Idiopathic chronic pancreatitis, pancreas stone: After 4th ESWL, small stones remained in the head duct which can’t be removed by basket catheter and severe pain continued, so EPDBD was done under good informed consent. After several dilations of the orifice and the head duct, stone was removed easily. This is our first case of EPDBD therapy for pancreatic stone. In our hospit

P0118 ENDOSCOPIC ULTRASOUND AS A PREDICTOR AND GUIDE TO SUCCESSFUL ENDOThERAPY IN CHRONIC Pancreatitis
M. Sharma, P. Sornani
Department Of Gastroenterology, Jawanti Sri Specialty Hospital, Meerut/India

Contact E-mail Address: sharmamalay@hotmail.com

Introduction: Pancreatic calculi (PC) are a sequelae of chronic pancreatitis (CP) and have important clinical implications. Endoscopic pancreatic duct stenting and minor papilla stenting are the successful management modality in CP. The rationale for endoscopic treatment of obstructing PC is based on the observation that pain subsides when the stone(s) is removed and drainage of pancreatic secretion is restored. Indications for endotherapy include stones <5 mm size, stones in head of pancreas which are not impacted and absence of downstream strictures. The assessment prior to the procedure is done by MRCP. EUS has an additional advantage of making a diagnosis of ampullary/papillary stones and biliary obstruction which can be treated endoscopically. It can guide whether endotherapy needs to be performed through major or minor papilla. EUS by diagnosing pancreatic (tumour/strictures missed on other imaging modalities) allows early diagnosis and hence improves long-term prognosis. It can prevent unsuccessful attempts at endotherapy and its possible risks/costs. We conclude that EUS before endotherapy plays an important role regarding further management decisions in patients with CP.

Introduction: IgG4-related disease (IgG4-RD) is characterized by the infiltration of inflammatory cells, such as plasma cells and macrophages, and fibrosis in tissues. We previously reported that apoptosis inhibitor of macrophage (AIM), which is secreted by macrophages, is related to the progression of hepatic fibrosis in chronic hepatitis C. Some studies have observed a relationship between IgG4-RD and malignancy. IgG4-RD is considered to represent a premalignant state or paraneoplastic condition.

Aims & Methods: To clarify the significance of the serum AIM levels in patients with IgG4-RD, we measured these levels in 22 healthy controls, 32 patients with IgG4-RD, and 36 patients with other pancreatic diseases (chronic pancreatitis [CP], intraductal papillary mucinous neoplasm [IPMN], pancreatic cancer [PC]). We also analyzed the prevalence of malignancy, the relationship between the appearance of malignancy and the diagnosis of 42 IgG4-RD, the type of cancer, and related factors, and we compared the age, gender, laboratory data, and AIM level.

Results: Fifteen malignancies were seen in 12 of 42 patients (28.6%). These malignancies were seen in 2 patients with IgG4-RD and 3 patients with IgG4-RD, and 3 patients with other pancreatic diseases (chronic pancreatitis [CP], intraductal papillary mucinous neoplasm [IPMN], pancreatic cancer [PC]). The serum AIM level was significantly higher in the IgG4-RD patients with malignancy than in those without malignancy. No significant differences were seen in the mean age or gender between patients with and without malignancy. Ten of 17 patients with IgG4-RD had malignancies. Among the 16 patients with IgG4-RD and malignancy, 15 patients had malignancies in the pancreatic ductal system, and one patient had testicular cancer.

Gastroenterology, University of Verona, Verona/Italy

Contact E-mail Address: francesco.vitali@uk-erlangen.de

Introduction: Endosonography (EUS) is one of the main diagnostic tools for the differential diagnosis of pancreatic masses. The aim of our study was to determine pitfalls of this technique in patients suspected of having pancreatic cancer.
This was done in consideration of the current knowledge about lesions mimicking cancer in the setting of a normal pancreatic parenchyma or existence of signs for pancreatic neoplasm.

Aims & Methods: Retrospective analysis of prospectively collected data in our tertiary University center. From March 2007 to October 2015, 218 (124 men, 94 women; age range, 20–80 years) patients underwent EUS for suspected solid pancreatic neoplasm because of cross sectional imaging results, idiopathic acute pancreatitis, weight loss, pancreatic hyperenzymemia, painless jaundice and elevated Ca 19-9 values. Cystic pancreatic lesions, pseudocysts and cystic pancreatic neoplasms were excluded from the analysis.

Results: Malignant lesions were diagnosed in 98 (45%) patients. 54 patients (24.8%) underwent surgery and 61 patients (28% of all patients) underwent clinical follow-up (16.5 ± 2.7 months, 18 needed surgery). 43 lesions not undergoing surgery needed EUS follow-up before achieving final diagnosis: pancreatic cancer (n = 6, 9.8%), neuroendocrine tumor (NET) (n = 10, 16.4%), paraduodenal neoplasms (n = 5, 8.9%), chronic pancreatitis (n = 13, 21.3%), necrosis (n = 3, 4.9%), autoimmune pancreatitis (AIP) (n = 3, 4.9%), microcystic serous neoplasms (n = 2). SDF-1 was elevated in 21 (35.4%) pancreatic lesions in the non-pancreatitis group (n = 121) and 44% and 87.1% in the pancreatitis group (n = 97). Ca 19-9 elevation, rapid onset jaundice, double duct sign are useful indicators of malignancy both in the setting of normal and inflamed pancreas. Patients without pancreatitis the presence of enlarged lymphnodes or a mass in EUS, weight loss and worsening diabetes are predictor of malignancy. In patients without pancreatitis and without jaundice Ca 19-9 sensitivity for malignancy was 95% and specificity was 39%. In the pancreatitis group, Ca 19-9 sensitivity for malignancy (in patients without jaundice) was 45% and specificity was 86%. IgG4 elevation presented a sensitivity of 83.3% and a specificity of 88.8% for AIP, where one false elevation was seen in a dural cholangiocarcinoma.

Conclusion: Diagnostic accuracy of EUS is lower in the presence of pancreatitis. Focal autoimmune pancreatitis and paraduodenal neoplasms are still confused with pancreatic cancer in the setting of normal or inflamed parenchyma. EUS in the setting of a normal parenchyma is an excellent tool to exclude pancreatic cancer. Tumor markers like Ca 19-9 and IgG4 values should be measured in the evaluation of pancreatic masses, also in the setting of chronic pancreatitis. Clinical and imaging features of the neoplasms were the most useful indicator for malignancy (usually EUS with CT) were necessary for achieving a definitive diagnosis. If there is a high clinical suspicion of pancreatic neoplasm in a patient that does not undergo surgery and if EUS or other available imaging modalities are not repeated EUS after 2–3 months may be useful for detecting an occult pancreatic neoplasm.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Intraductal papillary mucinous neoplasms (IPMN) are common pancreatic cystic neoplasms often detected by chance, and are sometimes precursors of invasive pancreatic cancer. Although the originate in the pancreatic ducts, these neoplasms are distinct from pancreatic ductal adenocarcinoma (PDA), conventional pancreatic cancer. In some IPMN cases, they cannot be detected before invasive and metastatic carcinoma development. Knowledge of genetic backgrounds may lead to the discovery of IPMN with poor prognosis. Although whole-genome sequencing by next-generation sequencing (NGS) has become popular, the use of minute samples obtained by EUS-FNA is scarce. The value of NGS of pancreatic cystic fluids or walls has not been clear relative to imaging impressions. On the other hand, in some kinds of cancer, genetic analysis by NGS was used to select the treatment method. In this study, we analysed whether minute clinical samples from EUS-FNA are useful for genetic analysis and whether that aids in deciding the appropriate treatment.

Aims & Methods: We analysed IPMN or PDA tissues using NGS and assessed the impact of NGS on clinical diagnosis. From January to December 2015, 14 tissue samples of undiagnosed pancreatic tumours (from 8 male patients, 6 female patients; mean age, 79 years; age range, 65–100 years; mean tumour size, 29.6 ± 17.9 mm; tumour size range, 10–66 mm) were collected by EUS-FNA. The locations of the tumours were the head (3), body (4), and tail (5); we obtained their samples through the stomach or duodenum. EUS-FNA was performed using a curvilinear echoendoscope (GF-UCT 260; Olympus Medical Systems, Tokyo, Japan) and 22- or 25-gauge needles (ProCore; Cook Japan, Tokyo, Japan/Expect; Boston Scientific, Tokyo, Japan). Both slow-pull and negative pressure techniques were used to obtain specimens. We performed whole-genome sequencing on EUS-FNA obtained from IPMN or PDA using the Comprehensive Cancer panel, and compared their genetic mutations. Additionally, in the case of IPMN, we compared the differences in results between mural nodules and cystic fluids or walls.

Results: Pathological diagnoses showed 2 adenocarcinomas, 3 intraductal papillary mucinous carcinomas, 7 intraductal papillary mucinous adenomas; the remaining 2 cases could not be diagnosed. We used minute specimens obtained from EUS-FNA, and analysed genetic mutations of 10 cases using NGS. Homogenous genetic mutations were approximately 18% and heterogeneous genetic mutations were approximately 25%. Five of the cases had mural nodules inside the cysts. We could analyse genetic mutations of cystic fluids or walls by the same way as of mural nodules. For the gradually growing IPMN without...
mural nodules, it is useful to analyse genetic mutations of cystic fluids or walls. Currently, inadequate samples from EUS-FNA were unsuccessfully used in and some cases, we could not make a pathological diagnosis. Even in such cases, genetic analysis and the subsequent diagnoses of malignant or benign tumours may be possible. We could identify several cancer-related genes, such as GNAS, Kras, Trp53, and BRAF.

Conclusion: In this study, we performed whole-genome sequencing of samples obtained from IPMN or PDA using EUS-FNA. Consequently, genetic analysis by NGS may be effective in addition to pathological diagnosis when deciding the management of pancreatic tumours.

Introduction: The ubiquitously expressed non-receptor protein tyrosine phosphatase SHP2, encoded by *PTPN11,* is involved in the regulation of multiple signal-transduction cascades. SHP2 was the first reported oncogenic tyrosine phosphatase, although more recently demonstrated tumor suppressive properties as well. SHP2 has been proven to be required for proper wild-type RAS activation, yet studies addressing the relevance of SHP2 for mutated KRAS dependent cancers, such as pancreatic and lung cancer are lacking.

Aims & Methods: In this study, we performed whole-genome sequencing of samples obtained from IPMN or PDA using EUS-FNA. Consequently, genetic analysis by NGS may be effective in addition to pathological diagnosis when deciding the management of pancreatic tumours.

Introduction: Intraductal papillary mucinous neoplasms (IPMNs) are precursors of pancreatic ductal adenocarcinoma (PDAC) and are also associated with multicentric lesions (field effect), where concurrence of neo PDA, independent of index IPMN lesion, can also develop. However, there are cases where PDAs arise adjacent to the index IPMNs, and occasionally they are pathologically indistinguishable whereas the carcinoma developed from IPMN or was coincidental to the IPMN. A genetic approach can be useful to clarify the origin of each tumor compartment to determine if they shared molecular signatures.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Aims & Methods: Twenty concomitant PDAs and IPMNs (39 samples, including concurrent lesions) from surgically resected patients were enrolled in this study. Resected pancreata were sliced at 5-mm intervals for whole-section histological analysis, and the distance between PDA and IPMNs was measured after precise pathological mapping. Target amplicon sequencing that covers 18 PDA-assos- ciated mutations including KRAS, GNAS, TP53, SMAD4, CDKN2A and RNF43, was performed using Ion PGM™ system (Thermo Fisher Scientific). Protein expression of TP53, SMAD4, p16, cathepsin, and RNF43 was also analyzed immunohistochemically.

Results: KRAS mutations were detected in 19/20 (95%) of PDAs and in 38/39 (97%) of IPMNs. “Adjacent” concomitant PDAs, defined as those that are 5 mm or less away from the IPMN (n = 11), tended to harbor identical KRAS mutations as the index IPMNs (KRAS identical; n = 8, 72%, KRAS different; n = 3, 27%). All three cases with contiguous neoplastic lesions via the main pancreatic duct between PDAs and IPMNs had identical KRAS mutations. In contrast, 7 of 9 “distant” concomitant PDAs, defined as those greater than 5 mm away from the IPMN (n = 9), possessed distinct KRAS mutations from the index IPMNs (75%) and the KRAS mutations were demonstrated in 14/20 (70%) of index IPMNs and in 29/39 (74%) of all PDAs, but not in PDAs, supporting de novo carcinogenesis rather than progression from the IPMNs. PDAs harboring identical mutations in KRAS as IPMNs were significantly closer to the IPMNs (KRAS identical; n = 16, 0.35 mm, versus 3.5 mm and 7.2 mm relative to cases with distinct KRAS mutations in the PDAs and IPMNs (n = 23, 0.75 mm, average 20 mm, p = 0.0397). The KRAS identical group had a better prognosis than the KRAS different group (disease-free survival p = 0.0245, overall survival p = 0.205). Curiously, the molecular signature of 18 PDA-associated genes was not significantly different between two groups.

Conclusion: Multiple clones with distinct KRAS mutations were identified in pancreata during initiation and progression of IPMNs, and a subset of PDAs arising within the field defect share the same KRAS mutation with index IPMN lesions. Interestingly, PDAs adjacent to IPMN tend to have identical KRAS mutations, suggesting PDAs and index IPMNs may arise from a common foun- dation. The KRAS identical group appears to have better prognostic relative to the KRAS different group, implying distinct molecular patterns may govern our biological evolution.

Introduction: The pancreatic cancer is a leading cause of death in cancer carriers worldwide.

Aims & Methods: To study the polymorphism of the TP53 gene on the suppressor and to evaluate proinflammatory cytokines in IL-1β, TNF-α, insulin blood serum levels at patients with various pathologies of the pancreas (cancer (PCa), acute and chronic pancreatitis (OP and CP)) with various geno- types of TP53. 150 patients were followed in a one-stage clinical trial (42 patients with PCa, 107 patients with OP, 8 patients with CP). The blood samples were collected by two independent teams: one - with patients with PCa and the other - with patients with OP and CP. The blood samples were collected at different time periods: the 1st set was included 47 PCa patients in stage I and II, and 21 patients with OP and CP. The 2nd set was included 16 PCa patients and 16 OP and CP patients. Patients were aged 30–75 years, average 61 years. The data were compared with age-matched healthy volunteers (HV). All patients were declared no conficts of interest.

Results: The concentration of insulin in different genotypes in patients with PCa with different genotypes of the TP53 gene did not differ significantly and amounted to 1.1 ± 0.2 pg/ml in patients with the Arg/Arg genotype, with Arg/Pro genotypes of 1.2 ± 0.3 pg/ml, p > 0.05. The level of TNF-α in the serum of patients with PCa with the Arg/Arg genotype was 1.2 ± 0.2 pg/ml, and did not significantly differ from the level in the serum of patients with the Arg/Pro genotype - 1.3 ± 0.1 pg/ml.

Conclusion: The Pro/Pro genotype of the TP53 gene was significantly more common in patients with PCa compared with the patients with CP. We detected significant differences in serum insulin levels in the comparison group and in patients with heterozygous genotypes, p < 0.05. The level of TNF-α in patients with CP was significantly lower than in patients with OP, and the level of IL-1β was significantly lower in patients with PCa than in patients with CP.

Contact E-mail Address: kobatakai@med.kobe-u.ac.jp

Introduction: Pancreatic cancer (PC) is one of the most lethal diseases due to the difficulty of early detection. There is no effective blood biomarker for screening. Recently metabolomics is considered to be a promising approach to discover disease biomarkers. We previously reported that the serum/plasma levels of metabolites in patients with PC were significantly changed compared with those of healthy individuals.

Aims & Methods: The aim of this study is to confirm and develop our candidate metabolomic biomarkers in blood of PC patients. Blood samples from PC patients (PC) and healthy volunteers (HV) were collected by two independent groups consisting of multiple institutions. The 1st set was included 55 PC in stage I and II and 58 HV. The 2nd set was included 16 PC and 16 HV. Sixteen candidate metabolites were selected from previous report. Quantitative analy- ses were performed by gas chromatography/tandem mass spectrometry (GC/MS/MS) together with their corresponding stable isotopes. In the 1st stage, diagnostic models were constructed via multivariate logistic regression analysis. These results were validated using the 2nd set.

Results: In the 1st set, the level of 14 metabolites differed significantly between PC and HV. Model Y consisting of 2 metabolites, i.e., histidine and xylitol showed high sensitivity (70.4%) than CA19-9. Furthermore, combination of model Y with CA19-9 increased its sensitivity (90.7%) and specificity (89.5%). In the 2nd set, combination of model Y with CA19-9 demonstrated high sensitivity (81.3%) and specificity (93.8%). In particular, it displayed very high sensitivity (100%) for PC in a resectable state.

Conclusion: Quantitative analysis using GC/MS/MS confirmed the possibility of metabolomics-based screening methods for PC.

Introduction: Diagnostic yield from EUS-FNAC (fine needle aspiration cytology) has improved in the past few years with better tissue acquisition techniques. Core biopsy needles are now available but are more expensive than FNAC needles. We assessed the diagnostic yield and accuracy of FNAC samples processed for both cytology and histology.

Results: A total of 211 patients (118 male) were included. Samples were sent to cytology (n = 135; 107 pancreas, 10 biliary, 7 lymph nodes, 11 other), or cytology & histology (n = 76; 56 pancreas, 12 biliary, 5 lymph nodes, 3 other). Sample adequacy was 80.7% and 98.7% (p = 0.0004). Diagnostic yield (64.4%, 94.7%) and accuracy (81.3%, 96.1%) was significantly better in the combined histology & cytology group (p < 0.0001, p = 0.003). Within the combined group, diagnos- tic yield and accuracy improved by 20.5% (p = 0.007) and 26% (p = 0.0002) respectively when the sample was processes for both histology and cytology.

Conclusion: Our study confirms significant improvement in diagnostic yield and accuracy when samples were sent for both cytology and histology using standard FNAC needles.

6MD Anderson, Madrid/Spain
7Department Of Pathology, Rigshospitalet, Copenhagen/Denmark

Aims & Methods: The aim of this study was to evaluate the use of the novel micro-forceps in a multicenter clinical setting. The patients referred for EUS evaluation of pancreatic cysts were included retrospectively from five European tertiary centers. Inclusion criteria were age of 18 or above and a pancreatic cyst of a size that allowed for FNA puncture. Exclusion criteria were pregnant or lactating females. A standardized data collection sheet includ-
ing the information about patient demographics, cyst size, EUS/FNA findings, technical and clinical success, and the results of the biopsies taken was sent to the collaborating centers. Technical success was defined as successful puncture of the pancreatic cyst, subsequent successful mounting of the micro-biopsy forceps, and extraction of at least one micro-biopsy. Clinical success was defined by obtaining useful histological results.

Results: Twenty patients were included. There was a slight overrepresentation of female patients (n = 12, 60%) and the median age was 65 (range: 41–80). The patients had a median cyst size of 30 mm (range: 15–130 mm) and a median procedural time was 30, 5 min (range: 17–58 min). We report a technical success rate of 85% (n = 17) - technical failure was only seen in transdudal puncture (n = 3, 15%). Biopsies were generally of good quality and contributed to the diagnosis in 14 patients (clinical success of 82%). Among these, there were ten cases of intraductal papillary mucinous neoplasia, two serous cystic adenomas, one mucinous cystic adenocarcinoma, and one pseudocyst. Two mild adverse events were recorded (10%), a case of re-admission due to non-specific abdominal pain and a mild acute pancreatitis.

Conclusion: The use of micro-biopsy forceps was until now only reported in case reports. It is a first larger-scale feasibility study. We conclude that the use of the micro-forceps seems feasible and safe with acceptable rates of technical and clinical success. However, prospective studies are needed in order to determine diagnostic potential of this instrument compared to the other modalities currently used.

P0131 PANCREATIC DUCTAL CYTOLOGY: AN UNDERUSED
DIAGNOSTIC TOOL
Centro Hospitalar De São João, Porto/Portugal

Contact E-mail Address: armandoafp5@gmail.com

Introduction: The diagnosis of pancreatic malignancy can be performed by brush cytology of the common bile duct or main pancreatic duct (MPD) during endo-
copic retrograde cholangiopancreatography (ERCP). We suggest that the use of
cystic brushing of the MPD is safe and has a sensitivity equal to or
slightly higher to that of bile duct cytology, although its clinical application is not
defined.

Aims & Methods: In this work we report our experience in the execution of MPD brush cytology. ERCPs between 2014 and 2015 that involved brush cytology of pancreatic strictures were included. Cytologies were obtained using the Brush Master V (Olympus Medical System). Histological evaluation was performed by two experienced cytopathologists.

Results: Of the 18 patients evaluated, 16 were men and 2 women, with a median age of 62 years (range: 43–89). All patients underwent abdominal computed tomography and 3 patients had magnetic resonance imaging. In addition to a pancreatic strictures, abdominal computed tomography revealed cephalic pancreatic lesions. 51% findings suggestive of chronic pancreatitis in 28%, pancreas divisum in 6%, and pancreatic inflammatory features in 6%. The distribution of the strictures was: head - 16, head and body - 1, tail - 1. The pancreatic duct was dilated in 16 patients (a median of 6.5–13). The diagnostic yield of MPD brush cytology for pancreatic cancer was: sensitivity - 81.8%, specificity - 100%, positive predictive value - 100%, negative predictive value - 77.8%, acuity - 88.9%, Sixty-one percent (n = 11) of the patients had a final diagnosis of pan-
creatic adenocarcinoma, 5.6% (n = 1) of neuroendocrine tumor and 33.3% (n = 6) inflammatory stricture. All the adenocarcinomas lead to strictures in the head of the pancreas. The diagnosis of neuroendocrine tumor was made by...
endoscopic ultrasonography fine needle aspiration. One patient developed mild pancreatitis (6.15%).

Conclusion: In patients suspected cephalopancreatic adenocarcinoma referred for ERCP, MDP brush cytology may be performed beyond biliary cytology, as it may improve cytopathologic diagnosis of malignancy without increasing complications rate.

Introduction: Pancreatic metastases (PM) account for 1–2% of pancreatic tumors. Several cancer types metastasize to the pancreas, but even recently developed cross-sectional imaging modalities have difficulties distinguishing PM from primary pancreatic tumors. Moreover, their prognostic significance is poorly defined.

Aims & Methods: The aims of this study were to clarify the incidence of primary tumors leading to PM, the clinical characteristics, and prognoses, and to define the prognostic factors for survival. A retrospective analysis was performed at 39 Japanese tertiary referral hospitals between January 2005 and August 2015, after receiving approval from the institutional review board of each hospital. We identified the patients based on data obtained from each institutional database, and analyzed patient and tumor characteristics, and survival time. All the patients enrolled in the analysis were histopathologically or cytopathologically diagnosed with PM. Kaplan-Meier analysis and Cox's proportional hazard models were applied to evaluate overall survival and survival analysis, respectively.

Results: We enrolled 159 patients (median age 74.5 years) with a pathologic diagnosis of PM. The most common primary tumor was renal cell carcinoma (38.4%, n = 61), followed by lung cancer (24.5%, n = 39), colorectal cancer (11.3%, n = 18), sarcoma (6.3%, n = 10), breast cancer (6.3%, n = 10), and other cancer (n = 21). At the time of the diagnosis of PM, 38 patients (24%) had at least one tumor-related symptom. Additional extra-pancreatic metastases were diagnosed in 94 patients (59%). Sixty-four patients (40%) underwent surgery resection, and no surgical resection was performed in 95 patients (60%). Additional therapies were chemotherapy (n = 69), chemoradiation (n = 4), radiation (n = 3), palliative care, and unclear (n = 2). Eight patients were lost during follow-up and 151 patients were included in the statistical analysis. All patients with PM had a median overall survival of 43.0 months, with 3- and 5-year survival rates of 52.5% and 42.6%, respectively. Among the five frequent primary sites of PM, prognoses of RCC, breast cancer, and colorectal were better than those of lung cancer and sarcoma. Univariate Cox proportional regression analysis identified four prognostic factors: pancreatic resection (hazard ratio [HR] 0.31, 95% confidence interval [CI] 0.18–0.57, p < 0.001), extra-pancreatic metastases (HR 3.07, 95%CI 1.71–5.51, p < 0.001), tumor-related symptoms at PM diagnosis (HR 3.83, 95%CI 1.77–8.41, p < 0.001), and pathologic diagnosis of primary tumors (p < 0.001). Multivariate Cox proportional regression analysis identified three independent prognostic factors: extra-pancreatic metastases (HR 2.13, 95%CI 1.11–4.07, p = 0.02), tumor-related symptoms at diagnosis (HR 5.39, 95%CI 2.92–9.91, p < 0.001), and pathologic diagnosis of primary tumors (p < 0.001).

Conclusion: Treatment strategies and prognoses for PM completely differ according to the primary tumor type. A definitive pathologic diagnosis of PM is essential for selecting the appropriate treatment.

Introduction: National Comprehensive Cancer Network (NCCN) guidelines recommend chest x-ray or chest computed tomography (CT) for the staging of potential resectable pancreatic adenocarcinoma (PDA). However, there is limited data supporting these guidelines, and the prevalence of lung metastasis is not well defined on staging CT scans. We report our findings of patients with lung metastasis during initial staging and follow-up of patients with PDA.

Aims & Methods: Data was prospectively collected from May 2013 to September 2016 for PDA patients who were presented at a multidisciplinary pancreas center (MDPC) at a large tertiary care center. All patients were staged with CT pancreatic protocol, CT chest and Endoscopic Ultrasound. Patients with findings of lung lesions on initial staging chest CT were followed prospectively. Metastatic lung lesions were determined based on definite imaging characteristics with clinical consensus or lung biopsy results.

Results: A total 278 PDA patients referred to MDPC were staged with CT chest (Table 1). Out of these, 36 (12.6%) patients were found to have either malignant (N = 6) or indeterminate (N = 30) lung lesions on initial staging CT chest. Out of the six malignant lung lesions, 5 (83.3%) patients had metastatic PDA lesions, and 1 (16.7%) patient had incidental primary lung cancer. On a follow-up of 30 patients with indeterminate lung lesions, 8 patients (26.7%) were later determined to be lung metastasis. The overall prevalence of definite lung metastasis was at least 4.8% (13/278). The prevalence of lung metastasis in pancreatic head cancer was 3.0%, while body and tail masses was 10.5%. Lung metastasis was almost four times more likely in the body, and tail masses (OR = 3.83, CI 1.2–11.8, p = 0.02) compared to head. Overall CT chest resulted in change in management plan in 9 (2.9%) patients due to change in the stage to metastatic (8) and diagnosis primary lung cancer (1). Staging with CT chest changed otherwise resectable disease to unresectable/metastatic in 5 patients (1.8%) and borderline resectable to metastatic disease in 2 (0.7%) patients. Prevalence of isolated PDA lung metastasis without any other metastasis was 2.8% (8/278).

Conclusion: Our study showed that the prevalence of pulmonary metastasis in PDA was clinically relevant to mandate routine staging with CT chest. Prevalence was significantly higher for pancreatic body and tail cancers compared to the head. Staging CT chest resulted in a change in the stage of PDA and management decisions.

P0134 VALUE OF EUS IN EARLY DETECTION OF TUMOR LESION IN THE REMNANT PANCREAS

H. Maruyama1, A. Shimizu2, T. Minami2, N. Hirano2, K. Hanada2
1Dept. Of Gastroenterology, Onomichi General Hospital, Onomichi/Japan
2Gastroenterology, Hiroshima onomichi city, onomichi/Japan

Contact E-mail Address: hiromaruyama99@gmail.com
Introduction: New lesions (metachronous pancreatic cancer) and recurrence may develop in pancreas after initial cancer and Intraductal Papillary Mucinous Neoplasm (IPMN). Endoscopic ultrasonogra-
phy (EUS) is proved as a more specific and sensitive method for pancreatic lesion. However, there is no report about EUS after pancreatectomy. If it is possible to observe the anastomotic part to remnant pancreas under the EUS, remnant pancreatic cancer may be pointed out an early stage.

Aims & Methods: The aim of this study was retrospectively to investigate the observation ability of EUS for remnant pancreas. In this retrospective study, 44 patients who underwent EUS for remnant pancreas were enrollment. The definition of observation under the EUS for remnant pancreas was as follows, total observation for remnant pancreas observed from linear white line (anastomotic part) to opposite side pancreas, otherwise it was insufficient observation. We compared the detection rate of EUS findings and that of CT or MRI findings.

Results: Among the 395 patients who underwent pancreatectomy at the JA Onomichi General Hospital between December 2002 and March 2016, the enrolled patients were 44 who underwent EUS for remnant pancreas. In the surgical procedure, pancreaticoduodenectomy (PD) including pylorus-preserving PD (PPPD) and subtotal stomach-preserving PD (SSPPD) was 20 cases and distal pancreatectomy (DP) was 24 cases. Total observation of remnant pancreas was possible in 41 cases (93%). Seven of 44 cases showed the lesion of recurrence in the remnant pancreas. Although CT or MRI was able to point out it in only 2 cases, EUS was able to point out it in the remnant pancreas of all cases. Stage of six cases were as follows, 1 case of stage 0, 2 cases of stage Ia, 3 cases of stage IIIb. The other cases were IPMN, we were able to perform EUS-FNA for lesion in the remnant pancreas in all cases. Pathological results were positive in 5 cases. One of the other 2 cases was negative (class II), but it was a recurrence by surgery. The other case was strongly suspected to recurrence by Positron emission tomogra-
phy (PET). Second pancreatectomy was performed in 4 out of 7 cases. The sensitivity of EUS-FNA was 71.4% (5/7), the specificity was 85.7% (6/7) and the accuracy was 71.4% (5/7). In addition, a comparison of detection ability of EUS and CT or MRI findings showed that EUS was significantly superior to CT or MRI (P < 0.001).

Conclusion: EUS was able to observe remnant pancreas in almost cases. We were able to perform EUS-FNA for lesion in the remnant pancreas. In addition, the detection ability of EUS was significantly superior to that of CT or MRI. We believe that EUS and EUS-FNA should be performed for lesion in remnant pancreas, and that remnant pancreatic cancer may be pointed out an early stage.

Disclosure of Interest: All authors have declared no conflicts of interest.
pared with 33.1 months (95% CI, 9.0–27.2) in the 2nd PDAC group (N: 259 vs. 215, respectively). 54% of patients in the 3rd PDAC group were excluded from this study: 51 lesions due to anticoagulation therapy; 25 lesions in patients receiving antitumor therapy excluding single-LDA and DAPT; and 20 lesions due to inoperable indications at the same time. Thus, a total of 495 patients were enrolled in this study. The patients were categorized according to antitumor therapy (APT). APT was defined as follows: oral administration of single-LDA (aspirin [100 mg/day]) or DAPT (aspirin [100 mg/day] plus clopidogrel [75 mg/day]). Logistic regression analysis was performed for risk factors of bleeding after gastric ESD. Results: The patients were categorized into two groups: no APT (n = 370) and APT (n = 125). APT included single-LDA (n = 74) and DAPT (DAPT plus clopidogrel; n = 51). Among them, 46 received continuous LDA on single-LDA and 40 received continuous LDA on DAPT. The postoperative bleeding rate in the APT group was significantly higher than that in the no APT group (16.0% vs. 5.9%; P < 0.001). Postoperative bleeding occurred in seven and nine patients in the continuous single-LDA group (15.2%) and the continuous LDA on DAPT group (22.5%), respectively. In multivariate analysis, specimen size of ≥ 40 mm (odds ratio [OR] 3.19; 95% confidence interval [CI], 1.65–6.16; P < 0.001) was a sole independent risk factor for postoperative bleeding (Table 1). In subgroup univariate analysis among APT users, continuous single-LDA and continuous LDA on DAPT were not related to postoperative bleeding. Table 1 Multivariate analysis for postoperative bleeding after ESD.

</tbody>
</table>

Conclusion: This study suggests that continuous LDA may be acceptable for gastric ESD in patients on DAPT. However, patients with continuous LDA on DAPT should be monitored carefully for postoperative bleeding after gastric ESD because the rate of postoperative bleeding in the continuous LDA on DAPT group was higher than that in the other groups. Disclosure of Interest: All authors have declared no conflicts of interest.

INTRODUCTION: Peroral endoscopic myotomy (POEM) has received wide acceptance as a first-line treatment for esophageal achalasia. In addition, small-scale studies are ample but long-term large-scale studies are few.

Aims & Methods: The aim of this study was to systematically analyze our long-term results of POEM, with particular emphasis on POEM failures and associated factors. This is a single-center study. Consecutive POEM patients between Aug, 2010 and Dec, 2012 were included. Kaplan-Meier survival function was used to estimate clinical success rate at each year. The Cox proportional hazards model was used to analyze risk factors related to recurrence.

RESULTS: A total of 564 patients were included. Mucosa injuries happened in 93 patients (16.5%) and 36 patients (6.4%) experienced major perioperative adverse events. The Eckardt score and lower esophageal sphincter (LES) pressure were significantly decreased after POEM (median Eckardt score 8 to 2, p < 0.05; median LES pressure 29.7 mm Hg to 11.9 mm Hg, p < 0.05). In a median follow-up period of 49 months (range 3-67 months), fifteen failures occurred within 3 months, 23 between 3 months and 3 years, and 10 after 3 years. The estimated clinical success rates at 1, 2, 3, 4, and 5 years were 94.2%, 92.2%, 91.1%, 86.0% and 87.1%, respectively. Multivariate Cox regression revealed long disease duration (> 10 years) and history of prior interventions to be risk factors for recurrence. Clinical reflux occurred in 37.3% (155/416) patients.

Conclusion: POEM is a highly safe and effective treatment for esophageal achalasia with favorable long-term outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO140 PATIENTS WITH CHRONIC GASTROINTESTINAL ISCHEMIA HAVE AN ALTERED SUBLINGUAL MICROCIRCULATION

Introduction: Chronic gastrointestinal ischemia (CGI) results of insufficient blood supply to the gastrointestinal tract. The majority of CGI patients have systemic disorders of the circulatory system including hypertension, diabetes and other cardiovascular risk factors. Studies in patients with chronic gastrointestinal ischemia found a correlation between intestinal ischemia and sublingual microcirculatory alterations. However, little is known about microcirculatory alterations in patients with CGI. We hypothesized that patients with CGI may reveal sublingual microcirculation alterations. We further hypothesized that such alterations will be amplified when challenging the patient to enteral caloric challenges. This would provide a patient-friendly means to identify CGI.

Aims & Methods: Consecutive patients with CGI and healthy controls were prospectively included between September 2014 and August 2015. All patients and controls were included. Mucosa injuries happened in 93 patients (16.5%) and 36 patients (6.4%) experienced major perioperative adverse events. The Eckardt score and lower esophageal sphincter (LES) pressure were significantly decreased after POEM (median Eckardt score 8 to 2, p < 0.05; median LES pressure 29.7 mm Hg to 11.9 mm Hg, p < 0.05). In a median follow-up period of 49 months (range 3-67 months), fifteen failures occurred within 3 months, 23 between 3 months and 3 years, and 10 after 3 years. The estimated clinical success rates at 1, 2, 3, 4, and 5 years were 94.2%, 92.2%, 91.1%, 86.0% and 87.1%, respectively. Multivariate Cox regression revealed long disease duration (> 10 years) and history of prior interventions to be risk factors for recurrence. Clinical reflux occurred in 37.3% (155/416) patients.

Conclusion: POEM is a highly safe and effective treatment for esophageal achalasia with favorable long-term outcomes.

Introduction: The operative link of gastritis assessment (OLGA) staging system is essential to assess the risk of Helicobacter pylori related gastric cancer on the basis of several biopsy samples taken from the antrum and corpus.

Aims & Methods: In this study we attempted to evaluate whether gastritis staging using conventional narrow band imaging (NBI) endoscopy is equivalent to that determined by histopathology. Fifty (50) consecutive patients with Helicobacter Pylori (H. Pylori) related gastric atrophy selected according to NBI endoscopic findings 1. The diagnosis of H. Pylori based on direct detection of the organism by histopathology assessment. The NBI grade of lower gastric atrophy scored from 0 to 3. The histopathological assessment of lower gastric atrophy was based on OLGA scoring system. Furthermore, we assessed the presence or absence of intestinal metaplasia. The NBI and histology stages of gastric atrophy were assessed using a combination of scores for the antrum and corpus. These stages further classified into low risk (stage 0, I and II) and high risk (stage III and IV). Finally the degree of correspondence between NBI and histopathology, in prediction of gastric cancer risk, was assessed.

Results: The mean age of included patients was 38.7 ±15.6 years, they were 21 (42%) males and 29 (58%) females. 38 (76%) and 13 (26%) patients have pseu-
doplyoric and intestinal metaplasia respectively. Overall 41 (82%) and 9 (18%) patients have low and high gastric cancer risk respectively. The sensitivity of NBI in diagnosis of Helicobacter pylori infection, gastric atrophy and intestinal metaplasia were 96% (n = 48/50), 100% and 61.5% (n = 8/13) respectively. The degree of correspondence between the scores obtained by NBI and by histology was 58% (29/50) for the lower gastric body atrophy and 86% (n = 43/50) for the antral intestinal metaplasia. The degree of correspondence between the high risk and low risk groups determined on the basis of NBI endoscopy on one hand and histopathology on the other hand was 80% (n = 40/50).

Conclusion: NBI is able to approximate histopathological staging of gastritis to a good extent. More studies and training will further improve the performance of our suggested new staging method.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) is a standard treatment for early gastric cancer. Development of the ESD device has been conducted recently with M-Knife® and the new multi-functional M device was invented to achieve complete ESD with a simple device. It achieves clear marking, better hemostasis and smoother operation during a procedure without replacing the knife.

Aims & Methods: The aim of this study was to investigate clinical outcome of ESD for early gastric cancer with a new device (Splash-M-knife®). In total, early gastric cancer treated by ESD with a needle-type knife between January 2012 and August 2016 at Kitakyushu Municipal Medical Center were retrospectively reviewed. Lesions treated by ESD with a conventional needle-knife (ESD-C, n = 76) and by ESD with a new device (ESD-N, n = 73) were compared. Multivariate analyses and propensity score matching were used to compensate for the differences in age (≥75 years vs < 75 years), sex (male vs female), underlying diabetes (none vs with cardiovascular disease or cirrhosis), anti-thrombotic drugs (not receiving or discontinuation vs continuation), tumor size (≥21 mm vs <21 mm), lesion location (in the upper or middle third of the stomach vs in the lower stomach), lesion position (in the lesser curvature of the stomach vs others), macroscopic type (flat or depressed vs elevated), presence of ulceration (presence vs absence) and operator level (experience of ≥50 vs experience <50). As primary endpoint, the rates of the lesions that need hemostatic forceps was compared.
among two groups. As sub-analyses, the cutting time, rate of en-block/complete resection and rates of adverse events were evaluated among two groups.

Results: Propensity score matching analysis created 46 matched pairs. Adjusted comparisons between two groups showed a significantly smaller usage rate of hemostatic forceps in ESD-N than that in ESD-C (4.35% vs 84.8%, p < 0.001), and similar treatment rates (en-block resection rate: 100% between both groups; complete resection rate: 97.8% vs 100%, p = 1; cutting time: 84.6 min vs 83.0 min, p = 0.89; perforation during ESD: 0% in both groups).

Conclusion: Splash M-Knife® achieved better hemostasis and safer ESD for early gastric cancer to reduce cost for ESD by reducing usage of hemostatic forceps during ESD procedure.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0143 INTUBATION FAILURE DURING GASTROSCOPY – INCIDENCE, PREDICTORS AND FOLLOW-UP FINDINGS

Introduction: Intubation failure (IF) when a trained endoscopist is unable to progress into the upper oesophagus via the oropharynx. The incidence is unknown, but estimated at 1.8%. There have been no studies exploring IF and follow-up findings. We aimed to assess the incidence, causes of IF, predictors of pathology in patients with IF, and follow-up findings.

Aims & Methods: We retrospectively identified all gastroscopists performed at a district general hospital between August 2010–August 2016 from an endoscopy database, and reviewed cases with IF. We excluded patients who had achieved oesophageal intubation. Data on sedation use, endoscopist status, indications, radiological and endoscopic findings were recorded. Procedural limitations were classified into 2 groups to ‘tolerance’ (e.g. pulling out scope, anxiety) and ‘failure to progress’. Statistical analyses were made using Pearson’s chi² and Wilcoxon signed rank test.

Results: The incidence of IF was 0.95% (284/29630). 238 patients were identified, with a mean age of 63.2 (SD 16.1), with ‘failure to progress’ in 41 and ‘failure to tolerate’ in 197. Subsequent investigations included barium radiology (59.7%, n = 142), CT (21%, n = 50), repeat gastroscopy (29.4%, n = 70) and no further investigations (19.7%, n = 47). Structural pharyngeal abnormalities were diagnosed comprising of cricopharyngeal hypertrophy (CPH) [49%], Zenker’s diverticulum (ZD) [14.6%], pharyngeal web [12.2%], CPH with ZD [9.8%], cervical spondylosis [7.3%] and other (7.3%). Endoscopist status was a predictor of IF (OR for medical vs. non-medical endoscopist 0.7, 95% CI: 0.5–0.9, p = 0.007). Within the IF cohort, predictors of structural causes on barium radiology included: dysphagia (OR 5.5, 95% CI: 2.5–11.8, p < 0.001), failure to progress (OR 5.2, 95% CI: 2.3–12.0, p < 0.001) and age ≥ 65 (OR 4.0, 95% CI: 1.8–8.9, p < 0.001). Repeat gastroscopy was successful in 65/70 (2 using nasendoscope) after increasing midazolam dosage (mean increase = 1.5 mg, 95% CI: 1.0–2.0 mg, p < 0.001). Diagnostic yield for barium radiology, CT and repeat gastroscopy were 69.0%, 54.0% and 64.3% respectively. The concordance of endoscopy indication and pathology on further investigation for IF was 110/192 (57.5%). In patients undergoing barium radiology and repeat gastroscopy, the false negative rate for endoscopy was 17/30 (56.7%), consisting of pharyngeal web (12.2%), Zenker’s diverticulum (ZD) [14.6%], pharyngeal mucus and 8.6 for enlarged fold in subjects with infected status.

Conclusion: We present novel data regarding IF, and report an incidence of 0.95% and similar treatment outcomes (en-block resection rate: 100% in both groups; cutting time: 84.6 min vs 83.0 min, p = 0.89; perforation during ESD: 0% in both groups).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Balloon tamponade, sometimes with Sengstaken-Blakemore tubes (SBT), remains the main immediate salvage therapy for acute variceal bleeding uncontrolled by variceal ligation or injection therapy. Previous cohort studies from the 1970–1980s report success rates of 40–94% for initial haemostasis but high re-bleeding rates of 40–70% on removal [1–3]. Despite guidelines recommending balloon tamponade as initial therapy in treating endoscopically uncontrollable variceal bleeding, specialists and trainees feel uncomfortable with SBT insertion [4] given the perceived difficulties and complications [5].

Aims & Methods: We aimed to describe the current practices surrounding inser- tion of SBT for acute variceal bleeding, the outcomes and to identify areas requiring improvement. A retrospective audit of all patients from 2008–2016 who required SBT insertion for control of acute variceal bleeding was undertaken at Monash Health, a large tertiary Australian centre. These patients were identi- fied from coding classifications. Details regarding their admission were obtained via electronic records.

Results: Approximately 14% of all patients with variceal bleeding required inser- tion of SBT. Of these 42 patients the majority were males (31), median age of 55 years (range 34–78). Alcohol was the most common aetiology for cirrhosis (62%), with 65% actively drinking. Most patients had cirrhosis severity scores of Child-Pugh B (67%) or Child-Pugh C (29%) and a median MELD score of 15 (range 6–39). At the time of initial variceal bleed, 87% were haemodynamically unstable and 29% were encephalopathic. All received standard medical therapy with octreotide or terlipressin, antibiotics and blood products as required. The time to initial endoscopy from 1st onset bleeding was prompt (median 6.62 hours). Most bleeding varices were oesophageal (90%). Initial liga- tion/injection was performed in 64% with the remaining patients having such large volumes of blood in the UGI tract that satisfactory views were unable to be obtained. The current practice surrounding SBT insertion is shown in the table.
below. Re-look endoscopy post-SBT insertion was performed in 86% patients at a median of 39 hours after insertion with further endoscopic therapy in 47%. Complications of SBT insertion occurred in 31% and included minor oesophageal ulceration (9%), significant oesophageal ulceration (3), aspiration pneumonia (4) and oesophageal perforation (1).

Current practice surrounding Sengstaken-Blakemore Tube insertion

<table>
<thead>
<tr>
<th>Variable</th>
<th>Results (n = 42)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Indication for SBT insertion</td>
<td>Incomplete haemostasis 74%, poor view 50%</td>
</tr>
<tr>
<td>Confirmation of position</td>
<td>Direct endoscopic visualisation 13, imaging 25, none 6</td>
</tr>
<tr>
<td>Volume of balloon inflation</td>
<td>Gastric balloon - 306 ml mean (60-450 ml) Oesophageal balloon - 25-300 ml (n = 15)</td>
</tr>
<tr>
<td>Duration of balloon inflation (median hours)</td>
<td>Gastric balloon - 35.1 (1-140.3) Oesophageal balloon - 16 (1-62.8)</td>
</tr>
<tr>
<td>Time to re-look endoscopy after SBT (median hours)</td>
<td>39.3 (11.5-348.2)</td>
</tr>
</tbody>
</table>

Re-bleeding occurred in 45% patients during the admission despite SBT insertion, of which 79% did not survive. Seven other patients subsequently underwent a palliative procedure for these still died. The median time of discharge and mortality was 50% and 41% respectively. The median duration of hospitalisation, intensive care and mechanical ventilation was 13 days (1-56), 6.2 days (0.3-36.2) and 120 hours (1-708) respectively.

Conclusion: Primary haemostasis was achieved in 93% of patients; however, re-bleeding occurred in 45% and was associated with a poor survival rate of 20%. Short and long-term survival overall has not significantly improved since studies in the 1970s-1980s despite advances in pharmacological therapy. Current practices of SBT insertion are variable and would benefit from further education. Rates of direct visualisation of balloon position prior to inflation with endoscopy should be improved as with referrals for early TIPS.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0146 CONSCIOUS SEDATION FOR ESOPHAGEAL SUBMUCOSAL RESECTION BY USING DEXMEDETOMIDINE

Department of Gastroenterology, Yamashita Hospital, Ichinomiya/Japan

Contact E-mail Address: m.eski@koto.kpu-m.ac.jp

Introduction: To evaluate the feasibility and safety of the dexmedetomidine (DEX) for conscious sedation during endoscopic submucosal dissection (ESD).

Aims & Methods: This study was a prospective trial, and was conducted at the Yamashita Hospital. Between January 2016 and December 2016, all 50 patients were enrolled in this study. The inclusion criteria for the study was the presence of esophageal, gastric or duodenal tumors. The criteria for exclusion from this study is as follows: patients who were allergic to the drugs used, a baseline heart rate less than 50 beats/minutes or systolic blood pressure was less than 90/60 mmHg. All patients were intravenously infused with atropine sulfate hydrate (0.125 mg-0.25 mg). During procedure, the percentage of the time that the depth of sedation from RASS –1 to –3 during procedure were evaluated. Body movement leading to the deviation of ESD were recorded appropriately. After the procedure, all patients were intravenously infused with fumazenil (0.3 mg) and observed until the Aldrete score reached 9 points.

Results: During this study period, 50 patients with esophageal, gastric and duodenal tumors were identified as eligible for participation. Among these patients, 37 males and 13 females, and the mean age was 67.5 ± 8.6 y. 27 patients regularly consumed alcohol and 5 patients use sleeping drugs regularly. Tumors were located in the following locations: 9 cases in the esophagus, 38 cases in the stomach. The mean tumor size was 23.8 ± 16.5 mm and the procedure time was 88.0 ± 59.5 minutes. The histologic results of ESD were squamous cell carcinoma (n = 9), adenoma (n = 17) and adenocarcinoma (n = 24). ESD by using DEX were successfully performed in all 50 tumors. No adverse events that were the results of procedures occurred. The mean achievement rate of conscious sedation during procedure was 84.7 ± 16.5%. The median frequency of disturbance by patient’s movement was 0 times (range 0-3 times). 33 cases reduced and 14 cases discontinued a continuous infusion of DEX. In 23 cases of 50 patients, the administration rate of conscious sedation was 0.1 mg/kg/hour.

Conclusion: Conscious sedation with DEX is effective, safe and a high level of satisfaction for endoscopists and patients for upper gastrointestinal ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0147 DIAGNOSTIC ACCURACY OF BLUE LASER IMAGING WITH MAGNIFYING ESOPHENDY SCOPY FOR INVASION DEPTH OF SUPERFICIAL ESOPHAGEAL SQUAMOUS CELL CARCINOMA

1Gastroenterology And Hepatology, Kyoto Prefectural University of Medicine, Kyoto/Japan

Contact E-mail Address: tm-ueda@koto.kpu-m.ac.jp

Introduction: Preoperative diagnosis of invasion depth of superficial esophageal squamous cell carcinoma (SESCC) is very important to select appropriate therapeutic procedure. The Japan Esophageal Society (JES) classification using narrow-band imaging with magnification (M-NBI) was used for evaluating gastro-intestinal neoplasms such as predicting invasion depth or tumor detection.

Aims & Methods: We aim to investigate the diagnostic value of M-NBI by comparing it with M-ULD. Our study was a single-center retrospective study and approved by the Ethical Review Committee of Kyoto Prefectural University of Medicine, and performed in accordance with the World Medical Association’s Declaration of Helsinki. All patients provided informed consent for undergoing both M-ULD and M-NBI. Consecutive 166 patients underwent endoscopic submucosal dissection (ESD) for esophageal tumor at Kyoto Prefectural University of Medicine between April 2014 and March 2016. Endoscopic images of SESCCs were recorded by both M-ULD and M-NBI prior to ESD. SESCCs were pathologically diagnosed by ESD specimens. Three endoscopists with no information of the lesions evaluated invasion depth of SESCCs using M-ULD and M-NBI images according to JES classification. The diagnostic value of each procedure was then evaluated.

Results: 124 SESCCs were analyzed in this study. The numbers of male/female were 104/20, respectively. Median age was 68.5 years old. Median size of tumor was 17.6 mm. The proportion of tumor location at U1/Me/L1 was 13/70/17%, respectively. The proportion of macroscopic type for 0-Ia/Ba/B1/B2 was 16.5%. The median size of tumor was 9.1±6.8 mm. The median frequency of disturbance by patient’s movement was 0 times (range 0-3 times). 33 cases reduced and 14 cases discontinued a continuous infusion of DEX. In 23 cases of 50 patients, the administration rate of conscious sedation was 0.1 mg/kg/hour.

Conclusion: Conscious sedation with DEX is effective, safe and a high level of satisfaction for endoscopists and patients for upper gastrointestinal ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0148 IMPACT OF NEEDLE-BASED CONFOCAL LASER ENDOMICROSCOPY (NCLE) IN IMPROVING DIAGNOSIS OF PANCREATIC CYSTIC NEOPLASMS: SINGLE CENTER EXPERIENCE
F. Shiranii,1 E. Verter,1 M. Lucas,1 C. Molina,1 J. Adams,2 V. Joshi1
1Ochsner Medical Center, New Orleans; 2United States of America

Contact E-mail Address: vjoshi@ochsner.org

Introduction: Endoscopic Ultrasound (EUS) has been found to be an effective tool in diagnosing pancreatic cystic neoplasms (PCN). Carcinomaenoxyantigen (CEA) tumor marker has also been used to differentiate PCN and is the most accurate marker of mucinous cystic neoplasms. Recently, needle-based confocal laser endomicroscopy (nCLE) has been increasingly used for the diagnosis of PCN. nCLE allows for evaluation of pancreatic cysts with results similar to that of a pathological diagnosis. In this study, we will compare our standard of care, EUS and the combination of CEA and nCLE to determine which combination of modalities is a better predictor of PCN.

Aims & Methods: In this retrospective chart review, 22 patients with pancreatic cysts were evaluated. Specificity and Negative Predictive Value (NPV) of EUS alone and of EUS with combined CEA and nCLE were evaluated and diagnostic accuracy was compared with pathology using McNemar’s test. Worrisome features (increased cyst size, wall thickness, main pancreatic duct size, and presence of non enhanced mural nodules, abrupt changes, distal atrophy and lymphadenopathy) were tested by determining dissimilar calculations using Euclidean distance and later were used in hierarchical clustering to create two clusters based on Euclidean distance.

Results: Diagnosis of PCN using EUS alone had a specificity of 0.75 and a NPV of 0.88. EUS and CEA had a specificity of 0.95 and a NPV of 0.90. Finally, EUS with CEA and nCLE combined had a specificity of 0.80 and a NPV of 0.94. Worrisome features clustering was able to predict pathology, p = 0.00289.

Conclusion: We concluded that specificity and NPV of EUS predicting PCN are positively impacted by the addition of CEA and nCLE. We also found that clustering of worrisome factors predicts pathology, however, a larger cohort is required for future studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) is accepted as the treatment of intestinal-type early-stage gastric cancer. However, ESD occasionally results in unfavourable outcome due to technical difficulties. Therefore, predictions of difficulties in ESD would preclude complications associated with ESD. Aims & Methods: The aim of this study is to determine the predictive factors of procedural difficulties in ESD. Between January 2009 and July 2016, 577 consecutive patients who underwent ESD for gastric lesions were enrolled. These patients were classified into 3 groups: group S, group L, and others. Group S comprised 30 patients who underwent ESD for the shortest duration (10–16 min). Group L comprised 30 patients who underwent ESD for the longest duration (149–215 min). Multivariate analysis was performed between Groups L and S using the following factors: location (cardia, posterior wall of angle, lesser curvature of lower gastric body and others), macroscopic type (protruded, depressed, or others), and morphological type (preoperative scar and others), mixed size of the resected specimen, preoperative scar, number of preoperative biopsies, and others, and as predictor for submucosal fat tissue, body mass index, waist circumference, visceral fat tissue measurements on CT, blood test findings (glycated hemoglobin, triglyceride and total cholesterol), blood pressure, and heart rate before ESD.

Results: Significant differences were found regarding the number of biopsies (group L, 8.5; group S, 6.8; P = 0.0211), (group L, 616.7mm2; group S, 998.5mm2; P = 0.0027), biopsy visualization of SCJ was good at 32% (108/340) (P = 0.0086). Based on these factors and odds ratio, we prioritized sensitivity to avoid missing cases with removal difficulties during ESD and suggested predictive factors for procedural difficulties during ESD. For example, when examining 43 cases, no patients underwent ESD for gastric neoplasms between August to November 2016 the sensitivity was 87.5% and the specificity was 80%.

Conclusion: Our results suggest that the number of biopsies, size of the resected specimen, biopsy diagnosis, preoperative scar, and biopsy location are predictive factors for difficulties in ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

in the lesser curvature (43.9%, 284/647). Posterior EGC was more frequent in the middle third stomach than the anterior part (20.4%, 31/157 vs. 16.4%, 11/67, respectively). For EGCG characteristics compared between the lower and mid-to-upper parts, submucosal invasive EGC was found to be significantly different (odds ratio, 1.919; confidence interval, 1.014–3.623; p = 0.045).

Conclusion: Most of the EGCs resectable with ESD were found in the lower part of the stomach and lesser curvature of the stomach. The incidence of the posterior part in the mid-to-upper part of the stomach was higher than that of anterior part. The EGCG located in the mid-to-upper part of the stomach was found to have a higher incidence of invasive cancer.

#P0152 A STUDY OF THE RECOGNITION OF ENDOSCOPIC IMAGES BY MACHINE LEARNING WITH CONVOLUTIONAL NEURAL NETWORK AND DEEP LEARNING

R. Yamakawa, M. Harada, K. Kawauchi, S. Nuzuki, M. Iwata
Gastroenterology, Kauta Hospital, Nigata, Japan

Contact E-mail Address: yamakawa_r@nigata-min.or.jp

Introduction: The recognition of general images by machine learning (ML) with the convolutional neural network (CNN) and deep learning (DL) is good. However, the possibility of the recognition of endoscopic images by ML with CNN and DL is undetermined.

Aims & Methods: The aim of this study was to clarify the possibility of the recognition of endoscopic images by ML with CNN and DL. We selected 816 endoscopic images of 8 categories which include laryngeopharynx (LP), thoracic esophagus (TE), abdominal esophagus (AE), gastric fundus (GF), gastric body (GB), gastric antrum (GA), duodenal bulb (DB) and descending part of the duodenum (DD). Each category had approximately 100 images. These images were randomly separated into two groups, 60% (489 images) for learning and 40% (327 images) for testing. We increased the learning group images to 8133 by addition additionally rotated images of each five degrees. We made an ML model with three CNN layers, three Activation Function layers, two Max-Pooling layers and two Dense layers by TensorFlow and Keras. We trained the ML model with the learning group images (n = 8133) and then tested it with the testing group images (n = 327) to determine whether it can recognize the endoscopic site. Two members of our hospital staff performed the same test utilizing the same images.

Results: It took 73 minutes for the ML model to learn and 6 seconds to answer the test. The percentage of correct answers of the ML model was 70.6% in all categories (n = 327), 77.1% in LP (n = 48), 91.5% in TE (n = 47), 64.4% in AE (n = 45), 73.7% in GB (n = 38), 61.5% in GA (n = 39), 52.8% in GF (n = 36), 65.6% in DB (n = 32) and 71.4% in DD (n = 42). The average percentage of correct answers of humans was 95.4% in gastroenterologists (n = 38), 85.2% in junior residents (n = 2), 81.2% in endoscopy nurses (n = 5), 54.4% in medical clerks (n = 5) and 51.8% in floor nurses (n = 4). The percentage of correct answers of the ML model was lower than those of humans who have knowledge about endoscopic images. However, it was higher than those of other humans who do not.

Conclusion: We suggest the possibility of the recognition of endoscopic images by ML with CNN and DL. Further study is necessary to confirm the ability of it because this study was conducted in a simple ML model with three CNN layers and a small number of images.

Disclosure of Interest: All authors have declared no conflicts of interest.

#P0153 CONVENTIONAL VERSUS TRACTION-ASSISTED ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC NEOPLASMS (CONNECT-G): A MULTICENTER, RANDOMIZED CONTROLLED TRIAL

Introduction: To clarify whether traction assist improves technical outcomes of conventional submucosal dissection (ESD).

Aims & Methods: A superiority, randomized phase 3 trial was conducted at 14 institutions across Japan. Patients with single gastric neoplasm meeting the indication of the Japanese gastric treatment guidelines were enrolled and assigned to conventional ESD or dental floss clip traction ESD (DFC-ESD) by a computer-generated random sequence with stratification by institution, tumor location, tumor size and operator’s proficiency. The primary endpoint was ESD procedure time, which was defined as the time from the start of submucosal injection to the end of lesion removal.

Results: Between July 2015 and September 2016, 640 patients underwent randomization. 316 patients assigned to conventional ESD and 319 patients assigned to DFC-ESD were included in the analysis set. Mean ESD procedure time was 60.7 minutes in the conventional ESD group and 58.1 minutes in the DFC-ESD group (p = 0.45). Perforation was less frequent in the DFC-ESD group (conventional ESD vs. DFC-ESD: 2.2% vs. 0.3%, p = 0.04). Among the lesions in the greater curvature of the upper or middle stomach, mean procedure time in the DFC-ESD group was shorter than the conventional ESD group (conventional ESD vs. DFC-ESD: 104.1 vs. 57.2 minutes, p = 0.01).

Conclusion: This study reveals that traction-assisted ESD does not result in quicker procedures in the entire population, but it can reduce the risk of perforation. Selectively applied to the lesions in the greater curvature of the upper or middle third stomach, traction assist contributes to a remarkable reduction of procedure time.

Disclosure of Interest: All authors have declared no conflicts of interest.

#P0154 MACHINE LEARNING-BASED AUTOMATIC DETECTION SYSTEM FOR DEMARCATION LINE OF GASTRIC CANCER WITH IMAGES

N. Ishida, N. Yagi, H. Kitaza, A. Tomie, H. Ichikawa, S. Hiwa, T. Hiroyasu

4 Endoscopy

Introduction: The vessel plus surface (VS) classification system proposed by Yao is widely used for endoscopice diagnosis of early gastric cancer1. However, this diagnosis is performed by visual observation and no quantitative index exists.

Aims & Methods: In this study, a method for automatically detecting early gastric cancer lesions by narrow-band imaging (NBI) using a magnifying endoscopic image in the stomach is proposed to support diagnosis. The proposed system quantitatively shows the demarcation line (DL) of lesions in narrow-band images. Machine learning is introduced into the VS classification and image processing system performed. In this study, texture and color features, which is a type of image processing, is used to assess the mucosal surface. In addition, the proposed system uses a color feature that quantitatively expresses mucosal vessels. Furthermore, the narrow-band image contained 200 superpixels, and each superpixel contained texture and color features; a superpixel is a collection of pixels with similar features. Finally, lesions were identified by a support vector machine, which is a model for machine learning, and DL was detected. In this computational experiment, the validity of the system was verified by identifying 25 early-stage gastric cancer lesions (50 endoscopic images) using NBI-magnified observation at the Department of Gastroenterology, Murakami Memorial Hospital, Asahi University, Gifu.

Results: The average detection rate of the lesion area greatly improved to 63.0% with the proposed method compared with 28.8% with the conventional method. In addition, the obtained DL was similar to that indicated by an experienced medical physician. Based on these results, the proposed system enabled the automatic detection of early gastric cancer DL in narrow-band images, suggesting that the proposed system is useful for the determination of DL.

Conclusion: In this study, a method to assess features of gastric lesions combined with the use of superpixels was proposed. The average detection rate of the lesion range using the proposed method greatly improved compared with that using the existing method, enabling the detection of DL without depending on a physician’s experience.

### P0155 ENDOSCOPIC TREATMENT OF FISTULAS AFTER SLEEVE GASTRECTOMY: ASSESSMENT FOR SWITCHING TOWARDS INTERNAL DRAINAGE IN A REFERENCE CENTER

**D. Loreno**1, T. Guillaud1, J. Gonzalez2, A. Benezech2, S. Berdañá3, T. Bege2, M. Barthet4

1Hospital Nord, Marseille/France
2Dept. De Gastroenterologie, APHM - North Hospital, Marseille/France
3Gastroenterology, Hopital Nord, Marseille/France

**Contact E-mail Address:** diane.loreneo@gmail.com

**Introduction:** Post-sleeve gastrectomy fistulas (PSGF) are major complication of bariatric surgery. Endoscopic management evolved from a fistula closure to an internal drainage (ID) strategy within the 2013 year. The main objective of this study is to evaluate the different endoscopic approaches.

**Aims & Methods:** This retrospective study included all patients treated for PSGF in a referral center. "Closure" management was defined as: initial treatment using covered-metal-stent and endoclips. ID management was defined as: initial treatment using nasojejunal tube and/or double-pigtail-stent. The failure was defined as: need for surgery, or death.

**Results:** Between 2007 and 2015, 101 patients (women: N = 78; mean age: 42 ± 12.2 years) were included. The mean delay between SG and the first endoscopy was 92 ± 48 days. Overall success of endoscopic treatment was 86% within 6 ± 2.7 months. Two patients died. Primary success of ID and closure management occurred in 19/22 (86%) and 49/77 (63%) patients, respectively. Among patients in failure of closure management, 22 had secondary ID (18 being successful). Success of initial management was significantly higher for ID (P < 0.05).

Factors associated with failure of closure management were in multivariate analysis: collection > 5 cm (P = 0.013, OR = 3.89% [CI: 1.3–10.9]), Factors associated with duration of management over 6 months were in multivariate analysis: reoperation before endoscopy (P = 0.044, OR = 3.95% [CI: 1.0–14.9]) and purulent flowing at endoscopy (P = 0.043, OR = 4.65% [CI: 1.0–20.4]). Factors associated with post-2013 management were in multivariate analysis: first endoscopy within 6 months (P = 0.016), Clavien-Dindo-type 4 and 5 (P = 0.016), and absence of glue sealing (P = 0.027).

**Conclusion:** Endoscopic management of PSGF healed in 86% of cases. In case of collection greater than 5 cm, an internal drainage should be proposed first. A stricture was defined as a difficulty in swallowing solids or an inability to pass an EGD (9.2 mm diameter endoscope). Management in our center has changed over time with earlier first endoscopy and management of more severe patients. **Disclosure of Interest:** M. Barthet: Boston scientific consultant. ### P0156 CLOSURE BY USING OVER-THE-SCOPE CLIPS AFTER ENDOSCOPIC FULL-THICKNESS RESECTION

**J. Guo**

Endoscopy Center, Shengjing Hospital of China Medical University, Shenyang/China

**Contact E-mail Address:** guoji@sj-hospital.org

**Introduction:** Endoscopic full-thickness resection (EFTR) is a mini-invasive technique for gastrointestinal subepithelial tumors, which enables a full-thickness resection of tumors and can provide a complete basis for pathological diagnosis. Gastrointestinal fistula closure after EFTR is a challenge for endoscopists. In this study, we introduced EFTR with fistula closure using the over-the-scope clip (OTSC) system for gastrointestinal subepithelial tumors originating from the muscularis propria.

**Aims & Methods:** We aimed to evaluate the feasibility and safety of fistula closure with OTSC by a retrospective analysis on the cases of EFTR with defect closure associated with long-term care. Management in our center has changed over time with earlier first endoscopy and management of more severe patients.

**Disclosure of Interest:** M. Barthet: Boston scientific consultant. All other authors have declared no conflicts of interest.

### P0157 EFFICACY OF ORAL MIXTURE OF HYDROCORTISONE SODIUM SUCINNATE AND ALUMINUM PHOSPHATE GEL FOR THE PREVENTION OF STRICURE AFTER ≥2/3 CIRCUMFERENTIAL ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR ESOPHAGEAL CANCER—A SINGLE CENTER PILOT STUDY FROM CHINA

**Y. Huang, X. Yan, H. Chang, Y. Zhang, W. Yao, K. Li**

Gastroenterology And Hepatology, Peking University Third Hospital, Beijing, China

**Contact E-mail Address:** 13911765322@163.com

**Introduction:** ESD has been performed on many patients with early stage esophageal squamous cell carcinoma and adenocarcinoma. Endoscopic submucosal dissection is the most important issues for quality of life in patients which is drastically decreased and repeat, periodic endoscopic balloon dilatation (EBD) is usually required over long periods. It is well known that hormone for external use is more easily absorbed in broken skin. Accordingly, We explored an innovative strategy with oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel for prevention of the stricture.

**Aims & Methods:** To evaluate the efficacy of this mixture in single center of Beijing, China.

**Patients and Methods:** In total, 13 patients who underwent more than 2/3 circular or complete circular ESD for esophageal superficial squamous cell carcinoma were included in this study. They all received preventative strategy for stricture and were divided into three groups randomly. Four patients received systemic steroid treatment (ST group), three patients received endoscopic intraluminal steroid (triamicinolone acetonide 80mg) injection accompanied with systemic steroid treatment (IT + ST group), six patients received oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel (OHA group). We compared the two groups in terms of stricture rate and total number of endoscopic balloon dilatation (EBD) sessions. ST group started with 30mg/day prednisolone on the second day post-ESD, and continued with a gradually tapering prednisolone dose, finally discontinuing systemic steroid administration 8 weeks later. IT + ST group started with 80mg intraluminal steroid at the end of ESD procedure, and 30mg/day prednisolone on the second day post-ESD which exactly was the same as ST group of tapering process. OHA group started with mixture of hydrocortisone sodium succinate and aluminum phosphate gel for 20g, qid for 2 weeks and continued with a gradually tapering OHA dose on the second day post-ESD. Esophagogastroduodenoscopy (EGD) was performed on demand whenever patients complained of dysphagia. Among those cases, EBD was performed when patients experienced persistent dysphagia. If the patient had progressive dysphagia, EBD was performed 8 weeks after ESD to evaluate any possible stricture. The primary endpoint in this study was the stricture rate after ESD followed by oral mixture therapy. The secondary endpoint was the number of EBD sessions required to resolve the stricture. A stricture was defined as a difficulty in swallowing solids or an inability to pass an EGD (9.2 mm diameter endoscope).

**Results:** There were two complete and two 75% circular ESD cases in IT + ST group, and one complete and five 75% circular ESD cases in OHA group. 12 cases were resected en bloc with tumor free lateral and basal margins. No complications were seen after this procedure. The stricture rates of ST, IT + ST, OHA group after ESD were 100% (4 of 4 patients), 33.3% (one of three patients), 0% (none of six patients), respectively. One patient with stricture after ESD had lateral recurrence at the margin of ulcer. One EBD was performed in three patients in ST group and one patient in IT + ST group with esophageal stricture. One patient in ST group underwent subsequent EBD operation in response to patient demand.

**Conclusion:** Short period, oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel showed promising results for the prevention of stricture after ESD for early stage esophageal cancers. **Disclosure of Interest:** All authors have declared no conflicts of interest.
P0106 ARTIFICIAL INTELLIGENCE DIAGNOSIS OF HELICOBACTER PYLORI INFECTION USING LINKED COLOR ENDOSCOPY

H. Nakashima, S. Kawanishi, T. Kawachi, N. Sakaki

1Department Of Pathology, The Cancer Institute Hospital, Japan; 2Foundation For Detection Of Early Gastric Carcinoma, Tokyo/Japan; 3Center For Frontier Medical Engineering, Chiba University, Chiba/Japan; 4Department Of Gastroenterology, Graduate School Of Medicine, Chiba University, Chiba City/Japan

Introduction: Esophagogastroduodenoscopy (EGD) is of growing importance in the diagnosis of Helicobacter pylori (HP) gastritis, because HP infection is strongly associated with gastric carcinogenesis. However, the accuracy of endoscopy diagnosis of HP infection may vary according to the experience and technique of the attending endoscopist. Here, we challenged to establish a computer aided endoscopic diagnosis system for HP infection using two novel technologies. First is a Link color imaging (LCI). It is a new Image-enhanced endoscopy (IEE) using a LASER light source to enhance slight differences in mucosal color. Second is an Artificial Intelligence (AI) technology. Deep Learning has attracted attention in diagnostic imaging. It is a type of AI which imitates neural network in the brain.

Aims & Methods: The aim of this study was to establish an AI diagnosis of HP infection using LCI. We designed a prospective study of all patients who underwent EGD and were tested for serum anti-HP IgG antibodies at our medical clinic. Subjects who had a history of HP eradication therapy were excluded in this study. A total of 220 examinees were candidates who underwent EGD and underwent HP IgG antibody testing, 147 of whom were HP IgG antibodies positive (test of anti-HP IgG antibodies were 112). The HP IgG antibody titer of each subject was taken as the gold standard for HP infection status for this study. During EGD an endoscopist took 3 LCI pictures of the lesser curvature, greater curvature and antrum of the stomach by EG-L580NW (FUJIFILM Co., Japan). Finally, we used a total of 639 LCI pictures in the study. The specifications of the AI used in this study were as follows: Operating system: Linux (Ubuntu 14.04 LTS), Neural network: GoogleNet1,2, Framework: Caffe1,2, and Graphic processor unit: Geforce GTX TITAN X (NVIDIA Co., Japan). The AI diagnosis of HP infection using LCI was developed with Fast Feature Embedding. ACM Int Conf Multimed [Internet], 2014: 675–8.

Reference
Esophageal perforation: Continuing challenge to treatment, Gastrointestinal intervention, June 2013, Pages 1–6.
Resolution Light Endoscopy (HR-WLE) followed by HR-NBI. A careful evaluation of the antrum and corpus mucosa was performed and EGGM score was calculated. Five different areas were considered (lesser and greater curvature in the antrum, lesser and greater curvature in the corpus and incisura) and in each area 0 (no IM), 1 (focal IM, less or equal than 30% of the area) or 2 points (extensive IM in that area, more than 30% of the area) were attributed for a total of 10 points. Biopsies were taken where the endoscopists observed IM and, if IM was not present, random biopsies were taken using the updated Sydney System protocol. Biopsies from the different sites were sent for histopathologic evaluation and IM grading. The diagnostic performance of EGGM was then compared to OLGIM (gold standard) and sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated.

Results: IM was staged as OLGIM 0, 2, 3 and 4, respectively: 32 (41%), 23 (29.5%), 17 (21.5%), and 6 (7.7%) pts (no patients with OLGIM 1 were found). Table 1 shows detailed the EGGM scores compared to OLGIM. Compared to OLGIM as gold standard for the evaluation of IM, sensitivity, specificity, PPV and NPV of EGGM classification were 97.8%, 81.2%, 88.2% and 96.3%, respectively. All 6 patients with false positive results using the EGGM classification were H. pylori positive. Analyzing the subgroup of patients with OLGIM 3 and 4, the diagnostic performance of EGGM was: sensitivity 95.6%, specificity 90.9%, PPV 81.5% and NPV 98.0%. Two of the 5 patients who resulted false positive using the EGGM classification were H. pylori positive. A high agreement between EGGM and OLGIM scores was observed (83%).

% of total (within each OLGIM grade) EGGM score
0 1–2 3–4 5–7 8–10
OLGIM 0 33 (81) 5 (12) 3 (7) 0 0
1 0 0 0 0 0
II 1 (4) 8 (26) 14 (48) 4 (13) 3 (9)
III 0 0 1 (6) 17 (76) 4 (18)
IV 0 0 4 (50) 4 (50)

Extent of intestinal metaplasia
Absent Focal Moderate Extensive

Conclusion: The EGGM classification showed a high diagnostic performance compared to OLGIM, in particular in patients with OLGIM 3 and 4. A possible confounding factor leading to overestimation of presence of intestinal metaplasia might be the presence of H. pylori infection. This approach could be used to simplify the surveillance of these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0163 COMPARISON OF PERCUTANEOUS ENDOSCOPIC GASTROSTOMY VERSUS RADIOLOGIC GASTROSTOMY IN TERMS OF INDICATIONS, EFFICACY, COMPLICATIONS; A RETROSPECTIVE ANALYSIS

A. Strijbos1, D. Strijbos2, M. van der Velden1, D. van Veen1, M. Groenestijn1

Introduction: Gastrostomy is the current method of choice for medium and long-term enteral feeding. Available techniques include Percutaneous Endoscopic Gastrostomy (PEG) and Percutaneous Radiologic Gastrostomy (PRG). Both methods are preferred over surgical gastrostomy. Previous studies that have compared outcomes between PEG and PRG are limited due to small sample sizes, high risk of confounding and selection bias. Our primary aim was to retrospectively analyse data from our centre with respect to complications and mortality between PEG and PRG procedures in relation to indications. These data may help to predict which technique is best for an individual patient.

Aims & Methods: A retrospective analysis including all adult patients receiving initial PRG (January 2010 until April 2016) and PEG (January 2008 until April 2016) in our university hospital. Inclusion criteria were patients with indication for gastrostomy and EGGM classification 0-4 were included. Outcomes were complications (early (5 days) and late), success rates and mortality (procedure related, 30-day, and overall). Chi², Fisher’s exact and t-tests were used. Multivariate logistic regression and Cox proportional hazards regression analysis were performed.

Results: A total of 760 initial procedures (469 PRG and 291 PEG) were included in the analysis (62.9% male, mean age 62.8yrs [SD 12.6yrs]). Most common indications for gastrostomy were Head and neck tumours (HN, PRG 69.9%, p < 0.001), and Radiotherapy (H, PRG 69.9%, p < 0.001). Cerebrovascular Accident (CVA, PEG 13.7%, PRG 2.1%, p < 0.001) and Motor Neuron Disease (MND, PEG 2.7%, PRG 9.8%, p < 0.001). Success rates for placement were 92.1% for PEG (failure mostly due to absence of transillumination, n=14) and 97.1% for PRG (p = 0.001). Major complications (e.g. abscess, buried bumper, perforation) were defined and classified. Complications did not differ amongst groups, neither did procedure-related mortality, which was 6.7% in PEG (n = 51) vs. 5.8% in PRG (n = 31). Procedure-related mortality between PEG and PRG procedures in relation to indications. These data may help to predict which technique is best for an individual patient.

P0162 PERCUTANEOUS TRANSESOPHAGEAL GASTROSTOMY (PEG) IN THE COMPRESSION TREATMENT FROM THE GASTROINTESTINAL TRACT AS THE IDEAL PALLIATIVE CARE FOR THE PATIENTS WITH MALIGNANT DISEASE

M. Murakami1, K. Nishino1, T. Okamoto1, S. Murakami1, K. Mori1, B. Murakami1, M. Azuma2, S. Tanabe3, M. Kida4, W. Koizumi2

Introduction: Percutaneous transesophageal gastrostomy (PTEG) was developed as an alternative route to access the gastrointestinal tract for the patients that cannot be managed conservatively. This approach could be used to simplify the surveillance of these patients.

Aims & Methods: The aim of this study is to evaluate the clinical usefulness of PTEG supported by endoscopy for the patients who need decompression from gastrointestinal tract due to malignancies. A rupture-free balloon (RFB) catheter is inserted into the upper esophagus. Percutaneous balloon puncture with a specialized needle is then performed from the left side of patient’s neck under ultrasonographic control. A guide wire is inserted through the needle into the RFB, followed by a dilator and sheath. A placement tube is then inserted through the sheath, and the sheath is removed. Double Balloons equipped Over tube type RFB are pulled over the balloon and the sheath is removed. Double Balloons delivered the over tube to the stomach, where the over tube is punctured into the over tube trough the balloon. We perform PTEG in a total of 62 patients (37 men and 25 women, mean age 61.8 years) in whom PEG was not feasible for decompression. Every patient suffered discomfort to the prior insertion of nasal tube especially for the patients with carcinomatous obstruction. Complications were minor oozing bleeding in three patients that did not require blood transfusion, thyroid puncture in three patients, which were treated conservatively. No patient required surgical treatment or died after PTEG.

Conclusion: PTEG is feasible, safe, and useful. PTEG could be an only procedure to be free from a nasal tube especially for the patients with carcinomatous obstructions. PTEG is the ideal solution for the patients with malignant gastrointestinal obstruction. PTEG is one of the best tool in palliative care for the patients with malignant disease.

P0165 COMPREHENSIVE EVALUATION OF THE LEARNING CURVE FOR PERORAL ENDOSCOPIC MYOTOMY: LESSONS FROM 1346 PATIENTS

Z. Liu1, X. Zhang1, Q. Li1, P. Zhou1
1Zhongshan Hospital, Endoscopy Center and Endoscopy Research Institute, Zhongshan Hospital, Fudan University - Zhongshan, Shanghai/China

Contact E-mail Address: liuzq16@fudan.edu.cn

Introduction: Peroral endoscopic myotomy (POEM) is being increasingly performed worldwide. However, studies on its learning curve are limited. A comprehensive evaluation based on risk factors is needed.

Aims & Methods: This study was aimed to evaluate the impact of various factors on the learning curve of POEM. From August 2010 to July 2015, 1346 POEM procedures performed in Zhongshan Hospital were analysed. The primary outcome of the study was a composite outcome of aborted procedures and complication. The secondary outcomes included procedure time and hospital stay. The impact of risk factors was assessed by backward conditional logistic regression on primary and secondary outcomes. The risk-adjusted CUSUM and moving average methods were used to evaluate the outcomes.

Results: Fifty-four (4%) patients had the composite outcome with 10 aborted procedures and 44 adverse events. The composite outcome was related to case number, full-thickness myotomy and procedure time in the multivariate logistic regression. Adjusted for these risk factors, the CUSUM analysis showed that the composite outcome gradually decreased after 150 cases. The procedure time was higher in the early stage and decreased after 71 cases. Case number, in representativeness of the operative experience, is also an independent risk factor for a longer procedure time and hospital stay.

Conclusion: For POEM operators, seventy cases might be considered a threshold for case volume, i.e., technical proficiency. A hundred-and-fifty cases might be considered a threshold for the decrease of aborted procedures and adverse events, i.e., technical reliability.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0166 CLINICAL CURATIVE EFFECT ANALYSIS OF 162 GASTRIC STROMAL TUMORS RESECTED BY ENDOSCOPIC TREATMENTS

L. Liu, W. Liu, Z. Fan
Digestive Endoscopy Center, The First Affiliated Hospital of Nanjing Medical University, Nanjing/China

Contact E-mail Address: kit9178@sina.com

Introduction: Gastrointestinal stromal tumor (GIST) is one of the most common tumors originating from mesenchymal tissue of gastrointestinal tract, which accounts for about 0.2% of gastrointestinal tumors. Gastric stromal tumors are more common, accounting for about 40% ~ 70% of GIST. At present, the endoscopic treatments of gastric stromal tumors includes endoscopic submucosal dissection (ESD), endoscopic full-thickness resection (EFR) and combined endoscopic and laparoscopic surgery.

Aims & Methods: Our study is aimed to assess the safety and effectiveness of endoscopic treatments for gastric stromal tumor. Clinical data of 1346 patients with gastric stromal tumor who underwent endoscopic treatments from June 1, 2011 to July 31st 2015 were analyzed retrospectively. The primary outcome of the study was a composite outcome of aborted procedures and complication. The secondary outcomes included procedure time and hospital stay. The impact of risk factors was assessed by backward conditional logistic regression on primary and secondary outcomes. The risk-adjusted CUSUM and moving average methods were used to evaluate the outcomes.

Results: Complications were observed in 8 patients (4.9%): bleeding during operation, i.e., technical reliability. The introduction of the Registrar of the Week Service provides a valuable opportunity for StRs to be trained in endoscopic haemostasis and acquire a measure to AVUGIB patients. As per this study case each StR on an average performed endoscopy on 24 AVUGIB patients. If this is extrapolated, each StR will be able to perform 48 procedures in 1 year and 240 procedures over 5 years. In the case of the StR, on average a StR can perform around 4 interventions over 6 months, which comes to 8 per year and 40 in 5 year program. 1

Conclusion: The introduction of the Registrar of the Week Service provides a valuable opportunity for StRs to be trained in endoscopic haemostasis and acquire a measure to AVUGIB patients. As per this study case each StR on an average performed endoscopy on 24 AVUGIB patients. If this is extrapolated, each StR will be able to perform 48 procedures in 1 year and 240 procedures over 5 years. In the case of the StR, on average a StR can perform around 4 interventions over 6 months, which comes to 8 per year and 40 in 5 year program. 1

P0167 GASTROENTEROLOGY REGISTRAR OF THE WEEK: A SOLUTION FOR AVUGIB ENDOSCOPY TRAINING?

S. Budihal1, P. Wurm1
1Digestive Diseases Centre, University Hospitals Leicester, GB/United Kingdom

Contact E-mail Address: shivbudihal@yahoo.co.uk

Introduction: Much concern surrounds Gastroenterology Specialist Registrar (SIR) endoscopy training, especially in regards to endoscopic management of Acute Upper Gastrointestinal Bleeding (AVUGIB). Recent evidence suggests there has been a decline in exposure and experience in AVUGIB endoscopy. 1 In July 2013 our University Hospital introduced a Consultant-led and Registrar-supported Monday to Friday, 9 to 5 pm in-reach service. It comprises of a morning visit to the acute medical units and a daily inpatient emergency list. This study looked at registrar AVUGIB endoscopy training after its implementation.

Aims & Methods: Endoscopy reports of patients presenting with haematemesis, melena or both who had undergone endoscopy during the period of 1st of March 2015 to 31st August 2015 were retrieved using the endoscopy reporting tool Unisoft and analysed. Reports where StRs were the primary operator were considered. Number of procedures, haemostatic intervention and nature of haemostasis was analysed. This was then compared to data from the year before implementation (01/03/2012 to 31/08/2012).

Results: A total of 7 StRs (5 Full Time and 2 Less than Full Time) performed gastroscopies on AVUGIB patients as first operators under Consultant supervision. Over the 6-month period a total of 166 gastroscopies were undertaken (Mean 24). On 26 occasions, endoscopic intervention (EI) was performed (Mean 4). On average, 16% of the AVUGIB patients required EI. In cases of Non Variceal Bleeding, Dual therapy was applied in 87.5% of the cases. In cases of Vascular lesions the dual therapy was used in all cases. 1

Conclusion: This study looks at registrar AVUGIB endoscopy service but provide adequate endoscopic procedure for current specialist registrars in order to ensure future competent and confident consultants.

Introduction: Endoscopic recognition of dysplasia or early cancer in Barrett’s esophagus (BE) is difficult. Experience in recognition of early neoplastic lesions is thought to increase the detection of visible dysplastic lesions. A previous study reported that endoscopists in community hospitals detect neoplastic lesions at a significant lower rate than referral centres. The aim of the study we want to assess the significance of dysplasia in random biopsies in BE, in the absence of reported visible lesions as well as the final outcome of pathology.

Aims & Methods: We retrospectively analysed all patients referred from 19 community hospitals to our tertiary referral centre with the diagnosis of BE with dysplasia (A2). Early adenocarcinoma (EAC) between February 2008 and April 2016. All patients underwent a dedicated imaging endoscopy with high-definition endoscopy supplemented with virtual chromoendoscopy and/or acetic acid staining at the discretion of the endoscopist. All procedures were performed by an endoscopist with extensive experience in the detection of early neoplastic lesions in BE. During endoscopy all visible lesions were noted and biopsied and/or removed by endoscopic resection (ER). Patients were included for analysis in case of absence of reporting visible lesions at referral.

Results: In total 184 patients were referred with dysplasia or EAC of which 82 patients (80.5%) made, age 42–81 years (median 68) did not show a visible lesion upon referral endoscopy. Referral diagnosis of these 82 patients was 32 low-grade dysplasia (LGD), 43 high-grade dysplasia (HGD) and 7 EAC. In three of 32 patients (9.4%) referred with LGD, a visible lesion during imaging endoscopy was detected. Two cases of histology proved EAC and one confirmed LGD. In twenty-six of 43 patients (60.5%) referred with HGD, a visible lesion with histology specimens corresponding to HGD (10) and EAC (16) were found,

Disclosure of Interest: All authors have declared no conflicts of interest.
respectively. All cases of EAC were detected (7/7). In 18/75 (24%) patients referred with dysplasia (LGD/HGD) without a visible lesion, the referral diagnosis was thus upstaged to EAC. Overall, 41/82 (50%) lesions were found additionally.

Conclusion: The presence of any grade of dysplasia in random biopsies in BE screening in community hospitals is a potential marker for more severe final pathology after endoscopic work-up in an expert centre. Training in Barrett imaging is mandatory for non-expert endoscopists.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Results:** A total of 22 patients were included and analyzed. The etiologies of ERF were esophageal surgery in 12 patients (54.5%), esophageal dilation in 3 (13.6%), invasive ventilation in 3 (13.6%), radiation therapy in 2 (9.1%) and tracheostomy in 2 (9.1%). A total of 93 procedures were performed with a mean of 4.2±4.5 per patient. At some point of the management, twenty-one patients (95%) had esophageal stents placement, eight patients (36%) had over the scope clips (OTSC) placement and seven had OTSC associated with esophageal stent. The clinical success rate was 45.5% (n = 10), and 55% of the patients had a functional success (n = 12). Serious adverse events occurred in 9 patients (40.9%) such as gastrointestinal bleeding (4 patients, 18.2%), stent migration (4 patients, 18.2%), thoracic spondylodiscitis (2 patients, 9.1%) alimentary esophageal impaction (1 patient, 4.5%), stent mucosal impac- tion (1 patient, 4.5%), major chest pain (1 patient, 4.5%). Six patients died (27%). Clinical success was reached for 67% of punctiform ERF (p = 0.193), 50% of medium ERF (p = 1) and 14% of large ERF (p = 0.17). The factor associated with the failure of endoscopic treatment was the persistence of the fistula after 6 months (OR = 44; IC95: 3.38–573, 4; p = 0.004 multivariate ana- lysis). The orifice’s size was associated with the mortality with 71% of death among large fistulas (p = 0.001 univariate analysis).

**Conclusion:** Endoscopic treatment of ERF can lead to 45.5% of clinical success and 55.5% of functional success. However, this outcome appears to be influenced by the size of the fistula. Moreover, the absence of resolution after 6 months of endoscopic treatment dramatically decreases the chance for ERF healing. In conclusion, the endoscopic approach seems reasonable for small or medium orifices, and has to be attempted during six months. After this time or for larger orifices, surgery or palliative therapy should be considered.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0169 ENDOSCOPIC MANAGEMENT OF BENIGN ESOPHAGEAL FISTULAS**

A. Debourdeau, J. Gonzalez, A. Benezech, M. Barthet
Gastroenterology, Aix Marseille University, AP-HM, Hôpital Nord, Marseille; France

Contact E-mail Address: antoine.debourdeau@hotmail.com

**Introduction:** Nonmalignant esophageo-respiratory fistulas (ERF) are rare but frightening clinical situations. They usually involve surgery, but the morbidity and the mortality is high. The knowledge about the modalities and outcomes after endoscopic management of ERF remain limited.

**Aims & Methods:** The aim of this study was to describe and assess the endoscopic management of benign ERF in our center. This was a retrospective study involving patients manage for benign ERF in our tertiary center between July 2012 and December 2016. The inclusion criterion was the presence of communication between esophagus and bronchial tree diagnosed and treated by endoscopy, and malignant ERFs were excluded. The ERFs were classified into three groups of sizes: punctiform (if the orifice was no larger than a straight catheter), medium and large (with visibility of bronchial tree). The primary endpoint was defined as the closure of the fistula confirmed by endoscopy and persisting >6 months. The secondary endpoints were to document the characteristics of endoscopic treatment, the functional success and death, and to identify factors associated with success and death.

**TABLE 1:** Clinical utilization of narrow band imaging magnifying endoscopy for MM/MM1 squamous cell carcinoma

Disclosure of Interest: All authors have declared no conflicts of interest.
emerging modality for refractory gastroparesis with promising preliminary results.

Aims & Methods: The aim of this prospective case series was to assess our first (single center) experience with POEP. Main outcomes were: 1) the efficacy defined by improvement of GCSI score; 2) gastric emptying evolution and 3) safety. From Nov 2015, a total of 7 patients underwent POEP. POEP for gastroparesis was post-operative in 4, diabetic in 2 and idiopathic in 1 patient. One patient underwent POEP for gastroparesis following a multisystemic transplantation; one patient underwent both POEP and POEM (as a single procedure) for coexisting refractory gastropathic symptoms and acidularis. All patients had severe gastroparesis as defined by elevated GCSI score and delayed gastric emptying scintigraphy. Follow visit at 3, 6, 12-months were completed in 7/7 (100%), 5/7 (71%) and 1/7 (14%) patients, respectively. Upper GI endoscopy and scintigraphy were performed 3 months after the procedure.

Results: POEP was successfully performed in all patients. Mean procedure time was 70 minutes (range 63–106). After POEP, mean GCSI decreased from 3.0±1.2 to 0.8±0.7 (at 3-months) and 0.9±0.8 (at 6-months). One woman failed to follow up and was lost to follow-up. Treatment success was reached in 6/7 (85%) of patients, one female patient with diabetic gastroparesis did not have a major symptomatic improvement despite normalisation of gastric emptying study. Gastric scintigraphy normalized in all patients, mean half emptying time decreased from 108±30 min to 62±23 min; and mean bolus retention at 4 hours decreased from 17±9.2% to 2.0±2.0%. One patient developed bleeding ulcer 10 days after POEP, this adverse event was successfully managed endoscopically (clips) and by parenteral proton pump inhibitor.

Conclusion: We report our first experiences with POEP for refractory gastroparesis, demonstrating its feasibility and safety with promising clinical efficacy.

5Gastroenterology, Portsmouth Hospitals NHS trust, Hampshire/United Kingdom

Contact E-mail Address: sharil1@gmail.com

Introduction: Neoplasia in Barrett’s can be subtle and difficult to identify. Blue light imaging (BLI) by Fujifilm is a novel advanced endoscopic technology that provides high-intensity contrast imaging for superior visualisation of mucosal surface and vessel patterns. This can improve the identification of Barrett’s neoplasia. To date there is no formal classification system that enables the characterisation of neoplastic and non-neoplastic Barrett’s. The aim of this study was to develop and validate a classification system for the diagnosis of Barrett’s neoplasia using BLI.

Aims & Methods: The aim of our study was to develop and validate a classification system to identify Barrett’s neoplasia using BLI. 3 expert endoscopists formed a working group to identify criteria characterising neoplastic and non-neoplastic Barrett’s on BLI using a modified Delphi method. A simple classification system utilising pit, vessel pattern and colour was developed using a database of 40 images. 6 experienced endoscopists then assessed a library containing 45 images of neoplastic and non-neoplastic Barrett’s using the proposed criteria. Sensitivity, specificity, positive (PPV) and negative predictive values (NPV) were calculated to assess its performance. The same parameters were then evaluated for each component criteria.

Results: The BLINC classification descriptors are as follows: Non Neoplastic Barrett’s: Pit pattern: circular, tubular or branching with normal density; Vessel pattern: regular, pericryptal non dilated vessels with normal density; Colour: pale Neoplastic Barrett’s: Pit pattern: irregular, crowded with increased density; Vessel pattern: irregular, non cryptal, dilated vessels with increased density; Colour: focal darkness The overall sensitivity and specificity, negative and positive predictive values with corresponding 95% confidence intervals are as follows:

<table>
<thead>
<tr>
<th>Pit pattern</th>
<th>Sensitivity (95% CI)</th>
<th>Specificity (95% CI)</th>
<th>PPV (95% CI)</th>
<th>NPV (95% CI)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal</td>
<td>96.0 (91.5–98.5%)</td>
<td>98.3 (94.1–99.8%)</td>
<td>98.6 (94.8–99.7%)</td>
<td>95.2 (90.7–99.7%)</td>
</tr>
<tr>
<td>Vessels</td>
<td>94.7 (89.8–97.7%)</td>
<td>93.3 (87.3–97.1%)</td>
<td>94.7 (90.1–97.2%)</td>
<td>95.2 (90.9–99.7%)</td>
</tr>
<tr>
<td>Colour</td>
<td>86.7 (80.2–91.7%)</td>
<td>78.3 (69.8–85.3%)</td>
<td>83.3 (78.0–87.6%)</td>
<td>82.5 (75.6–87.7%)</td>
</tr>
</tbody>
</table>

Conclusion: We have developed the first internally validated simple classification system for the diagnosis of Barrett’s neoplasm using BLI. The classification criteria demonstrated high sensitivity and specificity particularly with regards to mucosal pit and vessel patterns. We aim to use the proposed classification in future studies for real time optical diagnosis of Barrett’s neoplasia.

P0173 TREATMENT OF MULTIPLE GASTROINTESTINAL Submucosal TUMORS BY SUBMUCOSAL TUNNELING ENDOSCOPIC RESECTION

J. Liu, W. Qin, Y. Huang, Z. Ren, P. Zhou

Endoscopy Center And Endoscopy Research Institute, Fudan University Zhongshan Hospital, Shanghai/China

Contact E-mail Address: liu.jingzheng@zs-hospital.sh.cn

Introduction: Submucosal tunneling endoscopic resection (STER) is a novel technique to remove the gastrointestinal submucosal tumors. Previous studies mainly focused on technical feasibility for patients with one single gastrointestinal submucosal tumor. No systematic studies about multiple upper gastrointestinal submucosal tumors synchronously removed by STER are addressed. The aim of this study was to evaluate the safety and outcome of STER in treatment of multiple gastrointestinal submucosal tumors.

Aims & Methods: From January 2011 to January 2017, 42 patients with multiple gastrointestinal submucosal tumors undergoing STER were included. Variables of each tumor and patient were analyzed. Detailed tumor characteristics included max size, sum of max size and number of tumors, and longest distance of tumor. While detailed technique information included number of tunnels, tunnel length, hospital stay, procedure time, complication, follow-up, recurrence, and mortality.

Results: Among all the cases, 96 lesions of upper gastrointestinal submucosal tumors were removed by STER. The median procedure time was 50 min (range 13.6–84.9 min). The median number of tumors was 2 (2–4). The median max size of each tumor was 1.8 cm (range 0.7–3.5 cm) and the median sum of max size of each tumor of each patient was 3 cm (range 1.3–8.6 cm). Six patients had perioperative complications (14.2%), with 3 pneumothorax/hydropneumothorax (7.2%), 1 mucosal injury (2.4%), 1 pneumonia (2.4%), and 1 major bleeding (2.4%). Patients with different number of tunnels had similar tumor characteristics and techniques. There were significant differences in longest distance of tumors comparing two groups (p < 0.001). No local recurrence or distant metastasis was detected with a median follow-up of 33 months.

Conclusion: STER is a safety and feasible technique for multiple upper gastrointestinal submucosal tumors no matter in one tunnel or two tunnels resection. Based on the longest distance of tumors, different number of tunnels can be performed with similar procedure technique and prognosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

4Interdisciplinary Endoscopy, University Medical Center Mainz, Mainz/Germany

**Disclosure of Interest:**

Introduction: LCI is a new imaging technique based on 4 independently acting LEDs that is enhancing the mucosal vascular pattern and surface pattern morphology. To date, chromoendoscopy with acetic acid is considered the gold standard for diagnosis of Barrett’s oesophagus. Therefore, consecutive patients with Barrett’s oesophagus were prospectively included. All Barrett segments were carefully evaluated by using high-definition white-light imaging, followed by LCI and acetic acid spraying. At each examination targeted biopsies were taken from all visible lesions, followed by random four-quadrant biopsy samples. 

**Aims & Methods:** The aim of this prospective study was to evaluate the recently introduced LCI technique compared to conventional dye spraying with acetic acid for diagnosis of Barrett’s oesophagus. Therefore, consecutive patients with Barrett’s oesophagus were prospectively included. All Barrett segments were carefully evaluated by using high-definition white-light imaging, followed by LCI and acetic acid spraying. At each examination targeted biopsies were taken from all visible lesions, followed by random four-quadrant biopsy samples. 

**Results:** The diagnostic yield of conventional dye spraying was significantly higher for diagnosis of Barrett’s oesophagus compared to high-definition white-light imaging. Of note, no significant difference for diagnosis of Barrett’s oesophagus was noted between acetic acid chromoendoscopy and the LCI technique. LCI diagnosis was always consistent to traditional dye spraying (100% concordance). The random four-quadrant biopsy protocol did not add additional information to the one already obtained by using LCI.

**Conclusion:** The newly introduced LCI technique is superior to high-definition white light endoscopy for diagnosis of Barrett’s oesophagus and equally effective to acetic acid dye spraying. Therefore, the LCI technique has the potential to facilitate the diagnosis of Barrett’s oesophagus and to overcome the limitations of a random 4-quadrant biopsy protocol.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0175 ALBERTA FAMILY PRACTICE ELECTRONIC ENDOSCOPY STUDY (AFPEE)**

M. Kolber1, L. Green1, N. Olivier1, R. Torrie2, O. Babenko1
1Family Medicine, University of Alberta, Edmonton/Canada/AB
2Tuber Medical Clinic, Tuber/Canada/AB

**Disclosure of Interest:**

Introduction: In Canada, gastroenterologists and general surgeons perform 97% of the colonoscopies. There are a small number of rural Canadian Family Physicians who perform colonoscopies. These endoscopists may improve access for rural patients who require endoscopy and help improve provincial endoscopy wait times. Although some studies demonstrate that adequately trained Family Physicians are able to perform quality endoscopy, other studies question the quality of colonoscopies performed by non-gastroenterologists.

**Aims & Methods:** The Alberta Family Physician Electronic Endoscopy (AFPEE) study aimed to examine the quality of colonoscopies performed by Family Physicians. These endoscopists may improve access for rural patients who require endoscopy and help improve provincial endoscopy wait times. Although some studies demonstrate that adequately trained Family Physicians are able to perform quality endoscopy, other studies question the quality of colonoscopies performed by non-gastroenterologists.

**Results:** In this six-month study, 9 Family Physicians performed 1769 colonoscopies in 11 rural Alberta sites. The proportion of successful cecal intubations; proportion of patients 50 years and older having a polyp, and a polyp >10 mm found at colonoscopy were aged 55 (64.8% male). Additional ADR at colonoscopy was 35.2%, with malignant diagnoses in 15% (all detected at BS). The adenoma miss rate at BS was 5.2%. On univariate analysis (Table 1), polyp ≥10mm was the only indication associated with increased ADR at colonoscopy (OR 2.13, p = 0.001). Additional predictors identified included villous (not tubulovillous) histology (OR 4.41, p = 0.002), and male gender (OR 2.35, p < 0.001). These factors also significantly predicted new ≥10mm adenoma. 57% (14.8%) underwent colonoscopy outside protocol, which reduced ADR (OR 0.29, p = 0.05). After controlling for high risk indications, changing the conversion criteria from any villous to villous only altered sensitivity from 27.2% to 83.3%, and specificity from 84.5% to 80.5%.

**Table 1:** Indications for progression from BS to colonoscopy (in bold), [1] and likelihood of new adenoma detection. *Patients in multiple categories are included multiple times. **p < 0.05

1. WS Atkin, Lancet 2010, 375:1624-33
INTRODUCTION: Cold snare polypectomy is an established method for the resection of small colorectal polyps (SCPs); however, significant incomplete resection rates still leave room for improvement. We aimed to assess the efficacy of cold snare polypectomy with submucosal lift (SL-CSP) versus endoscopic mucosal resection (EMR), for nonpedunculated polyps 6–10 mm (ClinicalTrials.gov NCT02678663).

Aims & Methods: Dual-center, randomized, noninferiority trial. Consecutive adult patients with at least one nonpedunculated polyp 6–10 mm were enrolled. Eligible patients were randomized (1:1) to be treated with either SL-CSP or EMR. The primary noninferiority endpoint was histologic eradication, with a noninferiority margin of –1%. Evaluation of histologic complete resection relied on a postpolypectomy biopsy protocol (4 biopsies obtained in a 4-quadrant fashion from the polypectomy site margins; 1 biopsy from the base). Secondary outcomes included occurrence of intraprocedural bleeding (IPB; defined as any immediate episode requiring endoscopic haemostasis), clinically-significant postprocedural bleeding (CSPPB; any episode requiring emergency department presentation, hospitalization, or reinsertion within 30 days of the procedure) and perforation.

Results: Among 689 patients screened, 155 patients with 164 eligible polyps (SL-CSP: n = 83; EMR: n = 81) were included. The overall rate of histologic complete resection was 92.8% (77/83) in the SL-CSP group and 96.3% (78/81) in the EMR group (difference 3.5%; 95% CI, –4.1 to 11.56; showing noninferiority of SL-CSP compared with EMR). The rate of CSPPB technique was noninferior to EMR (5.5% vs. 1.0%, p = 0.05) and among those who did not perform advanced endoscopy (37.3% vs. 28.1%, p = 0.05). For small polyps (6–9 mm), cold snare polypectomy was most frequent among endoscopists who performed more than 10 colonoscopies per week (32.0% vs. 17.7%, p = 0.05). However, hot snare polypectomy was most frequent among endoscopists who performed less than 20 colonoscopies per week (40.7% vs. 27.2%, p = 0.05) and among those with more than 10 years in practice (<10 years vs. >10 years, 53.8% vs. 44.7%, p = 0.05).

Conclusion: There is a remarkable heterogeneity in the techniques used for removal of polyps <20 mm among Spanish endoscopists. Cold snare, hot snare and EMR are the preferred techniques to be an effective modification of standard cold snare technique, obviating the need to use diathermy for 6–10 mm colorectal polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colonicoscopy is a diagnostic tool that is essential to colorectal cancer. Variations in the technique have been implicated in the effectivity of the resection and in the complication rates. However, there is no consensus regarding the optimal polypectomy technique for diminutive (<5 mm) colorectal polyps. There are scarce of data about polypectomy practices among European endoscopists.

Aims & Methods: To determine the different techniques used by Spanish endoscopists for resection of sessile or flat colorectal polyps smaller than 20 mm. A 70-item survey was sent by email to all gastroenterologists in all Spanish hospitals (1678 gastroenterologists). The survey was conducted from December 2015 to February 2016.

Results: The rate of participation was 20.3% (341/1678). All physicians indicated they were practicing gastroenterologist (none were trainees). Most respondents (60%) were males and 50% had more than 14 years in practice. The mean number of colonoscopies per week was 21 ± 12.3. Half of participants performed endoscopies for ≥3 days per week and 49.6% did not performed advanced therapeutic endoscopy. The techniques used for the excision of polyps smaller than 20 mm were: cold snare (by Spanish clinicians are summarized in Table 1). Significant differences were noted in the polypectomy techniques used for the resection of polyps 1–3 mm, 6–9 mm and 10–19 mm in diameter; being cold forceps, hot snare and endoscopic mucosal resection (EMR), the preferred techniques respectively for the different sizes. However, for polyps 4–5 mm in size, both the cold snare and cold forceps were the most commonly used techniques, though no method was use more often than the other. Years in practice, colonoscopy volume per week and performing advanced therapeutic endoscopy were associated with different choices of polypectomy technique. For polyps measuring 4–5 mm, cold snare was the favourite method among endoscopists who performed ≥20 colonoscopies per week (>20 colonoscopies/week vs. <20 colonoscopies/week, 42.4% vs. 26.6%, p < 0.05), among those who performed endoscopies >5 days/week (≥5 days/week vs. <5 days/week, 49.6% vs. 25.7%, p < 0.05) and among those who performed advanced endoscopic advanced advanced (EMR) to non advanced advanced (EMR), 40.4% vs. 29.2%, p < 0.05). However, cold forceps was the preferred technique among endoscopists who performed endoscopies <3 days per week (38.9% vs. 22.6%, p < 0.05). No CSPPB or perforation occurred in either group.

Conclusion: There is a remarkable heterogeneity in the techniques used for removal of polyps <20 mm among Spanish endoscopists. Cold forceps, hot snare and EMR are the preferred techniques to be an effective modification of standard cold snare technique, obviating the need to use diathermy for 6–10 mm colorectal polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.
Results: On average, experts required the shortest time to reach the caecum, followed by video gamers, trainees then novices. Polyp detection rate (as a proportion of total number in the model simulator colon) was the highest in the novices (91.67%) followed by the experts (86.11%), then equally, trainee and video gamers (79.17%). Four out of nine participants attended the second session where they were asked to repeat the procedure from the first session. Each participant had a lower caecal intubation time during session 2 in comparison with session 1. The depth of improvement of the Accuracy, Sensitivity, and specificity was 90% and 70%, respectively. Each of the participants also had the same or higher polyp detection rate with range of improvement between 0% and 25%. Qualitative assessment of feedback from all participants indicated that most experts felt that the role of the novel test would be likely to provide a diagnostic priori in an out of hospital setting. Expert operators felt that training in the device was easier but also provided less ability to torque steer due to automated sequences.

Conclusion: This project is the first step in identifying specific training needs and providing improved early diagnosis of cancer. This study also has the potential to reduce the length of time for skills acquisition associated with standard colonoscopy training through the use of semi-automated robotic devices.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Yao et al. observed gastric epithelial neoplasms and chronic gastritis using endoscopy on magnification imaging, which visualized subepithelial microvasculature (1). Furthermore, the morphology of the WOS is a useful marker for differentiating between adenoma and carcinoma in gastric epithelial neoplasms (1). Recently, we reported for the first time that WOS is also detected in colorectal epithelial neoplasms (2). However, it is unclear whether the morphology of the WOS in colorectal epithelial neoplasms is useful in the differential diagnosis of adenoma and carcinoma in colorectal epithelial neoplasms. The primary endpoint was the diagnostic performance of morphological analysis of the WOS (accuracy, sensitivity, specificity) for early colorectal cancer taking irregular WOS as an indicator. The secondary endpoint was the diagnostic accuracy for the differentiation between early cancer and adenoma using irregular WOS as an indicator of cancer was 87%. The sensitivity was 91% and specificity was 86%. The frequency of irregular WOS in M or SM-s cancer and SM-m cancer was 67.8% (21/31) and 75% (19/25), respectively. There was no significant difference in the prevalence between irregular WOS in M or SM-s cancer and SM-m cancer (p = 0.727, chi-square test).

Conclusion: These findings suggest that in colorectal epithelial neoplasms in which irregular WOS was visualized because of WOS, the morphology of the WOS may be a useful marker in the differential diagnosis of adenoma and carcinoma using magnifying endoscopy.

References
Aims & Methods: Colon cleansing efficacy of NER1006 was compared to three currently used bowel preparations in patients aged ≤65 years and in patients aged >65 years. NER1006 was compared to sodium picosulfate + magnesium citrate (NaPic + MgCit), trisulfate and 2L PEG with ascorbate (2L PEG + Asc), in three multicentre randomised Phase 3 clinical trials: DAYB, NOCT and MORA, respectively. 2L PEG + Asc was administered over 2 days and in the MORA trial, the doses of NER1006 were administered either both in 1 day morning-only (N1D) or, as with 2L PEG + Asc, split over 2 days (N2D). In the DAYB study, NER1006 was administered evening-only the day before colonoscopy (NDB). Treatment-blinded central readers rated colon cleansing according to the Harefield Cleansing Scale. Following segmental scoring, overall colon cleansing was graded from A to D. Grades A and B were judged as successful cleansing; grades C and D were judged as failed cleansing.

Results: Pooling the data from the three trials to assess colon cleansing in the two age groups showed successful cleansing in 80.5% (1158/1438) of patients aged ≤65 years, whereas in patients aged >65 years, successful cleansing was 75.6% (277/368) of patients aged >65 years (difference of 8.9%, 95% CI: 4.1–12.3%). Within each trial the difference in colon cleansing in the age groups indicated that the effect of increased age on cleansing efficacy was greater in the NER1006-treated patients than in patients treated with the active comparators (Table 1). For example, in patients treated with NER1006 the rate of successful colon cleansing in patients aged >65 was 5.2% higher than in patients aged ≤65, whereas in patients treated with NaPic + MgCit, there was 3.5% lower successful cleansing rate in patients aged >65 than in patients aged ≤65.

Conclusion: NER1006 was efficacious in successful colon cleansing in patients aged >65 (in whom successful colon cleansing is harder to achieve) as well as in patients aged ≤65. Statistical significance was not reached in these comparisons.

P0184 ACHIEVING ADEQUATE LEVEL BOWEL PREPARATION WITH EVENING/MORNING OR MORNING-ONLY SPLIT-DOSING REGIMENS OF NER1006 VERSUS STANDARD 2L PEG WITH ASCORBATE: POST HOC ANALYSIS OF A PHASE 3 TRIAL

R. Bisschops1, L. Clayton2

1Gastroenterology, Katholieke Universiteit Leuven, Leuven/Belgium
2Clinical Development, Norgine Ltd., Harefield, Uxbridge/United Kingdom

Contact E-mail Address: ralf.bisschops@uliege.be

Introduction: Effective colonoscopy requires effective bowel preparation. For detection of polyps larger than 5 mm, an ‘adequate’ segmental cleansing level has recently been defined as 2 or more on the Boston Bowel Preparation Scale (BBPS). The Phase 3 trial MORA compared NER1006 as an evening/morning split-dosing or a morning-only dosing regimen, against 2L PEG with ascorbate as an evening/morning split-dosing regimen (2L PEG + Asc). Treatment-blinded central readers assessed the bowel cleansing efficacy using both the Harefield Cleansing Scale (HCS) and the BBPS. This post hoc analysis shows the BBPS scores for the two primary endpoints, in those patients who had a readable colonoscopy.

Aims & Methods: In the MORA trial, 794 patients aged 18–85 were randomised to bowel preparation with morning-only or evening/morning split-dosing using either NER1006 or 2L PEG + Asc. Adequate level cleansing success was assessed according to the BBPS for both overall colon (all segments ≥2) and right colon cleansing (segmental score ≥2). The analysis includes all subjects for whom colonoscopy videos were available for assessment by central readers.

Results: A total of 792 patients were analysed. When using an evening/morning split-dosing, 249/262 (95%) patients on NER1006 achieved adequate level overall colon cleansing compared to 232/260 (89%) on 2L PEG + Asc (Table 1). Using morning-only dosing, 243/270 (90%) patients on NER1006 achieved the same. Using evening/morning split-dosing, 254/262 (97%) patients on NER1006 achieved adequate level right colon cleansing compared to 242/260 (93%) on 2L PEG + Asc. Using morning-only dosing, 253/270 (94%) patients on NER1006 achieved adequate level right colon cleansing. Adequate level cleansing success was achieved significantly more often with NER1006 evening/morning split-dosing than 2L PEG + Asc, both in the overall colon (P = 0.013) and in the right colon (P = 0.042). The slight improvement seen with NER1006 morning-only dosing in the cleansing rate of the overall colon and right sided colon was not statistically significant. Table 1: Adequate level cleansing of the overall colon and right colon (BBPS segmental scores ≥2–3) as determined by treatment-blinded central readers

**P0186 SEDATION IN GASTROINTESTINAL ENDOSCOPY: CURRENT PRACTICES OF GREEK GASTROENTEROLOGISTS**

A. Protopapas, E. Stournaras, G. Neokosmidis, A. Protopapas
1st Department Of Propaedeutic Internal Medicine, Ahepa Hospital, Thessaloniki, Greece

**Contact E-mail Address:** adoprot@hotmail.com

**Introduction:** When it comes to gastrointestinal endoscopy, considerable heterogeneity is observed between gastroenterologists regarding the use of sedation and the preferred sedative agents. The sedation protocol used by a gastroenterologist may have a significant effect on endoscopic quality, patient cooperation and both the doctor's and the patient's satisfaction with the procedure.

**Aims & Methods**

The aim of this study was to document current endoscopic practices of Greek gastroenterologists and investigate whether they use sedation to perform gastrointestinal endoscopy and which pharmaceutical agents are usually involved. A 39-item online questionnaire was devised, addressing demographic data, use of sedation in endoscopy and monitoring practices. It was subsequently made available to 509 Greek gastroenterologists by e-mail.

**Results:** A total of 195 questionnaires were successfully completed (38.3%). 49 gastroenterologists did not use sedation to perform esophagogastroduodenoscopy (EGD) or colonoscopy (25.1%). The younger gastroenterologists were more likely to use sedation (p = 0.005). Among those using sedation, midazolam was the most frequently used agent in EGD (50%) and the combination of midazolam/fentanyl was the most frequently used in colonoscopy (24.6%), followed by midazolam (21.9%). Out of 137 physicians using benzodiazepines (midazolam, diazepam) as part of their endoscopic sedation regimen, 91 (66.4%) routinely used flumazenil to facilitate pharmacological antagonism after the completion of the endoscopy. In total, 45 physicians, 23.1% of the participants and 30.8% of those using sedation, used propofol or a combination of propofol and other agents. 30 gastroenterologists routinely administered propofol without the aid of an anesthesiologist (66.6%). Medicolegal issues (33%), inadequate training in the use of propofol (26.4%) and risk of cardiopulmonary complications (23.6%) were cited as the main reasons for not using propofol. As far as monitoring practices go, the majority of gastroenterologists observed heart rate and oxygen saturation (96% and 97% respectively). Regarding the safety equipment available to the gastroenterologists, 160 (82%) reported having access to devices or laryngeal airway masks, 92 (47%) to endotracheal intubation equipment and 86 (44%) to a defibrillator. When asked to rate their level of satisfaction with their preferred sedation regimen (or with not using sedation) in a scale of 1 to 10, 72 physicians rated their satisfaction level as 9 or 10 (36.9%) and 92 as 7 or 8 (47.1%). While there was no significant difference in terms of satisfaction between the doctors that used sedation and those who did not, there was a statistically significant difference between the gastroenterologists that used propofol (alone or in combination with other agents) and those who used other sedative agents (p = 0.003). When asked on their preferred method of sedation, if they were themselves subjected to gastrointestinal endoscopy, 104 physicians opted for propofol-based sedation regimens (53.3%).

**Conclusion:** Gastrointestinal endoscopy is performed with the use of sedation by the majority of Greek gastroenterologists. Propofol-based regimens are seldom used in everyday clinical practice, despite a vast number of Greek gastroenterologists identifying them as their preferred regimen, in case they themselves should undergo endoscopy. Compared to a past survey, Greek gastroenterologists are still hesitant about using propofol. However, an increasing tendency towards administering propofol without the aid of an anesthesiologist is observed. Also, physicians using propofol seem to be more satisfied with their sedation practices than the doctors using other sedation regimens. Absence of a distinct legal framework, inadequate training and fear of cardiopulmonary complications are identified as the main reasons preventing Greek gastroenterologists from using propofol.

**Introduction:** Indicators for colonoscopy quality assessment were developed and promoted during this last decade. However technical and human resources constraints limit local implementation of continuous recording of endoscopic quality indicators (QI). Automatic system of data extraction and presentation could help endoscopy units in their seek for quality improvement. We hereby report our local experience in implementing colonoscopy QI record through an automatic data extraction from separate databases (DB), and assess the colonoscopy quality at unit and individual levels.

**Aims & Methods:** We locally adapted a company reporting system for colonoscopy by adding in a dedicated tab, selected procedure indicators. Endoscopic QI data from reporting system DB and pathologic results from another DB were extracted and merged together in a separated DB. On a regular period basis or on request, key QI are calculated and extracted. It includes adenoma detection rate (ADR), polyp detection rate, caecal intubation rate, quality of bowel preparation (using the Boston bowel preparation score) and type of sedation. During a first period of 6 months starting in January 2016, endoscopists were encouraged to fulfill the dedicated tab on a voluntary basis. In a second period, filling of QI was mandatory for all endoscopists. Performance measures of all endoscopists were compared to global results of our department and results from second period are presented. Performance measures of all endoscopists were compared to global results of our department and results from second period are presented. Performance measures of all endoscopists were compared to global results of our department and results from second period are presented.

**Conclusion:** In a March-April 2016 “mandatory-filling period” (July-December 2016), 1802 colonoscopies were performed with a QI tab filled in 100% of cases compared to 63.1% after the “free-filling period” (p < 0.0001). The global caecal intubation rate for screening colonoscopy was 92.9%. Mean Boston bowel preparation score was 7.2 ± 0.76 with 86.9% of cases with adequate preparation (Boston score > 5; 89.9% among outpatients and 81.9% among inpatients). Colonoscopies were performed under propofol sedation in 94.1%. During this second period, the global ADR was 32.4% (range: 0–55.7%). The polyp detection rate was 44.4% with a mean of 1.19 polyp removed by colonoscopy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Aims & Methods: The aim of this study was to develop a computer-aided detection (CAD) algorithm for colonoscopy using deep learning. To evaluate the developed CAD algorithm, we retrospectively viewed colonoscopy videos from a previous randomized controlled study (UMIN000017083) conducted from April 2015 to October 2015. All examinations were performed using CF- HP500i (Olympus Medical Corp., Tokyo, Japan). In this study, two endoscopists (M.M, Y.M.) manually annotated 43 colonoscopy videos with 238 min of 17,903,967 frames. These videos included 75 polyps (48 neoplasms, 27 non-neoplasms), and annotations were made on the presence or absence of polyps in every frame. Forty-three videos were divided into 300 short video for machine learning and validation process. Among 300 short videos, 246 were used for the machine-learning process. The remaining 54 (33 included a lesion used to validate the CAD algorithm and 21 as independent data) were evaluated using a full high-definition quality using VHO-1000MD (Sony Corp., Tokyo, Japan).

The remaining 54 (33 included a lesion used to validate the CAD algorithm and 21 as independent data) were evaluated using a full high-definition quality using VHO-1000MD (Sony Corp., Tokyo, Japan).

Results: The mean probability of a poly-positive video was 62.1±27.9%, whereas that of a poly-negative video was 18.1±24.6% (P < 0.001). The area under the ROC curve was 0.887, indicating the present algorithm could detect a polyp with 90.9% sensitivity and 76.2% specificity.

Conclusion: Our preliminary results showed that state-of-the-art artificial intelligence has the potential for achieving automatic detection of colorectal polyps. A prospective study is now planned after more machine-learning sessions.

Introduction: The results of the Poloid Study Popy are premised on the removal of all adenomatous lesions. Cold forces polypectomy (CFP) using jumbo biopsy forceps is a simple and safe technique used for diminutive polyps (<5 mm). The recurrence rate after CFP for patients with diminutive polyps has not been elucidated.

Aims & Methods: We have prospectively enrolled patients with diminutive polyps treated with CFP from June 1, 2015 to March 2017. Multiple colonoscopy was used for all procedures. The location, size, endoscopic findings and procedures were recorded. The patients who have undergone CFP had their follow-up colonoscopy in one year after CFP.

Results: CFP was performed for total 515 polyps from 277 patients. The size of the polyps was <3 mm/4–5 mm/5 mm/3.3 ml/379/101.36. The rate of one-bit polypectomy for adenoma was <3 mm/4–5 mm/5 mm/379/101.36. There was no significant difference in the one-bit rate between endoscopists’ experience. No cancer was observed in histology. Rates of delayed bleeding after CFP was 0.19% (1/515). Concomitant use of anticoagulation use of antplatelet drugs was found in 14% (72/458), and none of them experienced delayed bleeding. No perforation occurred. Seventy-five patients had their follow-up colonoscopy so far. There are no polyps suspected residual or recurrent lesions. Among 75 patients, 62 patients had less than two polyps removed at their first colonoscopy (Group A). On the other hand, 33 patients had more than three polyps removed at their first colonoscopy (Group B). Follow-up colonoscopy revealed that the rates of newly discovered polyps in the same segment were 8% and 23% in groups A and B, respectively. The rates of newly discovered polyps in the different segment were 27% and 61% in groups A and B, respectively. When the initial CFP was performed by the endoscopist with the experience of <5 years/5–9 years/10 years/more than 10 years, the rate of newly discovered polyps found at follow-up colonoscopy was 54% (14/26)/42% (8/19)/37% (11/30), respectively.

Conclusion: The rate of one-bit polypectomy was significantly higher for diminutive polyps especially less than 3 mm. Importantly there are no polyps suspected residual or recurrent lesions in the following colonoscopy. CFP is a safe and effective option for diminutive polyps (5 mm). Although the rate of one-bit polypectomy was not related to the endoscopists’ experience, adenoma detection rate is seemed to be low in young endoscopists. Since achievement of “clean colon” is necessary to achieve “clean colon” especially if the patients have more than two polyps at the first examination.

Introduction: Colorectal cancer (CRC) accounts for up to 11% of all cancers in women and 14% of men in Ireland, and is the second most common cancer across sexes. The adenoma-carcinoma sequence of colorectal carcinogenesis lends itself to screening with the aim of complete excision of polyps. It has been estimated that incomplete resections of polyps are involved in 19–31% of interval cancers. ESGE guidelines state that polyps 5 mm or greater should be removed by snare resection. Previous cohort studies report non-adherence rates of up to 46% with some trend towards more propofol per kg body weight in women (3.98 ± 1.81 mg versus 3.72 ± 1.75 mg, p = 0.022, n.s.).

Main outcome measures: The effect of gender aspects should be taken into account upon polyp induced sedation for gastrointestinal endoscopy. That includes adequate dosing for female as well as cautiousness regarding potential overdosing of male patients.

Trial registration: ClinicalTrials.gov (Identifier: NCT02687568). Data were presented at a national meeting (DGEBV) in Germany.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Sedation for colonoscopy by using intravenous propofol has become standard in many Western countries.

Aims & Methods: While gender-specific differences have been shown for general anaesthesia used in dentistry, no such data exist as yet for gastrointestinal endoscopy. In a prospective observational study at an Academic teaching hospital of Hannover Medical School 219 patients (108 women and 111 men) were studied. After informed consent sedation was using EEG monitoring during a constant level of sedation depth (D0 to D2) performed by trained nurses or physicians after bodyweight adjusted loading-dose.

Main outcome measures: Primary endpoint was the presence of gender-specific differences in wake-up time (time from end of sedation to eye - opening and the complete orientation of the patient); secondary outcome parameters analysed were total dose of propofol, sedation associated complications (bradycardia, hypotension, hypoxia, apnoea), patient cooperation and patient satisfaction. Multivariate analysis was performed to correct confounding factors such as age and BMI.

Results: Women awake significantly faster compared to men with a time to eye opening of 26.2 ± 3.69 versus 31.9 ± 3.31 min. (p = 0.005) and time until complete orientation 9.14 ± 3.88 versus 10.4 ± 3.71 min (p = 0.008); propofol dosage was not significantly different, with some trend towards more propofol per kg body weight in women (3.98 ± 1.81 mg versus 3.72 ± 1.75 mg, p = 0.022, n.s.).

The effect of gender aspects should be taken into account upon polyp induced sedation for gastrointestinal endoscopy. That includes adequate dosing for female as well as cautiousness regarding potential overdosing of male patients.

P0196 EFFECT OF PREOPERATIVE COLONOSCOPIC TATTOOING USING BOTH SIDE INJECTION OF INDOCYANINE GREEN FOR IMPROVEMENT OF LYMPH NODE HARVEST IN COLORECTAL CANCER

Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of

Contact E-mail Address: mdkkwcock@gmail.com

Introduction: Consensus guidelines suggest to assess at least 12 lymph nodes for adequate staging of colorectal cancer and the correlation between number of lymph nodes retrieved and the patient survival has been formerly reported. To facilitate the retrieval of lymph nodes, preoperative endoscopic tattooing to mark the site of the tumor has been proposed. In this study, we aimed to evaluate the effect of preoperative colonoscopic tattooing (PCT) using indocyanine green (ICG) for lymph node harvest in colorectal cancer. Additionally, we evaluated the effect of both side injection of ICG for improving the rate of adequate lymph node harvest.

Aims & Methods: 1023 patients who underwent curative resection for colorectal cancer between Jan 2012 and Aug 2016 at the Pusan National University Yangsan Hospital in Korea were retrospectively divided into the tattooing group and the non-tattooing group depending on whether PCT using ICG was done. Pathological findings and lymph node harvest were compared between the two groups.

Results: The rate of adequate lymph node harvest (retrieval of more than 12 lymph nodes) was similar in tattooing group and non-tattooing group (91.9% vs. 91.4%). However, when comparing the both side injection group and...
nontattooing group, both side injection group was better result (94.7% vs. 92.0%, OR 4.235, p-value 0.047). Most results did not have statistical association with higher lymph node yield in colorectal cancer. But in T1 cancer, the rate of adequate lymph node harvest was higher in the both side injection group, statistically (94.7% vs. 81.0%, OR 4.235, p-value 0.047).

Conclusion: CSP was associated with higher lymph node harvest in colorectal cancer, especially in T1 cancer. And both side injection of ICG increased the rate of adequate lymph node harvest. Further studies and methods are needed to harvest adequate lymph nodes in colorectal cancer.

Introduction: Prevention of complications secondary to endoscopic resection techniques (EMR or ESD) requires avoiding deep thermal damage and increase mucosal healing. Platelet-rich plasma (PRP) has demonstrated efficacy in preclinical studies and endoscopic resection models [1]. The EndoPRP study was a prospective single-center study to assess the efficacy of PRP on endoscopic resection of large sessile lesions (larger than 35 mm). (Study registered at ClinicalTrials.gov: NCT02931149)

Aims & Methods: In the EndoPRP study 15 patients (males and females, aged 52–80) were assigned to receive PRP (6–15 mL); i) Endoscopic Shielding Technique (EST, n = 4), applying PRP as a shield after standard resection technique, and ii) Submucosal injection (SMI, n = 11), performing a submucosal injection of PRP prior to EMR or ESD. Patients were informed and accepted to participate with a written consent. PRP was obtained from a sample of patient’s blood (18–36 mL) drawn at the time of endoscopy. Patients underwent endoscopic follow-up after 4 weeks. The efficacy of PRP was assessed by the incidence of adverse events (delayed bleeding or perforation). Mucosal healing rate (MHR) was defined as a percentage of mucosal restoration after 4 weeks.

Results: Shielding technique with PRP was performed in 4 lesions at rectum (Æ 53.7±20.6 mm, range 35–80 mm). Submucosal injection of PRP was used in 11 lesions (2 at antrum, 3 at rectum, and 8 at colon) (Æ 41.6±9.6 mm, range 35–70 mm). Delayed bleeding occurred after EMR of 1 lesion (no required blood transfusion or endoscopic treatment; 6.6% of all lesions: 1 patient at EST group, 0 patients at SMI group). MHR was significantly higher in patients treated with SMI than EST (p = 0.03).

Conclusion: PRP applied as a shield over the scar or as submucosal fluid cushion has proved clinical efficacy in endoscopic resection of large lesions. Submucosal injection of PRP has showed better mucosal healing rate as comparison with shielding technique.

with a defined AE. Treatment options, including none required, were taken from SoC-defined lists and were examined by the AE committee. Unrelated procedures, unplanned hospital admission, and death. Payers were surveyed about costs for interventions, provider time, hospital administration, and admissions. Outliers were identified using Dixon’s Q test. The mean treatments and outcomes per AE per country were calculated with responses weighted by the AE frequency reported by physicians and the outliers replaced by global means. Mean costs were calculated per intervention and outcome, with outliers removed.

**Results:** 101 providers and 26 payers completed the surveys, with a minimum of 20 respondents per country with 52 (53%) respondents per country. Over 62% of providers were gastroenterologists and anaesthesiologists. Local guidelines determined practice in most cases, and propofol and midazolam were the main sedation agents employed. The most common AEs reported were hypotension and bradycardia, with 9% and 4% of respondents, respectively, estimating each to occur during >10% of procedures. Mean provider time required to treat AEs ranged from 1.7 minutes for mild desaturation in Germany to 3.10 minutes for cardiac arrest in the USA. Accounting for interventions and provider time, the median direct cost per range from EUR 12 for bradycardia in Germany to USD 3,877 for cardiac arrest in the USA (Table). When costs were “fully loaded” these became EUR 39 and USD 19, 722, respectively. Although of low direct cost, bradycardia in Germany was reported to cause procedure termination or substantial delay in 3.8% of cases. In Euro countries, the median of direct costs for an AE was EUR 40 (IQR: 29–67). When costs of outcomes of AEs were included the median “fully loaded” cost reached EUR 301 (IQR: 115–738).

**Table:** Costs of select adverse events by country. FL: Fully-loaded (costs including hospital administration, time, inpatient stays, delays, and cancellations, but excluding legal costs)

**Conclusion:** Costs of sedation-related AEs can be substantial regardless of country of origin. Disruption of patient flow and provider efficiency may add to the cost burden. Even relatively minor events may prompt additional intervention, increasing the overall cost of care.

**Introduction:** Performing CR-ESD remains challenging in Western countries and surveillance studies in this setting are not fully described. KAR has been advised as a reasonable strategy for non-expert endoscopists and difficult lesions. However, some KAR eventually requires a piecemeal resection (p-KAR). A direct comparison between these two techniques is lacking. Additionally, when the specimen is resected en bloc regardless of what procedure is used, and the only pathological risk factor for recurrence is lateral margin (LM) involvement, its implications concerning the recurrence rate should be assessed.

**Aims & Methods:** 1.) To compare the recurrence rate after R0 and R1/Rx endoscopic resection (ER), on an ESD “intention-to-treat” basis, in a Western European setting where CR-ESD is performed by non-experts. 2.) To evaluate the impact of LM involvement on local recurrence when neoplasms without risk factors for lymph node metastasis are resected en bloc. We prospectively included 89 consecutive CR neoplasms planned for ESD from September 2008 to December 2015. When technical difficulties arose or for patient’s safety reasons, we performed a KAR. Kaplan-Meier survival curves were used to assess the recurrence rate over time. The end of follow-up was considered when a local recurrence occurred or at the end of the surveillance period in those patients who did not develop the event. Comparisons were made using the log-rank test. The recurrence rate during follow-up was stratified considering advanced histology, en bloc resection and R0 resection.

**Results:** The ER was aborted in 5 cases (perforation n = 3; technical difficulties n = 2). Surgical intervention was needed after ER because of submucosal or linfvascular invasion in 4 patients. Five out of the remaining 80 cases, were lost to follow-up. Finally, 75 CR neoplasms were included in 74 patients (43 male; 58.1%). Median age was 71 years (range: 37–93). Median size of the lesions was 32 mm (range 10–100). Histology was 26 (34.7%) Vienna category 3; 46 (61.3%) Vienna 4 and 3 (4%) sm1-Vienna 5. En bloc resections were obtained in 44 cases (58.7%); 33 ESD (48%) and 11 KAR (14.7%). The ER finished as p-KAR in the 31 remaining lesions (41.3%). R0 resections (n = 23; 30.7%) were achieved in 18/33 ESD and 5/42 KAR [OR = 8.9 (CI 95%: 2.8–28.3); p < 0.0001]. The median follow-up period was 16 months (IQR: 9–61). Local recurrence occurred in 11 cases: 9 of the latter throughout the first year (18.8%). No surgery was needed because of recurrence. The overall recurrence rate at 36 months was 15%. The recurrence rate at 3 years showed a statistical significant difference when R0 resections were compared with R1/Rx: 0% vs. 21.5% (p = 0.03). When results were stratified according to histology and en bloc resections, no significant differences were found in the recurrence rate. When en bloc resections in pT1a/T1b (sm1); y; c; (+); pVM0 lesions (n = 44) were analysed separately, LM distribution was: 23 LM0 (52.3%), 18 LM1 and 3 LM3 (6.8%). There was a non-significant trend concerning the recurrence rate when LM0 (n = 23) lesions were compared with LM1/LMx (n = 21%): 0% vs. 14.8% at 3 years; p = 0.06.

**Main characteristics of the resected lesions by procedure**

**Conclusion:** ESD R0 resections were 9 times greater than that of KAR on an ESD “intention-to-treat” basis. R0 resections were associated with lower recurrence rates in comparison with R1/Rx resections. LM involvement increased the recurrence rate but without a statistical significance when it was the only pathological risk factor for recurrence and the specimen was resected en bloc.

**P0201 ASSOCIATION BETWEEN SIZE, LOCATION AND HISTOLOGICAL CHARACTERISTICS OF COLORECTAL LATERALLY SPREADING TUMORS**

F. L. Mota1, J. F. Loureiro1, L. S.N, Da Costa1

1Digestive Endoscopy, Hospital Sirio-Libane's, SAO PAULO/Brazil

**Contact E-mail Address:** lucasmo@gmail.com

**Introduction:** Laterally spreading tumors (LST) are important precursors of colorectal cancer (CRC). The endoscopic characteristics of the LSTs, such as size and location, appear to correlate with the histological findings, which is an essential data for the decision of the best therapeutic procedure to be carried out.

**Aims & Methods:** To determine the association between size, location and the histological characteristics of colorectal LSTs by reviewing of the colonoscopy and histopathological reports of the LSTs endoscopically removed between October 2013 and June 2015 at the digestive endoscopy department of a tertiary hospital. The Vienna revised classification was used for the adenomatous lesions, and the World Health Organization (WHO) classification for the “sessile serrated adenomas” (SSA). The regions of the colon were referred to...
as either “proximal” or “distal” colon. Thereafter the division into six anatomical segments was considered (cecum, ascending, transversal, descending, sigmoid and rectum).

**Results:** A total of 218 LSTs were included in this study. Most patients (59.4%) were female. The mean age was 66.1 years, and the average size of the LSTs included was 1.69 cm. The most common type of occurrence of the LSTs, with 34.3%, was the proximal ascending colon. The most common histological type was the low grade dysplasia adenoma (Vienna 3), followed by the SSA without dysplasia with 21.6%. There was significant correlation between size and histology (p < 0.005), where the adenomas/malignant lesions were found to be larger than the other categories. The SSAs, however, did not show this association. We identified association between location and histological type (p < 0.005): the adenomas with low grade dysplasia were most prevalent in the proximal colon. However, when the subdivision of the colon into anatomical segments was considered, the SSA without dysplasia was the most common type at the ascending colon.

**Conclusion:** There is association between the size and the histological characteristics of colorectal LSTs. Adenomas with high grade dysplasia were found to be larger than the other classifications. This association, however, is not observed between SSAs lesions. There is association between location and histology; with the SSAs without dysplasia being the predominant type at the ascending colon.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0202 SAFE AND SUCCESSFUL RESECTION OF DIFFICULT GI LESIONS USING A NOVEL SINGLE-STEP FULL-THICKNESS RESECTION DEVICE (FTRD)**

P.V. Valli, J. Mertens, P. Bauerfeld
Division of Gastroenterology And Hepatology, University Hospital Zurich, Zurich/Switzerland

**Contact E-mail Address:** piero.valli@usz.ch

**Introduction:** Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are well-established and effective techniques for the endoscopic resection of mucosal neoplasms along the gastrointestinal (GI) tract. However, these procedures are limited to superficial lesions. In the case of deeper ingrowth into the gut wall as well as anatomic sites prone to perforation, the removal of full-thickness resection device (FTRD®) opens a new dimension of possibilities for endoscopic resection.

**Aims & Methods:** Sixty patients underwent therapeutic endoscopic full-thickness resection (eFTR) at our institution. The procedures were carried out as follows: First, the target lesion is marked with electrocautery and the endoscope is then retracted. The full-thickness resection device (FTRD, Ovesco® Endoscopy AG, Tübingen), is fitted onto a therapeutic endoscope. The endoscope with the FTRD® is advanced to the previously marked lesion. Grasping forces are used to take hold of the target lesion and carefully pull it into the plastic cap of the FTRD®. Immediately after deployment of the OTSC®, eFTR is performed using the hydrothermic snare within the plastic cap. The full-thickness specimen is retrieved and processed for histopathological examination. Safety, learning curve, R0 resection rate and clinical outcome of all 60 interventions were studied.

**Results:** EFTR was performed for the following indications: 1. Recurrent adenomas (n = 22.3%) with a non-lifting sign after previous incomplete polypectomy and adenomas with a primary non-lifting sign on saline injection (n = 23%). 2. Non-lifting base after extensive piecemeal resection of a spreading adenoma (n = 4), rectal diverticulum (n = 3%). 4. Polyposis the cecal appendix (4.6%). 5. Submucosal lesions (n = 5,8%). 6. Early carcinoma (n = 7,1%). 7. Follow-up resection of a malignant polyp (n = 0,1%) had. 8. EFTR over endoloop resection (n = 2,3%). In 97% (38/40) of the interventions, the FTRD®-mounted endoscope reached the previously marked lesion and eFTR was performed (technical success). Full-thickness resection was achieved in 88% of the cases, with an R0 resection on histological examination in 79%. The clinical success rate based on follow-up histology was even higher (88%). The following adverse events occurred: Apendixitis of the residual cecal appendix after eFTR of an appendiceal adenoma (1/58,2%). Minor bleeding at the eFTR site (2/58,3%). EFTR performed accidently without proper prior deployment of the OTSC® (1/58,2%). There was no secondary perforation or eFTR-associated mortality.

**Conclusion:** In conclusion, after specific training, endoscopic full-thickness resection is a feasible, safe and promising resection technique. It allows complete resection of lesions affecting layers of the gut wall beneath the mucosa, without the risk of perforation. In the future, eFTR may become a valuable alternative to a surgical approach in cases where endoscopic resection was previously thought impossible.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0203 VASCULAR AND PIT-PATTERN ANALYSIS ACCORDING TO KUDO, SANO AND NICE CLASSIFICATIONS IMPROVES AFTER AN IMAGE-BASED TRAINING PROGRAM**

F. Desideri1, G. Esposito1, S. Angetelli1, F. Iacopini1, M. Haefner1, E. Di Giulio2

**Contact E-mail Address:** federico.desideri@gmail.com

**Introduction:** Narrow Band Imaging (NBI) and chromoendoscopy with methylene blue are enhancing techniques which are helpful in differentiating vascular and pit patterns of colorectal neoplasms. Therefore, they have a key-role for the adequate management of the lesions which might be candidates for endoscopic resection.

**Aims & Methods:** The aim of our study was to measure the interobserver agreement and the diagnostic accuracy in an endoscopic unit using methylene blue and NBI for the evaluation of the pit and vascular pattern according to the Kudo, Sano and NICE classifications of colo-rectal neoplasms, before and after an image-based training program. We retrospectively collected consecutive endoscopic images (NBI and with methylene blue) of colo-rectal neoplasms from the internal database. The image set was then evaluated by our gold standard composed by two expert endoscopists. Their evaluation resulted confident with histology reports in 88% of cases. The images set was then evaluated by the 9 endoscopists of the unit, before and after a 30-minutes image-based training program on enhancing techniques and surface colorectal patterns. NBI and colonic neoplasms' surface and vascular patterns. Interobserver agreement was calculated using the kappa statistic by Cohen. By using the gold standard evaluation as criterion standard, the accuracy of colo-rectal neoplasms' evaluation before and after the training was also calculated using the Mc Nemar test. A value of p < 0.05 was considered statistically significant.

**Results:** A total of 30 images were obtained (see Table). Before the training process, the interobserver agreement was minimal for Kudo (0.10 ±0.03) and Sano (0.12 ±0.04), and poor for the NICE classification (0.24 ±0.05). Diagnostic accuracy was 0.33 ±0.07, 0.54 ±0.12 and 0.60 ±0.10 for Kudo, Sano and NICE classifications, respectively. After the image-based training program, interobserver agreement moved to moderate for the Kudo classification (p < 0.0001) and to good for Sano and NICE classifications (p < 0.0001). Diagnostic accuracy increased significantly, too, with values of 0.60 ±0.05, 0.76 ±0.05, 0.80 ±0.05 for Kudo, Sano and NICE classifications, respectively (p < 0.0001).

**Conclusion:** To the best of our knowledge, we present the first study on the ability of an image-based training program in increasing the interobserver agreement and diagnostic accuracy in differentiating pit and vascular patterns of colo-rectal neoplasms using all the available endoscopic classifications (Kudo, Sano and NICE classifications). Such training seems mandatory for endoscopists using enhancing techniques especially when advanced lesions are planned to be treated endoscopically.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Data regarding the yield of 2nd surveillance colonoscopy after index procedure findings of advanced colonic neoplasia (ACN) are limited. The yield of ACN at 2nd surveillance is associated with high risk index or 1st surveillance findings (1). However, previous studies have been heterogeneous and definitions of ACN include characteristics of both "intermediate" (IR, >3 adenomas or any adenoma >10 mm) and "high risk" groups (HR, >5 adenomas or >3 adenomas with at least 1 >10 mm) as defined by BSG guidelines.

Aims & Methods: We aimed to evaluate the differences in yield of advanced colonic neoplasia at 2nd surveillance colonoscopy (S2) between “intermediate” and “high” risk patients at index colonoscopy in our unit. ACN was defined as ≤5 adenomas, any adenoma ≥1 cm, tubulovillous histology or high grade dysplasia, or cancer. Patients with HR or IR index procedures undertaken by 3 experienced, accredited bowel cancer screening colonoscopists and at least 2 surveillance colonoscopies, were identified from our local database between 2008 and 2016. Findings at 1st and 2nd surveillance procedures were assessed for the presence of ACN. Statistical analysis was undertaken using GraphPad Prism 5 using Fisher’s exact test. All tests were two tailed and a p value of <0.05 was considered significant. ORs with a 95% CI were calculated for significant findings.

Results: 218 patients meeting inclusion criteria were identified. 53% of patients had IR index findings. The median time to S2 was 49 months (IQR 48–49.4) for HR index patients and 72 m (IQR 70–73) for IR index patients. 11% of all patients had ACN at S2. 4% of IR patients v 18% of HR patients had ACN at S2. OR 0.4 (95% CI 0.2–0.6). 3% of HR patients without ACN at S1 had ACN at S2 v 15% of IR patients with ACN at S1 (ns). 11% of HR patients without ACN at S1 v 37% with ACN at S1 had ACN at S2; OR 0.2 (95% CI 0.07–0.6).

Conclusion: Stratification of high-risk index findings into HR and IR groups facilitates a low-risk group at second surveillance colonoscopy. The second surveillance interval for IR patients without ACN at first surveillance might be increased as ACN is infrequently detected in this group.

Narrow band imaging optical diagnosis of small colorectal polyps in routine use.

A novel blue laser imaging system for the diagnosis of colorectal polyps.

Aims & Methods: Between May 2014 and December 2015, 181 colorectal polyps in 65 patients were imaged and resected in our single center study. Each polyp was evaluated using white light endoscopy, BLI with and without magnification. An independent expert reviewed the pictures and the videos of the polyps and staged them using NICE, Sano and WASP classifications: his conclusions were compared with the actual histology of the polyps. Diagnostic performances of BLI and magnification were calculated with each endoscopic classification.

Results: 181 polyps were studied, among which 125 adenomas, 24 sessile serrated adenomas/polyps, 25 hyperplastic polyps, 2 adenocarcinomas and 11 normal colorectal mucosal samples. The median polyp size was 7 mm. Overall, the NICE, Sano and WASP classifications were comparable in terms of diagnostic performances for the optical diagnosis of colorectal adenomas (p = 0.7).

Conclusion: Our study did not establish significant difference between the three classifications. However, the ASEG criteria for the implementation of the "exact and discard" strategy were met for the classifications of Sano and WASP with a negative predictive value for the diagnosis of adenoma beyond 90% in the rectosigmoid.

Introduction: Endoscopic mucosal resection (EMR) is an established therapeutic option for large (>30 mm) colonic polyps. We aimed to assess characteristics and outcomes of this cohort. Primary outcomes consisted of rates, predictors and durability of EMR success, whilst secondary outcomes included complications, malignant risk, and conversion to surgery.

Aims & Methods: We prospectively identified patients referred for large polyp EMR from a polyp multidisciplinary team meeting between August 2008–2016 in a district general hospital with tertiary EMR expertise. Data on demographics, polyp site, morphology, size, accessibility (SMSA), histology and follow-up endoscopy were retrospectively collected. Binary logistic regression modelling was performed using SPSS, with components comprising of year, individual SMSA components, and histology. The Kaplan-Meier approach was used to measure durability of EMR success.

Results: Large polyp EMR was performed in 91 patients out of 125 MDT referrals (73%). Patients had a median age of 72 (interquartile range [IQR] 14.4), and were predominantly male (60%). Polyps were sessile (46%), flat (49%) or pedunculated (4%), with a median size of 40 mm (IQR 20.5 mm), and were left-colon in 81%. Bleeding occurred in 16.5%, of all whom achieved haemostasis. The 30-day complication rate was 1.1% (delayed bleeding in 1 patient), 54 (59%) were fully resected in one session, with overall EMR successful in 75 (81.5%) after an average of 1.5 sessions. On multivariable analysis, significant predictors of complete resection at first attempt (Table 1) included: increasing year, sessile vs. flat morphology, and non-malignant histology. Malignant histology (p < 0.001) predicted overall EMR failure, but not age, gender, year of EMR, SMSA score, or concomitant argon plasma coagulation. Of the EMR failure group, 11/16 (69%) underwent surgical resection, of which 7/11 (64%) harboured adenocarcinoma. Of the EMR success group, 4/80 were malignant polyps with R0 endoscopic resection. The overall malignant histology rate in this cohort was 11/91 (12%). In this cohort, the R0 EMR success rates was 4/11 (36%), with no recurrence after 60 months of follow-up. The overall 12-month recurrence rate following complete EMR was 1.5%, with no significant factors affecting EMR durability identified.

Table 1: Predictors of complete resection on first EMR attempt. p-values derived from bivariate regression, with bold values significant if p < 0.05. Increase in OR for each increase in year. **p-value < 0.05 considered statistically significant.

Introduction: Though numerous research has enabled decrease of the bowel preparation solution volume, it is still a major complaint of patients preparing for colonoscopy. There have been studied that additional administration of laxatives could lessen the amount ofavenous formula with prokinetic effect. Prucalopride is a serotonin (5-HT4) receptor agonist which stimulate colonic mass movements and provide main propulsive force for defeation.

Aims & Methods: The aim of this study is to compare 2-L PEG-Asc and 1-L PEG-Asc plus prucalopride while prepe for quality of bowel cleansing while investigating the result to traditional 2-L PEG-Asc preparation. 1-L PEG-Asc plus prucalopride preparation method could be an alternative method for bowel preparation which can relieve patient discomfort.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0213 IMPROVING SURVEILLANCE FOLLOW UP RATES AFTER COLONOSCOPY ENDOSCOPIC MUCOSAL RESECTION: A QUALITY IMPROVEMENT PROJECT**

Introduction: Endoscopic mucosal resection (EMR) is an effective and safe treatment for large (>20mm) laterally spreading colorectal lesions. Although colon EMR has been established as a minimally invasive technique for treatment of large colorectal lesions, risk of adenoma recurrence is the main limitation. Current guidelines recommend first follow-up at 3–6 months; however, there are no well-designed prospective-studies published establishing an optimal surveillance schedule. We aimed to identify an optimal surveillance schedule and assess adherence.

Aims & Methods: We performed a cross-sectional study of all patients who underwent colonoscopy with EMR followed by surveillance colonoscopy at our endoscopy center practices.

Results: 25 patients included in intervention group were compared to 66 patients in the nonintervention group (88%, 95% CI [0.80%-0.94%] vs 64%, 95% CI [0.54%-0.73%]). Table 1.

Conclusion: These preliminary results suggest significant improvement in SC1 compliance with our intervention. We believe that continuing these efforts and further refining the intervention process, requiring less personnel resources, may be helpful to improve the follow-up time until 3–6 months interval while also enduring as a sustainable change for our practice.

P0214 META-ANALYSIS SUGGESTS: INSPECT TWICE TO INCREASE RIGHT COLON ADENOMA DETECTION RATE
K. Triantafyllou, P. Gkofakis, G. Tzatzios, G. D. Dimitriadis
2nd Dept Of Internal Medicine And Research Institute, National and Kapodistrian University of Athens, Medical School, Athens/Greece

Contact E-Mail Address: ktrian@med.uoa.gr

Introduction: Missed adenomas in the right colon are of major concern for interval colorectal cancer (CRC) development. There is evidence from cohort and randomized controlled studies (RCTs) that a second examination of the right colon – either in direct view or in retroflexion- increases the diagnostic yield of the procedure. However, data are not accepted unanimously.

Aims & Methods: The aim of this meta-analysis was to examine the effect of a second, back-to-back mucosa inspection on the diagnostic yield of colonoscopy in the ecum and the ascending colon. We performed literature searches in MEDLINE to identify studies evaluating the effect of a second pass endoscopic examination on adenoma detection rate (ADR) and advanced ADR (AADR) in the right colon. Study outcomes effect sizes were calculated using RevMan 5.3 software fixed or random effect model, as appropriate, and they are presented as OR[95% CI]. Heterogeneity was measured using the I2 statistics. Publication bias was assessed by funnel plots inspection and the quality of the meta-analyzed studies was assessed using the Jadad criteria.

Results: We identified 8 studies (5 cohort and 3 RCT, with 9 sets of data and 5639 subjects – mixed CRC screening/surveillance and symptomatic population) that reported on the aforementioned outcomes. Two sets of data examined the yield of the second direct view as compared to that of a single inspection, one set examined the cumulative yield of two passes compared to that of an extended (timely) inspection of the right colon and six sets of data evaluated the yield of the second examination of the right colon with scope retroflexion compared to that of the single direct view. We were moderate risk of bias studies; suspicion for publication bias was detected in the direct view arm of the analysis. As compared to a single pass, the second right colon inspection significantly increased ADR (1.31 [1.15–1.49], I2 = 49%). The effect size of ADR was higher in the direct view second pass arm (1.73 [1.41–2.12], I2 = 0%) as compared to the retroflexion arm (1.17 [1.06–1.29], I2 = 0%). Sensitivity analysis with removal of one study each did not identify a single study responsible for the detected heterogeneity. Our analysis did not show significant increase in right colon AADR (1.5 [0.76–1.56], I2 = 0%) after the second exam.

Conclusion: In comparison to a single pass, the second inspection of the right colon either in direct view or with scope retroflexion increases ADR in this colon segment. However, results should be interpreted cautiously due to the small number of meta-analyzed studies with mixed indications populations, and the detected moderate levels of heterogeneity and risk for bias.

was defined as that dissection that is not done en bloc and/or had complications.

Results: 112 lesions were selected, discarding 4 due to deep invasion. We evaluated in this study 108 DSE-CR, 27 (25%) of which were compatible with our definition of "complex" ESD. In Table 1 you can see the characteristics of each group. Univariate analysis showed that variables such as size over 35 mm (P <0.001), size over 45 mm (P = 0.017), 5.78 in the presence of fatty tissue in the submucosa (P = 0.035) and larger lesion size and intraprocedural bleeding requiring endoscopic control in a multivariate analysis with an odds ratio of 2.8 (95% confidence interval 1.3–6.3, p = 0.012) and 2.3 (95% confidence interval 1.0–5.2, p = 0.042 respectively (Table 1).

Conclusion: Pain after EMR occurs in 20% of patients and is associated with larger lesion size and intraprocedural bleeding requiring endoscopic control in a multivariate analysis. If pain subsides after parenteral acetaminophen and does not recur the patient can be safely and confidently discharged to the step down recovery area and after medical review allowed to leave hospital. PP despite parenteral acetaminophen heralds a more serious scenario and imaging should be considered when stronger analgesics do not relieve the pain.

POLYPS USING COLD POLYPECTOMY IN OUTPATIENT SETTING: RESULTS FROM CLINICAL PRACTICE DATA OF SINGLE CANCER CENTER HOSPITAL IN JAPAN
Division Of Endoscopy, Shizuoka Cancer Center, Nagahama/Japan
Contact E-mail Address: k.hotta@scchr.jp

Introduction: Some high-quality, large-scale cohort studies proved removals of colorectal neoplasms achieved prevention of colorectal cancer incidence and deaths. We introduced a strategy of removing all neoplastic polyps in single session colonoscopic examinations using cold polypectomy was started.

Aims & Methods: The aim of this retrospective study was to investigate about achievement of colorectal polyp remove in our clinical practice setting. Scheduled colonoscopic examinations for 40–70 years outpatients who had at least one colorectal neoplasm between January 2015 and December 2016 were collected from our endoscopic data base. Exclusion criteria were as follows: patients who had colorectal neoplasm larger than 20 mm, pre-examination of colorectal surgery or endoscopic submucosal dissection, inflammatory bowel disease, familial adenomatous polyposis, uncontrolled malignancies, by trainee endoscopists (≤500 colonscopies), no agreements of polyp removal, and/or patients with continuation of anti-thrombotic agents. Outcome measurements were polyp removal rate (per-lesion analysis), complete polyp removal rate (per-patient analysis) and complications. Proportions of each endoscopic removal method according to size were also analyzed.

Results: A total of 2527 patients (mean age 66.8 ± 7.9 females) with 8203 colorectal neoplasms (CRNs) (7675 adenomas, 423 serrated polyps and 105 Tis and T1 cancers) who met inclusion and exclusion criteria were analyzed. Mean number of CRNs per patients was 3.2. Mean size was 4.7 (±2.9) mm. Polyp removal rate (per-lesion) and complete polyp removal rate (per-patient) were 97.0% (7955/8203) and 94.7% (2394/2527), respectively. Post-polypectomy bleeding requiring endoscopic hemostasis occurred in 7 patients (0.27%) and all origins of bleeding were mucosal bleeding (EMR) and hot snare polypectomy (HSP). Post electrocoagulation syndrome requiring admission was occurred in one patient (0.04%) after pre-cutting EMR. Mean procedure time was 27.4 (±13.3) minutes. Proportions of each endoscopic removal method according to size were presented in an attached table. In I–4 mm CRNs, both cold snare polypectomy (CSP) (51.8%) and cold forceps polypectomy (CFP) (45.8%) for 1–4 mm CRNs were main methods. In 5–9 mm CRNs, CSP was a leading method (73.8%) and EMR was the second one (24.1%). CRNs larger than 10 mm were almost removed by EMR (94.4%).
Conclusion: In our clinical practice setting, the polyp removal rates were satisfactory level in single session endoscopic examinations using cold polyectomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

1. Weiland T, Fehlker M, Gottwald T, Schurr MO. Performance of the OTSC clip. Thus, even in this distal problematic site usage of a traumatic OTSC should be avoided as it carries some difficulties because of little space, tissue tension and fibrous or scarry tissue is around the nearby located to L. dentata and anal sphincter, it includes a localization with heterogeneity, because of the fistula location (rectocutaneous fistulae was found to be successful in 71% (0–100%), depending on the size of perforation, type and nature of lesion and the endoscopists’ experience1–3. However, recto-urogenital fistula may arise from a variety of etiologies and are mostly leaks or fistula of chronic nature, rarely acute perforations with vital wound tissue. They may occur in Crohn’s disease, but can also be a consequence of abdominal surgery, traumatic lesions or post-radiation damage.

Aims & Methods: To further explore the role of the OTSC in this particular type of fistula we analyzed own cases and 21 reports from the literature dealing with any type of recto-urogenital fistula. In total, 25 patients. were identified with closure of a recto-urogenital fistula using the OTSC, but there was considerable heterogeneity, because of the fistula location (rectocutaneous n = 2, rectovaginal n = 10, rectoanal n = 7, rectourethral n = 2, other rectal fistula n = 3).

Results: In most situations a previous interdisciplinary discussion was reported before an OTSC attempt, or patients refused to undergo re-operation. However, special characteristics of these leaks were reported to make more difficult the OTSC procedure compared with other GI locations, e.g. the site of the fistula is nearby located to L. dentata and anal sphincter, it includes a localization with little space for endoscopic manipulation, fibrous and scarry tissue is around the fistula in rectum or anostomosis and there may be sometimes suture material in situ. Thus, the tissue is often fixed and there is not so much tissue for grasping tissue into the OTSC.

The diagnosis of recto-urogenital fistula was usually made by endoscopic visualization and radiologically documented extravasation of contrast media into the vagina, urethra, bladder or into other adjacent tissue. For fistula closure traumatic OTSC was mostly used, but sometimes other adjuvant therapeutic modalities were also combined locally (e.g. histoacryl injection, fibrin glue, argon plasma coagulation, bruising etc) or systemically (e.g. aspirin 7.5 g i.v.) to stimulate wound healing. The procedural success of occluding various types of fistula was found to be successful in 71% (0–100%), while a durable clinical success was found in only 52% (0–100%) of all 25 patients. The success rate was lower in cases of highly heterogeneity, because of the fistula location.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: To further explore the role of the OTSC in this particular type of fistula we analyzed own cases and 21 reports from the literature dealing with any type of recto-urogenital fistula. In total, 25 patients. were identified with closure of a recto-urogenital fistula using the OTSC, but there was considerable heterogeneity, because of the fistula location (rectocutaneous n = 2, rectovaginal n = 10, rectoanal n = 7, rectourethral n = 2, other rectal fistula n = 3).

Results: In most situations a previous interdisciplinary discussion was reported before an OTSC attempt, or patients refused to undergo re-operation. However, special characteristics of these leaks were reported to make more difficult the OTSC procedure compared with other GI locations, e.g. the site of the fistula is nearby located to L. dentata and anal sphincter, it includes a localization with little space for endoscopic manipulation, fibrous and scarry tissue is around the fistula in rectum or anostomosis and there may be sometimes suture material in situ. Thus, the tissue is often fixed and there is not so much tissue for grasping tissue into the OTSC.

The success rate was lower in cases of highly heterogeneity, because of the fistula location.
Results: According to endoscopic or pathologic judgment resection was complete in 40 or 30 patients, respectively. During hospital follow-up (12–14; median 4 days) abdominal pain, fever or local peritonitis were noted in 6 and bleeding in 3 patients (hypotension in 1) with antibiotics/transfusions/surgery needed in 4/0 patients. There was no hospital mortality. Among those with histologic incomplete resection (n = 21), surgery or FTR was performed in 5 patients, endoscopic follow-up is pending in 7 and revealed no residual neoplasia in 9. Among those with cancelled ESD or endoscopic incomplete resection (n = 11), surgery or FTR was performed in 5, endoscopic follow-up is pending in 2 and revealed no residual neoplasia in 4.

Conclusion: After appropriate training, even in low volume European case series ESD in the colorectum appears to be safe and partially effective.

Introduction: Colorectal cancer is the second leading cause of cancer death in US [1]. Its incidence can be mitigated by detecting its precursor lesion, the polyp, before it develops into cancer. Colonoscopy is the gold standard for colon screening though some polyps are still missed. This can be explained by technical limitations of colonoscopes (camera orientation, field of view, etc.), but also by human factors (such as experience). Several computational systems, being the majority still-frame-based, have been proposed to assist clinicians in this task [2] but, to the best of our knowledge, none of them is being used in the exploration room due to not meeting real-time constraints (40 ms max per image). In this abstract, we present a methodology to adapt and evaluate a real-time still frame-based method [3] to video analysis.

Aims & Methods: The still frame detection system used as reference [3] was based on an active learning method. We base the adaptation to video analysis on two aspects: (i) influence of the type of information used for polyp candidate characterization, and (ii) introduction of spatio-temporal coherence. The former studies whether the combination of different types of information may lead to improve system performance whereas the latter fosters stability in the position and acuity in histological prediction. Despite promising results, acuity and confidence levels were lower than the thresholds recommended in guidelines (>90%). This results justify implementing additional training and monitoring.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0223 RESECT AND DISCARD/DIAGNOSE AND DISREGARD STRATEGY FOR COLONIC POLyps: ARE WE READY TO START IT?
Gastroenterology, Amato Lisutano Hospital, Castelo Branco/Portugal

Contact E-mail Address: richardazevedo13@gmail.com

Introduction: The use of Narrow Band Imaging (NBI) technology for in vivo histological prediction of colonic polyps presents high accuracy in Referral Centers, particularly for diminutive polyps, which could be managed by the “resect and discard” strategy and, for sigmoid and rectum polyps, the “diagnose and disregard” strategy. However, the applicability of this practice in Community Hospitals still needs to be determined.

Aims & Methods: We aimed to determine the accuracy of NBI in predicting histology, according to NICE and WASP classifications, in a Center without previous NBI experience. This was a prospective study including patients submitted to colonoscopy between June 2016 and July 2017. Polyps characteristics: location, size, morphology (Paris Classification), NICE/WASP classification (hyperplastic, sessile serrated, adenoma, invasive carcinoma) and degree of confidence (low: <90% vs. high ≥90%). Comparison between NBI classification and histology SPSS 23.

Results: 163 polyps included (71 patients); mean polyp dimension of 6.1 mm (61.3% ≤5 mm; 91.4% sessile polyps; 62.6% on the left colon. Polyps classification according to NICE/WASP vs. histology: hyperplastic 49.7% vs. 42.9%; sessile serrated polyps 4.9% vs. 9.8%; adenoma 44.2 vs. 43.6%; carcinoma 1.2 vs. 0%; inflammatory reaction on histology ~ 3.7%. Adenoma diagnosis using NICE/WASP classification presents an accuracy, sensitivity, specificity, positive predictive value and negative predictive value of 80.9%, 78.1%, 84.2%, 85% and 77.1%, respectively. For left colon ≤5 mm (n = 61) the accuracy and negative predictive value were of 81.2% and 82.3%, respectively, with 79.4% high confidence classifications. Multivariate analysis showed that high confidence predictions and ≥3 polyps/exam had a significant association with correct NBI classification (p < 0.05).

Conclusion: NBI utilization by inexperienced endoscopists presented moderate acuity in histological prediction. Despite promising results, acuity and confidence levels were lower than the thresholds recommended in guidelines (>90%). These results justify implementing additional training and monitoring.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cold forces polypectomy (CP) is commonly used to remove diminutive colorectal polyps (<5mm). In addition, jumbo biopsy forceps are superior to standard forceps for removing colorectal polyps. However, problems remain for CP with regard to residual adenomatous tissue on histological evaluation after a complete endoscopic cold forceps polyp resection.

Aims & Methods: The aim of this study was to evaluate the efficacy and safety of jumbo forceps biopsy using narrow-band imaging in patients with diminutive polyps. In addition, we evaluated the factors related to one-bite resection of lesions. The present prospective, single-institutional study was performed at 11 institutes of the National Hospital Organization between January 2015 and September 2016. Patients aged 20 to 75 years with diminutive polyps were enrolled in this study. When lesions were found, we used magnification endoscopy (narrow-band imaging (NBI)) in all the cases. CFP was performed until no polyps were visible under magnified endoscopy with NBI. We evaluated the patients’ characteristics, clinicopathological features of the polyps, adverse events, and complete resection rates of the lesions. Additionally, we studied the factors related to one-bite resection using CP's method.

Results: A total of 503 patients were prospectively assessed, and 1015 polyps were resected. The median age of the patients was 65 years. The patients comprised 329 men (65%) and 174 women (35%). The polyp morphologies were 0-Is lesions in 886 cases (87.7%) and lesions in 65 (6.4%); 0-IIp lesions in 63 (6.2%) and 0-Ip lesions in 1 (0.1%). Polyps were most often resected in the ascending colon (289 lesions) or transverse colon (262 lesions). Of all the polyps, 88% (896 lesions) were adenomas, 10% (100 lesions) were hyperplastic, and 0.3% were adenoscarcinomas. The mean procedure and treatment times were 26.5 and 20.4 min, respectively. The complete resection rate was 99.3%. The rate of one-bite polypectomy was 71.8%, which included rates of 100%, 91.5%, 81.8%, 56.9%, and 40.5% for lesions 1, 2, 3, 4, and 5 mm in diameter, respectively. Delayed bleeding that required endoscopic hemostasis occurred in only one case, but no other adverse events occurred. The most important factor related to one-bite polypectomy was polyp size (≤5 mm; OR: 5.58), followed by macroscopic type of polyps (non-Ha; OR: 3.95).

Conclusion: In this large-scale multicenter prospective study, 99.3% of all diminutive polyps were completely resected by using jumbo forceps biopsy and magnified endoscopy with NBI. In addition, we were able to do one-bite polypectomy for more smaller polyps (≤3 mm). Jumbo forceps biopsy appears to be adequate for resecting diminutive polyps if no residual tissue is visible by using magnified endoscopy with NBI.

Introduction: Colorectal cancers are generally recognized to develop from“poly- pse” of adenoma-carcinoma sequence theory has been in the mainstream of development of colorectal cancers. But recently the existence of many depressed-type cancers has been revealed, which are considered to emerge directly from normal epithelium, not through the adenomatous stage. This theory is called “de novo” pathway. Now, it is possible to presume the histology of colorectal lesions using magnifying endoscopy(pit pattern classification) and endocytoscopy(EC classification). We can observe not only the structural atypia but also the cellular atypia in living colorectal lesions.

Aims & Methods: The aim is to clarify the endoscopic characteristics of depressed-type colorectal neoplasms demonstrating the validity of pit pattern diagnosis and EC classification. A total of 29,030 colorectal neoplasms excluding advanced cancers were resected endoscopically or surgically in our unit from April 2011 to December 2017. Of these, 17,763 lesions were low-grade dysplasia, 2922 were high-grade dysplasia and 1077 were submucosal invasive (T1) carcinomas. According to the developmental morphology classification, they were divided into 3 types: depressed, flat and protruded-type. We investigated the rate of T1 carcinomas and the characteristics of depressed-type neoplasms concerning pit pattern and EC classification.

Results: The rate of T1 carcinomas in depressed-type lesions reached to 62.0%, meanwhile that in flat-type and protruded-type lesions was 3.3% and 2.8%, respectively. In addition, within 5 mm in diameter, that was 10.6%, 0% and 3.3% respectively. Most (93.0% and 93.1%) of the flat-type and protruded-type lesions were classified as EC2 corresponding to adenomas. In contrast, the depressed-type lesions were observed as EC3a (38.9%) and EC3b (58.0%) corresponding to invasive carcinomas.

Conclusion: This study revealed the diagnostic characteristics of depressed-type cancers. They show typically type IIS, VI or VN pit patterns in magnifying
endoscopy and type EC3a or EC3b in endoscopy. These lesions tend to involve the mucosal layer even when they are small. Therefore, it is important to consider deeply and examine the development morphology of colorectal neoplasms.

### P0228 THERAPEUTIC ERCP USING A SHORT SINGLE-BALLOON ENTEROSCOPE IN PATIENTS WITH SURGICALLY ALTERED ANATOMY

**K. Masu, K. Ito, T. Ohira, S. Koshita, Y. Kanno, T. Ogawa**

**Introduction:** Recently, we have performed therapeutic ERCP using a newly developed short single-balloon enteroscope (sSBE) (working length of 152 cm, working channel of 3.2 mm) in patients with surgically altered anatomy.

**Aims & Methods:** We aimed to evaluate the usefulness and safety of sSBE for therapeutic ERCP in patients with surgically altered anatomy, and to assess the characteristics of patients with surgically altered anatomy who underwent therapeutic ERCP using a sSBE before August 2011 and February 2017 were included in this study. Patient anatomy consisted of Roux-en-Y anastomosis (R-Y) (n = 82), heptacolo- liotasis (n = 46), total or partial gastrectomy (n = 11), subtotal filling defects, 31 (45.6%) with difficult bile stones, and 4 (5.9%) with cystic ductal filling defects, 31 (45.6%) with difficult bile stones, and 4 (5.9%) with cystic ductal filling defects.

**Results:** The success rate of reaching the target site was 91.5% (95/104), and the overall technical success rate was 79.0% (80/104). Biliary interventions included 64 stone extraction (R-Y 58, HJ 5, SSPPD 1), and 12 metallic biliary stent placement (R-Y 7, HJ 1, SSPPD 4). Of 17 unsuccessful cases, nine with choledocholithiasis underwent surgical operation (R-Y 6, HJ 2, SSPPD 3) and EUS-guided drainage was successfully performed in six with anastomotic stenosis (SSPPD 3, R-Y 2, HJ 2). The success rate of reaching the target site was 91.5% (95/104), and the adverse event rate was retrospectively evaluated.

**Results:** The success rate of reaching the target site was 91.5% (95/104), and the overall technical success rate was 79.0% (80/104). Aims & Methods: Langiopancreatography (ERCP) in patients with surgically altered gastrointestinally and in pediatric patients.
Aims & Methods: To evaluate the indications, success rate, diagnostic and therapeutic yields, and complications of ERCP performed in Chinese children. A retrospective study was conducted in an academic, tertiary care, medical center, in which all children undergoing ERCP between 2005 to 2016 were identified from endoscopy databases. Data on demographics, indication, ERCP findings, ERCP interventions performed, and complications were collected.

Results: A total of 288 children (mean age 9.3 years, range 1 month to 18 years) underwent 312 ERCP procedures. General anesthesia and sedation were performed in 48% and 52% of procedures, respectively. Indications for ERCP were common bile duct obstruction (n=153, 54.2%), recurrent or chronic pancreatitis (n=64, 22.2%) and others. ERCP was successfully performed in 267 of 288 cases (92.7%). The most common ERCP findings was choledocholithiasis (n=146, 50.7%). A therapeutic intervention was performed in 70.8% patients (n=204), including sphincterotomy (n=97), stone extraction (n=55), and stent insertion (n=52). Complications occurred for only 13 patients (4.5%), including 12 cases of post-ERCP pancreatitis and 1 case of bleeding. No severe pancreatitis, or perforation was noted.

Conclusion: Diagnostic and therapeutic ERCP is effective and safe in the children population, with the high rates of technical success and low rates of complication.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0323 IMPACT OF HIGH DEFINITION, NEAR FOCUS-IMAGING AND SYNDY RECURRER CE TOOL (SERT) AFTER COLORECTAL ENDOSCOPIC MUCOSAL RESECTION: A PROPENSITY SCORE ANALYSIS

D. Guerrero Yinsard1, L. Lennon2, P. Kandel1, L. Ejeda4, R. Bingham3, T. Woodward2, V. Gomez2, M. Raimondo4, E. Bouras1, M.B. Wallace2

2Biostatistics, Mayo Clinic, Rochester/United States of America/MN
Contact E-mail Address: daniela.guerrero@mayo.edu

Introduction: Risk factors for colorectal adenoma recurrence after Endoscopic Mucosal Resection (EMR) such as size $\leq$20mm, high grade dysplasia, use of argon plasma coagulation (APC) and intraprocedural bleeding (IPB), have been well documented in literature. However, it is unknown if the latest generation dual-focus (DF) colonoscopes ability to visualize subtle residual neoplasia, has improved the rate of complete EMR.

Aims & Methods: We aimed to determine if the efficacy of the newer 190 colonoscopes versus standard 180 colonoscopes for complete resection of lateral spreading lesions (LSL) $\leq$20mm. A secondary aim was to identify risk factors for recurrence and the applicability of the Sydney EMR recurrence tool (SERT score) in our cohort.

This was a single-center retrospective study of patients who underwent EMR with 180 or 190 colonoscope series from 2010 to 2016. Lesions $\geq$20mm resected in a piecemeal fashion and patients with a surveillance colonoscopy after index EMR were included. A propensity score approach with inverse probability weighting (IPW) was used to control potential confounders affecting adenoma recurrence. Each lesion was graded according to SERT score and associations with recurrence were analyzed.

Results: 291 patients met inclusion criteria for the study. The rate of adenoma recurrence at the EMR site was 23.3% for the 180 colonoscope cases and 25.2% for the 190 colonoscope cases. Odds ratio (OR) for recurrence with 190 series was 1.06 (p = 0.85). Adenoma size (p = 0.002) and concomitant need for supplemental APC (p = 0.001) were risk factors for recurrence. SERT $>$0 lesions had a higher risk of recurrence during follow-up (OR 1.71; 95% CI 1.00–2.92; p = 0.048) and a higher cumulative incidence for recurrence. Conversely, SERT = 0 lesions reached a plateau for recurrence after 12 and 18 months in Kaplan Meier curves. Odds ratio estimates for 190 colonoscope effect on adenoma recurrence at different stages of adjustment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0231 EMERGENCY ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAHY IN PATIENTS WITH SURGICALLY ALTERED GASTROINTESTINAL ANATOMY: 11 YEARS’ EXPERIENCE AT A LARGE CENTER IN CHINA

T. Zhang, D. Zhang, C. Xu, X. Zhang
Department Of Gastroenterology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou/China

Contact E-mail Address: solitude5834@hotmail.com

Introduction: It is technically challenging to perform emergency endoscopic retrograde cholangiopancreatography (ERCP) in patients with surgically altered gastrointestinal anatomy.

Aims & Methods: The aims of this study were to investigate the yield, efficacy and safety of ERCP in surgically altered anatomy patients at a single tertiary-care center with a high volume of endoscopy. All patients with altered surgical anatomy were reviewed, and indication at our center from September 2005 to July 2016 were retrospectively reviewed. Data regarding to patients baseline characteristics, procedure-related details and adverse events were recorded and analyzed.

Results: A total of 304 procedures were performed in 236 patients, including 108 procedures with Billroth II gastrectomy, 45 cases (19.1%) with Billroth I gastrectomy, 52 cases (22.0%) with hepaticoduodenostomy, 18 cases (7.6%) with esophagogastrectomy and 13 cases (5.5%) with Roux-en-Y reconstruction.

Conclusion: ERCP can be performed in surgically altered anatomy patients with a high success rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0232 INCIDENCE AND RISK FACTORS FOR PANCREATITIS IN EMERGENCY ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY: A PROSPECTIVE MULTICENTER STUDY

Conclusion: In this study, recurrence was significantly associated with adenoma size and complementary use of APC for EMR. The use of the latest generation DF colonoscopes (CF-HQ190L/I) did not measurably affect adenoma recurrence at the EMR site during first surveillance colonoscopy (SC1). Lesions with SERT $>$0 were associated with higher recurrence rates. In our cohort, SERT $>$0 lesions that remain negative for recurrence at 18 months, may return to routine surveillance.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0230 DIAGNOSTIC AND THERAPEUTIC ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) IN INFANT AND CHILDREN: A LARGE RETROSPECTIVE STUDY

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is increasingly being used in the diagnosis and management of biliary and pancreatic ductal disorders in pediatric patients.

Aims & Methods: To evaluate the indications, success rate, diagnostic and therapeutic yields, and complications of ERCP performed in Chinese children. A retrospective study was conducted in an academic, tertiary care, medical center, in which all children undergoing ERCP between 2005 to 2016 were identified from endoscopy databases. Data on demographics, indication, ERCP findings, ERCP interventions performed, and complications were collected.

Results: A total of 288 children (mean age 9.3 years, range 1 month to 18 years) underwent 312 ERCP procedures. General anesthesia and sedation were performed in 48% and 52% of procedures, respectively. Indications for ERCP were common bile duct obstruction (n=153, 54.2%), recurrent or chronic pancreatitis (n=64, 22.2%) and others. ERCP was successfully performed in 267 of 288 cases (92.7%). The most common ERCP findings was choledocholithiasis (n=146, 50.7%). A therapeutic intervention was performed in 70.8% patients (n=204), including sphincterotomy (n=97), stone extraction (n=55), and stent insertion (n=52). Complications occurred for only 13 patients (4.5%), including 12 cases of post-ERCP pancreatitis and 1 case of bleeding. No severe pancreatitis, or perforation was noted.

Conclusion: Diagnostic and therapeutic ERCP is effective and safe in the children population, with the high rates of technical success and low rates of complication.

P0222 A241
Disclosure of Interest: 

normal saline was used for intra-procedural irrigation and consequently underwent necrosectomy. The conventional technique using a diag- 

nostic and therapeutic ERCPT at five Japanese institutions between April 2015 and May 2016. Exclusion criteria were active pancreatitis, choledochal 

chojunenotum, inability to approach a papilla, and inspection aimed at only the 

pancreatic duct (PD). Emergency ERCPT indicated unscheduled inspections 

performed within and outside daily hours in this study. PEP was considered when 

two of the following three conditions were met: (1) serum amylase level more 

than three times the upper limit of the normal range in each institution, (2) 

continuous abdominal pain for over 24 hours, and (3) presence of pancreatitis 

findings on computed tomography. The first study involved comparison of the 

incidence of PEP and its characteristics between emergency and elective ERCPT. 

The second study involved determining the predictive risk factors for PEP in 

emergency ERCPT using univariate and multivariate analyses.

Results: A total of 1677 cases were enrolled in this study. Study 1: PEP 

developed in 20 of 429 cases (4.7%) from the emergency group and in 101 of 

1248 cases (8.1%) from the elective group. The incidence of PEP was significantly 

lower in the emergency group than in the elective group (odds ratio [OR]: 0.56, 

95% confidence interval [CI]: 0.32–0.92, P = 0.017). Endoscopic sphincterotomy, 

stone removal, papillary balloon dilation, and intra-ductal ultrasonography 

were performed significantly more often in the elective group than in the 

emergency group (P < 0.001). Placement of a biliary stent was significantly more 

common in the emergency group than in the elective group. In addition, the 

procedure time was significantly longer (P < 0.001) and the number of endosco- 
pists who had more than five years of experience was significantly higher 
(P = 0.04) in the elective group than in the emergency group. <Study 2> 
Carla C with no naive papilla (n = 183) were excluded from the analysis of risk 

factors for PEP because no PEP was observed in these cases. Only cases with 
native papilla (n = 248) were analyzed. Univariate analysis showed that contrast 

injection into the PD (OR: 4.20, 95% CI: 1.64–10.80, P = 0.0028) increased and place- 
ment of a biliary stent (OR: 0.028, 95% CI: 0.011–0.88, P = 0.028) decreased the 

risk of PEP in emergency ERCPT.

Conclusion: The incidence of PEP was lower in emergency ERCPT than in elec- 
tive ERCPT, and it was largely unaffected by the endoscopist’s experience and 
the procedure time. This may be associated with a tendency to avoid invasive pro-
cedures as early as possible to prevent it from developing CP. Unfortunately, to date, most 

PEP-related studies have been concentrated on adults. Researches of PEP in chil-

dren is rare.

Aims & Methods: To evaluate the safety and efficacy of endoscopic retrograde 
cholangiopancreatography (ERCPT) for the treatment of pancreas divisum 
(PD) associated with recurrent acute pancreatitis (RAP) in children. We retro-
spectively analyzed patients of PD associated with RAP who were younger 
than 18 years old from January 2011 to December 2015 in our center. All the 

patients were diagnosed and treated with ERCPT. Patients of complete PD 
association with RAP under the age of 18 years were identified. A total of 257 

pediatric ERCPs were performed for these cases. All procedures were successful with 
100% (21/21) of cannulation rate of the minor papilla. The mean interval of 

cannulation attempts (OR: 2.85, 95% CI: 1.00–8.09, P = 0.028) increased and place-
ment of a biliary stent (OR: 0.028, 95% CI: 0.011–0.88, P = 0.028) decreased the 

risk of PEP in emergency ERCPT.

Conclusion: The incidence of PEP was lower in emergency ERCPT than in elec-
tive ERCPT, and it was largely unaffected by the endoscopist’s experience and 
the procedure time. This may be associated with a tendency to avoid invasive pro-
cedures as early as possible to prevent it from developing CP. Unfortunately, to date, most 

PEP-related studies have been concentrated on adults. Researches of PEP in chil-
dren is rare.

1. The overall rate of biliary stent insertion was not significantly different: 384/392 excluded leaving 6 prospective studies (total of 711 patients).

2. The bleeding was significantly different in patients without EBS: 0/351 of patients in no-EBS group versus 15/298 (5%) in the EBS group (OR: 0.12; 95% CI: 0.03–0.68–2.59). The bleeding was significantly different in patients with EBS: 0/351 of patients in no-EBS group versus 15/298 (5%) in the EBS group (OR: 0.12; 95% CI: 0.03–0.45). The rate of duodenal perforation was not significantly different: 1/320 (0.3%) in no-EBS versus 4/260 (1.5%) in EBS (OR: 0.52; 95%CI: 0.03–0.45). Early cholangitis was significantly less frequent in patients who didn’t receive EBS: 13/392 (3.3%) patients in no-EBS group vs 25/339 (7.4%) subjects in the EBS group (OR: 0.38; 95% CI: 0.17–0.83). Early mortality rate was 0% in both groups. Late complications: No significantly difference occurred in the overall adverse events in the two groups: 50/251 patients (19.9%) in no-EBS group vs 38/201 subjects (18.9%) in the EBS group (OR: 0.93; 95% CI: 0.56–1.53). No significantly differences in stent occlusion (11.6% in no-EBS vs 11.1% in EBS group). The difference in the rate of late complications was more frequent in patients controls (82.3%) compared to PAD group (71.4%vs 33.1% (p = 0.05). PAD predominantly occurred in patients without EBS and was found in 7 pts (14.3%), Type ll (at edge/brim) in 34 pts (69.4%), Type lll (within the cyst wall) in 1 pt (2%), Type lV (bulging) in 2 pts (4.1%), and Type lVb (cystic duct) in 1 pt (2%). No significant differences in stone migration (4%) in no-EBS group vs 5.5% - (OR: 0.81; 95% CI: 0.29–2.25). No significantly differences in late cholangitis (2.6%) in no EBS vs 0% in EBS group - (OR: 1.83; 95% CI: 0.17–19.85). Long-term mortality was not significantly different between 1.5% in no-EBS group and 2.9% in the EBS group - (OR: 1.18; 95% CI: 0.23–6.29).

Conclusion: Our meta-analysis showed no significant differences in technical success and in PEP. In consideration of the significantly increase of the overall adverse events with biliary stenting, the EBS seems not be recommended in patients not suitable to surgery undergone biliary stenting.

Introduction: Since the emergence of the fiberoptic single-operator cholangioscopy, the sensitivity for detecting bile duct lesions has been increased and the management of difficult stones is facilitated, establishing its superiority over standard endoscopic retrograde choledangiopancreatography and often altering the clinical management. Digital cholangioscopes provide higher-resolution imaging of the pancreatobiliary tract compared with the fiberoptic instruments.
Aims & Methods: The aim of the present study was to assess the frequency of digital cholangioscopy (DC) to alter the diagnosis and clinical management of bile duct disease compared with fiberoptic cholangioscopy (FC). A retrospective review of 68 cases needing cholangioscopy, and which were performed in our department, were included. Patients enroled exhibited stenosis of the biliary tract (67.6%), stones (20.6%), primary sclerosing cholangitis (PSC 4.4%) or other rare cause for cholangioscopy (e.g. stent migration, guidewire passage). All patients underwent endoscopic retrograde cholangiography (ERC) before cholangioscopy. Aim of cholangioscopy was to confirm ERC diagnosis, obtain adequate biopsy specimens for histological evaluation and remove biliary stones. From 5/2009 to 8/2015 all cholangioscopies were performed with the fiberoptic scope. From 9/2015 to 3/2017 all cholangioscopies were performed with the digital scope.
Results: 30 women and 38 men with a mean age of 61 years underwent cholangioscopy. Fibreropic cholangioscope was used in 39 cases and digital cholangioscope was performed in 29 cases respectively. Cholangioscopy-guided biopsies for malignancy were obtained in 11 and 15 cases respectively. In only one case of FC (9.1%) biopsy confirmed the endoscopic diagnosis, in contrast with 10 cases of DC-guided biopsies (66.7%) confirming the diagnosis. In 13 patients who underwent DC (44.8%) the initial diagnosis and clinical management was altered after cholangioscopy (e.g. cancer diagnosis, successful EHL lithotripsy), in contrast with 11 cases of FC (28.2%). Moreover it was unanimously felt by our staff that DC was an easier procedure compared to FC.
Conclusion: Our data suggest that DC has the advantage of improving the fiberoptic technique, provides increased sensitivity and specificity for visual impression diagnosis of malignancy and successful therapy of biliary stones. Moreover DC has the ability to alter more often the initial ERC diagnosis or management compared to FC and produces a new sophisticated and easy to use equipment.

Introduction: Tokyo Guidelines 2013 (TG13) have been used worldwide to assess the diagnostic criteria and severity grading of acute cholangitis. Acute cholangitis is a life-threatening disease, and the emergency biliary drainage procedure is necessary for moderate or severe cases, according to TG13, with an aging society, necessity to perform endoscopic retrograde cholangiopancreatography (ERC) in elderly patients is increasing. However, few studies have examined the efficacy and safety of emergency ERC in super-elderly patients.
Aims & Methods: In this study, we examined the efficacy and safety of emergency ERC in super-elderly patients with moderate to severe acute cholangitis, according to TG13. We performed 178 emergency ERC procedures in 132 patients during 3 years (June 2014–December 2016). We determined patients >90 years as “super-elderly” and those <90 years as “non-super-elderly”.
Evaluation criteria included comorbidities, oral administration of anticoagulants, cause of cholangitis, ERC procedure (examination time, endoscopic biliary sphincterotomy (EST) pre-cut papillotomy, treatment success rate, presence or absence of peripapillary diverticula and papilla after EST, seditation dosage), ERC-related complications (bleeding, perforation, post-ERC pancreatitis, ERC pneumonia, death within 30 days after ERC procedure), anesthesiology-related complications (blood pressure decrease, pulse reduction, respiratory depression).
Results: We examined 69 males (52.3%) and 63 females (47.7%). Women accounted for a larger proportion in the super-elderly group (71% vs 40%). The average age was 92.5 years (range, 90–97) in the super-elderly group and 77.9 years (range, 50–89) in the non-super-elderly group. The super-elderly group comprised 54 ERC procedures (moderate, 32; severe, 22) against 124 ERC procedures (moderate, 104; severe, 20) in non-super-elderly group. In the super-elderly group, there were no differences observed in the super-elderly group (12% vs 5%), but no difference was found. In the super-elderly group (9% vs 12%) and benign stenosis (0% vs 5%), but no difference was found.
Regarding ERC procedure, the procedure time was longer in the super-elderly group (35.7 ± 28.1 min vs 29.2 ± 24.0 min, p = 0.044), but there was no difference in the procedure success rate (93% vs 97%, p = 0.249) and the presence of peripapillary diverticula. The patients were sedated using midazolam (MDZ) plus pentazocine (PTZ). The amount of antiplatelet improvement was less in the super-elderly group (MDZ 2.2 ± 3.3 mg, p < 0.001, PTZ: 3.1 ± 5.4 mg, p = 0.005). Regarding (i) ERC-related and (ii) anesthesiology-related complications, these were higher in the super-elderly group (i) 15% vs 9%, p = 0.293, (ii) 17% vs 7%, p = 0.004).
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Dysplasia may persist at the termination of the common bile duct (CBD) after endoscopic ampullectomy. Radiofrequency ablation (RFA) could be an interesting alternative to surgery to reduce the risk of invasive cancer with less morbidity and mortality.
Aims & Methods: The aim of the study was to evaluate the efficacy and morbidity of endo-biliary RF for the treatment of residual endo-biliary dysplastic lesions after endoscopic ampullectomy. A prospective open-label multicenter study
included 20 patients with low-grade dysplasia (DBG) or high grade (DHG) lesions confirmed by a double blind endonaphathological lecture, in relation to a residual adenomatous bud after endoscopic ampullectomy for ampullary adenoma. The lesions should extend to a maximum length of 20 mm in the CBD. Endoscopic retrograde cholangio-pancreatectomy (ERCP) was performed with the HSt™ EndoHPB probe (EMcision, UK) (eff 8, power 10Watts, 30 s). Biliary + pancreatic stents were placed at the end of the procedure. The primary endpoint was the rate of residual neoplasia (eg, DBG, DHG or invasive carcinoma) at 1 year after treatment. Secondary endpoints were residual neoplasia at 6 months after treatment; 2) rate of surgery at 12 months; 3) adverse events.

Results: The mean age (±SD) was 67 years (±11), with 12 men and 8 women. RFA was performed on average (±SD) 1.9 years (±3.5) after ampullectomy. The mean resected ampullary adenoma size (±SD) was 24.9 mm (±10.2), and 7 patients had adjacent duodenal mucosectomy at the time of ampullectomy. The histology of the resected ampullary adenoma was DBG for 7 patients, DHG for 12 patients, and in situ carcinoma for 1 patient. Lateral margins were judged to be negative in 32 patients (80%). CBD recurrence was diagnosed predominantly on ERCP and/or endoscopic ultrasonography surveillance procedures with an estimated mean infiltration height (±SD) of 11.2 mm (±4.5). The passage of the RFA probe was judged to be easy in 100% of cases with visibility of the radio-paque markers judged satisfactory to very satisfactory in 80% of the cases. All patients included had RFA without any technical problems. All patients had biliary stent (4 SEMS 10 mm, 16 plastic stents 10 French) implanted following RFA and 5 (25%) had a pancreatic stent. The residual rate of DBG, DHG, invasive carcinoma at 6 months and at 12 months after treatment were 25% (5/20, DBG, carcinoma) and 45% (9/20, DBG, carcinoma) respectively. The adverse events were as follows: 4 benign pancreatitis all medically treated, 2 procedures had angioplasty requiring biliary stent replacement. 1 patient had an episode of unexplained spontaneously resolved abdominal pain (normal CT scan, colonoscopy and biological tests). At M12, one patient presented with a biliary stricture resolved by dilation and a calibration biliary stent.

Conclusions: Further studies are needed to evaluate the endo-biliary dysplastic buds after ampullectomy is an alternative to surgery, with a rate 55% dysplasia eradication at 12 months after a single RFA session. Regular monitoring of these patients is still necessary considering recurrence rate. Multiple RFA sessions may be proposed in case of incomplete results.

Disclosure of Interest: All authors have declared no conflicts of interest.
Results: There were cases of 1223 naive papilla out of 2226 cases in total. The success rate to access BD with naive papilla was 97.5% (1195/1223) and overall post-ERCP pancreatitis (PEP) was 1.3% (29/2226). The eligible patients were 908 (505 male and 403 female), among whom IAC was identified in 6.0% (54/908). The prevalence of IAC in the L/N, D and F types were 5.9% (48/842), 1.2% (4/330) and 0.7% (2/264) respectively. IAC was significantly higher in the L/N (p < 0.01) and F (p < 0.05) types than in the D type. The choledochocele shapes of Sh, Sh and Od were 59.3%, 13.0%, 27.8%, respectively. The average size was 8.1 mm (3.7–18.3) in diameter. The location of IAC in Ac and Ab were 60% and 40%. In Ac, IAC was found in LN shape only. Patients of 53.7% (29/54) required GW placement on PD to access BD. IAC was alternately seen on MRCP in 10%(3/30).

Conclusion: Choledochoele is rarely seen on even cERC, in addition the visually seen on MRCP in 10%(3/30).

Introduction: Most appropriate endotherapy of biliary anastomostic strictures (AS) remains to be defined.

Aims & Methods: Aim is to retrospectively report the endotherapy for duct-to-duct AS in 2013, procedure related complications and medium-term outcome results in Italy. A questionnaire was sent to the Endoscopy Units working with Italian Liver Transplantation Centers (BASALT study group).

Results: At present sixteen of the 19 Units (84%) returned the questionnaire. Complete endotherapy data and follow-up are available for 182 pts. One-hundred and two patients have been treated with plastic multistenting (PM), 27 with fully covered SEMS and 53 with single stenting (SS). Radiological success was achieved in 144 pts (79%), i.e. 86% of PM, 89% of fully covered SEMS and 60% of SS (p < 0.01 vs PM). Recurrence occurred in 31 pts, i.e. 21% of pts in whom radiological success was achieved: 11% of PM (p < 0.0001 vs SEMS and p < 0.05 vs SS), 41% of fully covered SEMS and 17% of SS. After failure of first-line endotherapy (36) or recurrence (31), patients were re-treated with endotherapy (75%), surgery (21%) or percutaneous balloon dilation (7%), one patient dropped out because of death unrelated to endotherapy. Second-line endotherapy was PM for 26%, fully covered SEMS for 52% and SS for 22% of pts and radiological success was achieved in 82% of them (in 86%, 89%, and 66% with PM, SEMS and SS respectively). Procedure-related complications occurred in 7.8% (51/66), i.e. 2.6% pancreatitis (1 severe leading to death), 4.1% cholangitis and 0.9% bleeding. Overall clinical success was achieved in 85% after a median f-up of 25 mos and no need of surgery in 92% of patients.

Conclusion: Endotherapy is confirmed as the preferred first-line and rescue option for AS. Progressive plastic multi-stenting is most frequently used. Single stenting has suboptimal results and should be abandoned. Use of SEMS is effective, but recurrences seem to be frequent, although a larger patients’ sample needs to be evaluated.

Introduction: EUES-guided Cysto-Enterostomy (EUCE), technique indicated for drainage of symptomatic pancreatic pseudocysts and other peri-enteric fluid collections, requires specific skills for which dedicated models are needed. Based on a compact EASE model (Active Simulating for Interventional Endoscopy) we developed two ex-vivo porcine models of retrogastric cysts and evaluated learning performance within the frame of a structured training program.

Aims & Methods: The first model was made of porcine colon (i.e. “natural cyst”), and second one was made with an ostomy bag (i.e. “artificial cyst”). All procedures were achieved with EUES scope under fluoroscopy. Both models were evaluated prospectively over a 2 days session involving 14 students and 5 experts. Results: “Natural cyst” and “artificial cyst” were prepared respectively within 10 and 16.5 minutes (p = 0.78). More than 10 EUCE procedures were done in each model. Model grading (analytic scale) showed no significant difference for primary endpoint of global satisfaction (p = 0.66). In terms of secondary endpoints, difference was not significant for overall impression of realism (p = 0.75) whereas it was significant favoring “artificial cyst” in terms of ability to teach procedural steps (p = 0.01) and ease of puncture (p = 0.03) because of less elasticity. Moreover, experts considered ability to improve students’ proficiency superior with “artificial cyst” (p = 0.008)

Conclusion: Both “artificial and natural cysts” are efficient for EUCE training in terms of global satisfaction. However, the “artificial cyst” model appears to make procedure easier and to teach procedural steps improving students’ proficiency. Larger applications of this model are needed to validate as a standard of training.

P2047 A COMPARATIVE STUDY OF SUCTION METHODS DURING ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE ASPIRATION (CONVENTIONAL SUCTION VERSUS CAPILLARY SUCTION)

K. Yamakita1, Y. Kitano2, H. Iwamoto2, K. Takahashi1, K. Wada2, S. Otake2, Y. Ota2, Y. Takami2, M. Okada1, K. Aso2, Y. Makino1

1Department of Gastroenterology and Hepatology, University of Tokyo, Tokyo/Japan, 2Department of Gastroenterology, Hoˆpital Cochin Dept. of Gastroenterology, Paris/France
Conclusion: EUS guided tissue acquisition using a 25G-gauge core biopsy needle (EUS-FNA) is an established procedure for obtaining a pathological specimen. However, the effectiveness of endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) for collecting specimens by EUS-FNA has been shown to be efficient for diagnosis of pancreatic masses. Only with the smear method, however, its diagnostic efficacy may vary greatly depending on the level of proficiency of the cytopathologist. On the other hand, in the cell block (CB) method allows cytological and/or histological evaluation with hematoxylin and eosin (HE) staining and with immunostaining for serial sections if necessary.

Aims & Methods: The aim of this study was to evaluate the diagnostic efficacy of EUS-FNA for a pancreatic mass using the CB method without rapid on-site cytology retrospectively. A total of 206 patients with pancreatic masses (head: 87; body: 86; tail: 33) who underwent EUS-FNA using a GF-UL240P or GF-UM240P (Olympus Medical Systems Ltd., Tokyo, Japan) between June 2005 and November 2016 were included in this study. The needles used were 22/25G needles. At least two passes were made during the procedure (mean 3.0 ± 0.9 passes). Adequate specimens were regarded to be those in which whitish flag fragments were macroscopically achieved. The samples were immediately fixed in 10% formalin and processed by the cell block method using sodium alginate.

Results: Rapid on-site cytology was not performed. All samples were stained by hematoxylin and eosin, periodic acid Schiff and Alcian-blue, and immunohistochemical staining using antibodies EV, V, and W were defined as malignant. The final diagnosis was based on histological findings of surgically resected specimen, image diagnosis and clinical course for more than six months.

Results: The final diagnosis was malignancy in 184 patients (pancreatic ductal cancer (PDC), 171; neuroendocrine tumor (NET); 9; malignant lymphoma, 2; metastasis of malignant melanoma, 1; solid pseudopapillary neoplasm, 1), and benignity in 23 patients (autoimmune pancreatitis (AIP), 11; chronic pancreatitis, 7; organizing pancreatic pseudocyst, 4; IPMN, 1). Tissue sampling was successfully achieved in 97% (199/206). Of 199 patients with successful tissue sampling, sensitivity, specificity and accuracy for malignancy were 98% (175/179), 95% (19/20) and 97% (194/199). The diagnostic accuracy of PEI-DCA using HE and PAN staining was 76% (129/170) (Class V 91; IV 36; III 2), but by adding immunohistochemical staining, the accuracy of PDC was 98% (167/170) (Class V 112; IV 30; IIb 5). In the cases of highly suspicious NET, all samples were stained by chromogranin A or synaptophysin and the final diagnostic accuracy of NET was 100% (6/6). No procedure-related complications occurred.

Conclusion: EUS-FNA of a pancreatic mass with the CB method without rapid on-site cytology showed high accuracy for definitive diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0249 A DIAGNOSTIC EFFICACY OF ENDOSCOPIC ULTRASOUND- GUIDED FINE-NEEDLE ASPIRATION FOR A Pancreatic MASS USING THE CELL BLOCK METHOD WITHOUT RAPID ON-SITE CYTOLOGY

A PROSPECTIVE COMPARATIVE STUDY OF EFFICACY OF EUS GUIDED FNA VERSUS ERCP GUIDED BRUSH CYTOLOGY IN ATTAINMENT OF HISTOPATHOLOGY OF DISTAL CBD MASSES

P.N. Desai, M. Kabrawala
Endoscopy, Surat Institute Of Digestive Sciences, Surat/India

Contact E-mail Address: drp_desai@hotmail.com

Introduction: Distal CBD masses have always been a diagnostic dilemma. They are difficult to diagnose with any modality used. Brush cytology under ERCP guidance was used until now and also intraductal biopsies were used. The yield was hardly around 60% using all together. We started doing EUS localization of these difficult to identify distal CBD masses and took FNA from them. We devised a protocol to see the results of EUS FNA and brush cytology in the diagnosis of these masses.

Aims & Methods: We aimed to study the efficacy of EUS guided FNA for attaining tissue from distal CBD masses and comparing it to ERCP guided brush cytology from the same masses. 56 cases with distal bile duct mass with obstructive jaundice in the last 3 years were taken for the study. The protocol we devised a protocol to see the results of EUS FNA and brush cytology in the diagnosis of these masses.

Results:
- Total Serum Bilirubin 90 mg/dl
- Results: FNA performed with a 25 G needle making 2 to 5 passes and material sent for obstructive jaundice in the last 3 years were taken for the study. The protocol we devised a protocol to see the results of EUS FNA and brush cytology in the diagnosis of these masses.

</table>

Conclusion: Except for shorter procedural duration, there was no significant difference in treatment outcomes between patients treated with LAMS or plastic stents. Given the faster resolution of WON, to minimize adverse events, patients undergoing LAMS placement should undergo post-intervention imaging at 3 weeks followed by stent removal if the WON has resolved.

Metal Plastic

(n=31) (n=29) p-value

With EUS the tumors were sometimes difficult to locate and identify. But giving some time and instilling water in duodenum were useful techniques to identify the masses. Only a 25 G needle was used as the FNA had to be taken almost always from the duodenum and with difficult angles. But we succeeded in taking FNA from all cases.

Conclusion: EUS FNA is a very effective method for diagnosis of distal bile duct masses with a certain diagnosis in almost 81% and a suspicious diagnosis in around 11% cases. Its efficacy is better than ERCP guided brush cytology. Even small masses are amenable to FNA using EUS guidance. Male over 57 years with jaundice and distal bile duct obstruction has a very likely hood of having a distal CBD cholangiocarcinoma.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We aimed to evaluate the feasibility, yield, and safety of EUS-guided fine-needle drainage of lung tumours with a new 20G biopsy needle. We undertook a retrospective case series of 12 consecutive patients with suspected lung cancer or tuberculosis who underwent transaortic FNA during a study period of 7 years. In all cases, the para-aortic lesion was the only site suspicious for malignancy (lesion/lymph node if present were negative). Based on CT/PE imaging, a transesophageal FNA performed through the aorta was considered as the only option to diagnose or stage these patients by means of a minimally invasive procedure. Seven patients had left-sided lesions, and four were right-sided. The mean lesion size was 18 mm (range 8–22 mm), suspicious for IASLC stations 5 (n=1), 6 (n=2), and 8 (n=5). One patient had anterior mediastinum mass. EUS was performed with a linear echoendoscope. All aspirations were obtained under real-time US guided FNA by using a 22/25-gauge needle. A single real-time FNA of the lung mass or lymph node was performed. The para-aortal area was observed on EUS for 5 minutes to assess for immediate procedure-related complications.

Results: The final diagnosis was known in 11 patients (5 non-small-cell lung carcinoma [NSCLC], 2 small-cell lung carcinoma [SCLC], 3 tuberculosis and 1 thymolipoma). EUS-FNA established diagnosis in 9 of 12 patients (75%) (4 NSCLC, 1 SCLC, 3 tuberculosis and 1 thymolipoma). One aspirate revealed reactive nodal tissue, and one demonstrated nonrepresentative material. One procedure was abandoned due to complication. Three patients in whom diagnosis was not established by transaortic FNA underwent subsequent surgical staging (1 thoracotomy, 1 mediastinoscopy, and 1 VATS), and malignancy was found in 2 of the 3 patients. Trans aortic FNA was found to be safe in one patient. EUS images after FNA were suspicious for a small para-aortic hemanoma. This patient recovered without any adverse event.

Conclusions: This study demonstrates the feasibility and probable safety of single EUS guided transaortic aspiration in para-aortic lesions. The diagnostic yield is 75 percent. Clearly, further study and very careful selection by expert EUS operators is needed before this procedure can be routinely recommended. Advantages of this procedure include day care procedure, less invasive than surgical procedures, low cost, good diagnostic yield and can be performed in poor surgical candidate. Limitations includes single centre study, require EUS expertise, more data is required. At present, Transaortic FNA should only be performed in the absence of alternative minimally invasive diagnostic procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0254 ULTRASOUND-GUIDED ENDOSCOPIC TRANSDOUCAL GLAND DRAINAGE OF PANCREATIC FLUID COLLECTIONS

M. Silva1, S. Lopes1, A. Peixoto1, F. Vilas-Boas1, P. Moutinho-Ribeiro1, G. Macedo2

Introduction: Ultrasound-guided endoscopic transgastric drainage (EUSTD) of pancreatic fluid collections (PFCs) by using double-pigtail plastic stents (DPSS) represents an option of multiple stents and can be restricted by inadequate drainage and leak risk. Recently, the use of fully covered self-expanding metal stents (FCSEMSs) has been reported as an effective alternative.  

Aims & Methods: We aimed to evaluate the successful placement of stents, the complete resolution of PFCs at 6-months, adverse events, and recurrence of EUSTD of PFCs using DPSS and FCSEMSs. This was a single-centre retrospective study (2012–2016) on 67 patients with walled-off necrosis or pseudocysts. The mean lesion size was 43.1 ± 17.5 mm. The lesion locations were esophagus (n=1), stomach (n=37), distal duodenum (n=5), rectum (n=6), and colon (n=1). The procedure was technically feasible in all patients. Mean number of passes required to reach a diagnosis was 2.2 (range 1–4). A definitive diagnosis with full histological assessment including IHC was obtained in 88% (44/50) of the patients. Diagnosis of EUS-FNB showed 36 (72%) malignant SELs (32 GISTs, 1 metastasis from breast cancer, 1 leiomyosarcoma, 1 carcinoma, 5 SEL-like adenomas, 1 schwannoma) and 16 (32%) benign SELs (1 leiomymyoma, 4 schwannomas, and 1 lipoma), and 6 (12%) indeterminate SELs. Considering malignant vs. benign lesions, the sensitivity, specificity, PPV, and NPV were 85% (95% CI 70·2–94·3), 100% (95% CI 98·7–100·0), 100% (95% CI 98·5–100·0), and 62·5% (95% CI 27·7–84·4), respectively. No major complications requiring additional care were observed.

Conclusion: In this multicenter study, we found that EUS-FNB with the new 20G core needle is an effective and safe method for the diagnosis of SELs with a high rate of producing adequate histological material and high diagnostic accuracy even from difficult-to-approach anatomical locations. Comparative studies with different needle sizes are awaited.

Introduction: Endoscopic ultrasound(EUS)-guided ethanol ablation for cystic pancreatic lesions (PCLs) is a recently introduced treatment option for PCLs. The aim of this study was to compare the clinical outcomes of EUS-guided ethanol ablation with those of the natural course of PCLs.

Aims & Methods: We performed retrospective study of patients with PCLs divided in two groups: EUS-guided ethanol ablation group (n=118, performed between June 2006 to August 2015) and natural course group (n=458, diagnosed between January 1993 to August 2015). The propensity score-matching analysis
between the two groups was applied in order to minimize the effect of selection bias. The result of significant reduction in size (< 20% of initial size). The secondary outcomes were the rate of significant growth in size (> 10 mm), complete remission rate, and surgical resection rate.

**Results:** In a propensity matched analysis of 88 pairs, the mean initial cystic size of EUS-guided ethanol ablation group and natural course group was 23.72±10.99, 23.16±13.15 mm and the mean follow-up duration was 75.45±38.12, 82.12±59.06 months respectively. Significant reduction in size was detected in 53 (60.2%) of the EUS-guided ethanol ablation group and 17 (14%) of the natural course group (p = 0.022). Significant growth in size was detected in 6 (8.9%) of ablation group and 11 (12.5%) of natural course group. (p = 0.202). Seven patients (7.95%) underwent subsequent resection in the EUS-guided ethanol ablation group and 17 patients (19.3%) in the natural course group (p = 0.001).

**Conclusion:** DBERC facilitated cyanoacrylate injection of SBV. Retrospective review of DBE facilitated cyanoacrylate injection of SBV. This case series evaluated the usefulness of DBE facilitated cyanoacrylate injection therapy of SBV.

**P0259 EUS-GUIDED RADIOFREQUENCY ABLATION OF DIFFICULT SITES IN THE LIVER: A PRECLINICAL STUDY**

**Aims & Methods:** We examined whether a novel 19-gauge RFA needle can be introduced to ablate the liver in a porcine model under EUS guidance. Two pigs were used in this study. All procedures were carried out under general anesthesia. Ethanol was delivered with a 19-gauge needle and a VIF™ model generator (TaeWoong Medical, Gimpo city, Korea) were used for the procedures. Three kinds of RFA needles (10-, 15-mm, and 20-mm exposed tips) were used. After the echoendoscope was advanced to the stomach, the RFA needle was inserted into the surface of the left lobe. EUS-RFA was performed at 5–40 W for 2–6 min in general mode. In each pig, three RFA needles with 10-, 15-, or 20-mm exposed tips were serially used for insertion and ablation. Subsequently, the needle attached with the 10-mm exposed tip was used in the quadrant lobe of the gallbladder through the bulwark of the duodenum.

**Results:** All procedures were technically successful. After the procedure, the liver of the pig was removed, and visible RFA effect was evaluated macroscopically. Histology with hematoxylin and eosin (HE) staining showed coagulative necrosis in the ablated area, corresponding with the macroscopic ablated area.

**Conclusion:** In this experimental study, EUS-RFA could be performed technically not only in the surface of the left lobe, but also in the adjacent to the gallbladder of the porcine liver. Further studies are required to confirm the efficacy and safety.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0260 CYANOACRYLATE INJECTION THERAPY OF SMALL BOWEL VARICES BY DOUBLE-BALLOON ENTEROSCOPY (DBE): A TERTIARY CENTRE EXPERIENCE**

**Aims & Methods:** We review 346 patients with surgically altered anatomy who underwent DBERC from April, 2002 to December, 2016 (47 patients with bowel assisted liver transplantation (LDBT), 33 with LDBT with out BA, 45 with biliary resection and choledochojunostomy, 111 with gastric resection and Roux-en-Y bypass, 48 with gastric resection and Billroth-Ileumen, 18 with pylorus-preserving pancreato-duodenectomy, and 42 others). We evaluate the success rate according to the type of gastrointestinal anastomosis, age, and age at surgery.

**Results:** The success rate for reaching the biliary anastomosis (or papilla of Vater) in all 346 patients (66.0% (3–91)) was 83%. The rate in 47 patients with BA after LDLT (12.0y (3–39)) was 57%. In the remaining 299 patients the rate was 87%.

The success rate of reaching the biliary anastomosis in patients with BA after LDLT was significantly lower than other patients (p < 0.01). There was no significant difference between the success rate in the patients over or under 13 years at the time of ERCP (50% vs 56%, p = 0.70). The success rate was lower in patients who underwent initial surgery as an infant (Kasai hepatoportovenostomy) than in those past infancy (54% vs 88%, p < 0.01). When reaching the biliary anastomosis is successful, the success rate of cannulation in the patients after LDLT is high (92%).

The success rate for reaching the biliary anastomosis in patients with BA after LDLT is significantly lower than other patients. The age at the time of ERCP did not affect the success rate of reaching the biliary anastomosis, but the success rate was lower in patients who underwent their initial surgery as infants.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0285 THE SUCCESS RATE OF DOUBLE BALLOON ENDOSCOPIC CHOLANGIOGRAPHY IN PATIENTS WHO UNDERWENT THEIR INITIAL SURGERY AS INFANT IS SIGNIFICALLY LOWER THAN OTHER PATIENTS**

**Aims & Methods:** We aimed to compare tissue acquisition between the 22G Fransene and 22G Fork-tip needles in patients undergoing EUS-guided sampling of pancreatic masses.

**Results:** Patients with pancreatic masses were randomized to undergo EUS-guided sampling using the 22G Fransene and 22G Fork-tip needles. Two dedicated passes were first performed using both needles in individual patients for cell block. Subsequent passes were then performed for rapid onsite evaluation (ROSE) under both ROSE only until a diagnosis was established. The main outcome measures were to compare total tissue volume and presence of desmoplastic stroma in pancreatic cancer. Secondary outcome measures were to compare rates of diagnostic cell block and diagnostic adequacy at ROSE.

**Conclusion:** Both the Fransene and Fork-tip needles appear equally effective in yielding histological tissue. By virtue of their ability to yield a diagnostic cell block in greater than 90% of patients, the new generation FNB needles may be expected to achieve a certain level of complete remission for PCLs. It is also expected to achieve a certain level of complete remission for PCLs.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

and injected with cyanoacrylate glue. There were no haemorrhagic or embolic complications. All patients developed an oral opening of a congenital perianal cyst, which was treated successfully with antibiotics. All patients underwent DBEs via the anterograde route and one patient required bi-directional DBE for treatment of both proximal and distal SBV and another patient required a 2nd anterograde DBE for treeting of further patent proximal SBV. At 30-day follow-up post-therapy, only 1 patient had experienced a mild recurrence of mid-gut bleeding.

Conclusion: Cyanoacrylate injection therapy of SBV at DBE appears to be a safe and effective management strategy for this condition when other first-line options are not feasible.

P0261 MAGNIFYING NARROW-BAND IMAGING FINDINGS EFFICACY FOR INFLAMMATORY ACTIVITY EVALUATION IN SMALL INTESTINAL CROHN'S DISEASE WHEN USING NEWLY DEVELOPED MAGNIFYING ENTEROSCOPY: A PILOT STUDY

N. Ogata1, K. Ohtsuka2, S. Sasanauma1, M. Misawa1, Y. Moril3, T. Kudol, T. Hisayukil, T. Hayashil, K. Wakamurul, S. Kudol

1Digestive Disease Center, Showa University Northern Yokohama Hospital, Yokohama/Japan
2Gastroenterology And Hepatology, Tokyo Medical and Dental University, Tokyo/Japan

Contact E-mail Address: n.ogata@hotmail.co.jp

Introduction: The development of balloon endoscopy and capsule endoscopy has made observation of the small intestine possible in clinical practice. The usefulness of magnifying endoscopy has already been reported in observing the pharynx, esophagus, stomach and colon. A single-balloon enteroscopy (SBE) with the usefulness of magnifying endoscopy has already been reported in observing the pharynx, esophagus, stomach and colon. A single-balloon enteroscopy (SBE) with 80x magnification has been recently developed. Aim & Methods: The aim of this pilot study was to assess the efficacy of narrow-band imaging (NBI) magnifying findings for evaluating the severity of inflammation in small intestinal crohn's disease (CD). The study was conducted in Showa University Northern Yokohama Hospital. We included CD patients who underwent enteroscopy with magnification from September 2013 to February 2015. NBI images and a biopsy specimen were obtained from small intestinal mucosa for CD patients with use of SBE (Y-0007, Olympus, Tokyo). Magnifying NBI was performed, and the images were evaluated by assessing visibility, increased vascularization, and the increased caliber of capillaries into three grades as follows: Normal, Visible and Irregular. Normal was indicative of inactive disease, while Visible and Irregular were indicative of acute inflammation in our study. The outcome measures included the diagnostic ability of magnifying NBI findings to distinguish active CD from inactive CD on the basis of histological activity.

Results: Twenty-four patients were enrolled. There was a correlation between magnifying NBI findings and the histological assessment (Spearman’s r = 0.540). Magnifying NBI findings showed a correlation with histological inflammation and could help in distinguishing CD from inactive CD on the basis of histological activity.

Conclusion: Magnifying NBI magnifying NBI findings in the small intestinal mucosa had a correlation with histological inflammation and could help in distinguishing between active and inactive CD.

Introduction: Double balloon enteroscopy (DBE) has revolutionised the diagnosis and treatment of small intestinal conditions. However, even in expert hands, deep small bowel (SB) insertion can be challenging, especially in patients with a history of abdominal/pelvic surgery. Moreover, if the findings at DBE are not amenable to endoscopic therapy, a further surgical procedure is usually required to provide definite treatment. Laparoscopic-assisted DBE (LA-DBE) using a standard multi-port technique has previously only been reported in a small series of 3 patients with Peutz-Jeghers Syndrome (PJS). Aim & Methods: This case series reports the development of LA-DBE using single-incision laparoscopic surgery (SILS) applied to a wide range of clinical indications. Retrospective review of LA-DBE procedures performed in a single tertiary centre over a 6 year period. Demographics, indication, findings, diagnostic and therapeutic interventions were recorded. Completion, complication rates and hospital length of stay were also captured.

Results: 17 procedures were performed over 6 years in 17 patients who had failed standard DBE. Mean (range) age was 40 (17-73) and 41% of patients were male. The enteroscopic approach was oral in 13/17 patients and rectal in 4/17. Laparoscopic approach was standard (multipor) in the 4 first cases. SILS was then used in all subsequent patients (13/17). The mean (range) procedure time was 147 (84–210) mins. Indications were PJS (n = 10), suspected submucosal/ subserosal mass lesion at small bowel imaging (n = 5) and obscure gastrointestinal bleed (OGBB) with vascular abnormalities seen at capsule endoscopy (n = 2). In 15/17 procedures the target pathology was reached using laparoscopic assistance only and 1/17 was converted to intraoperative enteroscopy (IOE). In 1/17 the suggested pathology at magnetic resonance enterography (MRE) was not identified. Therapy was applied in 15/17 (88%) cases. 7 underwent endoscopic therapy which of 6 polypectomy and 1 ablation with argon plasma coagulation (APC). 4 required limited SB resection and 4 underwent both endoscopic polypectomy and small bowel resection for a second polyp that could not be removed endoscopically. A total number of 57 polyps were removed with the largest measuring 40 mm. The range of length of surgically resected SB was 4–17 cm. Diagnoses were PJS polyps (n = 9), neuroendocrine tumour (NET) (n = 2), PJS polyps and NET (n = 1), tropical arteriovenous malformation (n = 1), angioectasia (n = 1), inflammatory polyp (n = 1), leiomyoma (n = 1), Mcekel’s diverticulum (n = 1). Median length of stay post procedure was 2 (1–19) days. 8/17 patients were discharged at 24 hours. 3/17 patients developed complications: 1 intra-abdominal bleed, 1 pelvis collection that was managed with antibiotics and 1 patient that was readmitted 8 days post procedure with subacute OB obstruction which resolved with conservative management.

Conclusion: LA-DBE appears to be a safe, effective and minimally invasive procedure that can be applied for the management of a wide range of small bowel pathology. A SILS approach allows all therapeutic modalities to be available as needed during the procedure, including conversion to IOE, laparoscopic small bowel resection and laparotomy.

P0263 GASTRIC EMPTYING IN CROHN'S DISEASE – EVALUATION BY SMALL BOWEL CAPSULE ENDOSCOPY

A.M. Singeap1, A. Trifan2, S. Chiria1, I. Girleau1, T. Cucireanu1, C. Stanciu2

Introduction: The complex relationship between inflammatory bowel disease (IBD) and motility disorders of the digestive tract is a complex area of study, so far incompletely elucidated. The association between Crohn's disease and gastric emptying time modification has been relatively less studied. However, there is no single standardized method to study gastric emptying, one particular investigation that could bring direct information in this field being the small bowel capsule endoscopy (SBCE).

Aims & Methods: We aimed to study gastric emptying by small bowel capsule endoscopy in patients with suspected and confirmed Crohn's disease. We evaluated gastric passage time showed by SBCE in patients with small bowel Crohn's disease, compared to patients without IBD, investigated by SBCE (PillCam), following recognized indications, in the Institute of Gastroenterology and Hepatology of Iasi, tertiary center in North-East of Romania.

Results: 144 SBCE studies were included, 24 were cases of suspected and confirmed Crohn’s disease. The mean time of gastric passage in patients with Crohn’s disease was 51 ± 2.1 minutes, longer than in patients without inflammatory bowel disease, in which the mean gastric passage time was 24 ±16.6 minutes.

Conclusion: Gastric passage time, evaluated by SBCE, is prolonged in patients with small bowel disease compared to patients without IBD, suggesting a relationship between chronic inflammation and gastric motor disorders. Globally, the values correlated with those considered as physiological by other exploration methods. SBCE studies may provide additional data on gastric motility (and in general gut motor disorders), with special usefulness in some individual cases, as particular symptoms or variations in the bioavailability of small bowel-released drugs.

P0264 META-ANALYSIS SHOWS THAT PURGATIVE PREPARATION INCREASES SMALL BOWEL VIDEO CAPSULE ENDOSCOPY DIAGNOSTIC YIELD AND IMPROVES THE QUALITY OF SMALL BOWEL MUCOSA VISUALIZATION

P. Gkolakis, G. Triantios, G. D. Dimitriadis, K. Triantafyllou

2nd Dept Of Internal Medicine And Research Institute, National and Kapodistrian University of Athens, Medical School, Athens/Greece

Contact E-mail Address: ktriant@med.uoa.gr

Introduction: The value of purgative preparation (PBP) before small bowel video capsule endoscopy (VCE) remains controversial and it has been recently challenged. Aims & Methods: The aim of this meta-analysis was to examine the effect of PBP on small bowel VCE outcomes. We performed literature searches in MEDLINE and Cochrane Library to identify randomized-controlled trials (RCTs) evaluating the effect of small bowel preparation –purgative (PEG, sodium phosphate,
In comparison to clear liquids diet, PBP significantly increased small bowel VCE DY. They were low risk of bias trials and no publication bias was detected. As assessed using the Jadad criteria.

**Results:** Five clear images of SB pathology were obtained using MiroCam® (Intromedic, South Korea), image resolution 320×320 pixels(px). P1 and P2 angioectasias, ulcer, aphtha and polyp. Each image was processed using GIMP2 image editing software (www.gimp.org) for 3 parameters: (1) opacity (opacity filter matched in colour to commonly-seen SB contents, 10–90% in 10% increments), (2) blur (Gaussian blur, radius 1–10px), (3) contrast (±50% to 50% in 10% increments). Gaussian blur was used to simulate the effects of rapid capsule movement as well as to affect image definition. A set of 5 original and 190 edited images was obtained. A web-based survey was created using Google Forms and 9 expert CE readers were asked to indicate whether each image was adequate or not for diagnosis. The order of images was randomised for each reader. For each type of pathology, we determined the threshold of image quality that was deemed adequate for diagnosis.

**Results:** For image opacity, both PBP and the polyoid lesion were adequately visualised below 40% opacity whereas the threshold was lower for both the ulcer and aphtha (10% opacity). Increasing blur radius significantly impacted the acceptability of images for reaching a diagnosis with confidence; for most images, blur radius 3px was the threshold for adequate visualisation but even 1px of blur radius decreased the visualisation quality of the aphtha image. The aphtha image was also affected the most by decreased contrast; conversely the ulcer was deemed more inadequately visualised with higher contrast. The other images were generally adequately visualised at ±10% contrast. Results are detailed in the table below.

**Conclusion:** This pilot study shows that image quality is a defining factor in accurate diagnosis in CE. Image quality is commonly affected by the opacity of luminal fluid/residue, and the quality of imaging delivered by the CE system. More subtle mucosal lesions such as aphthae are affected more by decreased contrast. Interestingly, a relatively high level of image opacity can be tolerated by CE readers whereas blurriness seems to have a greater effect on visualisation quality and reviewer confidence in the diagnosis. The effects of these aspects in combination merit further investigation.

Inflammatory bowel disease (IBD) is a chronic inflammatory disease that may affect the whole gastrointestinal (GI) tract, mainly the small bowel and colon. Endoscopic examination of these parts is essential to assess disease extent and severity. The small bowel capsule endoscopy (SBC-CE) system is a new system composed of a two-headed capsule with a panoramic field of view and adaptive frame rate, customized for complete coverage of IBD lesions in the entire bowel, data recorder and new disease specific software, allowing assessment and follow-up over time of disease severity and extent.

**Aims & Methods:** The aim was to evaluate SBC-CE system functionality in suspected or established IBD (Crohn’s disease [CD] and ULCeraive Colitis [UC]) patients. This was a prospective 5 center feasibility study assessing the performance of capsule and software. Subjects enrolled in the study ingested the new capsule after standard bowel preparation plus boosts. Contraindications for its use included obstruction, dysphagia or swallowing disorders, pacemakers etc. GI patency was assured using the patency capsule. The patient's capsule was successful procedure in terms of video creation and read generation in accordance to the video reading methodology. Secondary endpoints were subjective coverage of SBC, subjective duration of total and segmental reading time, over all video quality and occurrence/severity of adverse events.

**Results:** of which 54 were enrolled and 49 ingested the capsule (14 patency failure, 5 withdrew consent). Mean age was 40.1 years, 51% were females. 69% of patients had established CD, 10% UC and 21% suspected CD. The disease was active in 62% of known IBD patients. One patient who undergoing extensive colon resection was excluded from all colon analyses. Overall cleansing was regarded good or excellent in 96% of patients. All 49 videos met the primary endpoint, i.e. video was created and report generated under reading time, over all video quality and occurrence/severity of adverse events.

**Conclusions:** The new SBC capsule is a friendly, minimally invasive capsule allowing complete evaluation of the entire gut of IBD patients. The system may be used to assess disease severity and extent and for follow up of IBD patients.

**P0268** THE UTILITY OF A NOVEL TRANSPORTABLE DILATION TECHNIQUE WITH A DIATHERMIC CATHER FOR SEVERE MAIN PANCREATIC DUCT STRICTURE DUE TO CHRONIC PANCREATITIS

S. Kato, M. Kuwatani, R. Sugira, I. Sano, K. Kawabuko, N. Sakamoto

Gastroenterology And Hepatology, Hokkaido University Hospital, Sapporo/Japan

**Contact E-mail Address:** shinchun1231@gmail.com

**Introduction:** Transpanpillary biliary drainage for severe main pancreatic duct (MPD) stricture is sometimes difficult and diathermic dilation is now getting attention as a salvage technique for severe stricture; however its efficacy and safety remains unclear.

**Aims & Methods:** To evaluate the efficacy and safety of a novel transportable dilation technique with a diathermic catheter for severe MD pancreatic stenosis due to chronic pancreatitis. Between April 2011 and March 2017, 143 patients with chronic pancreatitis underwent endoscopic transpanpillary stent placement for MPD. MPD dilation was indicated in 18 patients, and diathermic dilation was required in nine patients. We evaluated (1) the patients’ characteristics, (2) procedure characteristics, (3) clinical outcomes, (4) adverse events. 

**Results:** (1) Six patients were men and three were women (mean age, 50.1 years). Alcohol use was unknown. 1. The strictures were in the head of pancreas: 8, body: 1.

The mean length of stricture was 20.2 mm (range, 10.0–30.8). The mean MPD diameter at the stricture was 6.2 mm (range, 4.0–5.7). A total of 13 patients (55.6%) among them had no former procedure for MPD including stenting. (2) A wire-guided 6Fr diathermic catheter with 30 W power was used for all cases. All cases underwent diathermic dilation as salvage procedure subsequent to conventional dilation. One to 7 diathermy procedures (mean 2.9) were performed in all cases. Passage of the diathermic catheter and stent placement was successful in all patients (100%). After diathermy and stent placement, 8 (88.9%) showed improvement of clinical symptoms (abdominal pain). Recurrence of stricture was observed in 2 patients (22.2%). One of them needed diathermic dilation again. (4) Two adverse events (22.2%) were observed and both of them were mild pancreatitis. Multiple diathermy procedures (6 times and 4 times, respectively) and relatively long duration total diathermy procedures (39 sec. and 25 sec. respectively) were observed in cases with pancreatitis.

**Conclusion:** Transpanpillary diathermic dilation is a relatively safe and effective salvage procedure for severe MPD stricture due to chronic pancreatitis. Care should be taken in cases that require multiple times and long duration diathermy procedures because of a risk of pancreatitis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P0270 OUTCOME OF ENDOSCOPIC REINTERVENTION FOR MALIGNANT OBSTRUCTION TREATED BY STENT-IN-STENT DEPLOYMENT
Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of
Contact E-mail Address: subsulup@naver.com

Introduction: Endoscopic biliary decompression is widely used for advanced hilar cholangiocarcinoma. Bilateral stenting has become more feasible with more experienced endoscopists and the development of new devices. However, stent dysfunction develops in 3% to 45% because of tumor ingrowth, overgrowth, or debris as disease progresses. Endoscopic reintervention is difficult and complex with worsening bile duct strictures. The present study aimed to evaluate a suitable re-intervention procedure for stent malfunction after stent-in-stent (SIS) deployment for malignant hilar obstruction.

Aims & Methods: From September 2009 to June 2016, a total of 52 patients who underwent bilateral stenting at Pusan National University Yangsan Hospital were enrolled in this study. Among them, 20 patients who underwent reintervention due to stent malfunction were analyzed. Reintervention was performed endoscopically or percutaneously. Technical and functional success rates were evaluated retrospectively.

Results: Technical and functional success rates of endoscopic reintervention were 83% (10/12) and 80% (8/10), respectively. Endoscopic bilateral and unilateral reintervention success rates were 75% (6/8) and 100% (4/4), respectively. Functional success was observed in 8 out of 10 patients (80%) who achieved technical success. For bilateral reintervention, either plastic or metal and metal stents were used. PTBD was performed in 8 patients because of duodenal stenosis (2 patients) and other conditions.

Conclusion: Endoscopic reintervention could be considered in the case of stent malfunction and fair patient conditions after SIS placement for malignant hilar obstruction. Decisions regarding bilateral or unilateral drainage and types of stents should depend on the conditions of the disease and the patient.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0271 LONG-TERM OUTCOMES OF ENDOSCOPIC ULTRASOUND-GUIDED TRANSMURAL RIGHT INTRAHEPATIC BILE DRAINAGE WITH TRANSMURAL COVERED METAL STENT
Gastroenterology, Asan Medical Center, Seoul/Korea, Republic of
Contact E-mail Address: dhcho81@daum.net

Introduction: Endoscopic ultrasound-guided biliary drainage (EUS-BD) has been regarded as an effective alternative in cases of endoscopic retrograde cholangiopancreatography (ERCP) failure or inaccessible papilla. However, EUS-BD for right intrahepatic duct obstruction (EUS-BDR) remains challenging, although recent studies showed promising result. The aim of current study was to evaluate the feasibility and long-term outcomes of EUS-BD with transmural covered metal stents for right intrahepatic duct obstruction.

Aims & Methods: Retrospective study, a total of 24 consecutive patients who underwent EUS-BDR after failed ERCP were enrolled. The patients were consisted of 12 cases of benign strictures and 12 cases of malignant strictures. The biliary stents used in this study was covered metal stent with anchoring flaps (fully covered metal stent with anchoring flaps or partially covered metal stent with anchoring flaps). The technical success rate, clinical success rate and adverse events were evaluated.

Results: The target bile duct was right anterior in 6 patients and right posterior segmental duct in 18 patients. Among them, percutaneous transhepatic biliary drainage assisted EUS-BDR was performed in 3 patients. The technical and clinical success rate was 95.8% (23/24) and 95.6% (22/23). Mean diameter of right intrahepatic duct before deployment was 6.5 (4–30) mm. A fully covered metal stent was used in 22 patients and partial covered stent in 2 patients. Early adverse events developed after EUS-BDR in 2 patients (1 case of cholangitis and 1 case of liver abscess in patients with malignant biliary stricture). Late adverse event that stent occlusion was observed in 5 patients. Neither proximal nor distal tumor stent migration or spontaneous distal stent migration was observed during follow-up periods. The stent patency duration was 275.2 (147.8–402.7) days. During follow-up period, stent revision via fistula tract was successful and additional percutaneous biliary drainage for right intrahepatic duct obstruction was not required in all patients who achieved clinical success.

Conclusion: EUS-BD using transmural covered metal stent with antimigration properties for right intrahepatic duct obstruction may be technically feasible, effective and relatively safe for both biliary strictures by expert hands. Furthermore, the route of hepatocoduodenostomy created by covered metal stent was durable and endoscopically easily managed.

P0272 UTILITY OF EUS-GUIDED HEPATICOGASTROSCOPY WITH ANTEGRADE STENTING FOR MALIGNANT BILIARY OBSTRUCTION OF ERCP INABILITY
H. Inui, M. Takenaka, M. Kudo
Gastroenterology And Hepatology, Kindai University, Osakasuayama/Japan
Contact E-mail Address: codenamegenchan1023@gmail.com

Introduction: Recently, EUS-guided biliary drainage (EUS-BD) techniques such as antegrade cholecodochoscopy (AGS) and rendezvous stenting (RVS) are useful for biliary drainage methods after unsuccessful ERCP. Among these procedures, CDS and RVS require the echoendoscope reaching duodenum. Therefore, HGS and AGS are accurate in cases with difficult duodenal access. However, HGS and AGS are associated with a higher risk of adverse events, compared with the other methods. When the stent dysfunction occurs, re-intervention is more difficult after AGS alone than after HGS or CDS. Thus, we started to add AGS during HGS in a single session from January 2011.

Aims & Methods: The aim of this study to assess the efficacy and safety of HGS combined with AGS for malignant biliary strictures-induced obstructive jaundice. Between Jan. 2006 and Dec. 2014, ERCP was attempted in patients with obstructive jaundice, which was successful in 641 patients and impossible in 154 patients (101cases due to post-surgical altered anatomy or duodenal stenosis, 53 cases due to difficult cannulation). A total of 145 patients received EUS-BD, HGS and AGS with were attempted in 42 (Group A; from Jan 2006 to Aug 2011) and 103 patients (Group B; from Aug 2011 to Dec 2014). The outcomes were evaluated during a median follow-up time of 157 days in Group A and 150 days in Group B. The two groups were comparable for the functional success rate.

Results: The technical success rate of Group A was significantly higher than Group B (97.6 vs 83.8%, p = 0.03). The two groups were comparable for the functional success rate (98.2% vs 95.8%, p = 0.3). The rate of adverse events tended to be higher in Group A than in Group B (26.1% vs 13.5%, p = 0.10). The re-intervention rate tended to be higher in Group A than in Group B (16.7% vs 8.1%, p = 0.25). Groups A and B did not differ significantly in terms of median overall patient survival (75 days vs. 81 days, p = 0.70), and median time to stent dysfunction or patient death (68 vs 63 days, p = 0.08). In patients who underwent chemotherapy, there were no difference in the overall patient survival time (121 vs 137 days, p = 0.08) between the two groups although the time to stent dysfunction in Group B was significantly shorter in Group A than in Group B (71 vs 95 days, p = 0.02).

Conclusion: Technical success rate of HGS with AGS was lower than HGS, although HGS with AGS is superior to HGS in terms of stent patency in patients who underwent chemotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0273 EUS-GUIDED GALLBLADDER DRAINAGE REDUCES LATE ADVERSE EVENT AND NEED FOR RE-INTERVENTION COMPARED WITH PERCUTANEOUS CHOLECYSTOSTOMY IN PATIENTS WHO ARE NOT ELIGIBLE FOR SURGERY
Gastroenterology, Asan Medical Center, Seoul/Korea, Republic of
Contact E-mail Address: dhcho81@daum.net

Introduction: Endoscopic ultrasound guided transmural gall-bladder drainage (EUS-GBD) with covered metal stent has become increasingly used to treat patients with acute cholecystitis who are not a candidate for surgical treatment. However, there are limited data comparing long-term outcomes of EUS-GBD with covered metal stent and conventional percutaneous cholecystostomy.

Aims & Methods: Retrospective study, the long-term outcomes of EUS-GBD and percutaneous cholecystostomy in patients who are not suitable for cholecystectomy. Data about the patient who underwent EUS-GBD for acute cholecystitis is obtained from prospective collected EUS database at Pusan National University Yangsan Hospital, and the clinical record of patients who underwent percutaneous cholecystostomy was reviewed and analyzed. Demographics and procedure related outcomes including early, late adverse events and need for re-intervention in each group was compared.

Results: A total of 181 patients (74 in EUS-GBD group and 107 in percutaneous cholecystostomy group) were enrolled in this study. The cause of cholecystitis and ASA class were similar in both groups. The technical/clinical success rate was 100%/98.6% in EUS-GBD group and 99.1%/97.2% in percutaneous cholecystostomy group (P = 0.591). However, adverse events such as migration of stent or dislodgement of drainage tube, stent or tube occlusion, tract inflammation around percutaneous tube, bile leakage and recurrence of cholecystitis were more frequently observed in percutaneous cholecystostomy group (5.74% in EUS-GBD group and 21.07% in percutaneous cholecystostomy group, P = 0.017). Percutaneous cholecystostomy tube was indwelled for

Introduction: The “fully covered self-expandable metallic stents” (FcSEMSs) were found to be non-inferior to multiple plastic stents (MPSs) for the treatment of anastomotic biliary strictures after orthotopic liver transplantation (OLT). However, there is scarce data about their efficacy in the treatment of anastomotic biliary strictures following LDLT. We aimed to compare the efficacy of FcSEMSs and MPSs for the treatment of anastomotic biliary strictures after LDLT.

Aims & Methods: We retrospectively analyzed the data of LDLT patients with duct-to-duct anastomotic biliary strictures who underwent endoscopic treatment at our center within the last 3 years. FcSEMSs were inserted in 23 patients (13 male, 10 female; mean age 51 ± 11 years) with MPSs insertion (Group-2). In Group-1, secondary branch ducts were prophylactically drained with the insertion of plastic stents in order to prevent the development of cholangitis due to occlusion. FcSEMSs and plastic stents were left in place for 2 months. In Group-2, maximum number of plastic stents were inserted and replaced every 3 months. Patients with a follow-up duration of at least 3 months after stenting were included in the study. Primary endpoints were the number of endoscopic procedures and the time required for strictures resolution. The secondary endpoint was the recurrence rate of the stricture.

Results: FcSEMSs were successfully deployed in all cases. The diameter of the FcSEMSs was 10 mm in 22 patients and 8 mm in 1 patient. The length of the FcSEMSs was 8 cm in 13 patients, 10 cm in 9, and 12 cm in 2 patients. Secondary branch ducts were prophylactically drained with a single plastic stent in 12 patients, 2 plastic stents in 8 patients, and 3 plastic stents in 3 patients. The median number of endoscopic procedures was 2 (2-4) in Group-1 and 4 (2-9) in Group-2 (p = 0.001). The time required for stricture resolution was shorter in Group-1 (65.7 ± 18.2 days) than in Group-2 (240.1 ± 183.4 days) (p < 0.001). The recurrence rates were similar in Group-1 (17.4%) and Group-2 (15.6%) (p = 0.87) after a follow-up period of 315.2 ± 290 and 378.6 ± 86 days, respectively.

Conclusion: FcSEMSs is an effective method for the treatment of anastomotic biliary strictures after LDLT, with a lesser number of endoscopic sessions and a shorter stenting duration required for the resolution compared to MPS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal stenting is a minimally invasive, reliable and effective intervention in patients with malignant colorectal obstruction, associated with a low complications rate compared to traditional surgical treatments. One of the actual problems associated with colorectal stenting is the recurrence of symptoms of obstruction. The most common cause is migration of covered stents and ingrowth of uncovered stents 1–3. The aim of our study was to compare the results of the use of stents of a new design, the development of which was aimed at preventing these complications.

Aims & Methods: We aimed to evaluate the results of the use of stents of the new design (double uncovered and dual coated colorectal stents). Between December 2012 and April 2017, 77 patients with colorectal malignant obstruction were implanted 78 stents (39 bare, 39 covered EGIS Colorectal stent, S&G Biotech Inc., South Korea). A double uncovered stent has a two-layer structure created by crossing two stents, resulting in a smaller cell size. Such a design theoretically can prevent the ingrowth of the tumor, localization and uncovred edges prevent the migration of the stent. All interventions are performed by one operator using endoscopic and radiological control. Groups of patients using coated and uncovered stents were comparable in terms of sex, age, duration of symptoms of obstruction, and stenosis localization. The reasons for the obstruction were primary tumors of the colorectum 97.4%. The localization of the tumor is most common in the sigmoid colon - 54%. The average follow-up period was provided to 43(55.8%) patients, «bridge to surgery» – 34 (44.7%) patients.

Results: Clinical success was achieved in 74 (96.1%) patients. In two cases, when using covered stents, the symptoms of obstruction could not be reduced, the patients were operated. In one case, 18 hours after stenting with an uncovered stent, was diagnosed perforation due to obstructive colitis. The average stay in hospital after the intervention was 3 days; the difference between the groups was statistically insignificant. 30 day mortality was 5.2%, the difference was statistically insignificant.

Conclusion: Double bare and double covered colorectal stents are feasibility and efficacy for relieving malignant colorectal obstruction. Reobstruction was rare complication and not different in both groups stent groups. Necessary to continue to research for the accumulation of material from other centers.

Introduction: Endoscopic therapy has been emerged as alternative treatment to bariatric surgery for reducing weight. We developed a new endoscopic gastrointestinal (GI) bypass stent and designed a preclinical study to assess the safety in a porcine model.

Aims & Methods: The aim of this study is to investigate the feasibility of our GI bypass device in animal. Before animal study, we performed an experimental study for durability test under simulated intestinal fluid flow. And next, we performed an animal study with 10 Yorkshire pigs. The stents were placed on pylorus with fixration by clippings or on duodenal bulb without fixation. Follow up endoscopy was done per one week after implantation. After they were sacrificed, gastric, duodenal, and jejunal tissues were harvested and examined for histologic assessment of any device or procedure-related effects.

Results: Our new GI bypass stent showed a good durability in simulated solution flow. No breakage or migration of stent occurred under continuous water flow in simulation system setting. In animal study, the mean starting weight was 30.1 ± 1.5 kg. Delivery of the implant took an average of 19.8 min (range, 11–33 min). pyloric stent group and 11.2 min (range, 6–18 min) in duodenal bulb stent group. It required an average clipping time of 10.8 min (range, 8–14 min). Followed for stent migration after implantation, the mean latency duration was 1.5 ± 0.7 weeks. One pig was died due to small bowel perforation and peritonitis after stenting. In histologic finding, there were moderate degree of mucosal erosions, but no definite ulceration on pylorus and duodenum.

Conclusion: Our new GI bypass stent has a good physiocompatible properties in simulated intestinal system. In animal, all stents were successfully deployed but migration of stent was found in this study. Future study is needed for comparison with current endoscopic bypass devices, such as endoscopic suture machine and modification of stent would be required. Introduction: Dysphagia may occur due to benign pharingo-esophageal strictures, orastradiation-induced complications. The aim of the study was to access long-term efficacy of pharingo-esophageal dilations due to anastomotic or post-radiation strictures.

Aims & Methods: Retrospective study of patients suffering of dysphagia due to radiation or anastomotic stenosis. Patients with previous dilations. The aim of the study was to access long-term efficacy of pharingo-esophageal dilations due to anastomotic or post-radiation strictures.

Results: Forty-eight patients (96 dilations) were evaluated (median of 4 dilations/patient). 85% were male, mean age of 62 years-old, 60% belonging in CaF1 group; between control dilations median interval of 5 weeks. Initial dysphagia Mellow-Pinkowsky score and luminal calibre were 3 ± 1 and 7 ± 2; 8,2 mm, respectively. Twenty-eight patients (out of 30 live patients non-submitted to additional therapies) answered to the interview: 96% had improved. 60% had no symptoms at all, 75% didn ´ t need further dilations, 8% PEG, with a combined efficacy of 58, 3%. Nine patients required additional therapy (6 PEGs, 2 prosthesis, 1 electroincision). Overall, 17 (out 21 with previous PEG) were able to resume feeding per os. Fifteen and 29% presented Kochen criteria for satisfactory and recurrence strictures, respectively. There were two post-procedure complications (< 1%): one deep laceration and one pharingo-esophageal fistula. Overall mortality was of 20% (10 patients died of non related procedure causes). Mean follow-up was 29, 2 ± 11, 2 months. Number of dilations and initial lumen calibre were significant predictors of combined efficacy in the univariate analysis; radic strictures predicted a greater final dysphagia in the uni- and multivariate analysis.

Conclusion: Our dilatation programme relevant benefit to these patients and a low rate of complications. Patients with post-radiation strictures presented a worse prognosis. Even though retrospective we present the longest follow-up and focusing not only in objective measures but also in patient perception of therapy (6 PEGs, 2 prothesis, 1 eletroincision). Overall, 17 (out 21 with previous PEG) were able to resume feeding per os. Fifteen and 29% presented Kochen criteria for satisfactory and recurrence strictures, respectively. There were two post-procedure complications (< 1%): one deep laceration and one pharingo-esophageal fistula. Overall mortality was of 20% (10 patients died of non related procedure causes). Mean follow-up was 29, 2 ± 11, 2 months. Number of dilations and initial lumen calibre were significant predictors of combined efficacy in the univariate analysis; radic strictures predicted a greater final dysphagia in the uni- and multivariate analysis; recurrent/refractory stenosis didn ´ t significantly predict global efficacy.

Introduction: Benign anastomotic strictures are common adverse events of gastrointestinal tract surgery. And, they are difficult to be managed conservatively. The first choices of treatment of anastomotic strictures are balloon dilatation and bougination. But, they are requiring repeated sessions. Self-expandable metallic stent (SEMS) placement has continuous expanding effect for a long period. But, it is problematic to inhibit stent migration. Therefore, the new method to inhibit stent migration is needed for more successful management of anastomotic stenosis.

Aims & Methods: The aim of this study was to evaluate the clinical feasibility of new method to inhibit stent migration in postoperative anastomotic stricture. From May 2013 until February 2015, patients with benign anastomotic stricture after subtotal gastrectomy were enrolled at a single tertiary referral hospital, prospectively. The Niti-S ComVi pyloric stents (Taewoong Medical, Korea), were used. The Danis-Stent was placed in the first week after surgery. The stent was replaced at weekly intervals until the dysphagia improved. If the stent was stable, the stent was removed after 2 weeks.

Results: Among 35 patients, 13 patients had an unsuccessful endoscopic balloon dilatation (EAD) prior to Danis-Stent for massive/refractory EVB at 4 tertiary care centers in Vienna (Medical University of Vienna, Krankenanstalt Rudolfstiftung, Wilhelminenspital and Krankenhaus Hietzing). Rates of bleeding control (5 days), bleeding-related mortality (6 weeks) and overall mortality were assessed.

Conclusion: The new method with fastening the stent with loop and clip can reduce the risk of stent migration.

References

Introduction: Benign anastomotic strictures are common adverse events of gastrointestinal tract surgery. And, they are difficult to be managed conservatively. The first choices of treatment of anastomotic strictures are balloon dilatation and bougination. But, they are requiring repeated sessions. Self-expandable metallic stent (SEMS) placement has continuous expanding effect for a long period. But, it has problem of frequent stent migration, because of slow stent expanding, 2–3 days. Therefore the new modified method to inhibit stent migration is needed for more successful management of anastomotic stenosis.

Aims & Methods: The aim of this study was to evaluate the clinical feasibility of new method to inhibit stent migration in postoperative anastomotic stricture.

From May 2013 until February 2015, patients with benign anastomotic stricture after subtotal gastrectomy were enrolled at a single tertiary referral hospital, prospectively. The Niti-S ComVi pyloric stents (Taewoong Medical, Korea), double-layered, covered, were inserted. We made two nylon thread loops at the proximal bared section of the stents. After stent placement, stent fastening with loop and clip method was performed. Patients’ symptoms and oral intake were assessed once or twice a week with a clinical check-up or telephone interview. After two weeks, the loop and stent removals were done.

Results: Among the patients, 30 patients had successfully inserted and patency were confirmed (technical success rate, 100%). The obstructive symptoms were subdued in 12 of 35 patients (clinical success rate, 92.3%). Stent migration was found in a follow-up endoscopy on 14 days (1 of 13, 7.7%). Anastomotic restenosis occurred in two patients 14 and 20 days after stent removal. However, obstructive symptoms were relieved by stent reinsertion.

Conclusion: The new method with fastening the stent with loop and clip can reduce the risk of stent migration.
Our fastening method can be feasible and useful technique for postoperative anal sphincter and subcutaneous plication, with some studies estimating the rate at around 20%.

Severity of intrathoracic and intrabdominal lymphadenopathy: mediastinal lymph nodes ≥1 at 19 (12.2%) and ≥20 (33.9%) patients, combined of 38 (64.4%) and 35 (59.3%). At pre-operated staging mostly met advanced form of cancer: T4N1 at 16 (27.1%), T4N2 at 23 (38.9%). Sensitivity in staging of tumor 89.8%. Long-term results: 1-year survival at I group 96.1%, 3-year is 42.3%, 5-year 19.6% II group 1-year survival 6.45%.

Conclusion: The use of 3D-modeling performed using MRI, spiral CT and EUS, allows to planning the optimal surgery and lymph node for locally common form of esophageal cancer, and improve the results of survival. The scope of surgery and lymph node is advised to plan taking into account the constructed 3D-models, which helps to solve the problem of the possibility of surgical intervention in esophageal cancer.

Introduction: Pharyngeal surgery of familial adenomatous polyposis (FAP) ranges from total colectomy with ileorectal anastomosis (IRA) to proctocolectomy with ileoanal anastomosis and J pouch (IAA). Rectal preservation is based on studies that did not include systematic endoscopic treatment that we perform. The objective was to compare IRA to IAA in terms of oncological safety and quality-of-life.

Aims & Methods: Between January 1965 and November 2015, all consecutive patients with non-inflammatory polyposis (NIP), on grey literature analysis, were searched with screening endoscopic follow up in our unit: systemic unitary endoscopic treatment of adenomas (organ, mucosectomy), were prospectively included. MYH-related polyposis and patients who underwent abdominoperineal resection were excluded from analysis.

Results: 296 patients were included: 92 proctocolectomy with IAA (31.1%), 197 total colectomies with IRA (66.5%), and 7 abdominoperineal resections (2.4%). Mean (SD) number of preoperative rectal adenomas was 24.7 (33.9) in the IRA group and 15.3 (26.9) in the IAA group (p = 0.06). Mean (SD) number of rectal cancer recurrence was 3.1% (n = 9). Mean (SD) follow-up was 16.6 (11.9) years, during which the mean (SD) number of lower endoscopies was 3.4 (2.5) in the IRA group vs. 3.4 (2.5) in the IAA group (p = 0.91); mean (SD) number of treated adenomas was 17.8 (20.8) and 12.9 (18.8), respectively (p = 0.06); secondary cancer incidence was 6.1% vs. 1.1% (p = 0.06). The 15-year recurrence-free and overall survival (IR vs. IAA) were respectively 99.5% vs. 100% (p = 0.09) and 98.9% vs. 98.8% (p = 0.82).

Conclusion: Combination of aggressive endoscopic treatment and extended rectal preservation appears to be a safe alternative to ileoanal anastomosis and J pouch.

P0288 ANAL PROBLEMS DURING PREGNANCY AND POSTPARTUM: A PROSPECTIVE COHORT STUDY
K. Ferdinande, Y. Dorreman, K. Roelens, W. Ceelen, D. De Loove
University of Ghent, Ghent/Belgium

Contact E-mail Address: kymenie.ferdinande@ugent.be

Introduction: Many pregnant women have anal symptoms during pregnancy and postpartum. The most common proctological problems reported are haemorrhoids, anal fissures and anal incontinence. Literature about this problem is scarce.

Aims & Methods: The aim of this study is to determine the prevalence of anal problems and constipation during the second and third trimester of pregnancy, in the immediate postpartum and up to three months after childbirth. We want to identify the risk factors for the development of anal symptoms. This is a prospective cohort study. Women between their 19th and 25th week of pregnancy are included. High-risk pregnancy and non-Dutch speaking are exclusion criteria. Nineteen women were followed up using a symptom questionnaire in the second and third trimester, in the immediate postpartum (within 3 days) and three months postpartum. Descriptive data were obtained from the patient files. A specific proctological diagnosis was presumed on the basis of combined symptoms (rectal bleeding, anal pain and swelling). Constipation was defined by the Rome III criteria. Statistical analysis was performed with SPSS and risk factors were identified using multivariate analysis with binary logistic regression.

Results: Sixty-eight percent of the women developed anal symptoms during the whole study period. Anal symptoms occurred in 50% of the women during the whole study period. The most prevalent symptom was anal pain. Constipation was reported by 60.7% during the whole study period. Most prevalent hemorrhoidal lesion was hemorrhoidal thrombosis (immediate postpartum to hemorrhoidal prolapse (3rd trimester and immediate postpartum) and anal fissure (not episode-related). Anal incontinence was only reported in 2% during the postpartum. Multivariate analysis identified constipation and a history of anal problems as significant risk factors for the development of anal complaints postpartum.

Conclusion: Two-thirds of pregnant women deal with anal symptoms during pregnancy or postpartum, especially hemorrhoidal complications and anal fissure. This high prevalence emphasises the clinical importance of this problem. The most important risk factor is constipation. Therefore, prevention of constipation in pregnant women is recommended.

Introduction: Diverticulitis is a common gastrointestinal disease in developed countries, especially among elders. It is classified into five stages according to the severity of the inflammation with stage 5 involving perforation as a consequence. Perforation and abscess formation occur with 30%–50% and lead to mortality reaching 32%. This indicates that acute diverticulitis is an emergency case requiring rapid management. However, the surgical interventions of diverticulitis vary according to its grade and severity, there is a controversy about the preferable surgical approach of these different complications and procedures.

Aims & Methods: We aimed to systematically review and meta-analyse randomized controlled trials (RCTs) comparing outcomes and complications between different surgical approaches for acute diverticulitis and its complications. Nine electronic databases, including PubMed, Scopus, Google Scholar, ISI Web of science, WHO Global health library (GHL), POPLINE, Virtual health library (VHL), NYAM (New York Academy of Medicine), and SIGLE (System for Information on Grey Literature in Europe), were searched for RCTs comparing different surgical procedures for different grades of diverticulitis. Out of 1738 articles, we included 14 studies with 1076 patients. The primarily assessed outcomes were post-surgical mortality rate besides short- and long-term post-surgical complications and costs. The risk of bias was assessed using the Cochrane Collaboration tool. The pooled risk ratio (RR) and 95% confidence interval (CI) were calculated in the meta-analysis using the RevMan platform. The protocol was registered in PROSPERO (CRD42015032290).

Conclusion: There has been enormous progress in diagnosing and treatment of diverticulitis and its complications (RR = 0.29, 95% CI [0.12–0.67]; P = 0.00) and all minor postoperative complications (RR = 0.29, 95% CI [0.12–0.67]; P = 0.00) were non-significant in both short-term and long-term precense of intra-abdominal abscesses were significantly higher in the LL group (RR = 1.55, 95% CI [0.79–3.04]; P = 0.32) and mortality (RR = 0.95, 95% CI [0.46–1.31], P = 0.34), and mortality (RR = 0.95, 95% CI [0.10–2.50]; P = 0.80), and all minor postoperative complications (RR = 0.98, 95% CI [0.62–1.57]; P = 0.94). Similarly, there was no difference between the two procedures regarding the long-term postoperative complications (RR = 0.92, 95% CI [0.37–2.47], P = 0.92) and long-term mortality (RR = 0.87, 95% CI [0.54–0.96], P = 0.07) follow up. Furthermore, the short-term reoperation rate and long-term precense of intra-abdominal abscesses were significantly higher in the LL group (RR = 1.55, 95% CI [0.79–3.04]; P = 0.32) and mortality (RR = 0.95, 95% CI [0.12–2.50]; P = 0.32) follow up. The remaining five RCTs compared laparoscopic lavage with resection (sigmoidectomy) for treatment of perforated diverticulitis with peritonitis, the postoperative mortality rate was non-significant in both short-term (RR = 1.55, 95% CI [0.79–3.04]; P = 0.21) and long-term (RR = 0.67, 95% CI [0.29–1.58]; P = 0.36) follow up. Hence, LL is feasible and can act as definitive treatment. Further RCTs are still needed to make a decision regarding these and other procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0290 NLR AND PLR IN DIAGNOSING SYNCHRONOUS LIVER AND LYMPH NODE METASTASES IN PATIENTS WITH CRC

Introduction: There has been enormous progress in diagnosing and treatment of colorectal cancer (CRC), however a great number of patients is nevertheless diagnosed at an advanced disease stage. It is of great importance to develop affordable, inexpensive, prognostic, diagnostic, and treatment predicting biomarkers in early diagnostics of CRC considering its incidence worldwide. There are studies suggesting that the systemic inflammation play an important role in CRC tumor stage development, which can be reflected by the levels of neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR).

Aims & Methods: This study was designed to investigate the efficiency of preoperative NLR, PLR as a tool for the assessment of synchronous lymph nodes
and liver metastases in newly diagnosed patients with CRC. Three hundred patients with CRC undergoing conforming resection were included in this cross-sectional study. Complete blood counts with automated differential counts were performed preoperatively. The NLR was calculated by dividing the absolute neutrophil count by the absolute lymphocyte count; also PLR was calculated by dividing the absolute platelet count by the absolute lymphocyte count. The diagnostic performance of NLR and PLR was estimated by ROC curve.

**Results:** Our results suggest that there was high statistically significant difference between NLR (p = 0.003), PLR (p = 0.002) and tumor stages (I to IV). ROC curve analysis showed high diagnostic efficiency of NLR (AUC 0.774, 95%CI = 0.683–0.790) and PLR (AUC 0.698, 95%CI = 0.663–0.742) for synchronic lymph node and liver metastases. Also combination of NLR and PLR improved diagnostic efficacy (AUC 0.841, 95%CI = 0.811–0.863) for synchronic liver and lymph node metastases.

**Conclusion:** Our results suggest that NLR and PLR could be useful diagnostic CRC biomarkers, and could have potential use in early recognition of different stages of CRC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

5. Zhang Z, Li C, Gao W, et al. Neutrophil-to-lymphocyte ratio: a powerful tool for cancer diagnosis (OAI 23) was better in the early closure group (p = 0.014), with significantly higher in the early closure group. Operative time (p = 0.0012) for the stoma closure surgery were significantly lower for the early closure group. There was no other perianal disease. Disease was limited to the rectum (n = 13; 75%), left-sided (n = 9; 54.5%), and extended to right-sided (n = 2; 4.5%). During follow-up, there were no complications such as sepsis, anal stenosis, abscess and fistula formation, and recurrence. There was no difference in complications and other clinical characteristics between BD and AD. There was no difference in complications according to disease extent (p = 0.158).

**Conclusion:** Our data suggest that haemorrhoidectomy may be performed safely in UC patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Haemorrhoidectomy in ulcerative colitis (UC) have been considered to be potentially dangerous, but the evidence is poor.

**Aims & Methods:** A study was conducted to ascertain the safety of haemorrhoidectomy in ulcerative colitis. 320 consecutive patients with UC were recruited from the year 2004 to 2014. Patients demographics and clinical characteristics (anorectal symptoms, prior non operative haemorrhoidal therapy, whether proven UC preoperatively (BD) and unproven preoperatively (AD), whether to use azathioprine, presence of other perianal disease, and activity, anatomic location of UC) were recorded. Postoperative complications, and differences between BD and AD were analysed.

**Results:** The patients were 29 males (65.9%), median age 44 (range, 19–72) years. Predominant symptoms were bleeding and prolapse (n = 24; 54.5%), prolapse only (n = 6; 13.6%), bleeding only (n = 14; 31.8%). 17 patients (38.6%) were diagnosed with UC prior to surgery. 4 patients (9.1%) had haithrohoid therapy before surgery. There was no perianal disease. Disease was limited to the rectum (n = 13; 75%), left-sided (n = 9; 20.5%), and extended to right-sided (n = 2; 4.5%). During follow-up, there were no complications such as sepsis, anal stenosis, abscess and fistula formation, and recurrence. There was no difference in complications and other clinical characteristics between BD and AD. There was no difference in complications according to disease extent (p = 0.158).

**Conclusion:** Our data suggest that haemorrhoidectomy may be performed safely in UC patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Temporary loop ileostomies are commonly performed to protect a colorectal anastomosis. Although they have been shown to reduce the number of leaks requiring surgery, they remain a source of complications and have an adverse effect on the quality of life. A few non-randomized studies have shown the feasibility of early stoma closure.

**Aims & Methods:** To compare the outcomes of early and delayed closure of temporary loop ileostomy in terms of operative parameters, morbidity, mortality, and quality of life. The study was conducted from May 2014 to September 2015. Following creation of loop ileostomy after colorectal surgeries, distal loop conti- stent closure was done on POD 7. Patients who had no leak were randomized to either early closure (8–13 days) or delayed closure (after 6 weeks) group. Patient demographics, operative parameters, morbidity, mortality and quality of life data were recorded in both groups.

**Results:** There were 24 patients in each group. Both groups were comparable in terms of demographic data except for age, which was significantly higher in the early closure group (p = 0.012) in the early closure group. Incidence of stoma related complications (p = 0.01) and Pitot stoma complication severity index (p = 0.01) were significantly higher in the delayed group. Operative time (p = 0.033) and Surveys assessment score (p = 0.0012) for the stoma closure surgery were significantly lower for the early closure group. There was no significant difference in the duration of hospital stay and the incidence of postoperative complications in the two groups. Quality of life as calculated by the Ostomy Adjustment Index score (OAI 23) was better in the early closure group (p = 0.014).

**Conclusion:** Early closure of a temporary loop ileostomy is feasible with the advantages of decreased stoma related morbidity, operative difficulties without increased morbidity and mortality when compared with conventional delayed ileostomy closure.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Ger reported the first laparoscopic hernia repair in 1982 by approximating the tissue with stainless-steel sutures. The laparoscopic transabdominal preperitoneal (TAPP) repair was a revolutionary concept in hernia surgery and was introduced by Arregui and Dion in the early 1990s. Institutions performing radical laparoscopic surgery for inguinal hernia have been rapidly increasing since the NHI point was amended in Japan. However, in the 12th JAPAN SOCIETY FOR ENDOSCOPIC SURGERY questionnaire survey, the recurrence rate after surgery employing the TAPP method was reported to be 4%, posing a problem regarding the thoughtless introduction of the TAPP method. Our hospital, with surgery employing the TAPP method only from June 2014 onwards until April 2015, but treatment of inguinal hernia was integrated, the indication was established in May 2015, and laparoscopic surgery employing the TAPP method has been performed for the indicated cases. In this study, we investigated the current state of inguinal hernia in our department as follows. Symptomatic inguinal hernia is treated using the TAPP method when there is only one POSSUM score-based risk factor. When 2 or more risk factors are present or the patient has undergone surgery of the prostate, the anterior approach is employed (the UHS and Mesh Plug methods for internal and external inguinal hernia, respectively). Treatment under local anesthesia is prioritized for patients aged 90 years or older and patients with PS2 or higher. Arrangement in operating room is that the operator and assistant stand on the left and right sides of the patient, respectively, an anesthesiologist stands at the patient’s head, and a nurse stands caudal to the assistant.

Aims & Methods: In this study, we investigated the current state of inguinal hernia treatment at our hospital. The subjects were 120 patients who underwent radical surgery for inguinal hernia before and after the full-scale introduction of the TAPP method (early period: October 2014-April 2015 (7 months), late period: May 2015-November 2015 (7 months), 47 and 73 patients were treated in the early and late periods, respectively). Changes in the surgical procedure, complications, and duration of hospital stay were investigated in 120 patients.

Results: The median age was 70 years (19-91 years). There were 114 male and 6 female patients, with a total of 132 lesions (unilateral in 108 (right: 60, left: 48) and bilateral in 12). The hernia classification (Japanese Hernia Society) was 1, 2, 3, 4, rec in 91, 37, 0, 3, and 1 lesions. Surgery was performed under local anesthesia in 43, lumbar anesthesia in 1, and general anesthesia in 76. A laparoscopic scope was used in 70, and not used in 50. TAPP, mesh plug, and UHS and others were used in 58, 54, 17, 3 lesions. There was no change for both the Early period and the Late Period about the median operative time (Early period: 93 minutes, Late Period: 102 minutes). Early Period was 4 days (4–24), Late Period was 3 days (1–18), and the Late Period was 3 days (2–18). The most frequent one was temporary urination disorder in 2 (20%) patients. The median number of harvested lateral lymph node was 20 (14–23). So far there are no recurrent cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Total mesorectal excision (TME) with lateral pelvic lymph node dissection (LLND) is a standard procedure for low rectal cancer in Japan. However, ME alone is the international standard surgical procedure for rectal cancer. The complete LLND is indicated because of the pelvic cavity and the complicated anatomical structure and invasive procedure which needs longer operative time and greater blood loss. Herein we introduce laparoscopic LLND as our new procedure securing equivalent range of lymph nodes.

Aims & Methods: After laparoscopic ME, the external iliac artery was exposed and the external iliac nodes were completely removed from inguinal ligament. Obturator nodes were completely dissected while preserving the obturator nerve, resecting the obturator artery and vein, and confirming lateral pelvic wall, bladder wall and sacic vein. Subsequently, proximal internal iliac nodes were removed and superior vesical artery was separated. Distal internal iliac nodes from the coccygeal muscle (Akcock’s canal) were completely dissected while preserving the superior vesical artery and the pelvic plexus, and transecting several inferior vesical arteries. Finally, bilateral hypogastric nerves were separated to be preserved. Common iliac nodes were dissected; aortic bifurcation nodes and presacral nodes were also dissected by exposing the aortic bifurcation and the pelvic surface of the sacrum.

Results: Between 2015 and 2016, we performed laparoscopic ME with LLND for 10 patients with cT2 or deeper low rectal cancer. The median operative time was 502 min (429–679 min), and the median blood loss was 90 ml (5–500 ml). Postoperative complications developed in 4 (40%) patients, and the most frequent one was temporary urinary incontinence disorder in 2 (20%) patients. The median number of harvested lateral lymph node was 20 (14–23). So far there are no recurrent cases.

Disclosure of Interest: Our laparoscopic LLND provides good visual field and reduces an amount of operative bleeding and results in favorable clinical outcomes.

Aims & Methods: After laparoscopic ME, the external iliac artery was exposed and the external iliac nodes were completely removed from inguinal ligament. Obturator nodes were completely dissected while preserving the obturator nerve, resecting the obturator artery and vein, and confirming lateral pelvic wall, bladder wall and sacic vein. Subsequently, proximal internal iliac nodes were removed and superior vesical artery was separated. Distal internal iliac nodes from the coccygeal muscle (Akcock’s canal) were completely dissected while preserving the superior vesical artery and the pelvic plexus, and transecting several inferior vesical arteries. Finally, bilateral hypogastric nerves were separated to be preserved. Common iliac nodes were dissected; aortic bifurcation nodes and presacral nodes were also dissected by exposing the aortic bifurcation and the pelvic surface of the sacrum.
lower abdomen. The bowel extraction was performed by invagination transrectal. The mesenteric distal linear stapling of the sigmoid, the colorectal anastomosis was completed by applying a circular stapling device transrectally, assisted by a transcutaneous inserted grasper. Function testing was performed by the colonoscope. Gastric access closure was performed by OTSC clips.

**Results:** The procedure was successful in all animals with operation time ranging from 4.5 to 6 hours. After weight gain in all cases, the animals were sacrificed after postoperative day 42 and the workup showed competent anastomotic healing with a stenosis and consecutive prestenotic dilatation in one case. These anastomotic peripheral abscesses beside the anastomosis. Gastric closure was healed and the OTSC clip still in situ in all animals. In one case we used two OTSC clips for gastric closure, there were severe adhesions with two peri gastric abscesses.

**Conclusion:** The use of an operating platform like the Anubisscope has the advantage of flexible preparation in opposite position of the instruments. The disadvantages are the only two degrees of freedom of the flexible instruments and the rotation-like movements. Flexible colonoscopy provided a fixed reference frame that enabled preparation and dissection. For resection and anastomosis, an additional transcutaneous access was necessary.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** In patients with pelvic tuberculosis (TB) advanced ovarian cancer, two conditions with different management and prognosis, have many similarities: ascites, complex adenal mass, peritoneal deposits, and raised CA-125 level. Symptoms such as weight loss, reduced appetite, and dull abdominal pain are also seen in both entities.

**Aims & Methods:** The aim of this study was to analyze patients’ characteristics, laboratory investigations, radiological and surgical findings in post-menopausal women with pelvic TB who were diagnosed after laparotomy or laparoscopy for suspected ovarian cancer. We report twenty-one cases of pelvic-peritoneal TB in post-menopausal women who presented with features mimicking ovarian malignancy from 2004 to 2014 in a Tunisian center.

**Results:** The mean age was 59.8 (46–87 years). Three patients have personal or family history of tuberculosis. Two women presented with abdominal pain and distension of varying duration of 1 month to 6 months. Eleven patients had reduced appetite and weight loss, and four women gave a history of low-grade fever. A CT scan showed the presence of solid-ectopic adenal masses ranging 3 cm to 12 cm in diameter in 100% and ascites in 90.4%. Ascitic fluid analysis was done in 19 patients which showed a lymphocytic predominant pattern, and absence of malignant cells. The volume of the ascitic fluid was up to 12 cm in 100% and ascites in 90.4%. Ascitic fluid analysis was done in 19 patients which showed a lymphocytic predominant pattern, and absence of malignant cells. Ascitic fluid cultures was negative in all. CA-125 was elevated in all and ranged between 183 and 13001U/mL. CA-125 > 600U/L was found in three women. Quantiferon-TB Gold (QFT-G) performed in 3 patients was positive in two. A laparoscopic evaluation with biopsies was performed in 16 patients and an exploratory laparotomy in 4 women for suspected ovarian cancer. Intraoperative findings of tubercles on the pelvic organs and peritoneal surfaces strongly support the diagnosis. In two, TB was not suspected intraoperatively. The diagnosis of TB was confirmed by histopathology in 95.2%. Response to therapeutic trial of anti-tubercular drugs was the basis of diagnosis in one case because of clinical risk.

**Conclusion:** It is a diagnostic challenge to differentiate pelvic-peritoneal TB from ovarian cancer which has entirely different management and prognosis. Ascitic fluid showing lymphocytic predominance and no malignant cells and CA-125 in the blood plasma showed (15.1±1.35 mmol/l (p<0.05 to control)), while spontaneous production of IL-8 chemokine in rectal biopsy samples went up (300.0±60 ng/ml, P<0.005). In case of the LPS stimulation the production of IL-8 chemokine in the CM went up markedly (750.0±60 ng/ml, P<0.005). There was significant inverse correlation (r) detected between the CA-125 levels in the blood plasma, on one hand, and indicators of the UC clinical, endoscopic activity and the intensity of the inflammatory infiltrate in the CM, on the other. Direct relationship was found between peritoneal abscesses and estimulanted production of the IL-8 chemokine and the density of the inflammatory infiltrate in the CM of patients with active UC. Through the period of the clinical remission development (an average of 8 weeks) the CA-125 levels increased up to 94.25±4.28 mmol/l (P<0.05), yet have not reached the control value (P<0.05 to control). Induction of the clinical remission was associated with a decrease to the level of the control values for spontaneous and LPS-induced IL-8 production, regardless of UC activity.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Conclusion: (1) *H. pylori* infection can alleviate the acute and chronic colitis induced by DSS. (2) *C. difficile* Mmp9 in preventing and accelerating colitis. (3) CD19*°* IL-10° Breg cells expanded significantly in *H. pylori*/DSS co-treated acute colitis mice. (3) CD19*°* IL-10° Breg cells expanded while CD4°CD25°Foxp3° Treg cells reduced significantly in H pylori/DSS co-treated chronic colitis mice. The potential protective effect on acute and chronic colitis induced by DSS may pass through the expansion and function of CD19° IL-10° Breg cells.

Introduction: The microbial dysbiosis plays a pivotal role in the pathogenesis of inflammatory bowel disease (IBD), however, the role of fungal microbiota in IBD was unclear. The aim of our study was to clarify the gut fungal composition in IBD patients with different treatment strategies.

Aims & Methods: 73 IBD patients were divided into three groups, Untreatment (n = 21), Antiinflammation (n = 43) and Immunosuppression (n = 9). Antiinflammation was defined as treatment with 5-aminosalicylic acid (5-ASA), salazosulfapyridine (SASP) and Immunosuppression as treatment with Glucocorticoid (GC), azathioprine (AZA), biologics and thalidomide. Noninflamed and inflamed mucose were acquired for 16S and ITS sequencing, respectively. Inflamed mucosa infected with fungi for RNA extraction and real-time PCR to detect the expression of IBD-associated biomarkers, such as TNF-alpha, IL-17A, MCP-1, etc. Analysis of Spearman’s correlation was performed to estimate the fungi-bacteria and microbiota-biomecorrelation.

Results: Compared with noninflamed mucosa, lower diversity and evenness were observed in inflamed mucosa in all IBD patients, but no significance in noninflamed (or inflamed) mucosa of different treatment strategies. Beta diversity between noninflamed and inflamed treated patients significantly altered fungi-bacteria correlation patterns in noninflamed mucosa of different treatment strategies. Beta diversity between untreated and inflamed treated patients significantly altered fungi-bacteria correlation patterns in inflamed mucosa.

Conclusion: Fungal microbiota may alter the gut inflammatory environment in IBD patients with different treatment strategies. Further study is needed to elucidate the underlying mechanisms.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0303 UCSAL CYTOKINE PROFILE IN INFAMMATORY BOWEL DISEASE PATIENTS: A LASER CAPTURE MICRODISSECTION APPROACH

Introduction: Crohn’s Disease (CD) and Ulcerative Colitis (UC) are inflammatory Bowel Diseases associated with a complex ecology, including an immune responsive against microbial and autologous antigens and an imbalance between pro-inflammatory and anti-inflammatory mediators. Different approaches have been used to study the pattern of cytokines in IBD and few data are available on cytokines production in different intestinal compartments.

Laser Capture Microdissection (LCM) is a powerful tool for the isolation of specific tissue compartments.

References

Aims & Methods: This work was designed to investigate the pattern of cytokines that regulate the mucosal immune response occurring in different intestinal compartments of IBD patients, using LCM technology (1). Frozen sections of colonic biopsies were obtained from 5 patients with active CD, 5 patients with active UC and 5 controls. None of the patients with CD or UC had been ever undergone mucosal inflammation and pathogenesis of UC. Although the etiology of ulcerative colitis (UC) has yet to be characterized, it is increasingly accepted that the cause of UC might well be related to mucosal inflammation and pathogenesis of UC. Further studies were needed to define the fungal composition in detail and to identify the role of different fungi in the gut, and determine the mechanism of the host-fungal interaction underlying the development of UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We aim to characterize here the functional relevance of the macrophage phenotype in fibrosis development. WT or STAT6 (-/-) mice were given TNBS (0.5, 0.5, 0.75, 0.75, 1, and 1 mg, intrarectally) or saline weekly and they were sacrificed 3, 5 or 7 weeks after the first TNBs administration. The percentage of CD206, CD16, and CD86 positive cells was analyzed by flow cytometry in F4/80+ macrophages isolated from the intestinal mucosa. The mRNA expression of Cd16 ligands was evaluated in F4/80+ CD16+ macrophages isolated from the mucosa, 7 weeks after the first TNBS administration and results are expressed as fold induction vs vehicle-treated mice. The mRNA expression of Cd16 and fibrosis markers were evaluated in the colonic mucosa.

Disclosure of Interest: All authors have declared no conflicts of interest.

before treatment in the active stage to possibly be associated with increased proliferation of Bacteroides, Parabacteroides, Rikenella, Clostridium, Flavonifractor, Pelagibacter, Bordetella, Massilia and Piscivectris species. In responders after treatment, populations of Bifidobacterium and Lactobacillus species were significantly increased. In this study, there was an especially strong negative correlation between Bacteroides and Bifidobacterium both before and after treatment.

**Conclusion:** These results suggested metagenomic analysis results to be associated with a remarkable change in gut microbiota after antibiotic combination treatment. In responders, the change in composition is associated with changes in Bifidobacterium and Lactobacillus species and a decrease in Bacteroides.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Classically, endoenteric cells (EEC) are regulated for metabolizing gastrointestinal motility, secretion, and insulin levels by release of peptide hormones like GLP-1. Via receptors and transporters, GLP-1 are capable of sensing the lamina propria and luminal environment, including the microbiota, and also mediate immune-related signals. In particular, the L-cell-derived incretin hormone glucagon-like peptide 1 (GLP-1) is increasingly recognized to exert direct effects on immune cells and to orchestrate a metabolic-inflammatory response. In inflammatory bowel disease (IBD), a role for EEC in disease pathogenesis is indicated by a risk-associated SNP and autoantibodies affecting EEC function. Ex-vivo findings regarding peripheral blood neutrophils and colon tissue specimens were verified using appropriate in-vitro stimulations of control neutrophils with corresponding sera and intestinal tissue-conditioned media, respectively. Identification and quantification of NETs were performed with immunofluorescence confocal microscopy (ICM), flow cytometry and MPO/DNA complex ELISA. The expression of TF on neutrophils/NETS was determined using ICM, qRT-PCR and western blot analysis. The bioactivity of TF on NETs was assessed by measuring thrombin-antithrombin complex levels with ELISA.

**Results:** Neutrophils from patients with active UC are characterized by increased NET formation in both the peripheral blood and affected colonic mucosa, compared to CD. Furthermore, NETs in UC are decorated with functional tissue factor (TF) and the amount of TF-bearing NETs was reduced from the inflamed to normal colon. In-vitro stimulations of controls neutrophils with sera or intestinal tissue-conditioned media corroborated the findings obtained ex-vivo.

**Conclusion:** NETs expressing bioactive TF may be involved in the induction of intestinal inflammation and systemic thrombosis in UC probably constituting a novel candidate diagnostic and/or therapeutic target.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Concomitantly, these cells were positive for the WNT ligand WNT10A and autophagy/mitophagy-associated LC3, suggesting autoregulatory mechanisms. Mitochondrial function not only reflects the maintenance of the stem cell niche and mitochondria-associated functional alterations, respectively.

Conclusion: Our results indicate that mitochondrial function not only reflects differences in disease phenotype of UC. For the UC cohort, robust models were obtained by OPLS-DA between SAs and Caucasians (R²Y 0.832, Q²Y 0.395, p < 0.0001). Combined analysis revealed 1611 significant features (faecal HILIC 60, urine HILIC 189, serum BA 489 and faecal BA 873). The assigned features are shown in Table 1. Faecal HILIC showed significantly higher essential amino acids (Adenine, L-phenylalanine, L-tryptophan) levels on UV and higher L-cytochrome and creatinine levels on MV analysis for SAs. Urine HILIC showed lower creatine, L-phenylalanine and hippuric acid levels. Serum primary (Cholic and chenodeoxycholic acid) and secondary bile acids (BA modified by the gut) were significantly reduced in SAs. Table 1: Significant metabolites in OPLS-DA model between South Asian (SA) and Caucasians with UC. *compound is increased or decreased in SA compared with Caucasians respectively.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** Previous studies have shown differences in disease phenotype of ulcerative colitis (UC) in South Asian (SA) migrants compared to Caucasians with pan-colonic phenotype predominant.1 The gut microbiota differs in Caucasian and SA patients with UC2 however, there is limited evidence on how this translates to the metabolome.

**Aims & Methods:** We aimed to examine the metabolic profile in a newly diagnosed cohort of UC patients recruited from St. Marks Hospital, London, UK. Patients were stratified by ethnicity (SA, Caucasian, Other), treatment (None, 5-ASA, Azathioprine and Steroids) and disease duration. Healthy controls (HC) were recruited locally among the staff at St. Marks Hospital. Biofluids (urine, faeces and serum) were collected at diagnosis (time point 1; months 0–3) and 1 further time points over one year (time point 2: months 4–8, time point 3: months 9–12). Metabonomics approach was applied using two different UPLC-MS profiling methods; for small metabolites (hydrophilic liquid chromatography, HILIC) and for bile acids (BA) platforms. Univariate (UV) and multivariate (MV) data analysis was implemented to build models using principle component analysis (PCA) and orthogonal partial least squares -discriminant analysis (OPLS-DA) to find metabolites that were expressed in significantly different amounts between the two populations, time points (1 vs 3) and treatment groups.

**Results:** Fifty patients with UC of SA and Caucasian backgrounds were recruited. A total of 309 samples were collected. Sample collection was completed for all time points for 18 SA (11 UC and 7 HC) and 21 Caucasians (9 UC and 12 HC). There was no significant difference between SA and Caucasian at time points 1, 2 and 3 and treatment groups. Significant differences were observed between HC vs. disease, SA HC vs. Caucasian HC and SA UC vs Caucasian UC. For the UC cohort, robust models were obtained by OPLS-DA between SAs and Caucasians; Faecal HILIC (R²Y 0.896, Q²Y 0.451, p < 0.0003) and urine HILIC (R²Y 0.783, Q²Y 0.526, p < 0.0001) and serum BA (R²Y 0.702, Q²Y 0.517, p < 0.0001) and faecal BA (R²Y 0.832, Q²Y 0.395, p < 0.0001). Combined analysis revealed 1611 significant features (faecal HILIC 60, urine HILIC 189, serum BA 489 and faecal BA 873). The assigned features are shown in Table 1. Faecal HILIC showed significantly higher essential amino acids (Adenine, L-phenylalanine, L-tryptophan) levels on UV and higher L-cytochrome and creatinine levels on MV analysis for SAs. Urine HILIC showed lower creatine, L-phenylalanine and hippuric acid levels. Serum primary (Cholic and chenodeoxycholic acid) and secondary bile acids (BA modified by the gut) were significantly reduced in SAs. Table 1: Significant metabolites in OPLS-DA model between South Asian (SA) and Caucasians with UC. *compound is increased or decreased in SA compared with Caucasians respectively.

**Conclusion:** This study highlights the promise of UPLC-MS profiling to differentiate between SA and Caucasian groups. There are several possible reasons but two important factors are differing microbial metabolism and diet between the two groups. We are conducting further studies incorporating dietary data and 16S microbial analysis in this cohort. In combination with matching disease extent (left-sided vs colonic disease) may help to identify possible explanations for the different disease phenotype in this group.

**Introduction:** Patients with active inflammatory bowel disease have elevated myeloid lineage leucocytes1 including the CD14+ CD16- DR+ e phenotype known as proinflammatory monocytes, and a major source of tumour necrosis factor-α.2 Accordingly selective depletion of myeloid leucocytes by granulocyte/monocyte apheresis (GMA) is expected to promote remission or enhance drug efficacy. However, studies in ulcerative colitis (UC) patients have reported contrasting efficacy outcomes, ranging from an 85%3 to statistically insignificant level.4 Patients’ baseline demographic features may guide to selecting responder patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Aims & Methods: In a retrospective and single-centre setting we aimed to under- stand if patients’ baseline clinical and endoscopic features were relevant guide for identifying likely responders and non-responders to adsorptive GMA. The sub- jects were 145 consecutive UC patients who had undergone GMA with the Adacolumn as remission induction therapy between 2012 and 2016. Seventy- five patients were steroid naïve, 70 were steroid dependent, and 2 patients were steroid refractory. Patients had received up to an 11 GMA sessions over 10 weeks. At entry and week 12, patients were clinically and endoscopically evaluated, allowing each patient to serve as her or his own control. Clinical activity index was defined as remission. Biopsies from endoscopically detectable inflamed large intestinal mucosa were processed to see the impact of GMA on leukocytes within the mucosal tissue.

Results: At entry, the average CAI was 12.8, range 10–17. Ninety-three patients (66%) had the ability to induce regulatory T cells (Treg) play an important role in maintaining immune tolerance and have been proposed for treatment of inflammatory bowel disease (IBD). Among SCFA, butyrate has been described as a potent communicator to the immune system eliciting an anti-inflammatory response and other positive effects to human health. A reduction of faecal butyrate levels has been reported in IBD but results have been conflicting or discrepant because of small study numbers and failure to distinguish disease type, activity or other variables such as diet. Microbiota is receiving increasing attention as a key environmental factor influencing IBD and butyryl-CoA:acetate CoA-transferase (BcoAT) is considered the main enzyme involved in butyrate synthesis by gut microbiota.

Conclusions: Reduced butyrate-synthetic capacity was found in patients with active and in active UC (p < 0.001 and p < 0.01, respectively), but only in active UC (p < 0.05). In patients with CD, low BcoAT gene content (below 9.5 log10 copies BcoAT/g) was associated with active disease, increased inflammation, lower microbial diversity, greater microbiota compositional change and decreased butyrogenic taxa, while no major changes were observed between patients with UC/grouped according to BcoAT gene levels. Reduced BcoAT gene content in patients with CD was, in part, linked with lower intake of certain foods containing fibre (vegetables, fruits, high-fibre cereals, brown/wholemeal bread) which may identify GMA responder patients should guide to stop futile use of medical resources.

P0312 THE EFFECTS OF GLIAL-DERIVED NEUROTROPHIC FACTOR PRODUCED BY ENTERIC GLIAL CELLS ON DENDRITIC CELL AND ITS ROLES IN DEXTAN SULPHATE SODIUM INDUCED COLITIS
Y. Hua
West China School of Medicine of Sichuan University, Chengdu/China

Introduction: Much research has demonstrated that enteric glial cell (DC) play an important role in maintaining immune tolerance and have been proposed for treatment of inflammatory bowel disease (IBD). In this study, we report on the use of glial-derived neurotrophic factor (GDNF) produced by Enteric glial cells (EGCs) as a novel approach to induce tolerogenic DCs with capacity to induce Treg, to restore immune tolerance in vivo, and to ameliorated experimental colitis.

Aims & Methods: DCs were generated from rat bone marrow (BMDC) in the absence or presence of GDNF (DCGDNF) and additionally stimulated with LPS to induce maturation (mDC). The expression of major histocompatibility complex II (MHC-II), CD40, CD80, and CD86 was determined by flow cytometry. Levels of IFN-γ, interleukin-4 (IL-4), and IL-10 in the culture supernatants were determined by ELISA. The expression of GDNF receptor-α1 (GFRα1) in DCs was detected by immune-fluorescence staining. The expression of GFRα1 and ERK1/ERK2 in DCs was tested by Western Blot. SD rats were fed with 5% Dextran Sulphate Sodium (DSS) to induce experimental colitis, the thymus were removed for further use. The severe clinical signs of the disease including weight loss, diarrhoea, colitis, histopathology were evaluated, and the mechanisms involved in the potential therapeutic effect of DCGDNF, such as inflammatory cytokines and chemokines (IL-4, IFN-γ, TNF-α, IL-1β, IL-17), the expression of IL-10, -12, 71, 17), the generation of IL-10, and the secreting Treg (Treg1), and the level of Treg1/Th2, Treg1/Th17 were investigated.

Results: GFRα1 was expressed in BMDC, and the expression of ERK1/ERK2 were significantly up-regulated after treatment with GDNF. DCGDNF did not up-regulate the expression of MHC-II, CD40, CD80, CD86, and induced very low levels of proinflammatory cytokines (IFN-γ, IL-6) but secreted significant levels of the anti-inflammatory cytokine IL-10 after LPS stimulation, as compared with DCcontrol. CD4 cells primed with DCGDNF resulted in weak proliferation and exhibited a Treg1-like phenotype, which characterized by IL-10, whereas DCcontrol induced a strong proliferation, exhibited a phenotype characterized by IFN-γ, IL-4. DCGDNF injection significantly ameliorated body weight loss, diarrhoea, and colonic histopathology injury in rat, and DCGDNF injection strikingly reduced the production of inflammatory factors such as IL-6, TNF-α, IL-1β, IL-17, generated Treg1 with suppressive capacity on autoreactive T cells, and demonstrated a higher level of Treg1/Th2, Treg1/Th17.

Conclusion: GDNF could induce tolerogenic DCs through ERK1/ERK2 signal pathway, and DCGDNF could alleviate the severity of DSS induced colitis in rats. The mechanism may be related to down-regulation of inflammatory and immune response, generating Treg1 and restoring immune tolerance.

Aims & Methods: We aimed to clarify how antibiotics affect the gut microbiota and the pathology of colitis. Mice were gavaged with ampicillin (ABPC), vancomycin (VCM), metronidazole, neomycin, or a combination of ABPC and VCM (AV) for three consecutive days. Colitis was assessed by fecal occult blood test (FOBT) and mRNA level of cytokines. Metabolites and short chain fatty acid (SCFA) in the feces were measured by a chromatography-tandem mass spectrometry. Fecal microbiota was determined by 16S rDNA sequencing. In the gluta mine (Gln) treatment exam, the mice were given 30 mg/mL of Gln in drinking water ad lib for six days, and additionally gavaged A-V for the last three days. In vitro experiments: mouse colon carcinoma cell line CMT93 and macrophage cell line RAW264.7 were stimulated by butyric acid.

Results: ABPC and VCM, but not other antibiotics, resulted in FOBT-positive in some cases. All A-V treated mice were FOBT-positive and IL-6, IL-12p40 and MIP-2 were increased. The colon were enlarged in the A-V mice. Moreover, Gln metabolites and SCFA including butyric acid were decreased and faecal S24-7 and order Clostridiales, which might disturb Gln and SCFA metabolisms.

Conclusion: A-V treatment induced mild colitis with reduced abundance of family Clostridiales, which might disturb Gln and SCFA metabolisms.

Results: Of 104 ileoocceal resections, 30 (29%) and 15 (14%) had inflammation at the proximal resection margin, respectively. AIEC strains, regardless of the surgical technique, were isolated from 17 (16%) of the 104 patients. After a mean follow-up of 8.6 years, clinical recurrence was seen in 57%, and surgical recurrence in 26%. A significantly increased recurrence rate was seen in patients with active inflammation at the distal resection margin whereas recurrence rates were comparable for inflammation at the proximal site and radical resections (87%, 61%, and 50% resp., p < 0.001). Active inflammation at the distal resection margin (HR: 3.189 (1.635–6.220); p = 0.001) and smoking (HR: 2.502 (1.331–4.703); p = 0.004) were the only independent predictors for clinical recurrence. The incidence of surgical necrosis was small to none in AIEC screening.

Conclusion: Inflammation at the distal (colon) resection margin, and not the proximal ileum, after ileocecal resection was associated with significantly increased risk of clinical recurrence. This unexpected finding suggests that radical ileocolic play a role in correctly diagnosed terminal ileitis (L1 disease), while it is of crucial importance to exclude colonic activity (L3 disease). As this different phenotype is unlikely to benefit from more extensive surgery, pathological finding of positive distal resection margin should be regarded as a risk factor, warranting prophylactic drugs or close monitoring.

Disclosure of Interest: All authors have declared no conflicts of interest.

5. Mowat C, Arnott I, Cahill A, et al. Mercaptopurine versus placebo to pre-
vent recurrence of Crohn's disease after surgical resection (TOPPIC): a mul-
Incidence rate of microscopic colitis appeared to increase with time (Table). The incidence of colitis in 2016 was twice that observed in 2009 (incidence rate ratio 1.86; 95% CI 1.41, 2.46). There was a strong, independent graded association between the incidence of microscopic colitis and the number of lower GI endoscopy procedures undertaken (p = 0.03).

Conclusion: Microscopic colitis diagnosis is becoming more common. It is unclear whether microscopic colitis itself is increasing or greater numbers of lower GI endoscopy are being undertaken causing an ascertainment bias. Further work is required to explore environmental exposures such as drugs associated with microscopic colitis and to observe its natural history.

P0321 EXTRA-INTESTINAL MANIFESTATIONS AT DIAGNOSIS IN PAEDIATRIC- AND ELDERLY-ONSET UC: A POPULATION-BASED STUDY

D. Duricova1, A. Leroyer1, G. Savoye2, H. Sarter1, B. Pariente3, D. Aoucheta4, M. Fumery1, J. Mathurin5, M. Fumery4

2Gastroenterology Unit, Epimad Registry, CHU Amiens Sud, Avenue Laennec-Saulieu, Amiens University Hospital, Amiens/France
3Gastroenterology Unit, Lille University Hospital, Lille/France
4Ibd Clinical And Research Center, ISCARE I.V.F. a.s., Prague/Czech Republic
5Gastroenterology, Lyon-Sud University Hospital, Pierre Benite/France

Aims & Methods: The aims of this population-based study were to assess 1) the occurrence of EIM in paediatric- and elderly-onset UC; and 2) their impact on long-term disease outcome. Paediatric-onset (<17 years at diagnosis) and elderly-onset UC patients (>60 years) from a French prospective population-based Registry (EPIMAD) were included. Data on EIM and other clinical factors at diagnosis and at maximal follow-up were collected.

Results: 158 paediatric- and 470 elderly-onset patients were included (median age at diagnosis 14.5 and 68.8 years; median follow-up 11.2 and 6.2 years, respectively). EIM occurred in 8.9% of childhood- and 3% of elderly-onset patients at diagnosis and in 16.7% and 2.2% of individuals during follow-up (p < 0.01). The most frequent EIM was joint involvement (15.8% of paediatric-onset and 2.6% of elderly-onset). Presence of EIM at diagnosis was associated with more severe disease course (need for immunosuppressive or biologic therapy or colectomy) in both paediatric- and elderly-onset UC (HR = 2.0, 95%CI: 1.0-4.2 and HR = 2.8, 0.9-7.9). Extensive colitis was another independent risk factor in both age groups.

P0322 LONG-TERM NATURAL HISTORY OF MICROSCOPIC COLITIS: A POPULATION-BASED STUDY

J. Loreau1, D. Duricova2, C. Gower-Rousseau1, G. Savoye1, H. Sarter1, C. Yzet1, M. Kohut5, F. Brazier3, D. Chatelain6, E. Nguyen-Khac1, J. Dupas7, M. Fumery1
1Amiens University Hospital, Amiens/France
2Ibd Clinical And Research Center, ISCARE I.V.F. a.s., Prague/Czech Republic
3Public Health, Epidemiology And Economic Health, Registre Epimad, Maison Regionale De La Recherche Clinique, Lille University and Hospital, Lille/France
4Gastroenterology Unit, Epimad Registry, Hopital Charles Nicolle, Rouen University Hospital, Rouen/France
5Gastroenterology Unit, Epimad Registry, CHU Amiens Sud, Avenue Laennec-Saulieu, Amiens University Hospital, Amiens/France

Aims & Methods: All new cases of UC diagnosed in the Somme area, France between January 1st, 2005 and December 31th, 2007 were prospectively included. Colonic biopsies from all patients were reviewed by a group of 4 expert gastroenterological pathologists to assess the diagnosis of CC or LC. Demographic and clinical data were retrospectively collected from diagnosis to February 31th, 2017.

Results: One hundred and thirty cases of MC, 87 CC and 43 LC were included (median age at diagnosis 70 and 48 years, respectively). The median follow-up was 9.6 years (Q1 = 7.6, Q3 = 10.6), By the end of follow-up, 37 patients (28%) relapsed after a median time of 3.9 years (1.2; 5) since diagnosis, without significant difference between CC and LC (30% vs 26%, p = 0.47). Twenty patients (15%) were hospitalized for a disease flare and 32 (25%) presented with another autoimmune disease. Budesonide was the most widely used treatment (n = 74, 59%), followed by 5-aminosalicylic acid (n = 31, 25%). Median duration of budesonide treatment was 92 days (70, 168) and no adverse event to budesonide were reported. Sixteen patients (22%) developed steroid-dependency and 4 (5%) were corticoreistant. Only one patient was treated by immunosuppressants (azathioprine). No colorectal cancer was reported during follow-up. Any of the death (n = 25) observed during follow-up were linked to MC. In multivariate analysis, age at diagnosis (HR 1.03; 95%CI, 1.00–1.06; p = 0.02) and budesonide exposure (HR 0.40; 95%CI, 0.18–0.90; p = 0.03) were significantly associated with relapse.

Conclusion: This population-based study showed that after diagnosis, two third of patients with MC observed long term clinical remission. Age at diagnosis and budesonide exposure were associated with a risk of relapse.

2Dept. Of Gastroenterology, CHU Estuing Clermont-Ferrand, Clermont-ferrand/France
3CHU Saint-Etienne, Saint-Etienne/France
4CHU Grenoble, Grenoble/France

Aims & Methods: The IBD-INFO included 3 parts: an original part (Q1), and 2 parts from the translation of the pre-existing questionnaires Crohns’ and Colitis Knowledge score (CCKNOW) (Q2) and Crohns and Colitis Pregnancy Knowledge score (CCPKNOW) (Q3). The reliability and discriminatory ability of the questionnaire were validated with 3 groups of non-IBD volunteers with various theoretical knowledge levels. The final questionnaire (64 validated questions) was then tested on 364 in- and out- IBD patients from 4 French university hospitals. The score for each part of the questionnaire was calculated and factors associated with low scores were identified by uni- and multivariate logistic regression analyses.

Results: The scores obtained by the 3 non-IBD volunteer groups differed significantly (p < 0.0001) and the IBD-INFO questionnaire showed excellent internal reliability and consistency (α = 0.98). The median total score obtained by the IBD patients was 27/64 [0–59], and scores for Q1, Q2 and Q3 were, respectively, 10/23

Introduction: Primary sclerosing cholangitis (PSC) is a chronic, progressive, cholestatic disease characterized by inflammation of the bile ducts and liver. Aims & Methods: To investigate differences in disease activity and treatment in patients with primary sclerosing cholangitis (PSC) and in a matched cohort of UC patients. Results: Of 1,122 UC patients and 168 PSC patients a total of 1,008 UC patients and 162 PSC patients were included. The median age of diagnosis was 37 years and 38 years, respectively. In the PSC population, median age at diagnosis was 31 years (range 11–79 years) and in the UC population median age at diagnosis was 37 years (range 11–84 years). The cumulative probability of CD patients receiving treatment with 5-ASA was 100% in Eastern Europe and 91% in Western Europe, 60% in Eastern Europe and 30% in Western Europe, respectively. Clinical data on surgery, hospitalizations and medical treatment in UC-PSC patients were available in 92% of the patient cohort.

Conclusion: Patients with PSC showed a different disease course with less relapse, lower disease activity, but earlier disease onset and higher risk for extensive disease manifestation as well as increased risk for colorectal dysplasia development.

Disclosure of Interest: All authors have declared no conflicts of interest.

24St. Mark’s Hospital, Imperial College London, London/United Kingdom

Introduction: The EpiCom-cohort is a European prospective population-based cohort of uniformly diagnosed patients with inflammatory bowel disease (IBD) diagnosed in 2010 in centres from Western and Eastern European countries. The cohort aims at describing differences in occurrence, treatment strategies, disease course and prognosis within Europe.

Aims & Methods: Patients were followed each 3rd month for the first year after diagnosis and then according to the treating physician for the 2-5th year of follow-up. Clinical data on surgery, hospitalizations and medical treatment in IBD patients were collected prospectively throughout the follow-up period and entered in a validated web-based database.

Results: Of a total of 1289 patients aged 15 years or older from 29 centres in 13 Western and 8 Eastern European countries were included. Results of all patients with PSC had ulcerative colitis in UC, 488 (38%) had Crohn’s disease in CD, and 426 (64%) had UC. Of note, in IBD-PSC patients, HGJEN/CRC occurred significantly earlier than in CD-PSC patients with 20-year-risk: 9.6% vs. 5.6%; p = 0.003.

Conclusion: In a large cohort study, IBD patients with coincident PSC showed a different disease course with less relapse, lower disease activity, but earlier disease onset and higher risk for extensive disease manifestation as well as increased risk for colorectal dysplasia development. The cumulative probability of CD patients receiving treatment with 5-ASA was 100% in Eastern Europe and 91% in Western Europe, while hospitalization rates were higher in Western Europe (p < 0.05). Cox regression analysis showed that in CD structuring (B2) or penetrating disease (B3) and progressing from luminal disease to B2/B3 increased while early (<6 months from diagnosis) treatment with immunosuppressives reduced the risk of surgery and hospitalization. In UC, progressing to extensive colitis increased the risk of colorectal while females, extensive disease, need for prednisolone at diagnosis, and progressing to severe colitis carried the highest risk for hospitalization. The cumulative probability of CD patients receiving treatment with 5-ASA was 90% in Eastern Europe and 56% in Western Europe, 69% and 75% for prednisolone, 54% and 66% for immunomodulators, respectively. For UC patients the cumulative probability of receiving treatment with 5-ASA within the first year of disease was 100% in Eastern Europe and 91% in Western Europe, 44% and 52% for prednisolone, 27% and 30% for immunomodulators, respectively.

P0326 OPIATE USE IN INFLAMMATORY BOWEL DISEASE. PRESCRIPTION TRENDS AND MORTALITY IN AN ENGLISH PRIMARY CARE COHORT FROM 1990–2014

N. Burr1, C. Smith1, R. West1, M. A. Hult1, V. Subramanian1
1Gastroenterology, Leeds Teaching Hospitals NHS Trust, Leeds/United Kingdom

Contact E-mail Address: nick.burr@nhs.net

Introduction: Chronic abdominal pain is a common symptom in inflammatory bowel disease (IBD). Pain management is complicated by clinically important gastrointestinal side effects of many of the available analgesics, particularly opiates. Opiate prescribing for cancer and non-cancer pain has increased dramatically in recent years but there is a paucity of data on prescription trends for individuals with IBD. The only population-based study is from Canada where 5% of subjects with IBD became heavy opiate users after 10 years of diagnosis and there was a strong association between heavy opiate use and mortality (OR 2.91, 95% CI 1.58–5.02). In this study we explore trends in the prescription of opiate medications and assess the association between opiate prescription and mortality in English primary care cohort of patients with IBD.

Aims & Methods: We used the English primary care database ResearchOne for this study which holds records from approximately 6 million individuals (>10% of the total population). We extracted relevant clinical codes and prescription data on all patients with IBD, and separated out those with ulcerative colitis (UC) and Crohn’s disease (CD). We created 4 categories of opiate medication use, namely; any opiate medication, codeine only, tramadol, and strong opiates. We defined 3 groups of prescription density as none/infrequent users, moderate and heavy users as <1, 1–3 and >3 prescriptions per calendar year respectively. We examined the trend in opiate prescriptions for all IBD patients in 4 year blocks from 1990–2014 using chi² for trend as a significance. Separate trends were produced for each of our opiate classes. We calculated a propensity score estimating the conditional probability of being prescribed an opiate medication based on pre-defined characteristics which may influence the prescription of opiates. All-cause mortality in opiate users and non-users was compared in a propensity score matched, Cox proportional hazards regression analysis to produce hazard ratios (HR) and 95% confidence intervals (CI). All analyses were performed for each opiate medication class in CD and UC patients.

Results: We included 3517 patients with CD and 5349 with UC. Opiate prescriptions increased from 10% in 1990 to 30% in 2014 (ch2 for trend p < 0.005). There was a similar, significant increase for codeine (ch² for trend, p = 0.008), tramadol (p < 0.005) and strong opiates (p < 0.005) when analyzed separately. Table 1 shows the association between opiate use and all-cause mortality in patients with IBD. Any opiate use in patients with UC was associated with increased mortality ((HR 1.67, 95% CI 1.25–2.23). The strongest associations were for heavy users of strong opiates in patients with CD (HR 2.18, 95% CI 1.20–3.95) and UC (HR 3.30, 95% CI 1.77–6.18). There was no association for prescriptions of tramadol at any prescription density in CD or UC.

Table 1: – The association between opiate prescription and all-cause mortality in patients with inflammatory bowel disease in the English primary care database Research One. Propensity score matched, Cox proportional hazards regression analysis.

Conclusion: Our study is the largest population based study of opiate use in patients with IBD. We have shown a significant increase in the prescription of opiates since 1990, with 30% being prescribed an opiate medication between 2010 and 2014. Prescriptions of codeine in UC and strong opiates in both CD and UC were associated with increased all-cause mortality. There appears to be a dose association as heavy users of strong opiates had the largest association with mortality. Observational studies are not proof of causality and there may be residual confounding. A dose response is a strong indicator that opiates could be responsible for the associations seen, which is consistent with other studies investigating opiates used for non-cancer pain in chronic disease. Randomised controlled trials would be unethical and not feasible to investigate this potential effect so population-based observational studies may provide the best estimate. Opiate prescriptions are increasing worldwide for chronic non-cancer pain, and individuals with IBD can now be included. Clinicians managing pain in individuals with IBD should consider the potential implications of prescribing, or continuing with opiate prescriptions as they are a marker for increased mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: In a prospective 6-months study, dental examination was performed on IBD and in 19 healthy matching controls. IBD related variables were prospectively collected, as well as markers for periodontitis including gingival bleeding (BOP index, marker of periodontal inflammation), gingival recession (REC index, marker of cumulative periodontal destructions) and probing depth. The severity of periodontal disease was measured for all patients. Additional dental examination was proposed 3 months after to all patients diagnosed with periodontitis.

Results: Among the 54 included patients, 44 had Crohn disease (81%) and 31 were women (55%). At the time of dental examination, median age was 33 years (Q1 = 26; Q3 = 41), 20 (36%) were smokers and the median IBD duration was 8.4 years (3.4–16.3). Eleven (20%) were treated by corticosteroids, 27 (49%) by anti-TNF, 5 (9.2%) by other biologics and 8 had no IBD treatment. IBD was significantly associated with periodontitis (81% vs 27%; Odds Ratio 2.9, 95%CI:3.6-2.3). Mild, moderate and severe periodontitis were respectively observed in 34 (63%), 8 (15%) and 3 (5%) IBD patients. As compared to healthy controls, IBD patients had significant increase of BOP index (p = 0.008), probing death (p = 0.03), and REC index (p = 0.01). Patients with active IBD (Harvey Bradshaw index > 2) or Mayo Score > 1) had a significant increase of BOP index (p = 0.007) compared to patients with inactive disease. A significant correlation between BOP and Harvey-Bradshaw index was observed (r = 0.44, p = 0.0018). Anti-TNF therapy was significantly associated with lower BOP index (p = 0.02). All patients with diagnosis of periodontitis were treated by periodontal debridement and subgingival irrigation with povidone-iodine which led to a significant decrease of BOP index three months after diagnosis.

Conclusion: Inflammatory bowel diseases were associated with an increased risk of periodontitis. Gingival inflammation was correlated to disease activity and anti-TNF therapy was associated with a lower risk of active parodental disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aim: To investigate if there is an association between genetic variations and periodontal disease (PPD) in patients with IBD.

Methods: A case-control study was conducted in four major gastroenterology centers in Sri Lanka. There is limited data on genetics of inflammatory bowel disease (IBD) in populations where the condition is emerging, especially from South Asia. Using a case-control study design, a total of 103 patients suffering from Crohn’s disease in Kuwait. The patients were matched with 100 healthy controls for age, gender, and smoking habits. The genomic DNA was isolated from peripheral blood samples obtained from patients and controls. The DNA was genotyped for 16 selected variants with known IBD disease associations in Western and East Asian populations [IL12B:rs1045431, IL23R:rs11805303, ARPC2:rs21621347, IRGM:rs13166189, IL26:rs1558784, CDH1:rs1728785, IL10:rs3024505, IL12B:rs11127240, PTGER4:rs4613763, IL17REL/PIM3:rs5771069. HNF4a:rs6017342, STAT3:rs744466, SMURF1:rs7897997, LABM1:rs866774, HLA DRB5, DQA1, DRB1, DRA:rs2068853, MCM1, UBA7, APEH:rs9822268] with maintained remission (p = 0.005); IL17REL/PIM3:rs5771069 with treatment-refractory IBD (all cases) (p = 0.005). To account for multiple hypothesis testing associations that had a p-value of <0.003 were considered significant.

Results: There were 411 (males = 46.9%) cases [UC-258 (62.8%), males=47.7%, CD-153 (37.2%), males=50.3%] and 465 (males=50.5%) controls. The following variants were associated with corresponding phenotypes: IL12R:rs1805303 with IBD (all cases) (p = 0.001); IL12B:rs1045431 with upper gastrointestinal (UGI) CD (p = 0.001); IL17REL/PIM3:rs5771069 with relapsing IBD (p = 0.003); IL17REL/PIM3:rs5771069 with treatment-refractory IBD (all cases) (p = 0.005). Two variants showed a non-significant trend towards association with Crohn disease (CD) of > 1 year duration) [unrelated, healthy, gender matched] study was conducted at four major gastroenterology centres in Sri Lanka. Phenotypic data (type, location, severity, treatment types, response to treatment and complications) of cases were obtained. Cases and controls were genotyped for 16 selected variants with known IBD disease associations in Western and East Asian populations [IL12B:rs1045431, IL23R:rs11805303, ARPC2:rs21621347, IRGM:rs13166189, IL26:rs1558784, CDH1:rs1728785, IL10:rs3024505, IL12B:rs11127240, PTGER4:rs4613763, IL17REL/PIM3:rs5771069. HNF4a:rs6017342, STAT3:rs744466, SMURF1:rs7897997, LABM1:rs866774, HLA DRB5, DQA1, DRB1, DRA:rs2068853, MCM1, UBA7, APEH:rs9822268] with maintained remission (p = 0.005); IL17REL/PIM3:rs5771069 with treatment-refractory IBD (all cases) (p = 0.005). To account for multiple hypothesis testing associations that had a p-value of <0.003 were considered significant.

Conclusion: This first study, confirms the association of genetic variants of IBD with treatment-responsive IBD (all cases) (p = 0.001); IL12B:rs1045431 with upper gastrointestinal (UGI) CD (p = 0.001); IL17REL/PIM3:rs5771069 with relapsing IBD (p = 0.003); IL17REL/PIM3:rs5771069 with treatment-refractory IBD (all cases) (p = 0.005).

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Among the numerous genetic factors associated with ulcerative colitis (UC), an increasing attention has been paid to the polymorphisms of the vitamin D receptor gene (VDR) associated with disorders of innate and adaptive immunity as well as the barrier function of the intestinal epithelium. However, the results of studies on the prevalence, clinical, diagnostic and prognostic significance of polymorphisms of the VDR gene in different populations are ambiguous and contradictory. In particular, associations of Bsm I polymorphism with UC in the Chinese population and in the Jewish Ashkenazi has been found, while in the Irish population, with a sufficient prevalence of Bsm I polymorphism, this association is absent [1–3]. In the Russian Federation, there is no data on the prevalence, clinical, diagnostic and prognostic significance of Bsm I polymorphism of the VDR gene with UC. These circumstances determined the purpose and objectives of this study.

Aims & Methods: The purpose is to assess the clinical, diagnostic and prognostic significance of the Bsm I polymorphism of the VDR gene (rs1544410) among the residents of the Kemerovo region of the Russian Federation. The study included 76 patients with UC and 85 controls. Genotyping was performed by PCR method (“SNP-express” reagents, Lytech Co., Ltd., Russia) with electrophoresis on an agarose gel. Statistical analysis was performed using the X^2 and Mann-Whitney tests. In the presence of statistically significant differences (p < 0.05), odds ratios (OR) with 95% confidence interval (CI) were calculated.

Results: It was found that the frequency of the allele B polymorphism of the VDR Bsm I gene was higher among patients with UC than in the control group (44% vs. 26%, p = 0.02), which increases the risk of this pathology by 2.2% (95% CI: 1.2–4.1). In the case of carriers of the B/B genotype, the risk of developing UC increased up to 3.5 times in comparison with the control group (21% vs. 7%, p = 0.02, 95% CI: 1.4–8.6), whereas in b/b genotype the risk of UC decreased (33% and 54%, respectively, p = 0.02, OR = 0.4, 95% CI: 0.2–0.7). Significant differences between carriers of the B allele Bsm I polymorphism and the features of the clinical course of the UC have not been established. However, it has been shown that in carriers of allele B, the clinical implementation of UC develops significantly later than in patients with b allele (43 and 28.5 years, respectively, p = 0.04).

Conclusion: For carriers of the B allele Bsm I polymorphism of the VDR gene is a predictor of a high risk of ulcerative colitis with an increase in the age of diagnosis. Genotype b/B Bsm I polymorphism of the VDR gene has a protective effect in the development of ulcerative colitis among the residents of the Kemerovo region of the Russian Federation.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
(IRE1), double-stranded RNA–dependent protein kinase (PKR)-like ER kinase (IRE1 and PKR-like ER kinase, respectively). Deletions or gain of function response have been shown to predispose to chronic inflammatory bowel disease (IBD). Genome-wide association studies identified disease susceptibility loci in or adjacent to several IPR-related genes including XBPI and ORMDL3. Additionally, a role of ORMDL3 in UPR signaling has emerged from studies showing that ORMDL3 colocalizes and directly interacts with ATF6/C11 and CHOP protein levels. In contrast, we observed an increase in fibrillarin expression by ORMDL3-deficient mice showing an increased susceptibility to acute DSS-induced colitis compared to their wild-type littermates. ORMDL3-deficient mice showed less body weight loss and improved survival rate.

**Results:** In vitro studies demonstrated that ORMDL3 facilitates ER stress-induced ATF6/C11 activation. Overexpression of ORMDL3 resulted in increased cleavage of ATF6 and augmented ERSE promoter activity. Mechanistically, we show that ORMDL3 colocalizes and directly interacts with ATF6/C11. Furthermore, ORMDL3 overexpression induced the PERK pathway by elevating IRE1 and CHOP protein levels. In contrast, we observed an inhibition of IRE1 signaling exorted by ORMDL3 proteins as shown by reduced XBPI splicing and decreased UPR promoter activity. ORMDL3-deficient mice showed an increased susceptibility to acute DSS-induced colitis compared to their wild-type littermates. ORMDL3 mice showed less body weight loss and an improved survival rate.

**Conclusion:** This study demonstrates for the first time the modulatory functions of ORMDL proteins as regulators of all three UPR signaling pathways. Altogether, these results suggest that ORMDL proteins constitute a precise fine-tuning mechanism of the UPR determining cell fate decisions in response to ER stress.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0334 THE USE OF LEMANN SCORE TO EVALUATE THE DAMAGE TO THE DIGESTIVE TRACT CAUSED BY CROHN'S DISEASE IN AN EGYPTIAN COHORT**

H. M. Saad1, O. E. Salem2, M. A. Salem3, M. E. Ibrahim4, S. M. El Kady1

Contact E-mail Address: hussienmahmoud7@hotmail.com

**Introduction:** Crohn's Disease (CD) according to disease activity using clinical, laboratory & radiological activity indexes; but few have analyzed the damage the disease bring about the GI tract. Lema'nn score was designed to develop a comprehensive assessment of the structural bowel damage, including strictureing lesions, penetrating lesions (fistulas and abscesses), and surgical resection.

**Aims & Methods:** To calculate Lema'nn score in a cohort of Egyptian patients to determine its ability to assess the structural damage caused by CD in Egyptian patients.

**Result:** In the present study, we aimed to prospectively evaluate the immunogenicity profile of the biosimilar infliximab and predictors of TDM in IB in the first year of therapy in a nationwide, multicentre cohort. Demographic data were collected and a harmonized monitoring strategy was applied. Clinical and biochemical activity were evaluated at weeks 14, 30 and 54. Routine therapeutic drug monitoring (TDM) was applied. Trough level (TL) and anti-drug antibody (ADA) concentration were measured by ELISA (LT-005, Theradiag (France) at baseline, week 2, 6, 14, 30 and 54 weeks right before anti-TNF administration during the induction treatment.

**Results:** 353 consecutive IB patients (209 CD patients and 144 UC patients) were included in the present cohort. 23.4% of CD patients and 19.4% of UC patients had received previous anti-TNF therapy. None of the patients had received infliximab within 12 months prior to initiation of the biosimilar infliximab. 60.51% of CD/UC patients received concomitant immunosuppressives at baseline. Mean TLs were 18.9, 17.3, 7.4, 4.3 and 5.3 μg/ml at weeks 2, 6, 14, 30 and 54 in CD and 19.1, 11.8, 5.0, 3.9 and 4.5 μg/ml in UC. Previous anti-TNF therapy was associated with lower early TLs in both CD (week 2, 14, and 30, p < 0.05) and UC (week 2 and 6, p = 0.03). ADA positivity rates were 4.3%, 12.0%, 20.9% and 28.6% in naive patients at weeks 0, 14, 30, and 54 in CD (m266, 321, 290 and 210). ADA positivity at week 14 was associated with lower TLs in all CD (week 2, 14 and 30, p < 0.007 for all) and UC (week 6, 14 and 30, p < 0.001 for all). Concomitant IS use prevented ADA formation in anti-TNF-naive patients. UC patients who were exposed to infliximab before initiation of anti-TNFs had lower early TL coupled with ADA positivity and were more likely to develop infusion reactions. Concomitant IS use prevented ADA development in anti-TNF naive patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Performance OMP IgA was equal to ASCA IgA, however sIgA not. Anti-perianal penetration (PP) with IgG type ASCA (p LogRank
development of internal penetrating and/or stenosing (IP/S) complications and absence of IgA type anti-microbial antibodies. Contrary, ratio of IgA2/A1 in CD p
ASCA IgA/IgG and anti-OMP antibodies. Both ASCA types occurred cytometry test system was established for characterisation of IgA type ASCA of various complications and subsequent surgical interventions. A novel flow to assess possible associations between serologic antibodies and the development
traditional anti-microbial antibodies (ASCA IgA/IgG, anti-OMP IgA).

Aims & Methods: Sera of 266 well-characterized CD patients (m/f:112/154, median age: 25 years, Bi80.1%, PI:18.0%) and 155 controls were assayed for serological markers (ASCA IgG, Omp IgA, Endotoxin core IgA (EndoCaB) and a panel of non-specific immunoglobulin A (IgA) antibodies (IgA1, IgA2 and sIgA) in healthy individuals. Both ASCA IgA and anti-OMP antibodies were increased in CD compared to controls. They were also associated with presence of IgA type anti-microbial antibodies. Contrary, ratio of IgA2/A1 in CD corresponded with the value of the controls. In Kaplan-Meier analysis, development of perianal disease and/or stenosing (IPS) complications and its achievement was significantly associated with IgA type (p=0.001 and p LogRank<0.001 respectively), while development of perianal penetration (PP) with IgG type ASCA (p LogRank=0.005). Performance OMP IgA was equal to ASCA IgA, however sIgA not. Anti-microbial antibodies remained independent predictors in multivariate Cox-regression analysis comprising relevant clinical factors.

Conclusion: Consideration of antibody classes is an important novel parameter in serologic assessment in CD. The absence of ASCA IgA subtyping assays revealed marked increase in the proportion of IgA2 subtypes and presence of the secretory component (60% of total ASCA IgA) concurrently.

Disclosure of Interest: All authors have declared no conflicts of interest.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: Aims were to examine deep small bowel either oral or anal it could be of great utility in the management of Crohn’s disease patients.

Conclusion: The diagnostic yield and therapeutic impact of DBE on small bowel CD. The medical records of 180 CD patients, from December 2009 to April 2014, were retrospectively reviewed. Patients were included if they had known CD based on clinical, colonoscopic and histological findings and had been subjected to DBE. If one patient underwent more than one DBE examination only the first examination was considered. The primary end point of our study was to evaluate small bowel involvement that is beyond the reach of conventional colonoscopy. The secondary endpoints were to determine the impact of DBE findings on management strategy of CD. The diagnostic yield of DBE in small bowel CD was determined. In addition, the changes in medical treatment, endoscopic intervention and surgical procedures, within three months after DBE, were analysed.

Results: Among 180 patients with CD, 90 patients underwent 168 DBE examinations and were included. The mean age of included patients was 40 ± 13.6 years. They were 63 males and 27 females. Eighty (91%) patients with established CD underwent DBE for evaluation of small bowel involvement and 8 (9%) patients underwent DBE because of suspicion of CD and had been newly diagnosed. The overall diagnostic yield of DBE was 69% DBE revealed small bowel involvement proximal to the terminal ileum in 40 (64.5%) patients; of them 17 (42.5%) patients had isolated small bowel CD. Within 3 months after DBE examination the management strategy of CD changed in 47 (52.2%) patients, based on DBE findings. The medical treatment escalated in 20 (32%) patients, and decreased in 7 (11%). Fourteen (24%) patients underwent DBE-assisted balloon dilatation, and 6 (9.6%) patients underwent CD-related surgery.

Conclusion: DBE is able to detect small bowel involvement in a significant proportion of CD patients. The DBE findings modified the management strategy in at least one half of CD patients.

P0340 IS THE CDMRIS USEFUL TO MONITOR PATIENTS WITH CROHN’S DISEASE BY MAGNETIC RESONANCE IMAGING?

C. Le Berre1, M. Tahora2, C. Trang1, M. Flamant1, P. Hallouin1, S. Bruley Des Varennes1, A. Bourreille1, E. Frampas1

Introduction: Magnetic resonance enterography is now recognized by the European Crohn’s and Colitis Organization (ECCO) as a reference procedure to assess the small enterocollimation of Crohn’s disease (CD), including extra mural complications, as well as to monitor patients under treatment. A new MRI index of severity was developed in 2015 by the GETAID consortium, specifically to evaluate lesions located in the small intestine. This score, labeled CDMRIS considers, for each 20-cm small bowel segment, the intensity of relative contrast enhancement (mild–moderate or severe), deep ulceration without fistula, “comb sign”, any fistula, and abscess. Although well standardized, this index has not yet been validated, either for the initial assessment of CD at diagnosis, or for monitoring patients under treatment. Its feasibility in routine practice has never been tested.

Aims & Methods: The aims of this study were to evaluate the feasibility of applying the CDMRIS score in clinical practice, to evaluate its variability after the initiation or optimization of an anti-TNF treatment, and to measure its correlation with an evaluation of clinical activity. Patients with known small bowel disease who underwent two consecutive examinations at least 3 months were included between 2010 and 2015. Each exam was interpreted twice and the CDMRIS score was calculated on both exams in addition to classical criteria. All patients had a clinical evaluation over time, separating them in two groups: “active” and “inactive” disease.

Results: Seventy-two patients were included, with a mean CDMRIS of 3.4 at baseline, decreasing to 2.6 (p = 0.052) independently of clinical disease activity. The mean interval between the two MRIs was 15.4 months, and there was a significant larger decrease in the CDMRIS score when the interval was above 12 months. Two other radiological parameters decreased significantly: the rate of patients with a mural T2-hyperintensity (36.1% to 20.8% p = 0.042), with a good clinicoradiological correlation, and mean wall thickness (5.5 to 4.4 mm, p = 0.014).

Conclusion: This study demonstrated the feasibility of applying the CDMRIS in clinical practice, but sensitivity was too low to detect early changes. Accuracy for a long-term monitoring needs to be evaluated. Wall thickening and mural T2-hyperintensity emerged as two additional radiological factors, significantly associated with the disease activity, allowing monitoring of the short-term efficacy of biotherapies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Correlation of components of the CDAI with SES-CD

- Weight (kg) 3.2 (6.1)
- HCT 21.1 (21.3) 0.09 0.355
- Stool frequency* 47.1 (35.2) 0.46
- Diarrhea/pain medications 3.2 (9.3) 0.01 0.927
- Extra-intestinal manifestations 14.0 (16.3) 0.22 0.017
- General well-being 63.3 (50.2) 0.16 0.073
- AP, extra-intestinal manifestations, and SF

The correlation of SES-CD with SF was similar regardless of whether the patient had ileal disease (r = 0.31 [P < 0.001]) and at week 52 (r = 0.31 [P = 0.005]). Similar results were observed for correlations between mean changes from baseline in CDAI and SES-CD at weeks 12 (r = 0.35 [P < 0.001]) and 52 (r = 0.31 [P = 0.005]).

Introduction: Crohn’s disease (CD) with complications such as penetrating, strictureting and perforation is a serious and frequent inflammatory disease called complicated CD. However, no validated, inexpensive, or sensitive models for prediction of risk are available in complicated CD. We have found that a novel immunological balance, the CD8+CD28−/CD8+CD28− , consisting of CD8+CD28− and CD8+CD28− T cells, can predict the prognosis for patients with inflammatory bowel disease (IBD). Thus, we hypothesize that the CD8+CD28−/CD8+CD28− balance (ratio) can predict the poor outcome for patients with complicated CD.

Aims & Methods: To test the efficiency of CD8+CD28−/CD8+CD28− balance to predict the subsequent active stage, and to explore the correlation between the balance and the risk factors, for the newly diagnosed complicated CD. Seventeen patients with complicated CD were enrolled as the observation group, while the other 48 CD patients with no complications were enrolled as the control group. Peripheral blood samples were drawn from all the 65 newly diagnosed CD patients for CD8+ T cells testing through flow cytometry (FCM) when enrolling. The potential risk factors, including demographic, pathophysiological, and therapeutic factors were compared between the two groups. A 30-week follow-up period was performed, and the CD8+ T cells testing were repeated. The sensitivity and specificity of the CD8+ T cells’ level and balance in predicting were analyzed through receiver operator characteristic (ROC) curves. The cumulative remission lasting rates (CRLRs) under the different risk factors were analyzed using the Kaplan-Meier method.

Results: I. Risk factors: compared with the control CD group, patients with complicated CD had a larger proportion in male (P = 0.001), younger in age (P = 0.019), lower body mass index (BMI) (P < 0.001), higher prescription rates in immunosuppressants (P = 0.029) and steroids (P = 0.015), as well as a significant higher surgical rate (P = 0.001). Pearson and Spearman correlation analysis showed that CD8+CD28−/CD8+CD28− was associated with BMI, CD8, and surgery (P = 0.005). II. Follow-up and dynamic changes of the balance was associated with BMI, CDAI, steroids, and surgery (P < 0.005). II. Follow-up and dynamic changes of the balance was associated with BMI, CDAI, steroids, and surgery (P < 0.005). A 30-week follow-up period was performed, and the CD8+ T cells testing were repeated. The ratios of CD8+CD28−/CD8+CD28− reached the bottom at the 30th week and were significantly lower at the 6th, 22nd, and 30th week during follow-up, in the complicated CD patients when compared to the control ones (P < 0.05). A shorter lasting time of remission (LTR) was found in complicated CD patients (P = 0.044). ROC curve showed that CD8+CD28−/CD8+CD28− ratio could accurately predict the active stage for the complicated CD patients [area under curve (AUC) of 0.890, and 95% CI of 0.822 to 0.938], and the best sensitivity of 89.2% and specificity of 85.3% were found when the ratio was 1.03. III. Kaplan–Meier analysis: Undergoing of steroids and surgery was closely related to worse outcome for the complicated CD patients, and patients who underwent steroids and surgery had the significantly lower CD8+CD28−/CD8+CD28− ratio and lower CRLRs (all P < 0.05).

Conclusion: Depending on steroids and surgery stands for a more severe disease activity and thus disqualify the immunological balance, which could be the main reason for lower CD8+CD28−/CD8+CD28− ratio, and this ratio can predict the active stage sensitively for patients with complicated CD. More strategies should be taken when the ratio is to be lower than 1.03.

P0344 BOWEL PREPARATION QUALITY OF NER1006 VERSUS ORAL TRISULFATE SOLUTION AS ASSESSED BY COLONOSCOPISTS AT SITE: A POST HOC ANALYSIS FROM A RANDOMISED CONTROLLED TRIAL

R. Ng Kwet Shing1, P. Bekal2
1Clinical Development, Norgine Limited, Harefield/United Kingdom
2Ohio GI and Liver Institute, Cincinnati/United States of America/Ohio

Introduction: The success of colonoscopy is dependent on efficient bowel cleansing. Inadequate bowel cleansing may decrease diagnostic sensitivity, necessitate repeat procedures and potentially delay appropriate treatment. The increasing frequency of the incidence of colorectal cancer arising in the ascending colon necessitates effective cleansing of this area; additionally these cancers are often associated with poorer prognoses. Data suggest that detection in the ascending colon is more dependent on higher grades of cleansing, perhaps due to the nature of polyps present, which may be more likely to be sessile or serrated. NER1006 is the first 1L polyethylene glycol (PEG)-based bowel preparation, a patented combination optimised for effective bowel cleansing. The NOCT study (a multicentre randomised Phase 3 clinical trial investigating bowel cleansing efficacy of NER1006 vs trisulfate solution) reported bowel preparation quality assessed by central readers. This post hoc analysis shows the cleansing assessment by site colonoscopists, who typically guide clinical decision making; hence this study may be more relevant for clinical practice than previous studies.

Aims & Methods: In the NOCT study 621 patients (males and females, aged 18–85) were randomly assigned in a 1:1 ratio to receive either NER1006 or trisulfate solution, each administered as an overnight split-dose. Data from the 523 patients achieving high-quality cleansing success in the right colon.

Table 1: Successful colon cleansing rates when treated with NER1006 or trisulfate solution.

</tbody>
</table>

Conclusion: For both preparations, site colonoscopist findings demonstrated similar very high rates of cleansing success for the overall colon (>93%) and high rates of high-quality cleansing of the ascending colon (>73%), however, statistical significance was not met in either comparison. The rates of cleansing success in the ascending colon reported by the site colonoscopists are notably higher than those previously reported by central readers.

Introduction: The efficacy of colonoscopy is dependent on the quality of bowel cleaning. NER1006 is the first 1L polyethylene glycol (PEG)-based bowel cleansing solution and is a patented combination optimised for effective bowel cleansing. The DAYB study was a European multicentre, randomised trial that tested the hypothesis that NER1006 would be non-inferior to sodium picosulfate and magnesium citrate (NaPsc + MgCit) in terms of overall bowel cleansing and high-quality cleansing of the ascending colon plus caecum [1]. Bowel cleansing was assessed using the Harefield Cleansing Scale (HCS) [2]. The primary endpoints of the study were assessed by video review by a central reader. Bowel cleansing on the HCS was also assessed by the site colonoscopist and this post hoc analysis assessed the cleansing grades as determined by the site colonoscopists.

Aims & Methods: In the DAYB study, 515 patients (aged 18–85, median age: 55.0 years) underwent screening, surveillance, or diagnostic colonoscopy and were randomly assigned in a 1:1 ratio to receive either NER1006 or NaPsc + MgCit, each on the day before colonoscopy. In this analysis, data from 479 patients who underwent a colonoscopy and had a completed assessment by the site colonoscopist were included. Colonoscopists were blinded to the preparation administered. Colonoscopy was assessed according to the HCS; cleansing of each segment of the colon was scored from 0 to 4. Grades 3 and 4 were judged as high-quality cleansing. For the overall colon, cleansing grades A to D; grades A (all segments scored 3 or 4) and B (≥2 segments scored 3 or 4) were judged as successful cleansing.

Results: As indicated in Table 1, in the overall colon, successful cleansing was achieved in 72% of patients who received NER1006 than who received NaPsc + MgCit (73.3% vs 61.3%, P = 0.003, 95% CI: 4.0–20.7). In the ascending colon, high-quality cleansing was achieved in 20% more patients who received NER1006 than those who received NaPsc + MgCit.
**P0346 LOW VITAMIN D LEVELS ARE RELATED TO CLINICAL ACTIVITY, MUCOSAL INFLAMMATION, AND INTESTINAL FIBROSTENOSIS IN CROHN’S DISEASE.**

T. Sawada1, O. Watanabe1, M. Nakamura1, T. Yamamura1, M. Matsushita1, M. Saito1, R. Matsuzara1, Y. Mizutani1, Y. Niwa2, E. Ishikawa2, G. Uchida1, H. Otsuka1, H. Suzuki1, T. Nishikawa1, T. Ishida1, K. Kuno1, S. Hattoni1, K. Yamada1, T. Ishiduki1, K. Furukawa2, K. Funatsuka1, E. Ohno1, R. Miyahara1, H. Kawashima1, H. Goto1, Y. Hirooka2

**Introduction:** Several recent studies have revealed new roles for vitamin D. For example, vitamin D plays a role in regulating skeletal muscle, as well as in cardiovascular and renal physiology, producing anticonvulsant effects, suppressing fibrosis, and as a regulator of the immune system. In light of these new roles, especially as a regulator of the immune system and suppressor of fibrosis—vitamin D deficiency is considered to be related to disease activity and intestinal fibrosis, including that seen in Crohn’s disease (CD). Several reports have demonstrated a relationship between vitamin D deficiency and CD activity according to clinical parameters such as Crohn’s disease activity index (CDAI) and quality of life (QoL). However, no reports have demonstrated this relationship by using endoscopic parameters such as endoscopic activity, mucosal inflammation, and intestinal fibrosis.

**Aims & Methods:** The aim of this study was to clarify the relationship between vitamin D deficiency and CD activity by using endoscopic parameters, as well as clinical parameters. Of the CD patients visiting Nagoya University Hospital from May 2011 to February 2016, 82 patients were enrolled in this study. Serum 25-hydroxyvitamin D (25(OH)D), disease activity, and clinical factors of the subject were investigated retrospectively. Endoscopic findings of 52 of the 82 total patients were investigated retrospectively from endoscopic records. This study design was approved by the ethics committee of Nagoya University Hospital. The aim of this study was to investigate the relationship between vitamin D level and disease activity in CD patients. The disease pathology of CD consists of repetitive intestinal inflammation and intestinal fibrostenosis formed during healing of inflammation. We consider it important to demonstrate this relationship not only using clinical parameters, but also using endoscopic parameters such as mucosal inflammation and intestinal fibrostenosis.

**Conclusion:** The results from this study demonstrated the relationship between vitamin D level and disease activity in CD patients. The disease pathology of CD consists of repetitive intestinal inflammation and intestinal fibrostenosis formed during healing of inflammation. We consider it important to demonstrate this relationship not only using clinical parameters, but also using endoscopic parameters such as mucosal inflammation and intestinal fibrostenosis.

**P0347 PATIENT SATISFACTION WITH HOME MONITORING OF DISEASE ACTIVITY AND FECAL CALPROTECTIN IN ADULT PATIENTS WITH INFLAMMATORY BOWEL DISEASE: INTERIM ANALYSIS OF 68 PATIENTS.**

P. Weimers, D. Marker, D. V. Andersen, J. Burisch, P. Munkholm

**Introduction:** Inflammatory Bowel Disease (IBD), mainly represented by Crohn’s Disease (CD) and Ulcerative Colitis (UC), is a chronic, relapsing and remitting disease impairing patients’ quality of life (QoL). To maintain a high QoL and to decrease the inflammation burden, it is important to tightly monitor the disease and promptly treat relapses when they occur. The quality of care perceived by IBD patients play an important role in the management of IBD. An eHealth web application consisting of a validated Fecal Calprotectin (FC) home testing set (Calpro Smart™), questionnaires regarding disease activity and QOL has been developed to improve disease monitoring, patient empowerment and patient-caregiver communication.

**Aims & Methods:** The aim of this study was to evaluate patient satisfaction with an eHealth home monitoring solution during the participation in a one year trial. The trial includes 120 adult IBD patients which have been randomized into two groups; one performing a disease activity screening procedure every 3 months (3M) and one screening only at the patient’s discretion, on demand (OD). Both groups used the web-program where they were requested to fill out a disease activity questionnaire, Harvey-Bradshaw Index (HBI) for CD or Simple Clinical Colitis Activity Index (SCCAI) for UC, and perform a home testing of FC. The results of the disease activity questionnaire and FC were used to calculate a Total Inflammation Burden Scoring (TIBS) which is visualized to the patient in a traffic light manner for instant recommendation of individualized treatment strategies. At baseline and upon completion of the trial the patients were requested to fill out a QOL questionnaire (Short-Inflammatory Bowel Disease Questionnaire (s-IBDQ)) as well as a questionnaire regarding their overall satisfaction with the trial and the home monitoring solution.

**Results:** To date, 83 patients have been included, 15 patients have dropped out (7 in OD-group and 8 in 3M-group) and 68 (3M-group: n = 32, 47%; OD-group: n = 36, 53%) patients have fulfilled the first year of follow-up and were included in the analysis. The trial lived up to the expectations in n = 63, 93% (3M-group: n = 29, 91%; OD-group: n = 34, 94%) of the patients and the support given to the patients was estimated to be sufficient by n = 67, 99% (3M-group: n = 31, 97%; OD-group: n = 36, 100%). Only n = 14, 21% (3M-group: n = 6, 19%; OD-group: n = 8, 22%) of the patients experienced difficulties with the application or the home testing kit and n = 64, 94% (3M-group: n = 29, 91%; OD-group: n = 35, 97%) wanted to continue to be monitored in an eHealth setting in the future. The mean s-IBDQ scores at baseline were 58 (95% CL: 55–61) in the 3M-group and 54 (95% CL: 59–58) in the OD-group as well as 58 (95% CL: 54–62) in the 3M-group and 61 (95% CL: 58–64) in the OD group at one year follow up. No difference in s-IBDQ measured QOL was found between the two groups. However, patients in the OD group had a significant increase in mean s-IBDQ score at follow up (p = 0.04).

**Conclusion:** Patients in both groups were generally satisfied by the home monitoring setup. Patients in the on-demand group also presented a significant increase in quality of life over time.

**Disclosure of Interest:**

**Conclusion:** NER1006 was shown to provide significantly better cleansing of the overall colon and high-quality cleansing of the ascending colon compared to NaPic + MgtCit, when both treatments were administered the day before colonoscopy. The cleansing efficacy rate of the comparator was within its previously reported cleansing rates for day before administration, suggesting the improvement seen with NER1006 is of clinical relevance.

Introduction: Inflammatory bowel diseases (IBD), such as ulcerative colitis (UC) and Crohn’s disease (CD), are chronic gastrointestinal diseases that are associated with protein-energy malnutrition (PEM). Although the frequency of altered body composition, such as reduced fat-free mass or skeletal muscle volume, has been shown to be high in patients with IBD, the relationships between skeletal muscle volume and the prognosis are yet to be elucidated.

Aims & Methods: We have conducted a retrospective study on 61 IBD patients who have admitted due to exacerbation of the disease. We have enrolled IBD patients who have had abdominal computed tomography and assessed the nutritional indices, such as the Onodera’s prognostic nutritional index (O-PNI) and controlling nutritional status (CONUT). O-PNI was calculated based on the serum albumin and total lymphocyte count, using the following equation: O-PNI = 10 × [serum albumin (g/dl) + 0.005] × total lymphocyte count (×10⁶/ml). The L3 skeletal muscle index (SMI) which is the cross-sectional area of the skeletal muscle at the level of the third lumbar (L3) vertebral normalized by the height squared is used to identify sarcopenia.

Results: Sarcopenia defined as low SMI were observed in 44% of all IBD patients (29% in CD, 54% in UC). In UC patients, the O-PNI, CONUT, height and L3 skeletal muscle index (SMI) which is the cross-sectional area of the skeletal muscle volume and the prognosis are yet to be elucidated.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Crohn’s Disease (CD) spans a wide spectrum of severity, from mild to severe, and may avoid under- as well as overtreatment. The patients are treated according to guidelines. 5 year follow up is planned for all patients. If initial therapy fails, treatment is escalated. Source data verification is performed by external monitors. Primary aims of the study is to confirm the previously identified score and to test its power to predict a mild disease course as indicated by the need of not more than mesalamin therapy. Additional analyses include the percentage of patients with a score indicating a severe disease and their characteristics at diagnosis. This interim analysis presents preliminary data.

Results: Currently, 78 patients (33 male, 45 female; age 16-72, mean 35 years) with newly diagnosed CD are enrolled. 56 CD-patients with follow up 2-8 weeks (mean 8.5 months), mean age 35 years, female 21, male CRP 12.2 mg/l were included into the interim analysis. In 28 patients a score from 0-2 step-up treatment occurred in 7%, whereas in 28 patients with a score ≥3, step-up rate was 43% (p = 0.0043). Differences between patients with a score 0-2 and ≥3 were (age 41 vs. 28 years, p = 0.0011), CRP < 2 mg/l (17/28 patients vs. 0/28, p < 0.0001), endoscopic score 1.4 vs. 2.7, p = 0.0011, perianal lesions 12/28 vs. 4/28, stenosis 1/28 vs. 6/28. There were no differences in terms of sex, fistula, extraintestinal manifestations and lever. Conclusion: In this early analysis of a prospective study planned with a 5-year follow up, a significant proportion of patients with mild CD and simple mesalamin therapy can be identified. These initial results encourage to continue and expand this prospective long-term study on the predictability of a mild CD course.

2Pediatrics, Hospital Virgen Concha, Zamora/Spain

Contact E-mail Address: amfcoronel@gmail.com

Introduction: The Spanish Working Group on Crohn’s Disease and Ulcerative Colitis (GETECCU) and other international guidelines recommend testing of latent tuberculosis infection (LTI) before anti TNF therapy by screening with tuberculin skin test (TST) and, in a potential state of anergy, double screening by TST and interferon-gamma release assays (IGRAs) or two-time tuberculin test (TST/booster). Routine repetition is not recommended.

Aims & Methods: We aimed to assess the correlation between (TST/booster) and IGRA using QUANTIFERON-TB (QFT) and the usefulness of repeating periodic (annual or biannual) screening in a population of IBD patients of Zamora (Spain). In a single cohort of IBD patients attended in the department of gastroenterology of Zamora Hospital, we implemented a questionnaire and collected TST,booster performed previously to February 2015. Afterwards, prospectively, between February 2015 to February 2017, TST and QFT were performed at the same day, and the TST/booster 7 days after. Finally we compared the results of the LTI screening performed prospectively with the screening of the retrospective cohort.

Results: A total of 404 patients were included with a mean age of 51.5 (SD 16.6, 225 (55.7%) male and 179 (44.3%) female. 227 patients (56.2%) were ulcerative colitis, 167 (41.3%) were Crohn disease and 10 (2.5%) were diagnosed of indeterminate colitis. 160 patients live in rural areas (40.6%), 60/355 (16.9%) were smokers. The prevalence of LTI and the correlation between TST/booster and QFT is shown in table 1.

Table 1: Prevalence of LTI and correlation between TST/booster and QFT.

</tbody>
</table>
Prevalence of LTI in retrospective testing was of 54/246 (22.0%). Prospective testing was of 26/246 (10.5%); among the follow up, 30/191 (15.7%) patients who were negative for screening before 2015 were converted in positive for LTI (95% CI [10.2–21.1]).

**Conclusion:** The prevalence of LTI in our area is high (32.6%). The simultaneous presence of the capsule endoscopy and QFT/QFT-L1 improves the detection of LTI. The QFT increases the detection of LTI even when is performed in patients without immunosuppressive treatments, in whom is not routinely recommended. The QFT is more useful in patients without immunosuppressive therapy. The results of QFT in every two years is useful in this population with high prevalence of LTI, since it may detect LTI in patients with previous negative tests (15.7%). The QFT is essential due to the possible false negatives of QFT when screening patients on anti-TNF therapy.

3Chaim Sheba Medical Center, Tel Aviv University, Tel Aviv/Israel

**Introduction:** Magnetic resonance enterography (MRE) and capsule endoscopy (CE) are prime modalities for evaluation of small bowel in patients with Crohn’s disease (CD). However, detection of proximal (jejunum and proximal ileum) small bowel inflammation by MRE is challenging. Current quantitative scores such as Magnetic Resonance Index of Activity (MaRIA) do not incorporate proximal small bowel data and were validated against ileocolonoscopy. Magnetic resonance enterography global score (MEGS) was designed for quantitative evaluation of the entire digestive tract; however, it was only validated against ileocolonoscopy and its accuracy in the proximal small bowel was not assessed. CE allows for accurate assessment of the entire small bowel and is the modality of choice for evaluation of the proximal small bowel.

**Aims & Methods:** We aimed to compare the quantitative evaluation of the small bowel inflammation by MEGS score and the Lewis capsule endoscopy score. Patients with known quiescent small bowel (CD) for at least 3 months (CDAI < 150) were prospectively recruited and underwent magnetic resonance enterography (MRE) and capsule endoscopy (CE). MEGS score was calculated for each bowel segment and the entire small bowel. MEGS is based on the involved segment length, wall thickness, mural enhancement, mural and per-mural edema and extra-intestinal findings. In addition, MARIA score was calculated for the terminal ileum. Small bowel inflammation on CE was quantified using the Lewis score (LS) (LS < 150 = mucosal healing; LS ≥ 790 = severe to severe inflammation). Proximal small bowel was defined as jejunum and duode-num on MRE and as 14th and 22nd tertiles LS on CE. Distal small bowel was defined as terminal ileum on MRE and 3rd tertile LS on CE. Fecal calprotectin (FCP) levels were measured and correlated with all scores.

**Results:** Fifty-two patients were included in the study. There was a strong correlation between MEGS and Lewis score (Pearson correlation = r = 0.61, p = 0.001) for the entire bowel. In the proximal small bowel, the correlation was moderate (for duodenum vs LS 1st tertile and proximal ileum vs 2nd tertile LS - both r = 0.54, p = 0.001). In the terminal ileum, there was a strong correlation between MEGS and MaRIA score (r = 0.74, p = 0.001) while both MRE based scores were moderately correlated with 3rd tertile LS (r = 0.5, p = 0.001 for both). The correlation with FC was stronger for MEGS (r = 0.68 p = 0.001) than for MaRIA (p = 0.40 p = 0.01) or for LS (r = 0.38, p = 0.02).

**Conclusion:** MEGS score provides accurate evaluation of the small bowel in CD. Lewis capsule endoscopy score allows for accurate quantification of small bowel disease.

**Contact E-mail Address:** ukopylov@gmail.com

**Introduction:** Small-bowel capsule endoscopy (CE) is a prime modality for evaluation of the small bowel. The Lewis score (LS) and the Capsule Endoscopy Crohn’s Disease Activity Index (CECDAI) are validated endoscopic indices for quantification of small bowel inflammation on CE. It is unclear whether these indices are interchangeable for evaluation of mucosal inflammation in established Crohn’s disease (CD).

**Aims & Methods:** We aimed to prospectively compare the quantitative evaluation of the small bowel inflammation by both scores. Patients with known quiescent small bowel (CD) for at least 3 months (CDAI < 150) were prospectively recruited and underwent CE. LS was calculated using the capsule reading software (RAPID 8) and CECDAI was calculated manually, by 2 independent experienced gastroenterologists (one for each score) unaware of each other’s results. Mucosal healing was defined as LS < 135; LS ≥ 790 signified moderate to severe inflammation. Fecal calprotectin (FCP) and C-reactive protein (CRP) levels were measured and correlated with the scores.

**Results:** Fifty patients were included in the study. There was a strong correlation between LS and CECDAI (Pearson’s r = 0.67, p = 0.001). CECDAI < 7.2 corresponded to mucosal healing (LS < 135), while CECDAI > 11.1 corresponded to moderate to severe inflammation (LS ≥ 790) by linear regression. There was a moderate correlation between both scores and FCP levels that was somewhat stronger for CECDAI (r = 0.39, p = 0.002 vs r = 0.53, p = 0.001 for both). There was a weak correlation between LS and CRP levels (r = 0.27, p = 0.04) and none for CECDAI and CRP (r = 0.2, p = 0.1).

**Conclusion:** In our prospective study, CECDAI and LS strongly correlated and performed similarly for quantitative assessment of mucosal inflammation in established CD.

P0354 THIOPURINE MAINTENANCE THERAPY FOR IBD: WHICH IS THE BEST METHOD TO MEASURE MEDICATION ADHERENCE? A. Ochieng, V. George, C. Selinger Gastroenterology, St James Hospital, Leeds/United Kingdom Contact E-mail Address: oduori.ochieng@nhs.net

Introduction: For the majority of patients with IBD long-term therapy is required to maintain remission, yet 30–45% of patients do not adhere to their IBD medication. Medication adherence can be assessed with prescription refill rates, biological markers (medication levels), trough levels, self-reported patient adherence in the IBD clinic and to correlate the results with thioguanine-nucleotide (TGN) levels. Aims & Methods: Consecutive outpatients on thiopurine maintenance therapy for IBD for >3 months were recruited from clinic. Patients self-reported adherence using two different self-report tools and the validated Health Assessment Questionnaire (HAQ). HAQ scores were recorded at the visit. For the majority of patients TGN levels were available for 69. These included 38 women. Diagnoses were Crohn’s disease in 27, ulcerative colitis in 41 and IBD-U in 3 cases. Concomitant therapy included 5/ASA (25 cases), anti-TNF (13 cases) and Vedolizumab (2 cases). The proportion of adherent patients was according to the relevant report tool 71% (TGN), 87% (VAS), 87% (Morisky) and 77% (MARS). VAS (Pearson 0.315; p = 0.005) and Morisky (Pearson −0.363; p = 0.001) correlated moderately with TGN, but MARS (Pearson 0.09; p = 0.39) did not. The patients, who were non-adherent by TGN were detected by VAS in 3, Morisky in 6 and MARS in 3 cases. However, patients showing non-adherence according to self-report tools had a TGN level in 6 of 10 cases for VAS, 10 of 26 for Morisky and 4 of 15 for MARS.

Conclusion: Self-report tools provided a patient-friendly and inexpensive way of assessing adherence, but the correlation with TGN levels was only moderate. While providing a more objective assessment TGN levels are problematic for routine use in all patients. TGN require a more invasive and expensive approach. Furthermore, TGN cannot detect “white coat adherence” (patients take medication only around appointments), which is the most likely explanation for normal TGN levels in 6 of 10 cases for VAS, 10 of 26 for Morisky and 4 of 15 for MARS.

Introduction: Diagnostic delay seems to be common in inflammatory bowel disease (IBD), especially in Crohn’s disease. We sought to investigate the diagnostic delay in Austrian IBD patients and to identify associated risk factors as well as the impact of delayed diagnosis on the risk of intestinal surgery in CD.

Aims & Methods: In a multicentre cohort study adult patients with IBD (CD, ulcerative colitis UC, inflammatory bowel disease unclassified IBDU) attending all the patients requiring ileocoloscopy, regardless the indication, were consecutively included between September 2015 and September 2016. Clinical and endoscopic findings alone were appropriate in the vast majority of CD patients. US is a convenient alternative.

Results: 1217 patients (CD 779, UC 400, IBD 21, missing 17; females 615) with a median age of 40 years (interquartile range (IQR) 31–52 years) and a median disease duration of 10 years (IQR 4–18 years) were analysed. The median diagnostic delay was 0.53 years (IQR 0.29–1.92 years) in CD and 0.28 years (IQR 0.11–0.80 years) in UC, respectively (p < 0.001). In the multivariable regression analysis patients with CD had a significantly longer diagnostic delay than patients with UC (HR 1.56; 95% CI 1.34–1.82; p < 0.0001) and a quadratic effect of age leading to higher risk of delayed diagnosis in older patients (p < 0.0001) was found. Diagnostic delay did not differ significantly between patients with intestinal CD-related surgery (53% of all CD patients) and those without surgery. However, in the Kaplan-Meier curve for the probability of being diagnosed after symptom onset a trend of a difference between both groups was seen after 10 months (p = 0.15).

Conclusion: The median diagnostic delay was longer in CD (6 months) than in UC patients (3 months) and was associated with older age at diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Enterobacteria, especially adherent and invasive E. coli (AIEC), are suspected to play a key role in Crohn’s disease (CD). These bacteria are able to highly adhere to the ileal mucosa of CD patients through the CEACAM6 receptor (Carcinoembryonic antigen-related cell adhesion molecule 6). It has been shown that therapies targeting enterobacteria and/or AIEC could be more effective in mice overexpressing CEACAM6. In this line, the overexpression of CEACAM6 in the ileum as well as the presence of AIEC in the ileum could be potential biomarkers to select the patients who could benefit from drugs targeting the host-pathogen interaction. Unfortunately, the identification of these biomarkers is time-consuming and invasive highlighting the need for more convenient alternative.

Aims & Methods: We aimed to assess the correlation between the level of ileal mucosa of CD patients through the CEACAM6 receptor (Carcinoembryonic antigen-related cell adhesion molecule 6). It has been shown that therapies targeting enterobacteria and/or AIEC could be more effective in mice overexpressing CEACAM6. In this line, the overexpression of CEACAM6 in the ileum as well as the presence of AIEC in the ileum could be potential biomarkers to select the patients who could benefit from drugs targeting the host-pathogen interaction. Unfortunately, the identification of these biomarkers is time-consuming and invasive highlighting the need for more convenient alternative.

Results: Overall, 102 patients were enrolled in the study (Table 1).

Table 1: Baseline characteristics of the 102 CD patients included in the study.
Ileal CEACAM6 level did not depend on disease severity or the site of biopsies as the median level of ileal CEACAM6 was 854 pg/mg [570.3; 1646] and there was no difference in healthy or ulcerated zones (756 pg/mg [487; 1617] vs 947 pg/mg [604; 1820], p = 0.08). The median level of CEACAM6 from saliva was 3837 pg/mg [1889; 7338]. There was a positive correlation between the levels of CEACAM6 in saliva and CEACAM6 in the ileum (r = 0.47; p < 0.0001) in both macroscopically healthy areas (r = 0.53, p < 0.0001) and ulcerated areas (r = 0.39, p = 0.0082). Using a ROC curve, we determined the best threshold of CEACAM6 in saliva for detecting ileal CEACAM6 bacteria. Using a ROC curve (area under the curve (AUROC) = 0.73), the cut-off value of 3800 pg/mg demonstrated the best performance to detect ileal CEACAM6 overexpression with substantial specificity (76.0% [54.9; 90.6]) and positive predictive value (67.5% [74.8; 95.3]). The number of enterobacteria was increased in CD patients with prior intestinal resection (562 [20;1674] vs. 116 [0;752] pg/mg, p = 0.004). Interestingly, the number of enterobacteria was also increased in AIEC positive-patients (640 [0;1329] vs. 116 [0;752] pg/mg, p = 0.004). Using a ROC curve, we determined the best threshold of enterobacteria in the ileum to detect the presence of ileal AIEC bacteria. We found an area under the curve (AUROC) of 0.70 ([0.61; 0.77]). The cut-off value of 60 cfu/biopsy demonstrated the best performances to detect the presence of ileal AIEC bacteria with high specificity (96.8% [94.2; 99.3]) and sensitivity (92.9% [73.8; 99.7]).

Conclusion: CEACAM6 measurement in the saliva is feasible, non time-bombing and non-invasive. It could be a reliable test to detect the overexpression of CEACAM6 in the ileum from CD patients and could then be proposed as a non-invasive biomarker to select patients who might benefit from anti-adhesive therapies. In addition, we identify the number of enterobacteria associated to the ileum is a convenient and reliable test to screen CD patients for AIEC bacteria.

Introduction:
Fibroblast growth factor 19 (FGF19) is the ileal hormone providing bile acid synthesis feedback inhibition of bile acid (BA) synthesis and reduction of excess colonic BAs.

Concentration: The increased FGF19 level in UC patients in remission, compared to patients with active UC, may be influenced by the treatment, in particular corticosteroids used to induce remission. Steroid-induced increase in FGF19 synthesis may be associated with anti-inflammatory effect. The stimulation of FGF19 release during UC remission may also have beneficial effect by the inhibition of BA synthesis and reduction of excess colonic BAs.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Increasingly, immunosuppressive medications such as azathioprine and cyclosporine are used in order to prevent or control inflammatory bowel disease (IBD) patients. It has been reported that such treatments increase the risk of developing all types of skin cancer. Education of these patients is key in order to promote their awareness of their increased risk and it is vital for gastroenterologists to counsel patients on sun protection strategies on initiating therapy. We recently performed a pilot study in this group which highlighted gaps in their knowledge of the increased risk and prevention strategies. We speculate clinician’s lack of knowledge was partly to blame.

Aims & Methods: Our aim was to determine Irish IBD clinicians’ knowledge of the skin cancer risk and advised photoproteective behaviours in this cohort. Cross-sectional descriptive study. We invited IBD clinicians via email to fill in an anonymous online survey designed to assess knowledge of skin cancer risk and photoprotection. The survey comprised of 5 questions, each question asked on a 5-point Likert scale based on the “SunSmart” guidelines, as currently gastroenterology based guidelines are lacking. In addition their grade of training and clinical experience was noted.

Results: To date, 45 Irish Gastroenterology clinicians completed the online questionnaire. Of these, fifteen (33%) were consultants, fourteen (31%) gastroenterology trainees, four (9%) general medical trainees and twelve (27%) IBD nurse specialists. Overall, clinician’s knowledge of general factors associated with increased risk of skin cancer was reassuring; with all 45 (100%) knowing sun beds increased skin cancer risk and almost 100% (44, 98%) knew working outdoors increased cancer risk. 42 (93%) knew a personal history of skin cancer and 42 (93%) knew a personal history of skin cancer.

Conclusion: Our study highlights IBD clinicians’ suboptimal knowledge of immuno-suppression and their lack of emphasis on preventative measures and skin examination in clinics. A targeted educational and awareness programme may address this.

Introduction: Home monitoring of disease activity and fecal calprotectin in adult patients with inflammatory bowel disease (IBD) is of significant importance to detect and treat a relapse as soon as possible in order to decrease the total inflammation burden and avoid progression of intestinal damage, and possibly improve the disease course. An validated Fecal Calprotectin (FC) home testing kit and smart phone application CalproSmartTM have been added to an existing eHealth web-application, enabling patients to control their disease activity using clinical scores and FC from home with results shown on their smart phone. eHealth allows for tight monitoring of disease activity, however, the frequency of an optimal screening procedure for adult IBD patients has not yet been determined.

Methods: Our study highlights IBD clinicians’ suboptimal knowledge of immunosuppression risk and their lack of emphasis on preventative measures and skin examination in clinics. A targeted educational and awareness programme may address this.

Disclosure of Interest: All authors have declared no conflicts of interest.

Disclosure of Interest: D. Kohoutova: darina.kohoutova@seznam.cz

Introduction: Ulcerative colitis (UC) and Crohn’s disease (CD) represent a serious medical, socio-economic problem worldwide. The family of S100 proteins represents a total of at least 25 relatively small calcium binding proteins. S100 A4 represents a total of at least 25 relatively small calcium binding proteins. S100 A4 is a two-domain as its profibrotic effect has been confirmed in the myocardium, liver parenchyma and in the intestine. Fibroblasts represent the key cell type in the pathogenesis of fibrostenosing/stricturing CD.

Patients and Methods: The aim of this prospective study was to assess serum concentration of S100A4 protein in UC and CD. We included 118 subjects: 93 patients with CD (44 men, 49 women, aged 22–79, mean 44 ±14), 16 patients with UC (8 men, 8 women, aged 20–74, mean 39 ± 15) and 9 controls (average risk population with normal findings on colonoscopy and with negative history of colorectal neoplasia and/or inflammatory bowel disease; 2 men, 7 women, mean 32 ± 17). CD group was divided according to the Montreal classification: 20/93 (22%) patients had B1 phenotype, 19/93 (20%) B2, 20/93 (21%) B3 and 34/93 (37%) B2+ B3. Perianal involvement was present in 27/93 (29%). L1 involvement was present in 15/93 (16%), L2 in 14/93 (15%) and L3 in 11/93 (12%). Serum concentration of S100A4 protein was investigated by means of Human Protein S100-A4 ELISA kit, the quantitative sandwich enzyme immunoassay technique (purchased from My Biosource, San Diego, California, USA).

Results: Serum concentration of S100A4 protein was significantly higher in UC (52.1 ± 56.2 μg/L) compared to controls (mean 104.8 ± 40.5 μg/L), p = 0.019 and in CD (mean 154.4 ± 52.1 μg/L) compared to controls, p = 0.007. In CD, no difference in S100A4 was revealed between UC and CD, p > 0.05. In CD group, serum concentration of S100A4 in each subgroup (divided according to bowel involvement) was higher compared to controls, p < 0.005. No differences in S100A4 were documented between each CD phenotypes. Serum concentration of S100A4 was significantly higher in L2 (mean 144.6 ± 44.2 μg/L) compared to controls, p = 0.041 and in L3 (mean 163.0 ± 52.8 μg/L) compared to controls, p = 0.002. Serum concentration of S100A4 was significantly higher in L3 (mean 163.0 ± 52.8 μg/L) compared to L1 (mean 126.9 ± 47.6 μg/L), p = 0.017. No difference in S100A4 was observed between patients with and without perianal involvement, p > 0.05.

Conclusion: Association of serum S100A4 protein with UC and CD was con-
firmed. In CD, disease behaviour did not have impact on serum concentration of S100A4 protein. In CD, higher levels of serum S100A4 were observed in patients with ileo-colic and colonic involvement compared to those with isolated small bowel involvement.

Introduction: Hypovitaminosis D is common in Inflammatory Bowel Disease (IBD) patients. Some studies suggest that the finding may relate to severity of the disease.1

Aims & Methods: The aim of the study was to determine the vitamin D (VitD) status in an Italian IBD cohort in relation to disease activity. Serum vitamin D5 was measured in 260 IBD outpatients, not supplemented with VitD (110 Crohn’s Disease (CD) and 150 Ulcerative Colitis (UC); 145 males and 115 females, mean age 50.7 ± 15 years), and compared to those of 205 healthy blood donors, matched by sex, age (+/-2 years) and month in which the blood sample was collected. VitD levels were correlated to C-reactive protein (CRP), erythro-
cyte sedimentation rate (ESR), Harvey Bradshaw Index (HBI) and Crohn’s Disease Activity Index (CDAI) for CD and Mayo partial score for UC. Chi square, T test and linear correlation were used when appropriate.

Results: IBD patients were at higher risk of VitD deficiency (defined as <20 ng/ ml) than controls (OR 4.5, 95% CI 2.9–6.9, p < 0.0001). Of 260 IBD patients, 156 (60%) had VitD deficiency, more often in CD than in UC (72.7% vs 48% respectively, p < 0.0001). Age <40 and ≥60 years, winter/spring season, CRP >0.5 mg/dl, ESR ≥20 mm/h, previous intestinal surgery and HBI ≥5 were sign-
ificant risk factors for VitD deficiency. No differences were observed in relation to sex, smoking status, BMI, age at diagnosis, localization and behavior of dis-
case, and need of steroids. There was a weak negative correlation between CRP and VitD deficiency. No differences were observed in relation to presence of ileo-colic involvement and colonic involvement respectively, p = 0.5 were sig-
ificant. Patients with active disease were more likely to have VitD deficiency compared to controls, more so in CD. Patients with active disease are more likely to have VitD deficiency (defined as

Disease Activity Index (CDAI) for CD and Mayo partial score for UC. Chi square, T test and linear correlation were used when appropriate.

P0365 MAGNETIC RESONANCE OF THE SMALL BOWEL WITH EARLY (70 MIN) VS LATE (7 MIN) PHASE POST GADOLINIUM IMAGING TO IDENTIFY FIBROSIS IN STRICTURING SMALL BOWEL CROHN’S DISEASE
R. Stack1, C. O’Brien2, T. Nuzum1, S. Cummins3, N. O’Morain1, A. O’Connor1, N. Breslin1, B. Ryan1, I. Murphy1, D. McNamar4

Introduction: Small bowel (SB) Crohn’s disease (CD) strictures can comprise of both inflammatory and fibrotic elements. An accurate tool to discriminate fibro-
sis and inflammation would be clinically useful to guide therapy and predict response. While the magnetic resonance index of activity (MaRIA) is a validated means to assess activity, to date, no specific tool has been developed to identify fibrosis from inflammatory disease. Lesions with a dense fibrotic matrix exhibit delayed gadolinium enhancement on MRI. The role of delayed enhancement in assessment of SB CD strictures is unclear. Recent evidence suggests relative contras-
tive enhancement (REC) of >24% on delayed MRI sequences may accu-
ately detect fibrosis.

Aims & Methods: To determine the feasibility of MRE SB stricture assessment with early (70s) and late (7min) phase post gadolinium imaging comparing MaRIA, RCE and biochemical activity in patients with ideal CD. We performed a retrospective review of 208 consecutive MREs with known and suspected SBCD. MRE was performed as standard with additional coronal T1 sequences 7 minutes post gadolinium administration. Demographics, MRE findings and biochemical markers were recorded. Patients with stricture disease were further assessed. Two independent blinded Radiologists calculated RCE and MaRIA’s at 70 sec and 7 min.

Results: Median age 40.5 years; male n = 83(39.9%); 117, 72 and 19 patients had known CD, suspected CD and indeterminate IBD, respectively. In total, 119(57.2%) MREs were normal. Ileitis, strictures and fistulas were found in 40(19.2%), 49(23.6%) and 10(5.0%) patients, respectively. While there was no difference in Hb between patient groups (Normal, Inflammatory and Stricture disease); Albumin and CRP were statistically different between normal subjects and those with disease; albumin 42.4±L v 38.9±L in normal v stricture disease (p <0.0181 95% CI -0.23–0.02). CRP 8.8±mg/L v 18.3±mg/L (p <0.003 95% CI -0.46 –0.10) and v 29.4±mg/L (p <0.002 95% CI -0.43–0.11) amongst normal v inflammatory and stricture subjects respectively. Neither parameter could detect fibrosis in inflammatory and stricture disease. 26 MREs performed with ileal CD have been further assessed; median age =41yrs, male =10(38%). RCE >24% and high T2 signal intensity (SI); 6/26 (23%) and 11/26 (42%). MaRIAs did not occur in only 1/10 with a visible stenosis. Average MaRIA 2.6–7.7 (7 mild; 3/26 (11.5%) 7–11 moderate; 21/26 (80.7%) >11 severe. MaRIAs did not change significantly between 70 sec and 7 min. As expected T2 SI increased with MaRIAs >11, 26 ±1 (p <0.001, 95% CI 7.7–17.27). RCE and HBI correlate with MaRIAs suggesting it has a predictive factor for fibrosis. Consistent with MRE findings, CRP was higher in patients with MaRIAs >11 [13.3 ± 5.2] and lower in patients with RCE >24% [1.9 ± 4].

Conclusion: Unlike biochemical markers, MRE may be a useful means to differ-
entiate between inflammatory and structuring disease. Further study is required to assess the long-term predictive value. RCE may be a useful adjunct to current MRE and help detect fibrosis in small bowel lesions and warrants further investigation.

**Results:** A total of 520 patients who underwent CT enterography were identified, with 44% being male and 56% being female. The median age was 43 (32-53) years and 53% were women. The main indication for CT enterography was CD staging (81%). A total of 531 incidental findings were detected (median of 2 [1-3] per patient). The main findings identified were hepatic nodules (n = 59), hepatic cysts (n = 55) and sacroiliitis (n = 46). The findings implicated orientation to another medical specialty in 80 patients (29%), the main ones being Urology (n = 14) and Gynecology (n = 11). The findings implied additional exams in 59 patients (21%). Five (2%) underwent subsequent surgical intervention. Clinically relevant findings were found in 38 patients (14%), including 2 renal tumors, 2 ovarian teratomas and 3 cases of primary sclerosing cholangitis. The detection of incidental findings implied a change in CD therapy in 9 patients (3%); 1 suspended biologic therapy, 2 suspended immunomodulator therapy and 6 initiated biologic therapy.

**Conclusion:** Incidental findings are relatively common in patients with CD who undergo CT enterography. A significant proportion is clinically relevant and may involve change CD therapy. A risk stratification may be important to avoid morbidity associated with unnecessary examinations to assess benign situations.

**PO368 CLINICAL SIGNIFICANCE OF ASYMPTOMATIC CLOSTRIDIUM DIFFICILE CARRIAGE IN PATIENTS ON IMMUNOMODULATOR FOR INFLAMMATORY BOWEL DISEASE**

*St. Law,* W.M., Yip, K.K. Li

**Introduction:** Clinical significance of asymptomatic Clostridium difficile (C. difficile) carriage in patients on immunomodulator for inflammatory bowel disease (IBD) is largely unknown. [1, 2]

**Aims & Methods:** The aim of this study was to investigate the clinical implication of asymptomatic carriage of C. diff in IBD patients. Consecutive IBD patients on immunomodulators in clinical remission for the past six months were prospectively recruited from the IBD clinic since 2013. Those cases were excluded if they had past history of total colectomy, the dosage of their immunomodulators were titrated according to their disease activity in the past six months or the types of their immunomodulators were other than azathioprine, mercaptopurine or methotrexate. Stool specimen for C. difficile cytotoxin real-time polymerase chain reaction (RT-PCR) assay was obtained to all eligible patients at the time of enrollment and every follow-up during the study period. Patients were monitored for any IBD flare-up in which if happened, an additional stool specimen for C. difficile cytotoxin RT-PCR assay was obtained.

The primary outcomes were the disease activity which was graded by Crohn Disease Activity Index (CDAI) in Crohn disease (CD) (graded as follows: \[ \text{CDAI} < 150: \text{remission}; 150 < \text{CD} < 450: \text{moderate/severe}; >450: \text{severe} \]) and Ulcerative colitis Disease Activity Index (UCDAI) in ulcerative colitis (UC) (graded as follows: the total index score ranges from 0-12; 0-2: remission; 3-6: mild; 7-10: moderate; >10: severe UC). The secondary outcome was proportion with C. difficile carriage which was defined in the patients with active lower gastrointestinal symptoms accompanying with positive RT-PCR assay of C. difficile at that instant.

**Statistical inference:** The primary outcome was the disease activity which was graded by Crohn Disease Activity Index (CDAI) in Crohn disease (CD) (graded as follows: \[ \text{CDAI} < 150: \text{remission}; 150 < \text{CD} < 450: \text{moderate/severe}; >450: \text{severe} \]) and Ulcerative colitis Disease Activity Index (UCDAI) in ulcerative colitis (UC) (graded as follows: the total index score ranges from 0-12; 0-2: remission; 3-6: mild; 7-10: moderate; >10: severe UC). The secondary outcome was proportion with C. difficile carriage which was defined in the patients with active lower gastrointestinal symptoms accompanying with positive RT-PCR assay of C. difficile at that instant.

**Data:** Data were expressed as median (interquartile range) *p*; all are UC cases and 3 for maintenance therapy with indications as follows: refractory colitis, spondyloarthropathy, rectovaginal fistula.

**Conclusion:** The incidence of asymptomatic carriage of C. difficile in the IBD patients on immunomodulators was not common. It did not associate with the disease flare-up but a significant portion of them could evolve subsequently into clinical infection.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

The etiology of the disorder comprises a permanent activation of immune cascades and imbalanced cytokine networks. Evidence has been put forward that alteration of the human gut microbiome may play a critical role in the pathogenesis of IBD. The influence of the self-monitoring to the course of the disease will also be evaluated. Between April 2015 and December 2016, 180 patients with colonic IBD (126 with UC, 47 with CD, and 7 with IBD unclassified) were included in the study and randomized in a study group and control group. Patients in the study group were instructed to perform the FC home test and fill in a symptom questionnaire every other month and with increasing of the symptoms, and sent the results to the study/IBD nurse by e-mail. The control group patients filled in the symptom questionnaire at baseline and at 12 months and with the appointment to the outpatient clinic according to normal practice. The patients were not reminded of performing the stool tests or filling in the questionnaires. The study period was 12 months, and it is still ongoing.

**Results:** By the end of February 2017, 134 of the 180 included patients had completed the 12 months' follow-up. In the study group, 20/91 (22%) patients had performed the stool tests and filled in the symptom scores according to the study protocol for 6 months, and 14/91 (15%) patients for 12 months. In the control group, 44/89 (49%) patients had filled in the symptom score at baseline and 12 months. There was a significant difference of the adherence between patients stratified for IBD-diagnosis, age, or sex. The satisfaction of the patients with the program was able to clearly show the improvements of the study and the influence of self-monitoring in the number of relapses, phone calls, e-mails, and appointments to the outpatient clinic in both groups will be evaluated. The satisfaction of the patients with the program was able to clearly show the improvements of the study and the influence of self-monitoring in the number of relapses, phone calls, e-mails, and appointments to the outpatient clinic in both groups. The self-monitoring of IBD activity with a rapid FC home test provides an option for individualized treatment for increasing amount of IBD patients. However, in this study the adherence to the self-monitoring program was rather low. The patients need to be reminded of performing the stool tests and filling in the questionnaires in time. Also, the selection and education of the patients, as well as the easy accessibility of the monitoring program are crucial and need further consideration.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Fecal calprotectin (FC) is a most reliable noninvasive means to distinguish remission from active inflammation in inflammatory bowel disease (IBD). Different commercially available FC tests are time-consuming, and consequently new rapid tests have been validated. As the incidence of IBD is increasing, self-monitoring and eHealth technologies have been evaluated in managing patients with this lifelong disease.

**Aims & Methods:** The aim of this prospective study was to evaluate the feasibility and cost-effectiveness of a semi-quantitative rapid FC home test and a validated symptom questionnaire, in patients with colonic IBD. The influence of the self-monitoring to the course of the disease will also be evaluated. Between April 2015 and December 2016, 180 patients with colonic IBD (126 with UC, 47 with CD, and 7 with IBD unclassified) were included in the study and randomized in a study group and control group. Patients in the study group were instructed to perform the FC home test and fill in a symptom questionnaire every other month and with increasing of the symptoms, and sent the results to the study/IBD nurse by e-mail. The control group patients filled in the symptom questionnaire at baseline and at 12 months and with the appointment to the outpatient clinic according to normal practice. The patients were not reminded of performing the stool tests or filling in the questionnaires. The study period was 12 months, and it is still ongoing.

this study, the clinical and endoscopic features of CAC and ST, treatment method, and prognosis are compared.

**Aims & Methods:** Among 261 UC patients who underwent colonoscopy (CS) and had neoplastic lesions, the clinical features, treatment and prognosis were compared between 71 patients (88 lesions) with CAC (including HGD; CAC group) and 47 patients (63 lesions) who underwent local excision (surgical or endoscopic resection) within the presence of the past/present infection of UC (ST group). Definition of CAC and ST was performed by conventional pathological and immunohistochemical findings.

**Results:** The age of UC onset (29.8 vs. 39.0) and tumor detection (45.5 vs. 57.3) in the CAC group were significantly higher than those in ST group (p < 0.01). The CAC (47.1%) has a higher percentage of chronic persistent type than the ST group (2.3%), and the Mayo endoscopic score is also significantly higher (p < 0.001) in the CAC group (1.43) than the ST group (0.38). The percentage of advanced cancer (35.2% vs. 7.9%) was higher in CAC group than ST group. In patients with intraepithelial neoplasia (IEN) or submucosal lesions, flat lesion was found in 15 lesions of CAC group and whereas no flat lesion was observed in ST group. One lesion in ST group could not distinguish the lesions from the surrounding mucosa without magnifying colonoscopy. In ST group who received resections, 4 patients after resections observed ectopic CAC or low-grade dysplasia during follow-up. In CAC group, 50, 5, 4 patients received total colectomy, local colectomy, ESD, respectively, whereas in ST group, 1, 7, 40, 15 patients received total colectomy, local colectomy, EMR and polypectomy, ESD, respectively. Although mortality from cancer was 11.4% (8/70 cases) in CAC group, no death due to cancer observed in patients whose lesions were found as IEN. On the other hand mortality from cancer was 2.1% (1/47 cases) in ST group.

**Conclusion:** Most sporadic lesions were endoscopically distinct and local resection was the sole treatment method. After follow-up CAC patients diagnosed with IEN or submucosal lesions were resected in remitting UC patients, regular surveillance colonoscopy is necessary because 8.5% (4/47) of patients was found CAC/dysplasia. Even in CAC group, prognosis is well in patients with IEN.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0373 CAN WE PREDICT THE LACK OF RESPONSE TO CYCLOSPORINE AS SECOND LINE THERAPY IN PATIENTS WITH ACUTE SEVERE COLITIS REFRACTORY TO CORTICOSTEROIDS?**

**Gastroenterology, University Hospital Sahilou, Tunis/Tunisia**

**Contact E-mail Address:** aya_med@hotmail.fr

**Introduction:** Acute severe colitis (ASC) is a dangerous clinical condition that requires intensive intravenous (iv) corticosteroids treatment. Nevertheless, about 30-40% of patients fail to respond. Intravenous cyclosporine is an effective rescue therapy in steroid-refractory patients.

**Aims & Methods:** The aim of our study was to identify the clinical and biological predictive factors of lack of response to cyclosporine as second-line therapy in patients with ASC refractory to iv corticosteroids.

**Results:** Our study included 52 females and 30 males, with a mean age of 35 years (14-70 years). There were 34 patients with Crohn’s disease and 56 diagnosed with ulcerative colitis. Among the 90 patients enrolled, 68 patients (75.5%) had a good response to cyclosporine. Eleven patients were non responders and underwent colonoscopy for histologic analysis, more than 6 bloody stools per day before initiation of cyclosporine therapy, a C-Reactive Protein (CRP) greater than 45 mg/l prior to treatment, and at day 3 and 7 of treatment by ciclosporine initiation of cyclosporine therapy, a C-Reactive Protein (CRP) greater than 45 mg/l prior to treatment, and at day 3 and 7 of treatment by ciclosporine (p = 0.007; 0.002 and 0.001 respectively), ESR greater than 30 mm at day 3 of treatment (p = 0.05), thrombocytosis at day 3 of treatment (p = 0.05), a Lichtenberg colitis activity index scoring greater than 10 at day 3 of treatment (p = 0.001) and the need for blood transfusion (p = 0.0001) were significantly correlated with the lack of response to cyclosporine therapy. In a multiple linear regression analysis, only a CRP greater than 45 mg/l on day 7 of treatment, and the necessity of transfusion were predictive factors of no-response to cyclosporine (p = 0.0008).

**Conclusion:** Cyclosporine therapy is rapidly effective in preventing surgery in patients with ASC with a response rate of 75.5%. A high CRP on day 7 of treatment with cyclosporine and the need for transfusion, predispose to poor response to intravenous cyclosporine.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0374 CHANGES IN THERAPEUTIC STRATEGY AND OUTCOMES IN NEWLY DIAGNOSED PATIENT WITH CROHN’S DISEASE IN THE BIOLOGICAL ERA IN HUNGARY: A NATIONWIDE STUDY BASED ON THE NATIONAL HEALTH INSURANCE FUND DATABASE**

**1st Department Of Medicine, Semmelweis University Faculty of Medicine 1st Department of Medicine - 1st Semmel, Budapest/Hungary**

**Statistical Analysis Department, National Health Insurance Fund (OEP), Budapest/Hungary**

**Contact E-mail Address:** zsuzsa.kurti@gmail.com

**Introduction:** Accelerated treatment strategy, including tight disease control and early aggressive therapy with immunomodulators (IM) and biological agents have become increasingly common in IBD.

**Aims & Methods:** The aim of the present study was to estimate the early treatment strategy and outcomes in newly diagnosed patients with Crohn’s disease (CD) diagnosed between 2004-2015 in Hungary based on the administrative database of the National Health Insurance Fund (OEP). We used the administrative database of the National Health Insurance Fund (OEP), the only nationwide state-owned health insurance provider in Hungary. Newly diagnosed CD patients were identified through prospectively reported algorithms in disease codes for Crohn’s disease in the out-, inpatient (medical, surgical) non-primary care records and drug prescription databases between 2004-2015. Patients were stratified according to the year of diagnosis and maximum treatment step during the first 3 years after the diagnosis.

**Results:** A total of 6173 (male/female: 46.12%/53.87%) newly diagnosed CD patients were identified during the observational period. Maximum treatment steps did not differ in patients diagnosed before and after 2009 (5-ASA: 11.7% vs. 11.4%, anti-TNF: 73.3% vs. 73.7%, p = 0.896). Distribution of maximal treatment steps and surgery rates were not different according to the maximum treatment steps at (36 ± 30-day period: overall 16.0% vs. 15.5% (p = 0.672) anti-TNF 26.7% vs. 27.2% (p = 0.809), 5-ASA 21.4% vs. 22.2% (p = 0.565), steroid 8.1% vs. 7.9% (p = 0.896), 5-ASA 10% vs. 11% (p = 0.816)).

**Conclusion:** Distribution of maximal treatment steps and surgery rates was not significantly different in patients diagnosed before and after 2009, although immunomodulator and biological treatment was more common after 2009.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0375 RELATIVE FREQUENCY OF RELAPSES IN PATIENTS WITH ULCERATIVE COLITIS AND CROHN’S DISEASE TREATED WITH MESENCHYMAL STROMAL CELLS - 5 YEARS OF FOLLOW-UP**

O. Knyazev, A. Kagramanova, N. Fadeeva, A. Lishchinskaya, I. Ruchkina, A. Konoplyannikov, A. Parfenov

**Introduction:** Numerous studies have shown that mesenchymal stromal cells (MSCs) have a high potential for differentiation and immunosuppressive properties. Currently under phase I-III clinical trials evaluating the efficacy and safety of MSCs in the treatment of patients with inflammatory bowel disease - ulcerative colitis and Crohn’s disease.

**Aims & Methods:** We aimed to compare the frequency of relapses and duration of remission for 5 years of follow up in patients with luminal Crohn’s disease (CD) and the total defeat of ulcerative colitis (UC) receiving therapy with mesenchymal stromal cells (MSCs), bone marrow. We compared the frequency of relapses in patients with luminal form CD and luminal form UC treated with UC (total lesion) receiving MSCs. A group of patients (CD) aged 22 to 56 years (Me-28) (n = 24) received MSC culture scheme (0-1-2 weeks, then every 26 days) and safety of MSCs transplantation longer contributes to clinical remission in patients with Crohn’s disease.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P0377 DYNAMICS OF PROINFLAMMATORY CYTOKINES IN PATIENTS WITH CROHNS DISEASE TREATED WITH MESENCHYMAL STROMAL CELLS OF BONE MARROW AND AZATHIOPRINE

Introduction: Mesenchymal stromal cells (MSCs) are used for the treatment of chronic inflammatory and autoimmune diseases in recent years, including rheumatoid arthritis (RA) and inflammatory bowel disease (IBD). In most cases, treatment of the patient requires concurrent immunosuppressive therapy. It is found that immunomodulatory drugs (azathioprine (AZA), methotrexate, 6-mercaptopurine, infliximab (IFP)), regardless of the concentration, do not affect the viability, differentiation, phenotype, and ability to inhibit proliferation of MSCs’s pericellular matrix and DNA [1]. Moreover, studies conducted by Huang HR et al. demonstrate that IFP rendered minimal impact on the MSC proliferation, apoptosis and cell cycle, while azathioprine inhibited cell proliferation and induced apoptosis of MSCs in vitro [2].

Aims & Methods: We aimed to compare the efficacy of combined therapy (local and systemic) mesenchymal stromal cells (MSCs) of bone marrow, infliximab (IFX) and antioxidants/inmunosuppression (IS) on the rate of healing of simple perianal fistulas in Crohn’s disease. 36 patients with Crohn’s disease with perianal lesions were divided into three groups depending on the method of therapy. The first group of patients aged from 19 to 58 years (Me-29) (n = 12) received culture of MSCS systemically via the scheme and locally; on the perimeter of the fistulas introduced 40 million MSCs - 4 point of inject and 1 ml of saline containing 10 million MSCs. Then after 4 and 8 weeks repeated 40 million MSCs in the area of the fistula. The second group of patients with CD (n = 10) aged 20 to 68 years (Me-36) were receiving anti-cytokine therapy of IFX. The 3rd group of patients with CD (n = 14) aged 20 to 62 years (Me-28) received antibiotics and is. In the dynamics evaluated the closure of the fistula in patients of the first group. After 36 months among the patients of the 1st group, healing of simple fistulas persisted in 8/12 (66.6%) with the 2nd group - 7/10 (70.0%) (OR - 1.11; 95% CI 0.32–3.84; p = 0.76). In the 3rd group – patients 4/14 (28.6%) (OR - 0.47; 95% CI 0.2–1.11; p = 0.12 in comparison with the 1-st group).

Results: After 12 weeks among patients of the 1st group simple healing of fistulas was observed in 10/12 patients (83.3%), in the 2nd group healing simple fistulas have a 8/10 (80.0%) (OR-0.83; 95% CI 0.14–4.9; p = 0.04) in comparison with the 1st group. After 6 months in the 1st group patients receiving MSCs, healing of simple fistulas persisted in 8/12 (66.6%) with the 2nd group - 7/9 (70.0%) (OR - 8.10; 95% CI 0.82–3.20; p = 0.77). In the 3rd group – patients 4/14 (28.6%) (OR - 0.47; 95% CI 0.2–1.11; p = 0.12 in comparison with the 1-st group).

Conclusion: Combined stem cell and anti-cytokine therapy of CD with perianal lesions can significantly contribute to more frequently and prolonged closure of simple fistula, compared with antibiotics/inmunosuppressant. Disclosure of Interest: All authors have declared no conflicts of interest.

V565, an oral domain antibody (Vorabody) to TNF engineered to be resistant to intestinal proteases, delivering high concentrations of active compound in ileal fluid following oral administration to human volunteers. The oral domain antibodies (Vorabodies) are delivered via enteric coated mini-tablets (MTs) designed to release active drug at pH 6.5.

Aims & Methods: Following prior placebo-controlled demonstration of the safety and tolerability of high single and multiple doses of V565, this open label assessment was performed to confirm the delivery of active domain antibody to the terminal ileum of human subjects. Four subjects with a terminal ileostomy were given a single oral dose of V565 and ileostomy bags were collected hourly for the first 6 h, post dose with further collections 12, 20 and 24 h post dose. Contents were analysed for V565 concentrations by competitive ELISA. In addition serial blood samples were taken for determination of V565 serum concentrations over 24 h.

Results: Four subjects with an ileostomy (3 with UC; 1 with a prior history of Crohn’s disease (CD)), it is important to deliver drug there if treatment is to be effective. This is the first report of a domain antibody to TNF, V563, engineered to be resistant to intestinal proteases, delivering high concentrations of active compound in the ileal fluid following oral administration to human volunteers. The oral domain antibodies (Vorabodies) are delivered via enteric coated mini-tablets (MTs) designed to release active drug at pH 6.5.

Aims & Methods: The study included 162 patients with UC who were assessed for at least 12 months after the last dose, using the Mayo Score. The study group was dominated by women (94%).

Introduction: The oral delivery of therapeutic concentrations of anti-TNF to affected mucosa of patients with inflammatory bowel disease (IBD) has remained challenging despite advances in protein engineering, the attractions of oral dosing for chronic therapies, and the acknowledged benefit of anti-TNF monoclonal antibodies in the management of IBD. As the ileum is commonly involved in Crohn’s disease (CD), it is important to deliver drug there if treatment is to be effective. This is the first report of a domain antibody to TNF, V563, engineered to be resistant to intestinal proteases, delivering high concentrations of active compound in the ileal fluid following oral administration to human volunteers. The oral domain antibodies (Vorabodies) are delivered via enteric coated mini-tablets (MTs) designed to release active drug at pH 6.5.

Aims & Methods: Following prior placebo-controlled demonstration of the safety and tolerability of high single and multiple doses of V565, this open label assessment was performed to confirm the delivery of active domain antibody to the terminal ileum of human subjects. Four subjects with a terminal ileostomy were given a single oral dose of V563 and ileostomy bags were collected hourly for the first 6 h, post dose with further collections 12, 20 and 24 h post dose. Contents were analysed for V565 concentrations by competitive ELISA. In addition serial blood samples were taken for determination of V565 serum concentrations over 24 h.

Results: Four subjects with an ileostomy (3 with UC; 1 with a prior history of Crohn’s disease (CD)) were given a single oral dose of V565 and ileostomy bags were collected hourly for the first 6 h, post dose with further collections 12, 20 and 24 h post dose. Contents were analysed for V565 concentrations by competitive ELISA. In addition serial blood samples were taken for determination of V565 serum concentrations over 24 h.

Results: Four subjects with an ileostomy (3 with UC; 1 with a prior history of Crohn’s disease (CD)) were given a single oral dose of V565 and ileostomy bags were collected hourly for the first 6 h, post dose with further collections 12, 20 and 24 h post dose. obviously evaluated by the IBD validated Functional Assessment of Chronic Illness Therapy-Fatigue Scale (FACT-F).

Aims & Methods: The main objective was to assess the efficacy of electroacupuncture (EAc) vs. sham EAc and no treatment for treating fatigue in patients with quiescent IBD in a single-blind randomized trial. Secondary objectives were to assess changes in quality of life, depression, anxiety and sleepiness after treatment with EAc.

Methods: Fifty-two patients with quiescent IBD and severe fatigue (FACT-F < 40) (65.3% female, mean age 42 years) were randomized to EAc vs sham acupuncture group. Patients in both EAc groups performed a total of 9 acupuncture sessions during eight weeks (2 sessions/first week and one session per week during and after the treatment periods).

Results: Both EAc and Sham group improved the FACT-F score post-treatment (EAP = 9.53 points, 95% CI [12.3 to 6.75], Basal Vs 9th session p = 0.001); Sham group (−9.7 to −2.06, Basal Vs 9th session p = 0.003); depression (8.9, points, 95% CI [4.3 to 13.8], Basal Vs 9th session p = 0.002), anxiety (10.6 points, 95% CI [3.6 to 17.6], Basal Vs 9th session p = 0.006) and sleepiness scales (1.46 points, 95% CI [0.096 to 2.83, Basal Vs 9th session p = 0.038). However, the differences in between EAc and sham and control groups were not significant (p > 0.05).

Conclusion: Both targeted and sham electroacupuncture are effective in managing fatigue in patients with quiescent IBD. NCT02733276.

Introduction: Anti-TNF, such as adalimumab (ADA) and infliximab (IFX), have improved the therapeutic care of Crohn’s disease (CD). However their use may be associated with loss of efficacy, adverse events and sometimes primary failure. A frequent cause of discontinuation, it is possible to switch to another anti-TNF. In France, three anti TNF are available in ulcerative colitis (IFX, ADA and golimumab), but only the first two are approved in CD, because golimumab has not been studied in this indication. The aim of this study was to report golimumab efficacy and safety in CD.

Aims & Methods: This national multicenter retrospective study included patients with CD from 12 French tertiary centers who received golimumab and analyzed: clinical response, duration of treatment, tolerance, reasons for discontinuation of treatment. Presence of phenotype, and treatments preceding and associated with golimumab. The main endpoint was the efficacy of golimumab defined by the duration of treatment before failure (need for therapeutic optimization or cessation).

Predictive factors of therapeutic response were determined (log rank and Cox model), and the tolerance was evaluated.

Results: One hundred and fifteen patients with a mean duration of the disease of 13.5 years received on average golimumab in 3, 6, 9 th line of therapy. The overall clinical response assessed by the physician was 55.8% at the time of the re-evaluation (on average, at 3.8 months [0.6–24] after initiation of therapy). The mean duration of treatment was 6 months (0.55 to 48.7%) patients were still treated with golimumab at the end of the follow-up. At 12 months, 34.9% of patients still received golimumab without optimization. At 24 months, this figure was 16.5%. In univariate analysis, the factors associated with a longer golimumab treatment duration without stopping or optimizing were the active smoking status (p = 0.043), the absence of aponeural lesions (p = 0.012), the presence of extra-intestinal symptoms (p = 0.035), the presence of a co-immunosuppression of more than 6 months (p < 0.001) and discontinuation of the first anti-TNFα for intolerance (p = 0.022). In multivariate analysis, discontinuation of the first anti-TNFα for intolerance and the presence of co-immunosuppression with thio-purine derivatives or methotrexate over 6 months were independently associated were golimumab efficacy (OR 2.16, 95% CI [1.25–3.66], p = 0.005 and OR 3.9895% CI [2.3–7.1], p < 0.001, respectively). Side effects led to discontinuation of treatment in 6% of patients. These were paradoxical psoriasis in three patients, paresthesia (n = 1), lower extremity edema (n = 1), injection site reaction (n = 1) and not reported reason for one patient.

Conclusion: After failure of the other anti-TNF agents, golimumab is well tolerated and results in sustained clinical response in one in two patients with Crohn’s disease, particularly when associated with a co-immunosuppression, and if the reason for the discontinuation of the first anti-TNFα was an intolerance.

P0383 BIOLOGICS AND BIOSIMILARS: WHAT MATTERS TO PHYSICIANS?

A. Molinari1, A. Louiza-Bonilla2, D. Charles1
1Global Alliance for Patient Access, Washington, DC/United States of America
2United States of America

Aims & Methods: The purpose of this survey was to determine physicians’ familiarity and comfort level with prescribing biosimilars to patients. The survey was sent to physicians residing in the European Union and specializing in the following clinical fields: dermatology, endocrinology, gastroenterology, oncology, and rheumatology.

Introduction: Biologic medicines and their biosimilar counterparts are effective therapies for many conditions, including inflammatory bowel disease, Crohn’s disease, and ulcerative colitis. The European Medicines Agency (EMA) has approved twenty-two biosimilar medicines, which are derivatives of eight original biologics, and four more biosimilar are scheduled to be reviewed this year. As the number of approved biosimilars rises, regulatory agencies must closely monitor their safety and efficacy.

Results: The majority of survey respondents specialized in endocrinology (19%) and gastroenterology (19%). Respondents were recruited almost equally from the five countries, with France being the most represented country (22%) and the UK being the least represented (18%). The majority of respondents (55%) indicated that safety and efficacy is the most important factor in determining whether a patient should be switched from a prescribed biologic therapy to its approved biosimilar. Thirty percent of respondents indicated that clinical trials related to the biosimilar’s condition being treated were the most important factor in switching. Only 12% of respondents indicated that cost to the government or insurance companies is a primary concern, and only 3% were primarily concerned with immunogenicity.

Conclusion: This survey suggests that the safety and efficacy of biosimilar medicines is of paramount importance to physicians and that physicians highly value clinical trial data for biosimilars. Given that biosimilars are structurally distinct from their original innovator biologics, the EMA should consider requiring more stringent clinical trials data for biosimilars seeking approval. Specifically, the EMA should require clinical trials for each proposed indication and should provide physicians with this data so that physicians can make informed prescribing choices for the safety of their patients.

Introduction: Oral steroids are effective in inducing remission of moderate flares of patients with either ulcerative colitis (UC) or Crohn’s disease (CD). However, we know little about their efficacy in immunosuppressed patients or their possible role in reducing biologics and/or surgical needs in these patients.
Aims & Methods: We aimed to determine the efficacy of systemic or low bioavailability biologic (ADA) treatment for moderate flares of patients with at least 6 months of immunosuppressive treatment, and describe long-term follow-up inflammatory bowel disease (IBD) immunosuppressed patients (thiopurines or methotrexate) from our population-data registry were analyzed. For statistical analysis, Chi-square test, U Mann-Whitney test and Kaplan Meier survival analysis were used.

Results: 392 IBD patients with a median of 86 (6-271) months of immunosuppressive (IMM) treatment were identified (table 1). 89 patients (23%) (33% UC and 67% CD) needed at least one steroid treatment during follow-up (63% systemic steroid and 37% low bioavailability oral steroid) with a median time of steroid treatment of 4 (1-168) months. Average time from IMM to steroid treatment was 26 (6-207) months. In IMM patients there were no differences regarding sex, age, disease, location, perianal disease, extra intestinal manifestations, appendectomy, smoke habit, need for steroids at diagnosis and previous abdominal surgery between patients with no need of steroids and patients with steroid treatment during follow-up. In CD patients, biological treatment for perianal disease prior to IMM (p=0.0039) and fistulizing (B3) or fistulizing (B3) behavior (p=0.005; OR 2.284) were risk factors for using steroids after IMM treatment. In UC patients, no statistically significant variables were identified. 49 of these 89 steroid treatment patients (55%) needed biological treatment or surgery after a median of 13 months (0-178); 19 (21%) needed more than one steroid treatment (2-5) and just 31 patients (35%) did not need any other treatment. CD patients had higher risk (p=0.007; OR: 3.529) to receive biological treatment or surgery versus UC patients. Otherwise, the more months using steroids in UC patients, the greater risk for biological or surgery treatment (p=0.009). During follow-up, though it’s not statistically significant (p=0.078), we observe that 75% probability of rescue treatment for UC patients in 62 months versus 36 months for CD patients.

Conclusion: 23% of IBD immunosuppressed patients needed at least one steroid treatment after 6 months of IMM. Previous biological treatment and B2-B3 behavior predicted steroid treatment in CD patients, who had 3.5 times more risk to receive biological treatment or surgery after steroid treatment using it earlier than UC patients. Just 1/3 of patients who needed steroid treatment after IMM did not need any other rescue treatment.

Introduction: PYRAMID was an international multi-center non-interventional postmarketing registry assessing long-term safety and effectiveness of adalimumab (Humira® [ADA]) as used in routine clinical practice. Patients with and without prior ADA experience were allowed to enroll. The final long-term effectiveness of ADA is reported in adult ADA-naive patients (those who had not received ADA before registry enrollment) with moderate to severe Crohn’s disease (CD) who were treated according to the local product label.

Aims & Methods: All patients entering the registry were followed for up to 6 years. Effectiveness of ADA was measured using Physician’s Global Assessment (PGA; [a composite of Harvey Bradshaw Index and rectal bleeding score]), Short Inflammatory Bowel Disease Questionnaire (SIBDQ), and 4 components of the Work Productivity and Activity Impairment (WPAI) questionnaire, including absenteeism, presenteeism, overall work impairment, and activity impairment. Effectiveness measures, captured in all patients who received at least 1 dose of ADA in the registry and had at least 1 post-enrollment measurement, were summarized descriptively by the number of observations that were not missing at each registry visit; data were reported as observed. Values at enrollment are considered as baseline values.

Results: Among 5025 patients evaluated in the registry, 2057 (40.9%) were ADA-naive. Of these, 1199 patients (58.3%) were female; mean age 37.1 years at enrollment. Mean ±SD ADA exposure for the ADA-naive subgroup during the registry was 1118.5 ±842.3 days. A total of 1082 patients (52.6%) had prior exposure to at least 1 anti-TNF/biologic; 583 (41.5%) and 831 patients (40.4%) used immunomodulators and corticosteroids, respectively, at enrollment. Mean change from baseline in effectiveness measures for patients with CD is shown in the table. Mean PGA score and SIBDQ as well as WPAI domains improved in ADA-naive patients from enrollment to 1 year and were maintained for up to 6 years (table). No new safety signals were identified in the registry.

Conclusion: At 1 year after entering the international postmarketing registry of ADA use in routine clinical practice, clinically meaningful improvements in disease activity, work productivity, and activity impairment were achieved in ADA-naive patients with moderately to severely active CD. These improvements were maintained for up to 6 years of the registry among the patients who remained in the study.

Introduction: Adalumab (ADA) has been shown to improve clinical outcomes and health-related quality of life (HRQoL) significantly in patients (pts) with ulcerative colitis (UC) in a clinical practice setting. Evidence is limited about benefits of ADA among UC pts with different characteristics.

Aims & Methods: The aim was to examine clinical and HRQoL effects of ADA in pts with UC based on disease severity and prior use of tumour necrosis factor inhibitor (TNFi). InspiraDA details have been presented. Pts received ADA 160 mg at week (wk) 0 followed by ADA 40 mg every 4 weeks through 26. Pts who did not respond to ADA by wk 8 were to discontinue. Pts who lost response at or after wk 8 could escalate to ADA 40 mg weekly. UC pts were categorized into subgroups based on physician global assessment (PGA) of disease severity (moderate [baseline PGA = 2] vs severe [baseline PGA = 3]) and previous TNFi use (naïve vs experienced). Proportions of pts with Simple Clinical Colitis Activity Index (SCCAI) response (defined as a decrease of ≥ 2 points vs baseline) and remission (defined as an SCCAI ≤ 2) were calculated for each cohort at wks 2, 8, 12, and 26. Change from baseline in HRQoL outcomes was calculated, including Short Inflammatory Bowel Disease Questionnaire (SIBDQ), European Quality of Life-5 Dimensions-5 Level (EQ-5D-5L), Treatment Satisfaction Questionnaire for Medication (TSQM) and Work Productivity and Activity Impairment (WPAI). Missing data were imputed using nonresponsive imputation for response/remission and last observation carried forward for all other outcomes.

Comparisons of remission rate (using logistic regression) and HRQoL outcomes (using linear regression) were performed in moderate vs severe UC and in TNFi naïve vs experienced cohorts.

Results: Among pts with moderate UC (n = 386) and severe UC (n = 74), SCCAI response rates were 74.6% vs 74.5%, 80.1% vs 71.6%, and 67.1% vs 64.9% at wk 2, 8, 26, respectively. Although remission rates were similar between moderate and severe pts at wk 26 (49.5% vs 40.5%, p = 0.16), ADA provided greater disease control for moderate pts at wk 2 (29.8% vs 9.5%, odds ratio [OR] 4.195, confidence interval [CI] 1.8-9.1; p < 0.0001) and wk 8 (52.3% vs 31.1%, OR 2.4, 95% CI 1.4-4.4; p = 0.01) compared to severe pts (Table). The rate of dose escalation (ADA 40 mg weekly) was 28.0% in moderate and 28.4% in severe UC pts. HRQoL outcomes were similar between the moderate and severe cohorts. Among pts who were naïve (n = 389) and those experienced to TNFi, response rates were 74.0% vs 76.4%, 79.2% vs 75.0%, and 66.3% vs 68.1% at wk 2, 8, 26, respectively. No significant difference was observed in remission rates for naïve vs experienced pts at wk 2 (28.0% vs 19.4%, p = 0.43) and wk 26 (49.4% vs 41.7%, p = 0.39), but naïve pts showed a significantly higher remission rate than experienced pts at wk 8 (52.2% vs 31.9%, OR 2.1, 95% CI 1.2-3.7; p < 0.001). The rate of dose escalation was 26.5% in naïve pts vs 36.1% in experienced pts (p = 0.09). In general, HRQoL outcomes were similar between naïve and experienced TNFi pts.

*Comparison between naïve and experienced groups was adjusted for baseline SCCAI. Because baseline SCCAI is highly correlated with PGA, adjustment for baseline SCCAI in moderate and severe UC pts defined by PGA was not performed.

Conclusion: ADA treatment achieved clinically relevant rates of SCCAI response and remission even in pts who had severe UC and those who were more treatment-refractory (experienced to TNFIs), in clinical practice. In addition, ADA was associated with greater disease control in the induction period for pts with moderate than severe UC and for naïve pts than those experienced to TNFIs.

Reference
Cmax ranged from 5016.4 to 14253.6 h*ug/mL and 10.0 to 23.1 ug/mL, respectively, after a single SC injection of CT-P13. SC CT-P13 formulation was absorbed slower into the systemic circulation (median Tmax ranging from 7.0 to 12.2 days) between SC and IV formulations, and both have resolved without any treatment. Mean AUC0-last and Cmax,T max and T1/2 were followed for 12 weeks (20 subjects in 3 different dosages of SC; 18 subjects received either SC injection or IV infusion of CT-P13 on Day 0 and Day 1, respectively, after a single SC injection or IV infusion of CT-P13 on Day 0 and Day 1 were followed for 12 weeks (20 subjects in 3 different dosages of SC; 18 subjects in 2 different dosages of IV). After reviewing safety data observed for 48 hours, the next cohort was conducted subsequently from low dose to high dose. The PK profiles after a single SC injection were linear by dose levels. SC administration of CT-P13 is feasible in terms of bioavailability and safety profiles.

Aims & Methods: This phase I and open label study, conducted at a single site in Korea, was designed to evaluate safety and pharmacokinetics (PK) of SC administration of CT-P13 in healthy subjects. In a single dose escalation study, 38 subjects received either SC injection or IV infusion of CT-P13 on Day 0 and were followed for 12 weeks (20 subjects in 3 different dosages of SC; 18 subjects in 2 different dosages of IV). After reviewing safety data observed for 48 hours, the next cohort was conducted subsequently from low dose to high dose. The PK profiles of SC and IV formulation were evaluated by measuring the AUC_{0-8}, C_{max}, T_{max} and T_{1/2}.

Results: A total of 38 male subjects with median age of 23 years (range 19, 30 years) were treated with a treatment-emergent serious adverse events or systemic hypersensitivity reaction. In SC cohort, two subjects experienced mild injection site reactions, and both have resolved without any treatment. Mean AUC_{0-8}, C_{max} and C_{mean} ranged from 5016.4 to 14253.6 h*ug/mL and 10.0 to 23.1 ug/mL, respectively, after a single SC injection of CT-P13. SC CT-P13 formulation was absorbed slower into the systemic circulation (median T_{max} ranging from 7.0 to 7.1 days) in comparison with IV formulation (median T_{max} ranging from 2.2 to 3.2 hours) but the drug elimination measured by half-life (T_{1/2}) was similar (mean range 11.3 to 13.7 days vs. 11.7 to 12.2 days) between SC and IV formulations, respectively. Bioavailability of CT-P13 SC was approximately 60.6%, when comparing across all CT-P13 SC cohorts to CT-P13 IV cohorts.

Conclusion: PK profiles after a single SC injection were linear by dose levels. SC administration of CT-P13 is feasible in terms of bioavailability and safety profiles.

Reference

of tumour necrosis factor antagonists (anti-TNF) treatment in this populations is ill-defined.

**Aims & Methods:** To assess the main adverse events (AE) of this therapy in the elderly population in comparison with the younger patients, we performed a retrospective cohort study of patients with IBD that initiated treatment with anti-TNF therapy at UCLH from October 2003 and 2014, with a follow-up until December 2013. Demographic, clinical and medication data were collected. AE (including opportunistic infection, malignancy, dermatologic, neurologic, cardiologic and vascular, hepatic, infusion reactions and others) occurring during anti-TNF treatment in elderly and younger patients were analysed and both groups were compared. The severe AE definitions from Food and Drug Administration (FDA) and European Medicines Agency (EMA) were used.

**Results:** Of the 219 patients (55.3% women; average disease duration 13.60 +/-7.74 years) 25 were more than 65 years-old (elderly group, mean age 70.0 years vs. younger group, mean age 41.77 years). Infliximab was used in 174 patients (on average 1585 days) and adalimumab in 93 (on average 1379 days), with a total 1106 years of anti-TNF exposure. In the elderly, azathioprine was used less frequently (68.0 vs. 95.4%, p<0.008). There were 14 severe AE overall, including 18 cancers and 16 opportunistic infections (5 tuberculosis). Malignancy (20.0% vs. 6.7%, p=0.039) and cardiovascular events (16.0 vs. 4.1%, p=0.036) occurred more frequently in the elderly, whereas dermatologic AE were more common in the younger group (4.0 vs. 0.0%, p=0.044). The elderly AE were more frequent (24.0 vs. 20.1%, p=0.794) including death (4.0 vs. 2.6%, p=0.521) was not significantly different between groups.

**Conclusion:** Despite being at higher risk of malignancy and cardiovascular events, the total number of severe adverse events was not significantly increased in elderly patients. Particular attention to malignancy surveillance and treatment of cardiovascular comorbidities is advised in this population.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Over the past twenty years, the introduction of biological agents into clinical practice has radically improved outcomes in patients with inflammatory bowel disease (IBD), Crohn's disease (CD) and ulcerative colitis (UC). Tumor necrosis factor (TNF) antagonists, such as infliximab, act by preventing TNF-α binding to its receptor, neutralizing its activity and alleviating mucosal inflammation. However, biological agents are much more expensive than traditional treatments, and the high cost of these drugs in the treatment of IBD imposes a considerable burden on the national healthcare system. As a result, physicians have grown accustomed to switching agents and prioritizing quality of life terms of quality, efficacy, and safety to already licensed biologics but are associated with lower development costs. CT-P13 (Remsima® and Inflectra®) is a biosimilar of infliximab (Remicade®), which is its reference product (RP). Both CT-P13 and infliximab RP are chimeric IgG1 monoclonal antibodies produced in cell lines derived from the same cell type of murine hybridoma. CT-P13 was authorized by the EMA in 2013 for several indications, including IBD, UC and rheumatoid arthritis (RA) and ankylosing spondylitis (AS). However, a number of observational studies of CT-P13 in clinical practice in both anti-TNF naïve patients and those who have been switched from infliximab RP have been published with good results.

**Aims & Methods:** We aimed to assess the effectiveness and safety of switching to CT-P13 from infliximab reference product (RP) in patients with inflammatory bowel disease. This was a prospective single-center observational study in patients with moderate to severe Crohn’s disease (CD) and ulcerative colitis (UC). All patients were switched from infliximab RP (Remicade®) to CT-P13 treatment and followed for up to 12 months. The efficacy endpoint was the change in clinical response assessed at 3-monthly intervals, according to the Harvey-Bradshaw (HB) score and partial Mayo score for patients with CD and UC, respectively. Safety endpoints were the only factor which was importantly associated with a higher response rate. Overall there were no serious adverse events.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0391 CLINICAL RESPONSE TO VEDOLIZUMAB IN IBD PATIENTS IS ASSOCIATED WITH THE CONCOMITANT USE OF IMMUNOMODULATORS**

I. Parisi, R. Vega, L. Whitley, S. Bloom, S. Mccartney

**Contact E-mail Address:** ioannaparisis@hotmail.com

**Introduction:** The role of biologics in medical management of inflammatory bowel disease (IBD) has been established since anti-TNF agents invaded the market several years ago. Vedolizumab, an anti-integrin gut-selective molecule, is a more recent biologic treatment which has been approved for the management of both Crohn’s disease and ulcerative colitis. Its efficacy in inducing and maintaining remission was shown in GEMINI studies, although a good percentage of the trial participants had previously failed anti-TNFs. We conducted this study in order to describe outcomes in a real-life cohort of IBD patients who were treated with Vedolizumab, consisting both of previously anti-TNF exposed but also anti-TNF naïve patients. Multivariate analysis searched for factors associated with response to treatment.

**Aims & Methods:** Patients with IBD who received at least three doses of Vedolizumab in UCLH since the drug was officially licensed in the UK were included in the study. Demographics, clinical and endoscopic response rates were recorded and analysis was conducted in the whole cohort and in the subgroups of Crohn’s and UC patients separately. Univariate analysis and logistic regression were conducted in order to identify important associations with clinical response.

**Results:** 59 patients with IBD were treated with vedolizumab from May 2015 to October 2016. 28 (47%) had Crohn’s disease and the majority (n = 43, 73%) had mainly colonic inflammation (12 colonic Crohn’s, 29 UC, 2 IBDU). Median time from diagnosis to Vedolizumab initiation was 8 years. 17 (29%) were anti-TNF naïve (all UC) and 28 (47%) had previously failed both Infliximab and Adalimumab. 36 (61%) were on a concomitant immunomodulator (IM), either methotrexate (28%) or azathioprine (7%). 28 (47%) patients had a clinical response to Vedolizumab based on a reduction of Harvey-Bradshaw index (HBI) from baseline >3 points for Crohn’s patients or a reduction of partial Mayo score ≥2 points for UC patients. The rates of response were similar in Crohn’s and UC patients while there was no difference in response according to gender, previous anti-TNF exposure, disease duration or location of inflammation. Patients on no concomitant IM were less likely to respond to Vedolizumab (Odds ratio 0.26, 95%CI 0.07-0.91, p=0.036). 11(18.6%) patients experienced adverse events while treated with Vedolizumab, five of which related to active IBD. There were two minor allergic reactions and two mild infections.

**Conclusion:** Clinical response to Vedolizumab was observed in two-thirds of our IBD patients, similarly in Crohn’s disease and ulcerative colitis. Concomitant IM were the only factor which was importantly associated with a higher response rate. Overall there were no serious adverse events.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Anti-TNFα therapies have helped improved response rates, reduced complication rates, and quality of life for patients with inflammatory bowel disease (IBD). However primary loss of response (LOR) is still a big concern. Therapeutic drug monitoring (TDM) potentiates the opportunity of adjusting doses of anti-TNFα in a treat to target fashion. The end of anti-TNFα induction therapy is a key time point in the management of IBD. TDM is a useful method to help explore an immune basis behind LOR. In addition anti-TNFα trough levels, are a significant predictor of future likelihood of clinical response and mucosal healing.

Aims & Methods: The aim of this study was to explore the relationship between infliximab (IFX) and adalimumab (ADA) trough and antibody levels with clinical response rates, at the end of anti-TNFα induction therapy. This was a prospective, single-centre study. Patients were recruited from the gastroenterology department at our centre, from July 2015 to August 2016. Inclusion criteria were all patients older than 17 years old with IBD who started treatment with anti-TNFα drugs, either infliximab or adalimumab, during the study period. Patient demographics, medication and clinical history were collected from the electronic hospital information system. Baseline clinical disease activity indexes were performed. Haematoxylin and Eosin Index for Crohn’s disease (CD), and partial Mayo scores for Ulcerative colitis (UC). Clinical response was defined as reduction in TNFa trough and antibody levels were measured using standard ELISA technique. The proportion of patients with histological remission at week 8 was significantly higher in the budesonide group than in the placebo group (intention-to-treat (ITT) 79% vs 42%; p = 0.001).

Conclusion: Oral budesonide 9 mg once daily is highly effective and safe for induction of clinical and histological remission in lymphocytic colitis, while oral mesalazine 3 g once daily was only numerically, but not statistically significant, better than placebo.

Introduction: Lymphocytic colitis (LC) is a common cause of chronic, non-bloody diarrhea. Budesonide has been reported to be effective in other colitis studies. Mesoralazine has been proposed as a treatment option but no placebo-controlled trials have been reported. Thus, we performed a placebo-controlled, multicenter study to evaluate budesonide and mesoralazine as induction treatments for lymphocytic colitis.

Aims & Methods: Patients with active lymphocytic colitis were randomly assigned to either budesonide 9 mg once daily or mesoralazine 3 g once daily, or placebo for 8 weeks in a double-blind, double dummy design. The primary endpoint was clinical remission defined by the Hjortswang-Criteria (1). Secondary endpoints included histopathology and safety.

Results: Based on an interim analysis the trial was stopped in accordance with the pre-specified adaptation design. The final analysis included 57 patients (19 per treatment group). Most patients were of female gender (72%) and mean age was 59 years. The proportion of patients in clinical remission at week 8 was significantly higher in the budesonide group than in the placebo group (intention-to-treat (ITT) 79% vs 42%; p = 0.001). The difference in clinical remission at week 8 between mesoralazine (63%) and placebo failed statistical significance (p = 0.09). The proportion of patients with histological remission at week 8 was higher with budesonide (68%) than with mesoralazine (26%: p = 0.02) and placebo (21%; p = 0.008). The rate of adverse events did not differ among groups.

Conclusion: Oral budesonide 9 mg once daily is highly effective and safe for induction of clinical and histological remission in lymphocytic colitis, while oral mesalazine 3 g once daily was only numerically, but not statistically significant, better than placebo.

P0394 PREGNANCY OUTCOMES IN THE TOFACITINIB ULCERATIVE COLITIS OCTAVE STUDIES

1University of California, San Francisco/United States of America/CA
2Department Of Gastroenterology And Hepatology, Charité Medical Center Virchow Hospital and Medical School of the Humboldt, University of Berlin, Berlin/Germany
3Ichan School of Medicine at Mount Sinai, New York/United States of America/ NY
4Pfizer Inc, Collegeville/United States of America/ PA
5Division Of Gastroenterology, Scripps Clinic, La Jolla, San Diego/United States of America/CA
6Krankenhaus der Barmherzigen Brüder, Salzburg/Austria

Introduction: A pregnant woman with ulcerative colitis (UC), compared with age-matched controls, is at higher risk of adverse outcomes including spontaneous abortion, stillbirth and low birth weight. 1, 2 Tofacitinib is an oral, small molecule Janus kinase inhibitor that is being investigated for UC. Tofacitinib has been shown to be foetotoxic and teratogenic in both rats and rabbits at exposures 146 times and 13 times, respectively, the human dose of 5 mg twice daily (BID). There is no adequate and well-controlled studies of tofacitinib in pregnant women.

Aims & Methods: We report the pregnancy outcomes from three randomised, placebo-controlled studies (OCTAVE Induction 1, NCT01465763; OCTAVE Induction 2, NCT0145955; OCTAVE Sustain, NCT01458575) and one ongoing open-label extension study (OCTAVE-long term study, NCT01470612) of tofacitinib monotherapy in patients (pts) with moderate to severe UC. 3, 4 Pregnancy outcomes following maternal or paternal exposure to tofacitinib 5 or 10 mg BID were identified from Pfizer’s internal safety database up to 23 March, 2017, and categorised as: healthy newborn, medical termination, foetal death, congenital malformation, spontaneous abortion or pending/lost to follow-up. Trial protocols required use of highly effective contraception for females of childbearing potential, and study drug to be discontinued in any female pts who became pregnant.

Results: A total of 1139 unique pts (incl. placebo) enrolled in the UC OCTAVE trials, of whom 296 were females of childbearing age. There were a total of 25 pregnancies reported with exposure to tofacitinib. Of these, 11 were cases of maternal exposure, all in the 1st trimester, including: 2 (18.2%) spontaneous abortions (5 mg BID, n = 1; 10 mg BID, n = 1), 2 (18.2%) medical terminations (both 10 mg BID), 4 (36.4%) healthy newborns (all on 10 mg BID) and 3 (27.3%) lost to follow up (all on 10 mg BID). Of the 14 cases of paternal exposure, 11 (78.6%) were healthy newborns (5 mg BID, n = 2; 10 mg BID, n = 9) and 3 (21.4%) were pending/lost to follow-up (5 mg BID, n = 1; 10 mg BID, n = 2). Overall, there were no cases of foetal death or congenital malformation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Case 1: the subject decided to terminate pregnancy based on potential risks of tofacitinib; Case 2: reason unknown;

BID, twice daily.

Conclusion: Based on the limited data and follow up available, pregnancy and newborn outcomes among pts with UC with prenatial (maternal/patalm) exposure to tofacitinib appear to be similar to those reported for the UC population, as well as those previously reported in pts with RA and P0. Larger, long-term follow-up studies are needed to examine safety of tofacitinib during pregnancy.

Introduction: Granulocyte and monocyte adsorptive apheresis (GMA) has been shown to be effective and safe in patients with inflammatory bowel disease (IBD). We report an interim analysis of a post-marketing surveillance study of granuloce and monocyte adsorptive apheresis using Adacolumn® for patients with inflammatory bowel disease who have special situations (PARTICULAR).

Aims & Methods: The aim of the PARTICULAR study was to assess the safety and efficacy of GMA treatment in patients with IBD who have special situations. This study was an interim analysis of the multi-centre observational study conducted at 80 institutions in Japan. Data were collected from patients with ulcerative colitis (UC) or Crohn’s disease (CD) who received GMA between November 2013 and September 2016. Patients who had at least one special situation were included in the study. GMA was performed using Adacolumn® (JIMRO, Takasaki, Japan). Each patient received up to a maximum of 11 GMA sessions. Safety assessments were performed on all patients in this study. All adverse events (AEs) during the study period were recorded. AEs for which the causality of the AEs could not be ruled out were defined as side effects (SEs). Feasibility problems (FPs) included blood withdrawal difficulty, venous pressure elevation, coagulation in the apheresis system and venous access difficulty. The safety of GMA was investigated in the following six special situation subgroups: the elderly ( 65 years), concomitant treatment with multiple immunosuppressants, retreatment with GMA, anaemia (haemoglobin <10 g/dl), paediatric (<18 years) and other groups. We also compared AEs, SEs and FPs between the subgroups with/without each special situation by univariate analysis. The efficacy of GMA was also assessed in patients with UC. Patients with a partial UC disease activity index score (pUC-DAI) of < 3, those with missing pUC-DAI scores and those receiving concomitant treatment with infliximab, adalimumab, tacrolimus or cyclosporine were excluded from efficacy analysis. pUC-DAI scores were calculated at the baseline and at the end of each GMA session or when GMA therapy had to be discontinued because of AEs or FPs. Remission was defined as a pUC-DAI score of ≤2 with no individual sub-score exceeding 1 point. Patients who received additional treatment by the final GMA session, including infliximab, adalimumab, tacrolimus or cyclosporine, were considered non-responders to GMA.

Results: This study included 363 patients (304 UC, 59 CD). Among these patients, SEs and FPs were observed in 3.0%, 10.7% and 16.3% of the patients, respectively. There were 105, 112, 103, 89, 43 and 39 patients in the elderly, concomitant treatment with multiple immunosuppressants, retreatment with GMA, anaemia, paediatric and other groups, respectively. The incidence of AEs was significantly higher in patients on multiple concomitant immunosuppressants compared with those not receiving them. Likewise, the incidence of AEs was significantly higher in patients in the anaemia group compared with patients with haemoglobin of ≥10 g/dl. The incidence of FPs was significantly lower in patients of the retreatment group with GMA than in those who received GMA for the first time (Table 1). The efficacy of GMA was assessed in 209 UC patients. The numbers of patients administered prednisolone, infliximab, adalimumab, tacrolimus and cyclosporine were 24, 6, 3 and 1, respectively, among these patients who were considered non-responders to GMA. The pUC-DAI score significantly decreased from 6.2 at baseline to 3.4 after the final GMA session (P < 0.001) and the remission rate at the final GMA session was 43.5%.

Conclusion: This multi-centre observational study showed that GMA has an acceptable safety profile in IBD patients and sufficient effectiveness in UC patients who have special situations. However, care should be taken when GMA is used in patients with anaemia or those who have received concomitant treatment with multiple immunosuppressants.

Introduction: People with Inflammatory Bowel Disease (IBD) commonly experience a range of health issues (MHI) such as anxiety and depression. MHI’s reduce quality of life and are associated with poor medication adherence and worse disease course. However, psychological support is not routinely provided to people with IBD. There are scant prospective, systematically gathered data on MHIs in IBD, despite solid evidence of the value of psychological input for people with other chronic diseases.

Aims & Methods: The current study is investigating: the prevalence of MHIs in an IBD cohort; the acceptability and uptake of psychological support; the acceptability and uptake of psychological support and treatment; whether MHIs correlate with higher healthcare utilisation; and potential benefits of integrated psychological care to patients’ mental health, physical health, and/or healthcare utilisation. Potential participants were prospectively recruited from the IBD service of a large tertiary hospital in South Australia via post and in-person at scheduled/routine outpatient appointments. Data were collected at two time points – at baseline screening and at 12 month follow-up. Mental health, medication adherence, and quality of life were measured by questionnaires: the Hospital Anxiety and Depression Scale (HADS), the Kessler 6 Scale of General Psychological Distress (K6), the Morisky Medication Adherence Scale (MMAS-8), and the Assessment of Quality of Life measure (AQLoL-SD). Demographic and healthcare utilisation data were collected by electronic,

*p < .05; **p < .01; ***p < .001

**Conclusion**: Psychological issues are prevalent in patients with IBD and association of depression with IBD severity and medication adherence may be more likely to participate in psychological screening, and in general the screening approach was widely accepted. In addition, high proportions of patients reported clinical levels of distress (irrespective of their IBD activity) and went on to accept psychological intervention. All of which demonstrates a widespread need for support in this cohort. Furthermore, preliminary data of treatment outcomes are promising. At study completion we will be better able to clarify the extent to which patients with IBD benefit from this new integrated approach.

**Introduction**: Demonstration of biosimilarity is based on the evaluation of physicochemical, biological, preclinical, and clinical data. Based on this totality of evidence, a biosimilar may be approved for use in the same indications for which the reference medicine is approved without conducting a clinical trial in each indication. A prerequisite for this extrapolation is clinical confirmation of biosimilarity in a patient population sensitive enough to detect potential differences in efficacy, safety, or immunogenicity between the proposed biosimilar and the reference medicine. GP2017, a proposed biosimilar to adalimumab, was compared with adalimumab in a long-term, double-blind, randomized study that involved patients with moderate-to-severe rheumatoid arthritis (RA) and/or psoriatic arthritis (PsA) who had previously received ankylosing spondylitis (AS) or psoriasis (Ps). The study included a 50-week treatment period with a subsequent 1-year follow-up period during which patients continued on treatment or were switched to a new medicine. Aims & Methods: To evaluate long-term efficacy, safety, and immunogenicity in patients continuously treated with either GP2017 or reference adalimumab from initial randomization to Week 51. Eligible patients with moderate-to-severe chronic plaque psoriasis were randomized to receive an initial dose of 30 mg subcutaneous GP2017 or reference adalimumab, followed by 40 mg every other week, starting one week after the initial dose, up to Week 17. At Week 17, patients with ≥50% improvement in Psoriasis Area and Severity Index (PASI 50) at Week 16 were re-randomized in a 2:1 ratio to either remain on their initial study treatment or undergo a sequence of three treatment switches between GP2017 and reference adalimumab until Week 35. Thereafter, patients were returned to their originally randomized treatment up to Week 51.

**Results**: From randomization to Week 51, 168 and 171 patients continued treatment with GP2017 or reference adalimumab, respectively. In the per-protocol analysis set, PASI 75 response rates for continual GP2017/reference adalimumab at Week 17 were 75.2%/67.8% (p = 0.015), and appointment cancellations (r = 1.11, p = 0.030), and appointment cancellations (r = 0.026). Anxiety was not related to overall healthcare utilisation, but was positively correlated with numbers of analgesic use (r = 0.119, p = 0.045), general distress was related to overall healthcare utilisation (depression r = -.787, p = 0.000; anxiety r = -0.43, p = 0.001) and quality of life (anxiety r = 0.2136*, p = 0.042). At baseline, anxiety and depression were both negatively correlated with medication adherence (anxiety r = -0.323, p = 0.000, depression r = -0.200, p = 0.000) and overall quality of life (anxiety r = -0.708, p = 0.000; depression r = -0.787, p = 0.000). Depression and general distress were related to overall healthcare utilisation (depression r = -0.131, p = 0.018, general distress r = -0.124, p = 0.026). Anxiety was not related to overall healthcare utilisation, but was positively correlated with numbers of emergency department presentations (r = 0.124, p = 0.042), outpatient appointments (r = 0.119, p = 0.050), and appointment cancellations (r = 0.155, p = 0.005). Currently, approximately half of the twelve month follow-up data has been collected. Preliminary analysis shows improvements for patients’ mental health, quality of life and medication adherence (see table below).

**Conclusion**: Efficacy was similar and sustained in patients with psoriasis continuously treated with GP2017 or reference adalimumab for up to 51 weeks. Safety profiles and immunogenicity were generally similar in both groups. Clinical data add to the totality of evidence suggesting GP2017 could be used as a biosimilar for the treatment of the same indications for which reference adalimumab is approved, including inflammatory bowel disease.

**Introduction**: Granulocyte-monocyte apheresis (GMA) can be employed for the treatment of inflammatory bowel disease (IBD), especially for ulcerative colitis (UC). The usual treatment schedule is a weekly session for 5 weeks processing 1800 ml in 60 minutes. It has been described that different factors of the disease and the technique can improve the response to this treatment.
Aims & Methods: We performed a retrospective study of all patients treated with GMA (Ada-column) in 3 IBD Units in Spain. The clinical and analytical data were assessed before and 1 month after the end of the GMA. The Ethics Committee of Euskadi approved the study protocol. The aim of our study was to evaluate the presence of clinical, analytical of technique–related factors associated to a better response to GMA.

Results: A total of 105 patients were included [51 female (49%), age 35.7 (SD 16.5)]. Ninety-three had UC (50% extensive, 45% left-sided), 10 Crohn’s disease (90% ileocolonic) and 2 IBD-U. Mayo score at baseline was 3.5 (SD 4.6) and Harvey-Bradshaw was 10.1 (SD 3.8). The Mayo endoscopic subscore was 1 (16%), 2 (56%) or 3 (27%). Almost all patients (97%) have been previously treated with steroids and 42% were exposed to biologics. At baseline, 85% were on steroids, 38% thiopurines and 18% biologics. None of the previous or concomitant treatments were associated with a better response to GMA. Fifty-six subjects received weekly sessions for 5 weeks processing 1800 ml/session in 60 minutes. Forty patients received an intensive GMA regime: biweekly sessions with a mean of 8 sessions (SD 2.6), processing 3880 ml/session (SD 1729) and laboratory 1 sessions (SD 24). The intensive group showed a slightly higher response rate to GMA as compared with those in the standard regimen (response rate 67% vs 55%, p = 0.28). Those subjects treated with > 5 sessions showed higher remission (24% vs 13%) and response rates (47% vs 24%) as compared to < 5 sessions (p = 0.004). A mean duration of > 60 min/session also showed better results in terms of remission (22% vs 16%) and response (45% vs 27%) when compared to ≤ 60 min/session (p = 0.04). There was also a trend towards higher remission rates in those with higher processed blood volume. Thirty-nine percent were able to wean off steroids completely one month after GMA. We observed a decrease in the mean platelet volume and the platelet to lymphocyte ratio after GMA in those cases who did not respond. Considering its clinical efficacy in this clinical practice study. Increasing the number of sessions or its length were associated with a better response to GMA. The mean platelet volume and the platelet to lymphocyte ratio could help to predict the response.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

The frequency of adverse events (AEs) was similar in the andecaliximab Q2W, andecaliximab QW and placebo groups: 53.7%, 58.9% and 60%, respectively. Common AEs included anemia, abdominal pain and nausea. Three AEs led to discontinuation in the andecaliximab QW group compared to one each in the andecaliximab Q2W and placebo groups. Two serious AEs occurred in the andecaliximab QW group (anemia and angiitis pectoris) compared to one in placebo.

Contact E-mail Address: s.schreiber@mucoasa.de

Introduction: Elevated levels of matrix-metalloproteinase-9 (MMP-9) and its degradation products are detected in patients with active Crohn’s disease (CD). Selective inhibition of MMP-9 reduced fibrosis in a murine model of intestinal fibrosis, suggesting that MMP-9 may contribute to intestinal complications in CD. Accordingly, MMP-9 has been proposed as a therapeutic target for CD. Andecaliximab (GS-5745) is a monoclonal antibody that selectively binds and inhibits MMP-9. It was found to be safe in a phase 1 dose-ranging study in UC patients, demonstrating clinical response and remission compared to placebo. The aim of this phase 2 study was to evaluate the safety and efficacy of andecaliximab in subjects with active CD.

Aims & Methods: This was a double-blind, randomized, placebo-controlled 8-week induction study in adult CD subjects with moderate to severe disease activity (defined as: CDAI total score 220–450, weighted PRO2 score ≥ 1 [standard CDAI weights: abdominal pain 0–3 ×7 plus mean number of daily stools x2] and SES-CD total score ≥ 6 [or ≥ 4 score if disease limited to ileum and/or right colon or ulcer presence and size score ≥2]). Subjects were required to have an inadequate response, or loss of response or intolerance to at least 1 of the following treatments in the last 5 years: corticosteroids, immunomodulators, TNF-alpha antagonist or vedolizumab. Subjects were randomized 1:2:2 to receive subcutaneous (SC) injections of: placebo, 150 mg andecaliximab every 2 weeks (Q2W), 150 mg andecaliximab weekly (QW) or 300 mg andecaliximab QW. Centrally-read colonoscopy/endoscopy scores were performed at baseline and week 8. Co-primary outcomes were clinical response (PRO2 score of ≥8 at week 8) and placebo response (SES-CD decrease of ≥ 50% from baseline at week 8).

Results: A total of 187 subjects were enrolled from 13 countries. No concerning baseline imbalances occurred between the treatment groups, overall. 17.6% of subjects had evidence of fistula at screening, mean (SD) disease duration was 12 (9.5) years. 84.5% of subjects had previous exposure to TNF-alpha antagonist and 44.4% of subjects were taking oral corticosteroids at baseline. The
The frequency of adverse events (AEs) was similar between the treatment groups: placebo (67.9%), 150 mg Q2W (60.4%), 150 mg QW (62.3%), 300 mg QW (69.8%). Common AEs included abdominal pain, nausea, fatigue, anemia and pyrexia. One AE led to study discontinuation in the placebo group (1.6%) compared to 2 in the 150 mg QW group (3.8%) and 4 in the 300 mg QW group (7.5%). Three serious AEs occurred in the placebo group (10.7%) compared to 1 in the 150 mg QW group (1.9%), 6 in the 150 mg QW group (11.3%) and 8 in the 300 mg QW group (15.1%). Frequency of arthralgia and musculoskeletal pain was similar or lower in adalimumab groups compared to placebo.

Aims & Methods: Our aim was to assess trends in adalimumab and AAA levels over time and their clinical implications. CD patients starting adalimumab therapy were followed prospectively in three participating medical centers in Israel, by establishing a program for home-visits by physicians at induction and every 3 months, or in case of relapse. At each home visit, patients’ clinical activity score were determined and blood tests obtained for CRP, drug and AAA trough levels. AAA levels were determined by a drug-tolerant assay. A comparison with temporal evolution of inflammasome immunogenicity in a previously reported cohort using the same assay and methodology was additionally performed.

Results: 102 CD patients starting adalimumab were prospectively followed. Fourteen (14%) experienced primary non-response and 20 (20%) lost response to adalimumab therapy during maintenance. Thirty-three (32%) developed AAA, which were more common among those previously exposed to adalimumab (p = 0.002) but were not affected by co-treatment with immunomodulators or not (p = 0.28). AAA developed as early as week 2 in 18/55 (33%) of AAA positive patients (7/18 with history of interrupted therapy), and in 26/33 (79%) within week 2. None of the 2 AAA had 34% of primary non-response compared to 9% in patients without early AAA (OR = 4.8, p = 0.009). In 92.6% of cases, AAA preceded loss-of-response or occurred simultaneously (median interval - 4 weeks). As compared to antibodies-to-infliximab (ATI), AAA formation over time was significantly lower (p = 0.01, log rank test), and some patients developed AAA even after one year of therapy. Transient AAA were much less common than transient ATI (7% vs 32%, p < 0.0001) and 85% of AAA events were associated with loss of response compared with 58% rate for ATI (p = 0.01).

Conclusion: AAA formation often occurs earlier than anticipated, and associates with primary non-response to adalimumab induction. Overall rate of immunogenicity is lower for adalimumab compared to infliximab. However, once they occur, AAA are more specific than ATI.

All other authors have declared no conflicts of interest.
of GLB with 47.4–49% of patients maintaining the effect after one year. Due to its relatively short half-life, it is still few studies on clinical efficacy of patients receiving golimumab in the routinely activities. In our region GLB became available starting July 2015.

Aims & Methods: Aim of this study has been to prospectively evaluate the efficacy of golimumab for the treatment of ulcerative colitis in the real-life setting of our referral centre. 13 patients (7 male, 4 female) with moderate to severe UC were enrolled in the study from June 2015 to December 2016. Patients received an induction dose of GLB 200 mg s.c. at baseline, 100 mg at week 2 and then a maintenance dose of 100 mg for a body weight < or ≥ 80 kg, respectively, with no optimization allowed. Partial Mayo score was computed at baseline and every 2 weeks for the first 6 weeks of therapy, then every 4 weeks throughout the maintenance period. Follow-up is still ongoing. Primary end point has been the clinical response at the end of the induction phase (intended as the reduction of Partial Mayo score >30% and >3 points vs baseline) and in the maintenance period, the secondary end point being the steroid-free clinical remission (Partial Mayo score <2 with all subscores <1) at the end of the induction phase and throughout the maintenance phase. Complete follow-up is available for all patients at week 30, with 4 patients reaching the week 54 of monitoring.

Results: At the time of GLB starting, localization of the disease according to Montreal classification was left-sides colitis (EC2) in 70%, pancolitis (EC3) in 23% and proctitis (EC1) in 7% of patients. Ten patients (77%) were anti-TNF naïve, 3 patients (23%) had already received one anti-TNF in the past. Clinical response was obtained in 6/13 (46%) at week 6 and in 2 further patients at week 10, for a total of 8/13 (62%). Three patients resulted in complete clinical steroid-free remission after 6 weeks. At week 30, 5 patients still showed a clinical response (38%), one of them (7%) resulted in complete steroid-free remission. Among the 4 patients reaching week 54, 2 experienced a flare of disease whereas 2 were still in remission. One patient is in remission at week 42, potentially accounting for a total of 3/13 patients in remission after one year (23%). No differences were found between naïve and non-naïve patients. No significant adverse events were reported in the study period.

Conclusions: Our data seem to suggest that Golimumab, as compared to regenerative trials, is able to induce a better initial clinical response but shows a higher secondary loss of response in the long term. Whether this really reflects a lower efficacy of GLB or could depend on the unavailability of dose optimization is still to be defined. Our patient prescription of GLB, needs to be evaluated.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The Observational Postmarketing Ulcerative colitis Study (OPUS) registry was conducted to collect long-term (5 years) real-world clinical and safety data in patients with moderate to severe ulcerative colitis (UC) treated with originator infliximab and to compare this safety profile to that of UC patients treated with standard therapies.

Aims & Methods: The OPUS registry was a prospective, non-randomized, observational study that followed patients with UC (in routine practice in 14 European countries) who were enrolled to receive treatment with either originator infliximab or standard therapy (defined as initiation or dose-increase of corticosteroid or infliximab) for the treatment of UC, as determined by their treating physician. Adverse events (AEs) were recorded during the 5-year follow-up period; at any time during the 5 years of observation, the patient’s therapy could be changed to any other UC therapy, based on the physician's clinical judgment. Frequency of events was evaluated in nine pre-specified categories (serious infection, infusion-related reaction, fatality, worsening or new case of congestive heart failure (CHF), central and peripheral demyelinating neurological disorder, hematologic condition, malignancy/lymphoproliferative disorder, hepatobiliary event, CHF, demyelinating disorder, or fatality). No new safety concerns were observed with originator infliximab in the OPUS registry.

PM049 DIRECT INTESTINAL PH-TRANSIT ASSESSMENT IN PATIENTS WITH ULCERATIVE COLITIS AS A STRATEGY FOR PREDICTING SUCCESS OF REGIONAL DELIVERY OF TOPICALLY-ACTING DRUGS

Introduction: Several oral mesalazine utilise pH-dependent release coating to optimise local delivery of mesalazine. Little data exists on clinical outcomes of intestinal pH and transit times in patients with UC to predict likely efficacy-based delivery profiles. No studies have accounted for acute variations in dietary fibre intake, which might affect regional transit and pH profiles.

Aims & Methods: This study: (1) Investigates the small intestinal luminal pH and transit after acute changes in fibre intake in quiescent UC patients; and (2) deduce delivery of topically-acting drugs using published pharmacokinetic (PK) data. In this randomised, double-blind study, patients with UC in clinical remission (partial Mayo Score ≤ 1 + faecal calprotectin < 150 μg/g) without recent antibiotic (including sulfasalazine), probiotic or fibre use were recruited. After a 7-day run-in, subjects were supplied with study meals containing high (13 g oligosaccharides and resistant starch) (HF) or low (<1g) fermentable fibre (LF) diets. After an 12-h period prior to the ingestion of a pH-motility capsule (Smart Pill). Telemetric recordings were made for 5 days or until the capsule had been excreted. After a ≥3-day washout period, they crossed-over to the other dietary arm and pH-motility test. Small and large intestinal pH profiles were defined as the length in time (h) of different intraluminal pH ranges – pH ≤ 5.6 to < 7.0 and ≥ 7.0 and compared between diets. Using published PK of pH-dependent coated mesalazine preparations, the patterns of dissolution in UC patients were estimated.

Results: 15 patients (aged 24-72; 9 males – 5 extensive, 5 distal and 5 proctitis), acute HF intake significantly increased median (IQR) time for colonic pH ≤ 5.6 [HF: 4.5 (2.4–10.2) vs LF: 0.9 (0.2–3.1) h; p = 0.004, Wilcoxon], tended to increase colonic pH ≤ 6 to <7 [HF: 7.5 (6.3–13.5) vs LF: 7.1 (4.5–15.2) h] and had no effect on colonic pH ≥ 7 [HF: 2.8 (1.1–5.6) vs LF: 2.0 (1.2–4.1) h; p = 0.17]. Table 1 summarises hypothetical dissolution profiles for pH-coated mesalazine in patients with UC. Considerable variations across release mechanisms were evident, but, despite alterations in pH and transit, the patterns were not affected by diet for Entudril L alone or with slow release mechanisms. Only minor differences were found for Eudragit S and MMX.

Conclusion: Current delivery mechanisms for mesalazine lead to a proportion of quiescent UC patients having incomplete release and suboptimal regional
P0406  HIGHER  EXPOSURE  TO  GOLIMUMAB  IS  ASSOCIATED  WITH  ENDOSCOPIC  RESPONSE  IN  PATIENTS  WITH  ULCERATIVE  COLITIS:  RESULTS  FROM  THE  GO-KINETIC  TRIAL

Introduction: Golimumab (GLM) is a subcutaneously administered anti-tumor necrosis factor (anti-TNF) antibody that is approved for the treatment of moderate to severe ulcerative colitis (UC). We investigated the association between systemic exposure (area under the curve (AUC)) of GLM during induction therapy and endoscopic response in moderate-severe UC.

Aims & Methods: In this prospective observational trial, patients with moderate to severe UC (Mayo endoscopy score ≥2) received induction treatment with GLM 200 mg SQ at week 0 and 100 mg at week 2 followed by 50 or 100 mg at week 6, in patients with a bodyweight of less or more than 80 kg, respectively. Serum GLM concentrations were measured at day 0, 4, 7, 14, 18, 28, 42 and 56, as well as anti-GLM antibody levels, C-reactive protein (CRP) and albumin serum concentrations. Serum GLM concentrations were measured with an enzyme-linked immunosassay and anti-GLM antibody levels were measured with a drug-sensitive antigen binding test, both developed by Sanquin laboratories. Endoscopic response was defined as ≥1 point reduction in endoscopic Mayo score at week 8–10 compared to baseline. AUCs were calculated using nonlinear mixed effect modelling (NONMEM®) and were compared using the non-parametric Mann-Whitney U test. Correlation analysis was performed using Pearson’s correlation coefficient. A receiver-operating characteristic (ROC) curve reported the predictive performance of GLM serum trough levels at week 2 and 6 for endoscopic response.

Results: A total of 20 patients were enrolled of which 19 patients underwent an endoscopy at baseline and 8–10 weeks after start of treatment. Median age [interquartile range] was 46 years [36–57], median baseline CRP serum concentration was 4.5 mg/L [1.1–13.7] and median baseline albumin serum concentration was 44 g/L [40–45]. None of the patients developed antibodies against GLM during induction treatment. After the induction phase, 12 out of 19 patients (63%) achieved an endoscopic response. Median AUC at week 2 and 6 was higher in endoscopic responders compared to non-responders (Table 1). Correlations between GLM trough concentrations and AUCs at week 2 (Pearson correlation coefficient: 0.86, P < .0001) and week 6 (Pearson correlation coefficient: 0.81, P < .0001) were statistically significant. Despite a low area under the ROC-curve (AUROC), a GLM serum trough concentration ≥3.3 mg/L at week 2 (AUROC: 0.75, 95% CI: 0.526–0.974, sensitivity: 67%, specificity: 71%) was associated with endoscopic response after the induction phase.

Conclusion: Serum trough concentrations of GLM and AUCs at week 2 and 6 were higher in endoscopic responders compared to patients without an endoscopic response. A significant correlation was found between GLM trough concentrations and AUC. A GLM trough level ≥3.3 mg/L at week 6 was associated with improved endoscopic outcomes.

Introduction: Tofacitinib is an oral, small molecule Janus kinase inhibitor being investigated for moderately to severely active ulcerative colitis (UC). We performed a systematic literature review (SLR) and network meta-analysis (NMA) to compare the efficacy and safety of tofacitinib to available tumour necrosis factor inhibitors (TNFi) and integrin receptor antagonists for induction therapy of adults with moderately to severely active UC.

Aims & Methods: Using indexing and free-text terms, searches were conducted in the EMBASE, MEDLINE, CENTRAL, DARE and CINAHL databases to identify RCTs published as of January 2015. Proceedings of relevant conferences from 2012–2014 were also reviewed. Comparators of interest were infliximab, golimumab, adalimumab and vedolizumab. Two reviewers independently assessed studies for inclusion, and extracted and validated the study/patient data. Fixed- and random-effects Bayesian NMA were conducted to compare efficacy outcomes and rates of adverse events (AEs) at 6–12 weeks in the overall population (TNFi-naïve or exposed) and by prior TNFi exposure.

Conclusion: Serum trough concentrations of GLM and AUCs at week 2 and 6 were higher in endoscopic responders compared to patients without an endoscopic response. A significant correlation was found between GLM trough concentrations and AUC. A GLM trough level ≥3.3 mg/L at week 6 was associated with improved endoscopic outcomes.

**Results:** Twelve induction trials were identified from the SRL (ACT 1 & 2, EUCALYPHTUS, GEMINI-I, POURSIT SC, TOFACTINIB PHASE 2, Feugen 2003, 2005, UC-SUCCESS, ULTRA 1, ULTRA 2, Suzuki 2014) and included in the NMA. Unpublished data from tofacitinib Phase 3 induction trials (OCTAVE 1 & 2) were also used in the analysis. Fixed-effects NMA showed that tofacitinib 10 mg twice daily (BID) is associated with a higher rate of mucosal healing 80/90/100 in the overall population (odds ratio [OR] 1.90 [95% confidence interval (CI) 1.63, 2.21]). In TNFi-exposed patients, a higher rate of clinical remission was seen with tofacitinib 10 mg BID vs adalimumab in TNFi-exposed patients (OR 11.93 [95% CI 1.84, 154.78]). AE rates were similar between tofacitinib 10 mg BID and comparators in the overall population and TNFα-naïve populations when analysed individually, but tofacitinib 10 mg BID was found to be associated with a higher rate of disaggregated AEs (“any AE”) than etrolizumab 300 mg in the overall population (OR 2.78 [95% CI 1.08, 7.41]). There were no statistically conclusive differences in the rates of specific AEs between tofacitinib 10 mg BID and comparators.

**Conclusion:** This NMA suggests that tofacitinib may be more effective as induction therapy in moderately to severely active UC than adalimumab and vedolizumab in TNFα-naïve patients, and is associated with a higher rate of mucosal healing than adalimumab in the overall population. Rates of specific safety events were similar between tofacitinib and TNFα inhibitors.

**Introduction:** Patients with inflammatory bowel disease (IBD) experience higher rates of *C. difficile* infection (CDI) than the overall population, often lack typical risk factors, and frequently experience severe and recurrent episodes. MODIFY I/II were global trials of the efficacy and safety of bezlotoxumab (bezlo: a human monoclonal antibody against *C. difficile* toxin B), in which bezlo was superior to placebo at preventing CDI recurrence (rCDI) in participants with primary or recurrent CDI given antibacterial drug treatment for CDI. Participants with IBD could be enrolled if, in the opinion of the investigator, symptoms were more likely due to CDI than IBD.

**Aims & Methods:** The objective of this post-hoc subgroup analysis was to summarize CDI-related outcomes, including initial clinical cure and rCDI, through 12 weeks in participants with IBD enrolled in the MODIFY trials. CDI-related outcomes through 12 weeks in the subset of IBD participants enrolled in the MODIFY trials included: initial clinical cure (no diarrhea during the 2 consecutive days following completion of ≤14 days of an antibiotic drug treatment for CDI); and rCDI (new episode of diarrhea associated with a positive stool test for toxigenic *C. difficile* in participants who had achieved initial clinical cure). For this post-hoc analysis, participants randomized to bezlo or actoxumab + bezlo were pooled and are referred to as the “bezlo” group and participants randomized to placebo or actoxumab were pooled and are referred to as the “no bezlo” group.

**Results:** Overall, 2559 participants were included in the mITT population; 1554 participants were randomized to a bezlo group and 1005 were randomized to a no bezlo group. There were 44 participants with IBD; 23 (52.3%) had ulcerative colitis; 18 (40.9%) had Crohn’s disease; and 3 (6.8%) had non-characterized IBD. Compared with participants without IBD, participants with IBD tended to be younger, were more often treated as outpatients, were more often immunocompromised, and a smaller percentage had severe CDI. Among IBD participants, a higher proportion had initial clinical cure in the no bezlo group compared with the bezlo group and there was a higher proportion of participants with rCDI in the no bezlo group compared with the bezlo group. In IBD participants who did not receive bezlo, most of the recurrences (5 of 7) occurred within 4 weeks after study infusion, while most of the recurrences among participants who received bezlo occurred after week 4 (3 of 4).

**Conclusion:** Participants with IBD and CDI enrolled in the MODIFY trials were younger, more likely to be diagnosed with CDI as an outpatient, to be immunocompromised, and to develop rCDI compared with non-IBD participants. Bezlo yielded a 27.2% absolute reduction (50% relative reduction) in the incidence of rCDI in participants with IBD. The efficacy of bezlo in preventing rCDI may extend to patients with IBD, but additional data are needed due to the limited cohort size.

**Disclosure of Interest:** C. Kelly: travel support and fees for serving on advisory boards from Seres Therapeutics, Summit Pharmaceuticals, and Synthetic Biologics, lecture fees from Seres Therapeutics, and grant support from Institut Mérieux, ntera Health, and Mercik.

All other authors have declared no conflicts of interest.
AIMS & METHODS: We randomized patients with CD or UC in clinical and biochemical remission to either switch to IFX-biosimilar or to continue using IFX-biological. Randomization was performed by a computer (65% to IFX-biosimilar). Patients in both arms received 4 to 6 doses of 5 mg/kg to 10 mg/kg during the 30-week study period. Patients eligible for inclusion had to be in clinical remission (HBI < 5 and MAYO ≤ 2) and have a fecal calprotectin < 250 μg/g. The primary endpoint of patients in remission at week 30. We measured C-reactive protein [CRP], fecal calprotectin [FCP], infliximab trough level [TL] and pharmacokinetics.

RESULTS: From 1005 mg/kg (529–1579) to 1450 mg/kg (1221–1778). Microbiota analysis

Conclusion: Fecal microbiota transfer in patients with chronic pouchitis is a promising therapeutic option and donor microbiomes could successfully be transferred via capsules or via jejunoscopy delivering fresh stool filtrate. However, a simple increase in microbial diversity and successful establishment of members of the butyrate producing Lachnospiraceae and Ruminococcaceae families is not sufficient for a successful outcome of FMT.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction**: Ustekinumab (UST) has been shown to induce and maintain clinical response and remission in moderate to severe Crohn's disease (CD) in 2 induction ([UNITI-1 (anti-TNF failures) and UNITI-2 (anti-TNF non-failures) and 1 maintenance [IM-UNITI]) randomized, placebo controlled Phase 3 trials. We evaluated the efficacy (response and remission) for all patients who received an intravenous (IV) induction dose of approximately 6 mg/kg, including responders (CDAI decrease ≥100) and non-responders, 8 weeks after the first UST maintenance dose of 90 mg subcutaneous (SC), i.e. 16 weeks from the IV induction dose.

**Aims & Methods**: Patients achieving clinical response 8 ws after a single IV induction dose were randomized to SC placebo (PBO), UST 90 mg every 12 weeks (q12w) or every 8 weeks (q8w). UST patients not in clinical response 8 weeks after the IV induction dose were given UST 90 mg SC and if in clinical response 8 weeks later were continued on 90 mg SC q8w. A total of 458 patients were exposed to an IV induction dose of 6 mg/kg (UNITI-1, N = 249 and in UNITI-2, N = 209) with a response rate at week 8 of 37.8% and 57.9% vs. PBO response rate of 20.2% and 32.1% respectively. The remission rate at week 8 in UNITI-1 and UNITI-2 was 20.9% and 40.7% vs. PBO of 7.3% and 19.6% respectively. For this evaluation, the response and remission status of the entire population exposed to an IV induction dose of 6 mg/kg of UST was evaluated 8 weeks after the first subcutaneous maintenance dose of UST. All patients who received 6 mg/kg IV UST induction were included, including responders randomized to SC PBO (who did not receive SC UST at week 8).

**Results**: Of the 219 patients not in clinical response in UNITI 1&2, 37.6% and 60.5% respectively were in clinical response 8 weeks after the first maintenance UST dose (90 mg SC). Evaluating all patients exposed to 6 mg/kg IV UST induction, response rates 8 weeks after the first subcutaneous injection were 37.6% and 57.9% respectively in UNITI-1 and UNITI-2 (N = 480) and non-responders, 8 weeks after the first maintenance dose of UST. All patients who received 6 mg/kg IV UST induction were included, including responders randomized to SC PBO (who did not receive SC UST at week 8).

**Conclusion**: These numbers at week 16 are expected to reflect real-world experience in patients who receive the induction dose and one additional maintenance dose 8 weeks later. The resulting rates of response and remission are higher than previously reported in the induction studies across all populations (anti-TNF non-failures and anti-TNF failures). About 73% of anti-TNF non-failures attain clinical response and over half are in remission. The data support the clinical rationale for providing at least one SC maintenance dose of ustekinumab irrespective of clinical response 8 weeks after IV induction.

**Disclosure of Interest**: J. Colombel: Investigator for Janssen Scientific Affairs, LLC

**Response rates and Remission rates for all patients 16 weeks after induction of 6 mg/kg IV UST**

**Only subjects with non-missing data for all segments at BL and W10 were included in the calculation; *Subscore for GHAS data is activity subscore and for SES-CD data is ulcer subscore; bolded texts indicate p-value < 0.05 from t-test**

Corr = 0.43, p < 0.001:BL and W10 respectively) (CGHAS v CSES-CD: Corr = 0.38, p < 0.001; Corr = 0.77, p < 0.001:BL and W10 respectively) (aCGHAS v uCSES-CD: Corr = 0.77, p < 0.001; Corr = 0.79, p < 0.001:BL and W10 respectively).

**Conclusion**: Improvements in endoscopic severity induced by fitcoltinib are parallelized by reductions of histologic scores. In line with previous findings from anti-TNF therapies colonic mucosa is more prone to improve than ileal disease. Spontaneous reductions of histologic activity under placebo were not observed.

Introduction: Biologics such as infliximab (IFX) (an anti-TNF) and vedolizumab (VDZ) (anti-integrin) are treatment options for patients with moderate-to-severely active inflammatory bowel disease (IBD), who have failed conventional therapy.

Aims & Methods: Our aim was to compare time to treatment discontinuation, flares, and hospitalisations among patients with IBD initiating VDZ versus IFX who were biologic-naïve. All patients with IBD (ulcerative colitis or Crohn's disease [CD]) who initiated biologic treatment with VDZ or IFX between 01/05/2014 and 22/02/2016 were identified in the US Explorys Universe database; the first infusion was deemed the index date. Analyses focused on patients who: (1) successfully completed induction therapy (≥3 infusions within 98 days of index date); (2) were ≥18 years of age at index; (3) had ≥365 days of medical history prior to index (“baseline”); and (4) had 365 days of follow-up after the index date. VDZ initiators were matched to IFX initiators (1:3) using propensity scores. Kaplan-Meier Method was used to compare median time to discontinuation of VDZ and IFX during follow-up, defined as the first of either: no receipt of biologic ≤90 days of previous infusion, or switch to another biologic. Similar method was also used to compare median time to IBD-related hospitalisations, surgeries, and flares (defined as use of intravenous steroids, respectively). Interquartile range (IQR) was also calculated.

Results: 105 VDZ initiators were matched to 315 IFX initiators. Baseline characteristics of both cohorts are described in Table 1. CD accounted for ≥60% of patients in each cohort. In the baseline period, ~70% of patients in both cohorts had received corticosteroids; 20% of VDZ vs. 38% of IFX initiators received an immunosuppressive therapy. Median time since diagnosis was 2.4 years for VDZ initiators and 3.1 years for IFX initiators. Median time to treatment discontinuation was 244 (IQR: 194–307) days for VDZ initiators vs. 190 (IQR: 125–300) days in both cohorts. Median time to first IBD-related hospitalisation was 153 (IQR: 78–209) days for VDZ initiators vs. 98 (IQR: 45–168) days for IFX initiators. For IBD-related flares, median time was 111 (IQR: 40–226) days for VDZ initiators vs. 93 (IQR: 35–182) days for IFX initiators.

Conclusion: Among biologic-naïve IBD patients, there was a trend toward prolonged median times to first IBD-related hospitalization or first flare with VDZ compared to IFX. The median time to discontinuation was comparable between the therapies. Future studies should examine comparative effectiveness outcomes in a larger cohort over a longer follow-up period.

United European Gastroenterology Journal 5(5S) A309
**Aim & Methods:** We aimed to determine if colonic antimicrobial gene expression profiles differ between IBS and healthy subjects and if potential alterations are linked to immune activity or gut microbiota composition. The expression of 84 key antimicrobial genes in sigmoid colon biopsies from patients with IBS, defined as being either immuno-active or immuno-norm based on systemic and mucosal cytokine profiles (Bennett et al. Am J Gastro, 2016), and healthy subjects was assessed by Human Antibacterial Response RT2 Profiler PCR Array. Targeted 16S rRNA pyrosequencing was performed on faecal microbiota. To identify discrimination profiles based on multiple variables between IBS patients and healthy subjects, orthogonal partial least squares discriminant analysis (OPLS-DA) with a cut off for Variable Importance for the Projection >0.7 was performed. 

**Results:**

**Table 1:** Differences in mucosal antimicrobial mRNA expression between IBS (Immuno-active and Immuno-norm) and healthy subjects.

Data presented as p-values (Mann-Whitney U-test) *p < 0.05 is significant. We included 31 IBS patients (16 females, median age 32 (25-44) years) and 16 healthy subjects (8 females, median age 27(24-30) years). An OPLS-DA model demonstrated that the antimicrobial profiles differed between IBS and healthy subjects (R2 = 0.54, Q2 = 0.16). The mucosal mRNA expression of 14 antimicrobial genes was downregulated, while one gene was upregulated in IBS patients compared to healthy subjects (Table 1). Antimicrobial profiles did not differ between IBS patients subtyped according to their predominant bowel habit (R2 = 0.02). An OPLS-DA model showed discrimination between immune-active (n = 16) and immuno-norm (n = 15) IBS patients based on their mucosal antimicrobial profiles (R2 = 0.91, Q2 = 0.61). This finding was corroborated by four antimicrobial genes being altered between the two IBS groups (Table 1). Adding healthy subjects to the model revealed three different discriminating profiles for each respective group (R2 = 0.44, Q2 = 0.30). Compared to healthy subjects, 19 genes in the immune-active and immuno-norm IBS groups were differently expressed (p < 0.05, Table 1). Only one of the antimicrobial genes differently expressed between IBS patients and healthy subjects was associated with faecal microbiota in immuno-norm IBS patients (Conserved Helix-Loop-Helix Ubiquitous Kinase (CHUK) with Anaerovorax r = –0.76, p < 0.01). In the immune-active IBS group 11 associations were identified, including TNF...
Receptor Superfamily Member 1A (TNFRSF1A) with Bifidobacterium ("4 mg/kg") may play a role in the complex pathophysiology of IBS.

Introduction: Internal biliary drainage has been confirmed better than external biliary drainage in alleviating the damage of intestinal mucosa barrier caused by obstructive jaundice, but the relevant mechanism is still unclear.

Aims & Methods: We aimed to investigate the effect of internal and external drainage on obstructive jaundice rats on intestinal mucosal barrier function with special reference of intestinal immune-related index expression. Thirty male Sprague-Dawley rats were randomly assigned to four groups: OJ, sham operation (SH), internal biliary drainage (ID) and external biliary drainage (ED). All animals underwent surgical ligature of the bile duct, except SH was produced by separating common bile duct locally but not dividing on day 1. Then ED and ID were reoperated on day 8 for biliary drainage procedure. Blood from inferior vena cava were collected for the test of DAO and sIgA activities by the method of ELASA. The terminal ileum specimens of each groups were collected for observation of the morphological changes with haematoxylin-eosin (HE) staining. The expression of IgA mRNA, plgR mRNA, GB-AR1 mRNA, RD-5 mRNA were measured by reverse transcription polymerase chain reaction (RT-PCR).

Results: After bile duct ligation, the injuries of the intestinal mucosa were obvious in OJ group with thinner mucosa, sparser villi, destruction of the epithelial layer. The results were accompanied by inflammatory cell infiltration. The expression of IgA mRNA and plgR mRNA were decreased (p<0.01), while the impaired intestinal mucosa has different degrees of recovery and ID group was more similar to SH group in intestinal mucosal morphology. The levels of the DAO in OJ group were increased more dramatically than that in SH, ID and ED groups while sIgA were decreased (p<0.01), and the activities of the DAO, sIgA in ID group were similar to the level of SH group (p>0.05), different to the level of ED group (p<0.01). The changes of the plasma DAO and sIgA activities were significantly correlated with the conditions of intestinal mucosa (p<0.01). The expression of RD-5 mRNA in OJ group were decreased significantly than that in SH, ID and ED groups while GB-AR1 mRNA, IgA mRNA, plgR mRNA were increased (p<0.01). Interestingly enough, after external bile drainage, there is no improvement in IgA mRNA and plgR mRNA (p>0.05). But in ID, the relative expression of IgA mRNA and plgR mRNA reduced markedly (p<0.01), while the mRNA expression of GB-AR1 and RD-5 mRNA in ED group was changed less than that in ID which were more similar to SH group. The protein expression of GB-AR1 was increased significantly in the intestinal mucosal of OJ group, which was higher than that of SH group (p<0.01). After internal and external biliary drainage to alleviate OJ respectively, the GB-AR1 expression was decreased significantly in ID group, similar with SH group (ID vs OJ, p<0.01; ID vs SH, p>0.05), and lower than that of in ED group (p>0.05). Conclusion: The differential expression of IgA mRNA, plgR mRNA, GB-AR1 mRNA, RD-5 mRNA and activities of DAO and sIgA in OJ, ID, ED and SH reflect internal biliary drainage better than external biliary drainage. There may be a regulating mechanism between GB-AR1 and intestinal immune-related index, which thus appears to be a key factor in maintaining function of intestinal mucosa barrier. P0419 COMPARATIVE EFFECT OF XYLOGLYCAN ASSOCIATIONS WITH COMPOUNDS FROM ANIMAL OR ALGAE ORIGIN ON LPS-INDUCED ENTERITIS IN RATS

H. Eutamene, C. Harkat, V. Theodorou
Unite´ De Neuro-gastroenterologie & Nutrition, Toxalim UMR 1331 INRA/UPS/INPT-El-Purpan, Toulouse/France

Introduction: Xyloglucan (XG) is a film-forming agent exhibiting protective effects against diarrhea linked to infectious gastroenteritis in humans; further in animal models, xyloglucan efficacy against cholera-toxin-induced diarrhea was tested when prolonged when this mucoprotectant agent is associated with gelatin from animal origin. The use of compounds from animal source in gaelic formulations is nowadays questionable.

Aims & Methods: Thus, in this study, we aimed at comparing the efficacy of XG associations with gelatin vs XG associated with gelose a moiety from algae origin on LPS-induced enteritis in rats. Since LPS-induced enteritis is characterized by increased intestinal permeability and mucosal inflammation, the efficacy of xyloglucan associations was evaluated by measurement of these two parameters. Male Wistar rats (200–225 g) were orally treated with either E. coli LPS (10 mg/kg) + gelatin (25 mg/kg) or XG (10 mg/kg) + gelose (25 mg/kg) or XG (10 mg/kg) + gelose (50 mg/kg) or vehicle (NaCl 0.9%) 3h before intraperitoneal (IP) administration of LPS from E. coli (1 mg/kg). Six hours later after LPS administration, the animals were sacrificed and strips of ileum were collected in order to evaluate (i) intestinal epithelial paracellular permeability to FITC-dextran 4Kd in Ussing chambers and (ii) mucosal inflammatory response by myeloperoxidase (MPO) activity measurement.
Results: Compared with control, LPS administration induced a significant increase (p < 0.05) of intestinal paracellular permeability (53.0 ± 4.9 vs 181.6 ± 21.1 pmol/cm² respectively) associated with jejunal mucosal inflammation (302.1 ± 9.5 vs 655.6 ± 108.9 U MPO/g protein, respectively). XG (10 mg/kg) + gelose at the lowest dose (25 mg/kg) failed to reverse the intestinal hyperpermeability and mucosal inflammation induced by LPS. In contrast, XG (10 mg/kg) + gelatin (25 mg/kg) and XG (10 mg/kg) + gelose at 50 mg/kg significantly (p < 0.01) and equally prevented LPS-induced hyperpermeability (34.8 ± 2.8, 38.7 ± 3.9 vs 181.6 ± 21.1 pmol/cm² respectively) and jejunal inflammation (27.70 ± 3.22, 286.2 ± 28.8 vs 655.6 ± 108.9 U MPO/g protein respectively).

Conclusion: This study shows that oral treatment with xyloglucan associated with gelose at 50 mg/kg has similar protective effects on LPS-induced enteritis in rats than xyloglucan associated with gelatin. These data demonstrate that algae is an effective and safe substitute for replacing compounds from animal origin in xyloglucan mucoprotectant formulations.

Introduction: The old age is one of the most important risk factors for recurrent C. difficile Infection (CDI). However, risk factors among the elderly patients are largely unknown.

Aims & Methods: The purpose of this study was to investigate risk factors associated with recurrent CDI in the elderly. Patients 65 years or older with positive CDI toxin test between January 2005 and December 2016, who received either oral metronidazole or oral vancomycin therapy were included. Recurrent CDI was defined as another positive laboratory result for C. difficile toxin between 15 days and 90 days after initial positive diagnostic test. Clinical charts of relevant factors in 633 patients with positive CDI toxin test between January 2005 and December 2016, who received in the other.

Results: The overall mean age was 77.0 ± 9.5 years. In 96 (15.2%) of 633 patients, C. difficile toxin was detected again after the initial test. The length of hospital stay was longer in recurrent CDI group than in non-recurrent group (80.54 ± 49.44 vs. 43.81 ± 65.42, P < 0.001). Patients with eGFR < 60 ml/min/1.73 m² were at higher risk for the development of recurrent CDI than those with normal renal function (OR 1.844; 95% CI, 1.139-2.985, P = 0.015). There were no significant differences on mean age (77.21 ± 6.65 in recurrent CDI group vs. 77.01 ± 7.04 in non-recurrent CDI group, P = 0.799) and proton pump inhibitor therapy (OR 1.277; 95% CI, 0.825 to 1.977, P = 0.272) between both groups. Renal function and length of hospital stay were significantly associated with recurrence of CDI.

Conclusion: In this study, impaired renal function and prolonged hospitalization were related to the increased risk of recurrent CDI.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0421 CLINICAL CHARACTERISTICS OF CYTOMEGALOVIRUS COLITIS: 15 YEAR-EXPERIENCE IN A TERTIARY MEDICAL CENTER

P. Le1, R. Wu1, C. Chiu1, C. Kuo1, M. Su1, C. Lin1, J. Hsu3
1Department Of Gastroenterology And Hepatology, Linkou Chang Gung Memorial Hospital, Taoyuan/Taiwan
2Department Of Pathology, Linkou Chang Gung Memorial Hospital, Taoyuan/Taiwan
3Department Of General Surgery, Linkou Chang Gung Memorial Hospital, Taoyuan/Taiwan

Contact E-mail Address: puoshuen@gmail.com

Introduction: Cytomegalovirus (CMV) colitis in adults is mostly described in immunocompromised patients (solid organ or hematopoietic stem cell transplant recipients, patients with human immunodeficiency virus (HIV) infection, use of immunosuppressive drugs, including steroid or chemotherapy agents), and often has poorer outcome than in children. Besides, it was also frequently presented in patients with known or subsequent new diagnosis inflammatory bowel disease [1, 2]. However, there are only case reports and few case series with limited patients (below 15 cases) among immunocompetent individuals without known use or inflammatory bowel disease [3-5]. The largest meta-analysis study of cytomegalovirus colitis in immunocompetent hosts included 44 patients and noted advanced age, male gender, presence of immune-modulating comorbidities and need of surgical intervention negatively influencing survival in 2005 [6]. The case number of CMV colitis in immunocompetent patient seemed increasing in our hospital these years. There was no single study showing comprehensive clinical characteristics, identifying the independent factors of in-hospital mortality and comparing the differences between immunocompetent and compromised patients with CMV colitis. Therefore, we tried to clarify the issue in this study.

Aims & Methods: We enrolled 42 immunocompetent patients and 27 immunocompromised patients with CMV colitis diagnosed by immunohistochemistry stain between April 2002 and December 2016 in Linkou Chang Gung Memorial Hospital, a 3383-bed tertiary medical center and referral center in Taiwan. We analyzed the risk factors of in-hospital mortality and overall survival. Furthermore, we compared the clinical differences between immunocompetent and immunocompromised patients with CMV colitis.

Results: Early diagnosis (before 9 days) was independent predictor of in-hospital mortality in CMV colitis patients. ICU admission (P = 0.010), requisite days of diagnosis>9 days after admission (P = 0.018), shock (P = 0.001), respiratory failure (P = 0.003), hemoglobin < 10 g/dL (P = 0.002), Creatinine > 1.37 mg/dL (P = 0.004) and CRP>29 mg/dL (P = 0.011) negatively impacted on overall survival. There were older and more comorbidities in immunocompetent group. However, the in-hospital mortality rate and overall survival rate was similar to immunocompromised group. Besides, Closstridium difficile infection or steroid didn’t affect in-hospital mortality rate and overall survival rate neither. Melena was first and most common symptom in immunocompetent group, but diarrhea in the other.

2. Khan TV, Toms C. Cytomegalovirus Colitis and Subsequent New Diagnosis of Inflammatory Bowel Disease in an Immunocompetent Host: A Case Study and Literature Review. Am J Case Rep 2016; 17: 538-43.

Aims & Methods: The aim of this study was to assess effectiveness of FMT for recurrent CDI therapy in the hospital of Lithuanian University of Health Sciences (LUHS KK, Kaunas, Lithuania). Clinical data of patients who were treated for recurrent CDI (>2 times) using FMT in the Department of Gastroenterology of LUHS KK during 2015–2016, were analyzed. All patients were monitored for disease relapse for six months. Clinical data, the use of antibiotics and immunosuppressive drugs were included in analysis. Statistical analysis was performed using statistical software package SPSS version 17.

Results: FMT was used for 18 patients with recurrent CDI. The mean age of patients was 60.4 ± 8.4 years. The patients were treated with antibiotics 14.8 days on average before manifestation of CDI. FMT procedure was performed using nasoenteral tube. After the first procedure, the positive clinical effect was observed in 15 patients with a cure rate of 83.3%. FMT procedure was repeated for two out of the three patients without positive effect (one patient refused repetitive FMT). Normal stool habits were restored in both patients leading to the increase of cure rate to 94.4% (17 out of 18 patients). Seventeen patients that were successfully treated with one or two FMT procedures in the short term also remained asymptomatic (100%) at 6 months of follow up. All patients without positive effect of first FMT procedure were on immunosuppressive drugs (3/3).

Conclusion: FMT is an effective therapy for recurrent CDI infection both in short and long term follow up. Effectiveness of primary FMT treatment could be associated with the use of immunosuppressive drugs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The traditional fear that every acute appendicitis will eventually perforate leads to prompt surgery, but this fear may be outdated. In-hospital delay of surgery for acute appendicitis has been subject of a large number of studies. However, consensus about the consequences of delaying appendectomy is lacking, which is reflected in variety or absence of recommendations in guidelines.

Aims & Methods: The aim of this study was to assess in-hospital delay of surgery and its relation with complications in patients with acute appendicitis. PubMed and EMBASE were searched from 1990 to July 2016. Outcome measures of interest were complicated appendicitis, surgical site infections and postoperative morbidity. All studies reporting surgically treated patients with one of these outcome measures in two or more predefined time intervals were included. Adjusted odds ratios were pooled using forest plots if possible. All unadjusted data was pooled using generalized linear mixed models.

Results: Forty-five studies with 152,314 patients were included. Pooled adjusted odds ratios revealed no significantly higher risk for complicated appendicitis when delaying appendectomy for 6 to 12 hours or 13 to 24 hours; odds ratio 1.07 (95% CI 0.98–1.17) and 1.09 (95% CI 0.95–1.24), respectively. For a delay of 24 hours or more the sufficient adjusted data was available for risk analysis. Pooled unadjusted data showed a decreased risk for complicated appendicitis when appendectomy was delayed for 24 to 48 hours, however statistical uncertainty in this interval increased considerably compared to the first 24 hours.

Conclusions: In-hospital delay of appendectomy for up to 24 hours after admission did not result in higher rates of complicated appendicitis, surgical site infections or morbidity. When prompt surgery is hampered by logistic or personal reasons, delaying appendectomy up to 24 hours is an acceptable alternative for patients with no preoperative signs of complicated appendicitis.

P0432 EARLY VERSUS STANDARD COLONOSCOPY – A RANDOMIZED CONTROLLED TRIAL IN PATIENTS WITH ACUTE LOWER GASTRO-INTESTINAL BLEEDING: RESULTS OF THE BLEED STUDY

I. Van Rongen1, B. Thomassen2, L. Perk1

1Gastroenterology, Haaglanden MC, The Hague/Netherlands

2Landsteiner Institute, Haaglanden Medical Centre, The Hague/Netherlands

Contact E-mail Address: inge.van.rongen@gmail.com

Introduction: The incidence of acute lower gastrointestinal bleeding (LGIB) is estimated at 21 adults per 100,000 person years and male (82.1%) in the anticoagulant group were higher than those in the normal group (67.7 ± 11.2 years and 64.1%). There was a difference between the groups in size of polyp and morphology. In the anticoagulants group, 34 patients received heparin brid-

Warfarin. But, direct comparison of DOAC and warfarin in the patients with gastrointestinal bleeding was little reported.

Aims & Methods: We retrospectively analyzed 18 on DOAC and 60 cases on Warfarin of the patients with gastrointestinal bleeding from January 2011 to March 2017 on the basis of single-center experience in Japan. We analyzed concerned red cell (CRC) and fresh frozen plasma (FFP) transfusion, bleeding rate during hospitalization, the duration from bleeding to endoscopy, from endoscopy to discharge and from bleeding to discharging in both group.

In DOAC group, each 6 patients took Darbropabin, Rivaroxaban and Apixaban.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0433 THE COMPARISON OF DIRECT ORAL ANTICOAGULANTS (DOAC) AND WARFARIN FOR ANTICOAGULATION IN THE PATIENTS WITH GASTROINTESTINAL BLEEDING

Gastroenterology, Mitsui Memorial Hospital, Tokyo/Japan

Contact E-mail Address: kenken.kojiken.529@gmail.com

Introduction: Direct oral anticoagulants (DOAC) are now popularly used as anticoagulation for atrial fibrillation and deep vein thrombosis, as well as Warfarin. But, direct comparison of DOAC and warfarin in the patients with gastrointestinal bleeding was little reported.

Aims & Methods: We retrospectively analyzed 18 on DOAC and 60 cases on Warfarin of the patients with gastrointestinal bleeding from January 2011 to March 2017 on the basis of single-center experience in Japan. We analyzed concerned red cell (CRC) and fresh frozen plasma (FFP) transfusion, bleeding rate during hospitalization, the duration from bleeding to endoscopy, from endoscopy to discharge and from bleeding to discharging in both group.

In DOAC group, each 6 patients took Darbropabin, Rivaroxaban and Apixaban.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference

(continued)
Results: Patient characteristics such as age, anti-platelet therapy, location of bleeding and bleeding after endoscopic procedure had no significant difference in both groups. Upper gastrointestinal bleeding occurred 6 (33.3%) of DOAC group and 2 (8.3%) of Warfarin group (p = 0.20), lower gastrointestinal bleeding occurred 2 (11.1%) vs 9.6 g/dl and 9.6 g/dl (p = 0.26) and international normalized ratio of prothrombin time (PT-INR) was significantly prolonged in Warfarin group (1.51 ± 0.36 vs 2.50 ± 0.20, p = 0.02). CRC transfusion rate had no significant difference in both group (3.0 days vs 5.5 days (p = 0.02), but the duration from endoscopy to discharge was significantly longer in Warfarin group (9.0 ± 5.5 days vs 23.0 ± 3.0 days, p = 0.03). The duration from bleeding to discharge was significantly longer in Warfarin group (9.8 ± 5.4 days vs 24.2 ± 3.0 days, p = 0.02). Thrombotic embolism during hospitalization occurred only 1 (1.7%) of Warfarin group.

Conclusion: The duration of hospitalization was significantly shorter in DOAC group of the patients with gastrointestinal bleeding, and the rate of bleeding and re-bleeding tended to be lower in DOAC group. This study showed that DOAC may be more superior to Warfarin as anti-coagulation for atrial fibrillation and deep vein thrombosis at the quality of life (QOL) in the patients with gastrointestinal bleeding.

Disclosure of Interest: All authors have declared no conflicts of interest.

The duration from bleeding to endoscopy, days 0.8 ± 0.5 1.2 ± 0.2 0.52
The duration from endoscopy to discharge, days 9.0 ± 5.5 23.0 ± 3.0 0.03
The duration from bleeding to discharge, days 9.8 ± 5.4 24.2 ± 3.0 0.02

Introduction: Colonoscopy is an imperfect tool. Several publications confirm colorectal cancer may manifest after a negative colonoscopy(1)-(3). The term “interval cancer” has often been used for cancers appearing after a negative colonoscopy. However, this is primarily a screening term(1). Post-colonoscopy colorectal cancer (PCCRC) is a broader term for cancers detected after a negative colonoscopy in any setting, including screening(2). Although there is overlap between these terms, they are not synonymous. PCCRC can be thought of as the overarching term. PCCRC can be subcategorised into interval cancers (identified prior to the next recommended screening or surveillance procedure) and non-interval cancers (identified at or after a recommended screening or surveillance interval, or where no subsequent screening or surveillance interval had been recommended, up to 10 years following the colonoscopy).

Aims: The goal of this consensus process was to provide a framework for the terminology, identification, analysis and reporting of cancers appearing after a negative colonoscopy or computed tomographic colonography (post-colonoscopy/post-imaging colorectal cancers- PCCRC/PICRC respectively). We based our methodology on The Appraisal of Guidelines for Research and Evaluation (AGREE II) tool(4). An international multidisciplinary team (gastroenterologists, pathologists, epidemiologists, a radiologist and a patient representative) who were summoned by the World Endoscopy Organisation (WEO); the final panel consisted of 20 voting members. The following topics were addressed by 2 working groups (WGs): 1. Aetiology WG 1.1 Terminology of aetiology categories. 1.2 Risk factors/potential explanations of PCCRC 1.3 How to ascribe potential explanations 1.4 Minimal colonoscopy, histology and radiology datasets to examine PCCRC 1.5 Molecular tests to be performed to examine PCCRC 1.6 Prevention of PCCRC in high-risk groups 2. Performance WG 2.1 PCCRC calculation & reporting 2.2 PCCRC monitoring 2.3 PCCRC papers peer-review 2.4 Post-imaging CRC A literature search was performed in MEDLINE and Cochrane using terms “colorectal cancer AND interval cancer”; “healthcare quality assurance AND colorectal cancer” and “healthcare quality assurance AND colorectal cancer AND interval cancer”. The final output consisted of 391 articles. Proposed statements were subjected to anonymous voting via e-correspondence. Each statement was scored on a scale of 1 (strongly agree) to 5 (strongly disagree)
5 (strongly disagree). A modified Delphi process was followed; consensus reached at maximum. In areas containing disagreement, a recommendation for or against a particular statement required both >50% of participants in favour and <20% preferring the comparator. Failure to meet this resulted in no recommendation. The GRADE system for rating evidence and strength of recommendations was applied to final statements. Results: The final output consists of 21 statements providing guidance on key aspects of PCCRC/PICRC, namely definitions, terminology, qualitative review/ aetiology attribution and quantitative assessment of cases. A Root-Cause Analysis checklist as well as a PCCRC/PICRC manuscript peer-review checklist were also developed.

Conclusion: This is the first consensus aiming to standardise terminology around PCCRC. Each previous study defined PCCRC differently, making its use for benchmarking purposes impossible. This consensus presents a methodology for analysis of causation of PCCRC/PICRC and defines its potential role as a key quality indicator, providing recommendations for future investigators, policy makers, services and patients.

Introduction: Early colorectal cancer (CRC) is still the third most common malignancies in the US according to Colorectal Cancer Statistics, 2017[1]. During past decades, the incidence and mortality of CRC among individuals aged over 50 years are declining significantly, while the rate of CRC in the young is sharply on the rise[2,3]. Excluding rate of young-onset CRC, coupled with increased survival rate, would definitely lead to accumulation of young survivors considerably. There is a growing study reporting the risk of second primary malignancies considerably. There is a growing study reporting the risk of second primary malignancies. The incidence of CRC survivors and this trend was consistent among different subgroups. About 44.6% young patients died of their SPCs. We hope our results may provide some implication for future surveillance and prevention strategies for young CRC survivors.

P0438 INCIDENCE OF FECAL OCCULT BLOOD TEST INTERVAL SCREENING IN COLORECTAL CANCER SCREENING: A SYSTEMATIC REVIEW AND META-ANALYSIS

E. Wieten1, E. Schreuder1, E. Grebbee1, D. Nieboer2, I. Lansdorp-Vogelaar3, M.J. Bruno1, E.J. Kuipers1, M.C.W. Spaander1

Contact E-mail Address: e.wieten@erasmusmc.nl

Introduction: Worldwide, many organized colorectal cancer (CRC) screening programs use non-invasive fecal occult blood tests (FOBTs). Although the interval colorectal cancer (iCRC) rate is an important performance indicator of a screening program, data on iCRC after negative FOBTs are limited. Aims & Methods: In this systematic review and meta-analysis we compared the incidence of iCRCs following a negative fecal immunochromatographic test (FIT) or gFOBT with fecal occult blood test (gFOBT). Second, we assessed if screening-relating or patient-related factors are associated with FOBT/iCRCs. Ovid Medline, Embase, The Cochrane Library, the Science Citation Index, PubMed publisher and Google scholar were searched up to May, 2016. All studies reporting on the incidence of iCRC following FIT or gFOBT and average CRC screening populations were included, without language restrictions. Main outcome was pooled incidence rate of iCRC per 100,000 person-years (p-y). FOBT iCRC was according to international standards defined as cancer that developed after a negative FOBT and before the next FOBT was due. Pooled incidence rates were obtained by fitting random effect poisson regression models. The between-study heterogeneity of effect-size was quantified using the I2.

Results: We identified 5,873 records, of which 413 full-text articles were assessed for eligibility and 30 studies were included in both qualitative and quantitative analyses. Meta-analyses comprised data of 5,252,563 screening participants, in which 14,030 screen-detected CRCs and 5398 FOBT iCRCs were documented. Pooled incidence rates of iCRC following FIT and gFOBT were 20 (95CI:14-28; F=94%) and 40 (95CI:26-61; F=93%) per 100,000 p-y, respectively. The pooled incidence rate ratio of FIT iCRC compared to gFOBT iCRC was 0.50 (95CI:0.30-0.84, n=30 studies). For each FIT iCRC, three CRCs were found with FIT, while for gFOBT the ratio between iCRC and screen-detected CRC was 1:13. Table 1. No significant differences were found between the relative risk of FIT iCRC in the second and third screening round compared to the first, with 1.03 (95CI:0.94-1.13) and 1.08 (95CI:0.93-1.22), respectively. Incidence rate ratio of FIT iCRC compared with CRC in CRC screening per 100,000 p-y was 0.85 (95CI:0.84–1.7) for males relative to females and 5.0 (95CI:1.2-21) for screennees aged ≥60 relative to <60 years.

Table 1: Baseline data of 30 studies included in quantitative meta-analyses displayed per test type

<table>
<thead>
<tr>
<th>Screening</th>
<th>n= 5, 252, 563</th>
<th>CRCs n= 14, 030</th>
<th>FOBT iCRCs n= 5, 398</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIT n, (%)</td>
<td>4, 774, 516 (85)</td>
<td>12, 172 (87)</td>
<td>400 (80)</td>
</tr>
<tr>
<td>gFOBT n, (%)</td>
<td>478, 047 (9)</td>
<td>1858 (13)</td>
<td>1395 (20)</td>
</tr>
</tbody>
</table>

Conclusion: This is the first study to report on the pooled incidence of FIT and gFOBT iCRC in screening setting. The incidence rate of iCRC after a negative
FOBT is two-fold higher in gFOBT than in FIT, which supports the use of FIT over gFOBT as screening tool. However, for every three FIT-detected CRCs, still one CRC is missed, which highlights the importance to adequately inform screeners about the risk of developing a colorectal carcinoma after a negative FIT.

4 Skane University Hospital Malmo, Department of Gastroenterology and Hepatology, Malmo/Sweden

Contact E-mail Address: anna.forsberg@ki.se

Introduction: Age and family history of colorectal cancer (CRC) are the strongest risk factors for CRC. Obesity, commonly assessed based on body mass index (BMI), is associated with an increased risk for CRC in men but the association is weaker in women and differs between studies. We investigated which of the following body composition measures: BMI, waist circumference (WC), waist-hip ratio (WHR), weight-height ratio (WHHR), weight-height-hip ratio (WHHR), A Body Shape Index (ABSI) and percent body fat that best predict the development of CRC in men and women.

Aims & Methods: We used data from Malmö Diet and Cancer cohort in Sweden, including 16,840 women and 10,903 men (mean age, 51.8 years at baseline), followed for a median of 19.8 years. We identified cases with CRC until the end of 2014 using national Swedish registers. Hazard ratios (HR) for CRC, colonic cancer (CC) and rectal cancer (RC) per one standard deviation increase in each body composition measure respectively were calculated using Cox regression models, stratified by sex and adjusted for age, alcohol consumption, smoking, education and physical activity. Likelihood ratio tests and C-statistics were calculated to identify the anthropometric measure that improves the null model the most.

Results: Incident CRC occurred in 880 individuals (477 women) during follow-up. All body composition measures apart from WHHR significantly predicted CRC in men and waist circumference (WC) was the best predictor based on C-statistics and LR-test (HR per standard deviation [SD] increment, 1.19; 95% CI, 1.08–1.31, LR-test p < .001, C-statistics 0.6278). The association between WC and CRC was only found in men with a BMI above 25. All body composition measures apart from WHRR and percent body fat significantly predicted CC in men, again WC was the best predictor (HR 1.25; 95% CI, 1.11–1.42, LR-test p < .001, C-statistics 0.6444). ABSI was the only measure significantly associated with risk for RC in men (HR, 1.24; 95% CI, 1.05–1.47). In women neither of the measures was significantly associated with an increased risk for CRC, CC nor RC.

Conclusion: In this Swedish population-based cohort study on well-characterized participants, body composition measures predicted CRC in men but not in women of the study cohort. For age, education and health behavior WC was the best predictor of CRC and CC in men and the association was only significant in overweight/obese men in stratified analyses. Gender difference in the interplay between sex and measured adipose tissues in the adipose tissue may explain the lack of associations in women.

P0440 TH17 CELLS INDUCE EPITHELIAL-MESENCHYMAL TRANSITION VIA IL-17/PI3K/AKT/SNAIL PATHWAY IN COLORECTAL CANCER

Q. Li1, X. Xu1, P. Zhou2

1 Endoscopy Center, Zhongshan Hospital, Fudan University, Zhongshan Hospital, Fudan University, Shanghai/China

Contact E-mail Address: liquorin321@126.com

Introduction: T helper 17 (Th17) cells participate in the progression of various cancers. Both tumor-promoting and tumor-suppressing effect have been reported. The role of Th17 cells in colorectal cancer (CRC) remains controversial and the specific mechanism of how Th17 cells affect the development of CRC remains to be explored.

Aims & Methods: The study aimed to clarify the role of Th17 cells in CRC and identify the underlying molecular mechanisms. The percentage of Th17 cells and IL-17 expression were evaluated via flow cytometry, enzyme-linked immunosorbent assay (ELISA), and immunohistochemistry in tissue samples and peripheral blood. Effects and underlying molecular mechanisms of IL-17 cells on epithelial-mesenchymal transition (EMT) process were explored in vitro using IL-17 transfection and in nude mice by implanting IL-17 overexpressed CRC cells. To detect the expression of Th17 cells and EMT process, SW480 cells were co-cultured with Th17 cells via transwell system. Cancer signaling phospho antibody microarray was used to explore the potential signaling pathway. The clinical significance of Th17 cells was investigated in tissue microarrays containing CRC tissues from 90 patients following surgery using immunohistochemistry.

Results: A higher percentage of Th17 cells and serum IL-17 level were found in CRC patients than healthy controls, and Th17 cells presented a gradual upward trend in normal epithelium-adenoma-carcinoma sequence. The overexpression of IL-17 significantly promoted cell proliferation and invasion, and inhibited apoptosis in vitro and in vivo. IL-17 overexpression reduced the expression of E-cadherin and induced the expression of Snail, p-catenin, and Vimentin in both SW480 cells and tumor xenografts, suggesting that IL-17 could induce the EMT process in CRC. When co-cultured with SW480 cells with Th17 cells, we found Th17 cells could directly promote the EMT process of tumor cells. Furthermore, using cancer signaling phospho antibody microarray, we found that PI3K/AKT/Snail signaling pathway played a key role in the regulation of EMT. EMT process could be reversed by LY294002 and IL-17 mAb intervention, suggesting that IL-17/Pi3K/Akt/Snail pathway played a vital role in Th17 cells-induced EMT in CRC. Supporting these findings, in human CRC tissues, immunostaining indicated that the percentage of Th17 cells was significantly associated with E-cadherin expression and AKT phosphorylation. The clinical significance of Th17 cells was authenticated by revealing that the combination of intratumoral Th17 cells and E-cadherin served as a better prognosticator for postoperative tumor recurrence than either marker alone.

Conclusion: Th17 cells promote EMT process and facilitate tumor progression via activating IL-17/PI3K/AKT/Snail signaling pathway in CRC.

CONFOUNDING? A MENDELIAN RANDOMIZATION STUDY

P0443 MUSCARINIC-3 RECEPTOR TARGETED MiRNAs ARE INVOLVED IN BILE ACID-INDUCED PROLIFERATION ON H508 COLON CANCER CELL LINE

F. Tekin, C. Aktan, N. Oruc, O. Oztunc
Gastroenterology, Ege University Medical School, Izmir/Turkey

Contact E-mail Address: drtekinifalti@gmail.com

Introduction: Studies with the colon cancer cell lines which express muscarinic-3 (M3) receptors showed that taurine conjugates of lithocholic acid, but not other bile acids, bind to M3 receptors, and stimulate an increase in cell proliferation. On the other hand, many microRNAs (miRNAs) are involved in colon carcinogenesis. However, the interaction of bile acid-M3 receptors and miRNAs and their potential effects in colon carcinogenesis remains to be elucidated.

Aims & Methods: For the first time in the literature, we examined the possible role of M3 receptor-targeted miRNAs on two human colon cancer cell lines: H508, which expresses M3 receptors, and SNU-C4, which does not. Cell proliferation for 6 days after sodium tauro lithocholat (ST) and atropin (A) treatment was analysed by WST-1 method. Expression of M3 receptor gene at mRNA level was analysed by qPCR, and at protein level by Western Blot method. Apoptotic experiments were analysed by Annexin V assay. MiRNAs which possibly targeted M3 receptors were identified by in silico analyses. The methods were repeated three times, and the average values were calculated.

Results: When compared to SNU-C4 cells, M3 receptor gene expression was found to be increased 70-fold on H508 cells. After a 6-day incubation, maximum H508 cell proliferation (300%) was achieved on fifth day with a dose of 300 μM ST, inhibited by a dose of 1 μM A. In contrast, the SNU-C4 cells showed no significant change in cellular proliferation. Treatment of H508 cells with ST caused a decrease (2.53-fold) of M3 receptor gene expression, however, no change of M3 receptor at protein level was seen. No changes in apoptosis on both colon cancer cell lines were observed. Of 25 M3 receptor-targeted miRNAs, expression levels altered in 9; 6 of them were up-regulated (hsa-miR-129-5p, hsa-miR-30c-5p, hsa-mir-224-5p, hsa-miR-30b-5p, hsa-miR-222-5p, hsa-miR-1246) and 3 of them (hsa-miR-30e-5p, hsa-miR-147b, hsa-miR-885-3p) were down-regulated on H508 cells (p < 0.05).

Conclusion: ST interact with M3 receptors which modulate colon cancer cell proliferation on H508 cells. M3 receptor-targeted miRNAs are involved in ST induced proliferation. Whether the use of ursodeoxycholic acid, selective anti-miRNAs, anti-cholinergic agents or other approaches to blocking potential interactions of bile acids/salts with neoplastic colonic epithelium may be a useful adjunct to colon cancer prevention or treatment remains to be determined.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0443 COLORECTAL CANCER AND DYSLIPIDAEMIA: CAUSE OR CONFOUNDING? A MENDELIAN RANDOMIZATION STUDY

G. Ibañez1, A. Diez-Villanueva1, M. Riera-Ponsañ1, E. Guinó1, B. Pérez-Gómez2, M. Bustamante1, V. Martín1, J. Llorca5, P. Amiano6, E. Ardanaz7, M. Kogevinas3, M. Pollán2, V. Moreno1

6Public Health Division Of Gipuzkoa, Biodonostia Research Institute, San Sebastián/Spain
7Navarra Public Health Institute, Navarra/Spain
8University Institute of Oncology of Asturias, Oviedo/Spain

Introduction: Dyslipidaemia and statin use have been associated to colorectal cancer (CRC), but prospective studies have shown controversial results. Dyslipidaemia has been thought to have an important role in inflammatory pathways, oxidative stress and insulin resistance, which could contribute to the pathogenesis of cancer. However, findings from prospective studies that have examined the association between serum dyslipidaemia (low density lipoprotein cholesterol (LDL), HDL or TG) and colorectal neoplasia have been inconsistent. [4-1] It is unknown whether lipids and lipoproteins cause cancer or are intermediate or correlated factors within carcinogenic pathways. Epidemiological studies could be confounded by 3-Hydroxy-3-methylglutaryl-coenzyme A reductase inhibitors (statins) use, which might also have a protective effect to CRC. It is unclear whether it is statin use or dyslipidaemia that prompted statin use, which may be associated with CRC. Indeed, a large number of epidemiological studies have examined the effect of statins on colorectal cancer risk, with often inconsistent results.[5-6] A Mendelian randomization approach could help to establish a causal relationship between dyslipidaemia and CRC.

Aims & Methods: We aimed at determining whether dyslipidaemia is causally linked to CRC risk and to explore association of statins with CRC. A case-control study was performed including 1336 CRC cases and 2744 controls (MCC-Spain) between 2008 and 2013. Subjects were administered an epidemiological questionnaire that included lifetime regular use of prescription drugs. Also, subjects were genotyped with an exome array supplemented with 5000 custom SNPs. We applied the Mendelian randomization approach. The array included 136 SNPs previously shown to be associated with blood lipids levels in GWAS, that were used to build three genetic lipid scores, as the count of risk alleles. The scores were specific for low density lipoprotein cholesterol (LDL), high density lipoprotein cholesterol (HDL) or triglycerides (TG). We tested on the association on regular statin use and the genetic lipid scores with logistic regression models, adjusted for potential confounders.

Results: The LDL genetic risk score was significantly associated with statin consumption (OR = 1.07, 95%CI 1.05–1.10, p = 4.4e-11). The dyslipidaemia genetic risk score was not significantly associated with CRC for either of the target lipids studied. Cases had the same average alleles as controls in all the lipids traits. Statin use was a borderline significant protective factor for CRC (multivariate adjusted OR = 0.83; 95%CI 0.69–1.00, p = 0.049).

Conclusion: Using the Mendelian randomization approach, our study does not support the hypothesis that lipid levels are associated with the risk of CRC. This study does not rule out, however, a possible protective effect of statins in CRC by a mechanism unrelated to lipid levels.

Disclosure of Interest: All authors have declared no conflicts of interest.

METACHRONOUS LESIONS

P0444 LINCO00152 LONG NON-CODING RNA FACILITATES CELL POLYPYSIS THROUGH REGULATION OF CELL CYCLE AND WNT SIGNALING PATHWAY

O. Galamba, B.K. Barták1, A. Kalmár1, A. Sebestyén1, T. Danko1, C. Tolnai-Kriston1, G. Valczi2, K. Szürtet2, Z.B. Nagy2, G. Barna2, Z. Tulassay3, P. Iglasz1, B. Buzás4, B. Molnár5, M. Alustiza2, J.R. Aparicio1, F.A. Ruiz1, J.F. Martínez1, J.A. Casellas1, J.L. Soto3, P. Zapater1, R. Jover1

Introduction: Long non-coding RNAs (lncRNAs) contribute to different cancers including colorectal cancer (CRC) through influencing cancer-related processes such as cell proliferation, apoptosis, and invasion. Previous studies have shown altered LINCO00152 expression in CRC, but the detailed mechanism of its effects during colorectal carcinogenesis and cancer progression is not well studied.

Aims & Methods: We aimed to study the effects of LINCO00152 to the cell cycle regulation and promoter DNA methylation of several CRC-associated tumor suppressor genes in colon cancer cells. We also analyzed the expression and promoter DNA methylation of LINCO00152 and of its regulated molecules in human colon tissue samples. LINCO00152 were silenced in SW480 colon tumour cells using Stealth siRNAs. Cells were harvested 48 or 72 hours after transfection.

Flow cytometric cell cycle analysis was performed using propidium iodide staining. Cyclin D1 protein expression was detected using flow cytometry after labeling with anti-cyclin D1 antibody. The effect of LINCO00152 silencing to DNA methylation levels of SFRP1, SFRP2, SDC2 and APC promoter gene promoters was studied using Methylation technology. Promoter methylation and expression of the above molecules were also studied on human colon tissue samples.

Results: LINCO00152 expression was successfully silenced in SW480 cells with 93–99% efficiency. Colorectal cancer cell line decreased cell growth, apoptosis and decreased cyclin D1 protein expression. LINCO00152 knockdown did not affect the promoter methylation status of SFRP1, SDC2 and PRIMA1 genes, while reduced the DNA methylation level of SFRP2 promoter. Remarkable hypermethylation of SFRP2 and PRIMA1 promoters was detected in CRC compared to normal samples (p < 0.01), which correlated with increased expression (R = 0.90). SFRP2 promoter hypermethylation and decreased expression were measured in CRC and adenoma tissues compared to normal samples (p < 0.05). Conversely, expression of mutant KRAS in CRC can contribute to CRC development by facilitating cell proliferation through upregulation of cyclin D1 cell cycle progression gene and by affecting promoter methylation of SFRP2 tumor suppressor gene. On human tissue level, similar signaling pathway alterations were detected.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0445 GENETIC PROFILE OF POLYPS AND RISK OF ADVANCED METACHRONOUS LESIONS

O. Morcila1, M. Jáurez2, E. HERNÁNDEZ-Illán1, M. Rodriguez-Soler1, C. Egavil1, C. Muñozcar1, C. Marínc1, M. Alustiza1, J.J. WU2, J.A. XÜ1, W. Kang3, Y. Quan4, H. Chen5, X. Li6, Z. Cai5, J. Jiao-Yiu Sung7, J. Yu7

Introduction: Colorectal cancer (CRC) frequently harbours concomitant mutations in KRAS and APC that promote carcinogenesis. Epigenetic dysregulation plays essential roles in the tumorigenesis of KRAS mutant CRC. Our preliminary data demonstrated that simultaneous KRAS gain-of-function mutations in APC-null CRC cells induced the hypermethylation of DNA and histones, an effect driven by metabolic rewiring of glutamine metabolism. We recently unveiled that glutamine metabolism in KRAS mutant CRC could be rewired by the mitochondrial glutamate transporter, SLC25A22, a synthetic lethal gene against KRAS-mutant CRC in vivo and in vitro. In this study, we investigated the potential role of SLC25A22-mediated glutaminolysis in regulating DNA and histone methylation in CRC, its underlying mechanisms, and the association of SLC25A22 with epigenetic dysregulation in human CRC cohorts.

Aims & Methods: We aim to 1) evaluate the impact of mutant KRAS on DNA and histone methylation in CRC; 2) examine the role of SLC25A22 in DNA and histone methylation in KRAS-mutant CRC; 3) elucidate the underlying mechanisms that underlie SLC25A22-mediated epigenetic dysregulation; and 4) investigate the clinical relevance of the genetic association between SLC25A22 and CRC risk.

Results: Using three pairs of isogenic cell lines harbouring wild-type and mutant KRAS (DKS80WT vs DLD1(mutant); HKE3(TOT) vs HCT116(mutant); ICT(WT) vs ICT-KRAS(mutant)), we demonstrated that significant DNA and histone H3 hypermethylation in cell lines expressing mutant KRAS. DNA hypermethylation was associated with the up-regulation of 5-hmc, indicating suppressed DNA demethylation in KRAS mutant CRC cell lines. Metabolic analysis revealed that KRAS mutation modified glutaminolysis via TCA cycle leading to high succinate and fumarate to α-ketoglutarate (αKG) ratio, which was to pivotal in suppressing the enzymatic activity of dioxygenases such as TET1 and thus, favoring DNA hypermethylation. Interestingly, simultaneously APC-loss and KRAS activating mutations synergistically up-regulated the expression of SLC25A22, a key regulator of glutamine metabolism via the TCA cycle. CRISPR-Cas9 mediated knockout of SLC25A22 suppressed glutaminolysis in KRAS-mutant CRC cell lines, which in turn, reduced the ratio of succinate and fumarate to α-ketoglutarate. The impact of SLC25A22 knockout on glutaminolysis had a profound effect on epigenetic regulation, as DNA methylation profiling revealed that SLC25A22 knockdown restored DNA hypermethylation levels in non-mutated KRAS-mutant CRC cell lines. Moreover, histone H3 methylation was reduced at multiple histone marks after the knockout of SLC25A22. These data implied that SLC25A22 inhibited DNA and histone demethylases by promoting the production of succinate and fumarate, which in turn, reversed the effect of SLC25A22 knockout on DNA and histone methylation in KRAS-mutant CRC cell lines. In addition, succinate restored cell growth in SLC25A22 knockout cell lines, suggesting that epigenetic dysregulation was closely associated with tumorigenesis. In human CRC, SLC25A22 expression was positively associated with CIMP (P < 0.0001) and histone H3K36me2 methylation status (P < 0.0001).
Conclusion: SLC25A22 promotes the tumorigenicity of KRAS mutant CRC by driving aberrant DNA and histone hypermethylation, an effect mediated by increased production of TCA cycle intermediates succinate and fumarate, which inhibits DNA and histone demethylases. SLC25A22 is correlated with CIMP and histone hypermethylation in CRC patients.

P0447 FOLLISTATIN-LIKE PROTEIN 1 SUSTAINS COLON CANCER CELL GROWTH AND SURVIVAL
G. Bevivino 1, V. De Simone 1, R. Iezzi 2, M. Di Giovangiulio 2, S. Sedda 1, E. Franzoni 2, A. Rizzo 1, P. Rossi 2, C. Stolfi 1, G. Monteleone 1

Introduction: Follistatin-like protein 1 (FSTL1) is a secreted glycoprotein, widely expressed in human tissues, which plays key functions in the regulation of cell survival, proliferation, differentiation and migration. Moreover, deregulated expression of FSTL1 has been described in malignancies but its contribution to carcinogenesis remains controversial.

Aims & Methods: We here investigated the expression and role of FSTL1 in sporadic colorectal cancer (CRC). FSTL1 was evaluated in human CRC samples and cell lines by immunohistochemistry, Western blotting and real-time PCR. Cell proliferation and survival cell culture were evaluated in human CRC cell lines (i.e., HCT-116, DLD-1) treated with a specific FSTL1 antisense (AS) or control oligonucleotide. Western blotting, Western blotting and flow-cytometry were used to assess the expression of proteins involved in cell cycle progression, poly ADP-ribose polymerase (PARP), caspase-9 and active caspase-3. Moreover, the effect of FSTL1 knockdown on cell death was evaluated in cells cultured in the presence or absence of the pan-caspase inhibitor Q-VD-OPh by flow-cytometry.

Results: FSTL1 was significantly increased in both epithelial and lamina propria compartments of human CRC specimens as compared to controls. In CRC cell lines, FSTL1 knocked down caused accumulation of cells in G1 phase of the cell cycle and reduced CRC cell proliferation. FSTL1-deficient CRC cells had reduced levels of proteins involved in late G1 cell cycle phase, such as phosphorylated retinoblastoma protein (pRb), E2F-1, cyclin E and cyclin-dependent kinase-2 (CdK2), with no modification of early G1 phase proteins (i.e. cyclin D). Treatment of CRC cells with FSTL1 AS increased the percentages of apoptotic cells and this effect was associated with activation of PARP, caspase-9 and caspase-3. Pre-incubation of HCT-116 and DLD-1 cells with Q-VD-OPh abolished the FSTL1 AS-induced cell death and reduced PARP and caspase activation, thus indicating that FSTL1 silencing induces CRC cell death through a caspase-dependent mechanism.

Conclusion: Our data indicate that FSTL1 is over-expressed in CRC cells and suggest a role for this protein in promoting intestinal tumorigenesis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0448 TP53 MUTATION ACQUIRES HIGHER MALIGNANT POTENTIAL IN HUMAN COLON CANCER CELLS
S. Watanebe 1, K. Tsuchiya 2, T. Shirasaki 1, S. Hibiya 1, S. Oshima 1, T. Nakamura 1, F. Nakamura 1, M. Akimoto 1, M. Watanabe 2, R. Nishimura 1, R. Okamoto 1, T. Nakamura 1

Introduction: TP53 mutation in colon cancer. TP53 mutation is well known to occur in the late phase of colon carcinogenesis as adenoma-carcinoma sequence. Although numerous reports about clinical information of the patients with colon cancer have suggested that TP53 mutation might be related to various malignant potentials, the effect of TP53 mutation on malignant potential of colon cancer is still unknown. Notably, there is no report about a relationship between TP53 mutation and cancer stemness. Therefore we aimed to assess the function of TP53 mutation in colon cancer cells, by using recently established lentiviral CRISPR Cas9 system.

Aims & Methods: Two types of TP53 mutation were generated in LS174T cells, which are derived from human colon adenocarcinoma with wild-type TP53 (WT-TP53), by using lentiviral CRISPR Cas9 system. The guide RNAs were designed to bind exon 3 or exon 10 of TP53, respectively. TP53 mutation in LS174T was confirmed by direct sequencing. The expression of TP53 protein was assessed by immunohistochemistry. Loss of function of TP53 was assessed by Nutlin-resistance and the expression of TP53 target genes. Malignant potentials of TP53-mutated LS174T cells were measured by soft agar formation assay and cell migration assay for cell proliferation, cancer stemness and cell migration, respectively. Chemo-resistance was also assessed by the treatment with 5-FU and L-OHP.

Results: We first selected LS174T cells with WT-TP53 because TP53 gene has already been mutated in almost colon cancer cell lines. We then successfully established 2 types of TP53 mutation in LS174T cells due to high effectiveness of gene-mutating by lentiviral system. Mutation in exon 3 (TP53Ex3e) and exon 10 (TP53Ex10) of TP53 created the shorter form of TP53 (TP53Ex3: 55a.a.; TP53Ex10: 377a.a., respectively) compared to WT-TP53 (393a.a.). Mutant TP53 (TP53Ex10) is strongly expressed in nuclei as often shown in colon cancer region, whereas both WT-TP53 and mutant TP53 (TP53Ex3) are not expressed in LS174T cells. In contrast, both TP53 mutants (TP53Ex3e and TP53Ex10) showed Nutlin-resistance and the down-regulation of TP53 target genes, suggesting that both mutants induced loss of function of TP53. We then assessed the effect of both TP53 mutants on various malignant potentials, resulting in accelerated cell growth, enhanced invasiveness and the resistance against Nutlin-3 treatment compared to WT-TP53. Moreover, both mutants showed more frequent formation of 3D sphere and more expression of Lgr5 than WT-TP53, suggesting the promotion of cancer stemness by TP53 mutation even after being adenocarcinoma.

Conclusion: We found the first time showed the direct effect of TP53 mutation on malignant potential in colon cancer cells. Loss of function of TP53 induced by not only TP53Ex10 but also TP53Ex3 mutation, might promote malignant potentials including cancer stemness at the late phase of carcinogenesis. In general, TP53 is a tumor suppressor gene in cancer region is represented as TP53 mutation. However, negative staining of TP53 might also be careful for TP53 mutation to estimate malignant potential in colon cancer, since N-terminal mutation of TP53 in colon cancer has already been reported.

Introduction: Endogenous opioid system is involved in the maintenance of the intestinal homeostasis. Recently, we proved that stimulation of opioid receptors using P-317 – a novel cyclic morphinepeptan analog with mu- and kappa-opioid receptor affinity, resulted in alleviation of acute phase of experimental colitis (induced by dextran sodium sulfate [DSS]) in mice. Chronic inflammation is associated with increased risk of colitis-associated colorectal cancer. Stimulation of opioid receptors produces different effects on cancer progression depending on the cancer type and stage of disease.

Aims & Methods: The aim of our studies was to characterize the role of the endogenous opioid system in pathogenesis and treatment of colitis-associated colorectal cancer using P-317. Colitis-associated colorectal cancer was induced by a single intraperitoneal injection of azoxymethane [AOM] (10 mg/kg) and subsequent addition of DSS (1.5% v/v) into drinking water (week 2, 6, 9). From week 3, P-317 was injected intraperitoneally at the dose of 0.1 mg/kg twice per week and the body weight and clinical score (rectal bleeding, stool consistency) were assessed. After 14 weeks, the macroscopic colon damage score and the samples were collected and used for biochemical, molecular and histological studies.

Results: A significant difference in colorectal tumor development was observed between vehicle- and P-317-treated mice. P-317 significantly increased total number of colonic tumors as well as colon thickness and width after 14 weeks of disease induction. Myeloperoxidase activity, a marker of neutrophil infiltration, was inhibited by P-317 injections. Hematoxylin and eosin staining confirmed anti-tumor activity of P-317 as indicated by histological score connecting the following features: muscle thickness, damage of the intestinal wall, immune cell infiltration, invasion depth, crypt hyperplasia and disruption. The expression of IL-1β and TNF-α at mRNA level was decreased in P-317-treated mice as compared to vehicle-treated group.

Conclusion: P-317 may become an important pharmacological tool to study the factors that determine the development of inflammatory bowel disease and to define the role of the endogenous opioid system in chronic colitis and colorectal cancer.

Introduction: Colorectal cancer (CRC) is the third most common type of cancer in the world and one of the leading causes of cancer-related mortality. HMGB1 expression and subsequent death due to colorectal cancer is associated with its stage 1, 2. Because of its insidious onset, the diagnosis of CRC is usually delayed. However, serological markers can be a relatively easier and cheaper alternative tool for early-stage CRC, which require high risk population. In CRC, several recent studies have shown that high-mobility group box 1 (HMGB1) plays a critical role in tumorigenesis, disease progression and metastasis by activation of cancer cells, promotion of tumor angiogenesis, suggesting that HMGB1 may be useful as a new biomarker of cancer 1, 2, 3, 4. Studies have shown that HMGB1 is over-expressed in various types of cancers, include CRC, and those cases with higher expression of HMGB1 are associated with lymphatic metastasis, distant metastasis and poor prognosis 5,6. Several reports have demonstrated that HMGB1 is
secreted by cancer cells may be involved in occurrence of tumor metastasis [6, 7]. In a study by Luo et al., authors found that HMGB1 secreted by the primary tumors had an apoptotic effect on the Kupffer cells which promoted development of liver [6, 7]. Furthermore, some researchers showed that increased levels of c-IAP2 and pERK, the downstream effector molecules of HMGB1, are significantly up-regulated in cancers compared with adenomas (P = 0.022) compared with SA. The expression levels of miR-7 were significantly up-regulated in cancers compared with adenomas (P = 0.001). The expression levels of miR-34a were significantly reduced in all tumors compared with paired non-tumorous samples in the same patient. Especially, these miRNAs were significantly reduced in MA (P = 0.042 and P = 0.004) and FAP (P = 0.027 and P = 0.022) compared with SA. The expression levels of miR-7 were significantly up-regulated in cancers compared with adenomas (P = 0.001). The expression levels of miR-34a were significantly down-regulated in CA (P = 0.001), MA (P < 0.001), and FAP (P = 0.006) compared with SA. Conclusion: These findings suggest that the malignant potential of MA and FAP was higher than SA, therefore MA needs strict follow-up like FAP.

P0453
UTILITY OF MEAN PLATELET VOLUME, PLATELETIR, PLATELET-LYMPHOCYTE RATIO AND NEUTROPHIL-LYMPHOCYTE RATIO IN THE DIFFERENTIATION OF COLON CANCER AND COLONIC POLYPS IN OLDER PATIENTS

F. Karakaya, C. Kalkan, I. Soykan
Gastroenterology, Ankara University, Ankara/Turkey

Contact E-mail Address: mkarakaya@yahoo.com

Introduction: Colorectal carcinoma (CRC) is an important cause of mortality and morbidity in the elderly and an important area of research for the early detection of colorectal cancer. The aim of the work was to investigate the lipodic profile of serum, red blood cells (RBCs), the serum metabolomic profile from patients with CRC to identify the stage of the disease and the preventive measures of various localizations.

Aims & Methods: Sera, RBCs from 64 patients (52 ± 7 years old) with colorectal adenocarcinoma were analyzed by 1H NMR spectroscopy, gas chromatography. The metabolomics, lipodic profiles generated from each platform were compared between groups locating a total of 98 metabolites (N = 28, 75 and 85 years of age should be tailored on the basis of the presence of coexisting conditions because the risk of serious complications from colonoscopy also increase with age.

Aims & Methods: The aim of this study was to investigate whether MPV, plateletIR, PLR and NLR may have a role in the discrimination of CRC and colonic polyps in older patients. 418 patients aged > 65 years with colorectal carcinoma (n =93) (Group I) and colonic polyps (n =325) (Group II) were included into the study. Also 601 (Group III) patients aged > 65 years with normal colonoscopic findings served as a control group. All study subjects were investigated by using MPV, plateletIR, PLR and NLR in order to establish sensitivity and specificity for predicting colorectal carcinoma and colonic polyps for each parameter studied.
Results: MPV, PCT, NLR and PLR were significantly higher in Group III compared to Group I. However, only MPV significantly decreased in Group II compared to group I (6.2±1.1 vs 8.2±1, p < 0.001). The cut-off value of MPV in predicting CRC from patients with normal colonoscopic findings was 9.15 fL with a specificity and sensitivity of 80% and 91% respectively (r = 0.892). MPV and PCT were also significantly higher in patients with neoplastic polyps compared to patients with non-neoplastic polyps (MPV: 8.7±1.1 vs 8±1, p < 0.001 and PCT: 0.23±0.07 vs 0.19±0.05, p = 0.003).

Conclusion: MPV and PCT may have a role as useful and simple markers in the diagnostic approach of patients with colorectal cancer from patients with normal colonoscopic findings. In the clinical settings, these simple markers may be useful in selecting older patients for colonoscopic examination.

Introduction: Rectal cancer patients with clinical evidence of a complete response after chemoradiotherapy may be selected for watchful waiting instead of surgical resection. This strategy and help improve the identification of potential candidates for watchful waiting in the future.

Aims & Methods: We aimed to determine the diagnostic performance of the Radimics signature1 of patients with LARC and evaluate its potential value for pre-treatment prediction of the response to neoadjuvant chemoradiotherapy.

We retrospectively assessed the primary survival stage MRI (1.5T) of 124 LARC patients treated with CRT. The standard MRI protocol included T2-weighted (T2W) and diffusion-weighted imaging (DWI) sequences, as well as quantitative apparent diffusion coefficient (ADC) maps derived from the DWI scans. For each patient, the whole volume of the rectal tumour was delineated on pre-treatment MRI. A final subset of 266 features remained stable and performed across all five readers/delineations. These features resulted in a mean AUC of 0.67 (range 0.64–0.73) as well as reproducible performance (Wilcoxon test, False Detection Rate [FDR] 10%) across different readers/delineations. The cut-off value of 70% vs residual tumour (yT1-yT4) using histology and/or long-term FU as the standard reference.

Conclusion: Various Radimics features extracted from pre-treatment MRI correlate to neoadjuvant treatment response and may be used as imaging biomarkers to predict the response to chemoradiotherapy in rectal cancer. Best results are obtained for textural features (representing tumour heterogeneity) derived from diffusion-weighted MR sequences. Features extracted from semi-automated (software generated) delineations show inferior performance compared to features extracted from manual delineations, emphasizing the need for adequate tumour delineation. Interestingly, however, delineations from expert and non-expert readers rendered similar good results, suggesting that the selected features are robust and do not necessarily require highly expert input.

P0456 CORRELATION OF ELECTRICAL AND VISCOELASTIC PARAMETERS OF ERYTHROCYTES WITH FATTY ACID COMPOSITION OF THEIR MEMBRANES AND SERUM IN PATIENTS WITH COLORECTAL CANCER
I. Prudnikova
Institution of Internal and Preventive Medicine, Academic Scientific Institution, Novosibirsk, Novosibirsk/Russian Federation
Contact E-mail Address: dr.prudnikova@mail.ru

Introduction: An analysis of the efficient implementation of the guidelines for screening colorectal cancer (CRC) in patients with first diagnosed CRC (according to the archival case histories of the two medical institutions in Novosibirsk) was performed in 2013-2016, and leading reasons of late CRC diagnostics were identified.
Aims & Methods: We aimed to investigate the correlation of the electrical and viscoelastic parameters of erythrocytes with the fatty acid composition of their membranes and blood serum of patients with colorectal cancer (CRC) of different stages. 46 patients (median age of 53 + 9 years old) with CRC of various localizations and stages and 16 conditionally healthy patients were examined.
Results: Saturated fatty acids prevailed in composition of erythrocyte membranes in patients with CRC; omega 6/omega 3 fatty acid index was decreased, while the level of linoleic acid was significantly increased as related to oleic acid in serum of the patients with CRC compared to the healthy people (p < 0.001-0.05).
Conclusion: Revealing changes in the parameters of erythrocytes and fatty acid composition in blood serum associated with a stage of the disease can be promising for diagnostics and the case follow-up of patients with CRC.

P0458 POST-INVESTIGATION COLORECTAL CANCER RATES INCLUDING POST COLONOLOGY COLORECTAL CANCER RATES IN A DISTRICT GENERAL HOSPITAL: THE POOLE EXPERIENCE MARCH 2015 TO FEBRUARY 2017
S.D. Parry, T. Deacey, E. J. Williams
Dept Of Gastroenterology, Poole Hospital NHS, Poole Dorset/United Kingdom
Contact E-mail Address: sally.pARRY@poole.nhs.uk

Introduction: Post-colonoscopy colorectal cancer (PC-CRC) rates are proposed quality indicators for screening programmes. Existing data is interesting but important to assess local practise and to compare with recent published National Data. We aimed to calculate the PC-CRC and the post CT (Colonoscopy + abdomen) CRC rate at Poole Hospital using the number of colonoscopies or CT scans done within 3 years of a CRC diagnosis as the denominator for post-investigation PI -CRC calculations as outlined in a previous study.

Aims & Methods: Retrospective audit of all patients diagnosed with CRC during the period from 1st March 2015 to 28th February 2017 was defined via the Somerset Cancer registry database for Poole Hospital using Crystal software. Previous colonoscopy and CT Colonoscopy (CTC) or CT abdomen results in the 3 years preceding the diagnostic investigations were reviewed across two neighboring hospitals sharing the same electronic patient records. If patients had multiple surveillance colonoscopies the latest was counted as false negative as in previous studies.

Results: 416 patients were identified, 67 were excluded (39 non adenocarcinoma, 3 out of area, 12 patients where earlier decision was best supportive care, 6 patients diagnosed at laparotomy, 2 patients with abnormal PET scans and 6 with incomplete datasets). 348 patients were included for analysis. Colorectal cancer was diagnosed by colonoscopy in 200 patients and by CTC or CT in 148 patients.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0459 RISK OF DETECTION OF GASTROINTESTINAL NEOPLASMS AND DEATH IN SYMPTOMATIC PATIENTS WITH A POSITIVE FECAL IMMUNOCHEMICAL TEST WITHOUT COLORECTAL CANCER

N. Pin, M.J. Iglesias, D. Remedios, P. Vega, J. Cubiella Servicio De Aparato Digestivo, Complejo Hospitalario Universitario de Ourense, Ourense, Spain

Contact E-mail Address: noel.pin.vieito@sergas.es

Introduction: The fecal immunochemical test (FIT) has a high diagnostic accuracy for the detection of colorectal cancer (CRC) in symptomatic patients. However, we do not know the risk of other gastrointestinal neoplasms associated with a false positive test.

Aims & Methods: To calculate the risk of detection of gastrointestinal tract tumors (GITT) and death in symptomatic patients with a positive FIT determination and without a CRC in a complete colonoscopy with an adequate bowel preparation. We designed a prospective cohort study with follow-up. Patients from the COLONPREDICT study with complete colonoscopy without CRC were included. Two cohorts were defined: FIT positive and negative according to the ≥20mg hemoglobin/g of feces threshold. We performed a descriptive analysis of the outcomes detected during follow-up and mortality. We estimated the differences in the risk of GITT detection and mortality between the two cohorts by logistic regression and proportional hazards after adjusting for age, sex, and significant colonic lesions (CSL) detection at baseline colonoscopy.

Results: We included 1061 patients without CRC and a complete baseline colonoscopy, 320 (30.2%) with a positive FIT and 741 with a negative FIT. The median follow-up was of 36.0±8.9 months with no difference between both groups (p=0.2). There were significant differences regarding age (67.5±12.7 years vs. 64.8±13.5 years, p=0.04) and sex (45.9% vs. 52.0% females, p=0.04) between both cohorts. We detected a GITT in 14 (4.4%) patients with a positive FIT: 5 CRC, 6 gastric, 1 small intestinal lymphoma and one patient with a CRC and a small intestine adenocarcinoma; and in 12 (1.6%) with a negative FIT: 4 CRC, 6 gastric, 2 small intestine adenocarcinoma, 1 one esophageal, and one patient with a gastric and a CRC. Patients with a positive FIT had a non-significant increase in the risk of GITT detection (OR 2.1, 95% CI 0.9–4.8) after adjusting for age, sex and SCL. The overall risk of death in both groups was 8.8% and 6.7%, respectively, with no significant differences between both groups in the survival analysis (HR 1.3, 95% CI 0.8–2.1). However, the risk of death due to a GITT was 3.1% (10 deaths) in the positive FIT group and 0.8% (6 deaths) in the negative FIT group, with a significant difference after adjusting for age, sex and SCL (HR 3.2 95% CI 1.2–8.9).

Conclusion: Symptomatic patients with a positive FIT and complete colonoscopy without CRC are at increased risk of death due to GITT regardless of age, sex or the presence of CSL.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There is a significant demand for colorectal cancer (CRC) with acute colorectal obstruction (ACO), Transanal colorectal tube (TCT) placement is an alternative endoscopic treatment for ACO; however, the oncological outcomes of TCT placement for the curative treatment of CRC remain unknown.

Aims & Methods: Data were retrospectively reviewed from patients with distal stage II/III CRC who underwent surgery between January 2007 and December 2011 at two Japanese affiliate hospitals with an interexchange of endoscopists and patients. Following clinical endoscopic emergent surgery and the other performed TCT placement as the standard treatment for CRC with ACO. To analyze the efficacy of TCT placement, we compared long-term outcomes for stage II/III CRC with ACO among patients in the two institutions.

Results: In total, 764 patients with distal stage II/III CRC were identified for this study. Among the 764 patients, 690 did not have ACO (non-ACO group), and 74 had ACO (ACO group). In the non-ACO group, we confirmed that the surgical quality was equivalent between the two institutions, with no significant differences in overall survival (OS) (P=0.271) or disease-free survival (DFS) (P=0.184). Among the 74 patients with ACO, 27 underwent emergency surgery (surgery group) and 47 underwent TCT placement (TCT group). The rate of primary resection/anastomosis was higher in the TCT group than in the surgery group (91.5% vs. 22.2%; P=0.001). No significant differences were noted between the two groups in OS (surgery vs. TCT; 5-year OS, 65.9% vs. 58.1%; P=0.452) or DFS (surgery vs. TCT; 5-year DFS, 47.6% vs. 43.1%; P=0.755). Subset analysis also showed no significant differences in OS and DFS between patients with stage II and stage III CRC.

Conclusion: TCT placement can achieve similar long-term outcomes to those of emergency surgery, with a high rate of primary resection and anastomosis for distal stage II/III CRC with ACO.

Introduction: Self-expandable metallic stent placement for malignant colorectal obstruction has been widely used; however, factors affecting the technical difficulty of stenting remain unclear.

Aims & Methods: The aim of this study was to clarify the factors associated with the technical difficulty of stenting for malignant colorectal obstruction. We established the Colonic Stent Treatment Research Group to provide instructions on how to safely perform stent placement, and then, we conducted this prospective, single-arm, observational, multicenter clinical trial between October 2013 and May 2014 in Japan. Thirty-two facilities participated in this study. A double-wire woven uncovered stent was placed by using a standard through-the-scope colonoscopic placement technique in each patient. Stent deployment time was defined as the time from reaching a lesion with a colonoscope to finish stenting. Technically difficult cases of stenting were defined as independent factors affecting the technical difficulty of stenting by using univariate and multivariate analyses.

Results: A total of 205 consecutive patients were enrolled in this study. Nine patients including 3 patients with technical failure of stenting, 5 patients with non-stenting and 1 patient with stenting for benign lesion were excluded. The remaining all 196 patients were succeeded in stenting. Of these, 100 were men (51%), and the median age was 72 years old (interquartile range (IQR), 62–82 years old). One hundred eleven patients (57%) underwent stenting as a bridge to surgery, and 85 (43%) underwent stenting for palliation. The technical and clinical success rates were 98.5% and 97.0%, respectively. None of the patients had complications of colorectal perforation. The median total procedure time in the cohort with technical success was 30 minutes (IQR, 18–42 minutes). The median deployment time was 21 minutes (IQR, 11–31 minutes). Forty-nine patients with a deployment time longer than 31 minutes were regarded as technically difficult cases of stenting. The following were identified as independent factors of the technical difficulty in stent placement: presence of ascites (odds ratio, 2.483; 95% confidence interval [95%CI], 1.17–5.29; p=0.02), placement of ≤1 stent (odds ratio, 4.80; 95%CI, 1.10–21.1; p=0.04).

Introduction: Colorectal cancer is the third most common cancer in the world and the fourth leading cause of cancer death1. Treatment strategy for colorectal cancer is selected considering clinical stages. TI colorectal cancer (T1CRC) can be treated with endoscopic resection. If patients have pathological risk factors such as deep submucosal invasion, budding, por/muc pathological features and lymphovascular invasion, they considered to be at high risk of lymph node metastasis based on the indication of Japanese Society for Cancer of the Colon and Rectum guidelines2. In such cases, the selection of subsequent option is important and has been frequently decided by clinicians’ customs and preferences. However, it is not clear whether these risk factors adequately predict patients’ prognosis in clinical practice.

Aims & Methods: This research aims at revealing the prognosis and clinicopathological features of pathologically high-risk T1CRC patients (the high-risk group) with and without additional surgery; followed up by computed tomography, ultrasound, endoscopy, and tumor marker (CEA: carcinoembryonic antigen). 1. To evaluate the difference of overall survival (OS), cancer specific survival (CSS) and recurrent-free survival (RFS) between the patient performed additional colectomy with lymph node dissection (AS) and the patient followed up without additional surgery (FU). 2. To reveal what clinicopathological factors are considered in the selection of subsequent option, whether AS or FU, in the high-risk group. We retrieved the clinical data of 162 patients who had diagnosed and treated as T1 colorectal cancer at Kyoto University Hospital (Kyoto, Japan) between February 2005 and February 2015. Treatment strategy after diagnosis was considered as “high-risk” and clinicopathological features, presence or absence of recurrence, and the final state at the end of February 2017. We used the Kaplan-Meier product limit method and the Log-rank test to compare OS, CSS, and RFS between AS and FU groups. In clinical setting, based on the guideline indication, the clinician offered subsequent options and described their risks and benefits, and the patient expresses his or her preferences and values. Factors considered during selecting treatment strategy were extracted from informed consent and provider’s note of electronic medical records.

Results: Among 162 T1CRC patients, 78 cases were treated with endoscopic resection for the first time. Of them, 46 patients had at least one pathological risk factor (high-risk patients). Among 46 high-risk patients, 22 patients were carefully followed up (FU). 20 patients were performed additional surgery with lymph node dissection (AS). Four patients treated with additional radiation therapy were excluded. Median survival time was 39 (FU) and 62 (AS), respectively. There were no recurrences among the 62 e-curable patients. On the other hand, five recurrences (5%) were found in non-e-curable patients, and they were all in Group A. They consisted of local recurrence (one patient who also had lung metastasis), LN metastasis (two patients), lung metastasis (three patients), and liver metastasis (one patient who also had LN metastasis). There were no significant differences in DSS between Group A and Group B+C (LST-NG). However, OS was 93% in Group A, which was significantly lower than that (96%) in Group B+C (p < 0.05). DFS in Group A was 90%, which was significantly lower than that (100%) in Group B+C (p < 0.05). The prognosis of patients with non-e-curable disease after ER alone showed no significant differences in OS, DFS, and DSS between Group A and Group B+C. The prognosis of patients with non-e-curable disease after surgical resection showed no significant differences in DFS or DSS. However, OS in Group A was 94%, which was significantly lower than that (97%) in Group B+C (p < 0.05).

Conclusion: Long-term outcomes supported the JSCCR criteria for e-curable patients after ER for T1 LSTs. All recurrences occurred in patients with T1 LST-G-M cancer. OS and DFS in the LST-G group were significantly shorter than in the LST-NG group.

Introduction: Cholangiocarcinoma and pancreatic adenocarcinoma account for over 190,000 new cases of pancreaticobiliary malignancy worldwide annually. For palliation of obstructive jaundice in these patients, plastic or self-expanding metal stent (SEMS) are placed. However, re-occlusion rates for currently available stents range as high as 36% for uncovered metal stents, 25% for covered metal stents and 52% for plastic stents. Tissue ingrowth accounts for up to 76% of occlusions of bare metal stents.1, 2, 3 Stent occlusion can result in recurrent obstruction and typically requires endoscopic re-intervention. Therefore there is a real clinical need to reduce tissue ingrowth and improve biliary stent patency rates.

Aims & Methods: In this study we developed and tested a controller-release paclitaxel-eluting SEMS designed to prevent tissue hyperplasia and stent occlusion. A polymer matrix was coated on a nitinol stent with paclitaxel (n = 3, no polymer), standard dose paclitaxel (n = 6, 149.4 µg/paclitaxel) and challenge dose (n = 3, 538.0 µg/paclitaxel). Two stents were endoscopically implanted in each swine from its assigned group, one in the intrahepatic/hilar region and a second in the common bile duct placed proximal to the papilla. Aims of the study was to test the correlation between stent occlusion depth and the rate of residual malignant disease in complete endoscopic mucosal resection (EMR) of malignant colonic sessile polyps. The secondary outcomes include risk factors such as: lymphovascular invasion, tumor budding, differentiation, resection margin status and the presence of tumor budding. A prospective review of the endoscopy charts for the period 2000-2016 was conducted. All patients enrolled exhibited a malignant colonic sessile polyp which was endoscopically completely resected. Histological findings of the polyps were also recorded. Thorough computed or magnetic scanning was performed in all patients before deciding on further management. All patients were advised for the option of surgical treatment or endoscopic follow-up.

Results: 51 patients with confirmed adenocarcinoma in sessile colonic polyps undergoing endoscopic mucosal resection (EMR) were retrospectively included in this study. A total of 33 (64.7%) patients underwent subsequent surgery after EMR, and 18 (35.3%) chose endoscopic follow up. The histological characterizations of these patients presented in Table 1. In Table 2, the patients that underwent surgical follow up and EMR plus Surgery. Factors Total (N = 51), n (%), n (N = 18), n (N = 33), n (%) Submucosal invasion ≤ 1 mm 44 (86.3) 2 (22.2) 64 (88.9) Submucosal invasion > 1 mm 7 (13.7) 4 (22.2) 0 (0) Resection margin status (mm) median (IQR; range) 1 (2, 0–7) 1 (1, 0–4) 0, 4 (1.55; 0–7)

Conclusion: Our data suggest that even in cases with submucosal invasion > 1 mm and the presence of other high-risk features (lymphovascular invasion, tumour budding), complete EMR in malignant colonic sessile polyps supported by the histological findings predicts for a good clinical outcome.

Aims & Methods: In this prospective study, we evaluated the overall survival (OS) of patients treated with chemotherapy and chemoradiation therapy group based on CD-DST. Moreover, we evaluated additional effects of EGFR (Cetuximab; Cmb, Panitumumab; Pmab) to FOLFOX/FOLFIRI using CD-DST. Between Mar. 2008 and Aug. 2016, we obtained tumor specimen from 131 CRC patients without preoperative chemotherapy. Informed consent for measurement of individual chemosensitivity was obtained from all patients in writing. Approval for the present study was obtained from the Tobu Chiki Hospital Institutional Review Board (No: 02.03.29. #1). The growth inhibition was determined by CD-DST. The criteria for complete response (CR) were as follows: FOLFOX; Cmb, Pmab, and FOLFIRI+Cmb. The incubation conditions were as follow: FOLFOX; 5-FU and I-HPH (6.0 and 3.0μg/ml, respectively) for 24h. FOLFIRI; 5-FU and SN-38 (6.0 and 0.2μg/ml, respectively) for 24h. FOLFOX+Cmb; Cmb 250μg/ml for 24h. Pmab; Pmab 200μg/ml for 144h. FOLFOX+Cmb; Cmb 250μg/ml for 120h after FOLFOX/FOLFIRI incubation process. The cumulative distribution of IR values under each condition was evaluated on the basis that the clinical response to the chemoradiation strategy (11/2014–11/2016) were evaluated. W&S

Introduction: The standard treatment for locally advanced low rectal adenocarcinoma (ADC) is to conduct surgical resection after neoadjuvant chemoradiotherapy (CRT). In our wait-and-see (W&S) strategy, those who achieve clinical complete response (cCR) after CRT undergo regular clinical, radiologic and endoscopic surveillance, with surgery being reserved for tumor “regrowth”. Aims & Methods: To evaluate the impact of a W&S strategy for low rectal ADC, regarding overall and disease-free survival. Single-center prospective observational study. All patients with low rectal (up to 6 cm from the anal verge) and then confirmed by the other surveillance methods. This patient underwent a R0 low anterior resection and there were no complications. There were no distant recurrences or deaths. In the subgroup of patients with cCR, pathologic complete response was observed in 20%; there was one lymphatic recurrence; the overall survival was 95.2%.

Conclusion: Preliminary results of our series confirm that the W&S strategy is associated with overall and disease-free survival not inferior to those of the traditional approach, favoring its implementation.

Introduction: A total of 1078 patients were colonoscopically followed-up during a long-term period in our hospital. They were divided into group A, B, or C as follows: 445 in group A (mean age 64.7 yr, M:F = 2.37:1); 31 patients with 34 high-grade adenomas or cancers in group A, 6.9% (17 with 17 in group B, and 12.3% (48 with 55) in group C, respectively. The prevalence of metachronous non-index lesion was lower in group C compared to that in group A (P < 0.007), and group B compared to that in group A (P < 0.007). The cumulative incidences of metachronous invasive cancer were 0.9% (4 patients with 4 invasive cancers) in group A, 1.2% (3 with 3) in group B, and 3.6% (14 with 14) in group C, disclosing highest prevalence in group C (p < 0.005). Logrank test revealed that the cumulative incidence of non-index lesion was highest in group C, and statistical significance were observed between group A and C (p < 0.01), and between group B and C (p < 0.001). Logrank test also revealed that the cumulative incidence of index lesion was highest in group C, but no significant differences were observed compared to those in group A and B. Conclusion: Significant higher prevalence of metachronous index lesion including invasive cancer and, in contrast, significant lower prevalence of metachronous non-index lesion were observed in patients after resection of colorectal cancer compared to those after endoscopic resections of colorectal adenoma and intramucosal cancer.

Introduction: A total of 1595 patients were colonoscopically followed-up during a long-term period in our hospital. They were divided into group A, B, and C as follows; 581 in group A (mean age 65.0 ± 8.9 yr, M:F = 411:170) with colorectal adenoma more than 5 mm in size resected at baseline, 495 in group B (65.2 ± 9.6 yr, 328:167) with diminutive polyps left untreated at baseline, and 519 in group C (62.5 ± 10.7 yr, 255:264) with no polyps at baseline. During follow-up colonoscopies detected metachronous neoplasms more than 5 mm in diameter were resected and pathologically evaluated into non-index lesion (low-grade adenoma) or index lesion (high-grade adenoma or cancer). The cumulative
incidences of metachronous colorectal neoplasms were compared with each other using Log Rank test.

Results: Median follow-up periods and frequencies of colonoscopy were 61.9 months and 3.6 times in group A, 61.6 months and 3.4 times in group B, and 72.3 months and 2.7 times in group C, respectively. The cumulative incidences of metachronous adenoma were 24.4% (102 patients with 375 low-grade adenomas) in group A, 14.7% (73 with 168) in group B, and 6.6% (34 with 56) in group C, respectively. The prevalence of metachronous non-index lesion was highest in group A followed by group B and C, and significant difference was observed between group A and C (P < 0.001), and B and C (P < 0.05). The cumulative incidences of metachronous invasive cancer were 1.0% (6 patients with 6 invasive cancers in group A), 1.4% (7 with 7) in group B, and 0.2% (1 with 1) in group C with no significant difference. Logrank test revealed that the cumulative incidence of non-index lesion was highest in group A, and statistical significances were observed between group A and B (P < 0.0001), and between group B and C (P < 0.0001). Logrank test also revealed that the cumulative incidence of index lesion was highest in group A, and statistical significances were observed between group A and B (P < 0.005), and between group B and C (P < 0.005).

Conclusion: The results of a longer colorectal follow-up disclosed a significantly higher prevalence of metachronous advanced neoplasms in patients with adenoma > 5 mm in size resected at baseline compared to those with diminutive polyps left untreated at baseline. Persons with no polyps at baseline were at very low risk of advanced neoplasia within five years during follow-up.

P0470 A NEW SCORING MODEL FOR PREDICTING ADVANCED COLORECTAL NEOPLASIA IN ASYMPTOMATIC SCREENING POPULATION AND COMPARISON WITH THE MODIFIED ASIA-PACIFIC COLORECTAL SCORING MODEL
M. Sekiguchi1, T. Matsuda2, Y. Kakugawa2, M. Matsumoto2, Y. Saito2
1Cancer Screening Center, National Cancer Center Hospital, Tokyo/Japan
2Endoscopy Division, National Cancer Center Hospital, Tokyo/Japan

Contact E-mail Address: maseki@ncc.go.jp

Introduction: Colorectal cancer (CRC) is still a major cause of death even in countries with a CRC screening program, indicating the need for improved screening methods. Risk-stratification of populations is one strategy that might satisfy this requirement. Currently, in the Asia-Pacific region, the use of the modified Asia-Pacific Colorectal Scoring (APCS) score [age ≥60: 2, male sex: 1, presence of a first-degree relative (FDR) with CRC: 1, current or past smoker: 1, body mass index (BMI) ≥23 kg/m²: 1] has been proposed for risk-stratification.2 However, further validation studies are required to appraise the model and considering the reported discriminatory capability of the score for advanced colorectal neoplasia (ACN), 4 the development of a more useful scoring model is expected.

Aims & Methods: The aim of this study was primarily to develop and validate a new scoring model for predicting ACN in asymptomatic screening populations that is more useful than the APCS score. We externally validated the APCS score in a Japanese screening population and compared its discriminatory capability with that of our new scoring model. Data were reviewed from 5218 consecutive asymptomatic screened individuals who underwent colonoscopy for their first time at the Cancer Screening Center, National Cancer Center Hospital, Tokyo between February 2004 and March 2013. Multivariate logistic regression was used to investigate the associations between clinical variables and the presence of ACN in the subjects, and then a new scoring model was developed based on these associations. Scores were weighted according to the beta coefficient obtained from the logistic regression model. Thereafter, the discriminatory capability of the new model was assessed using the c-statistics in the development set. Performance of the new model was internally validated using bootstrapping with 1000 replicates. The discriminatory capability of the modified APCS score in the 5218 subjects was also assessed using the c-statistics. The value obtained was compared with our new scoring model using the DeLong test. The c-statistics of the new score were significantly higher than those of the modified APCS score, both in the 5, 218 subjects (P = 0.03) and in 1, 000 bootstrapped replicates (P = 0.03).

Conclusion: An 8-point scoring model to predict ACN in asymptomatic screening population that might have a higher discriminatory capability than the modified APCS score was developed and internally validated in this study. Our simple scoring model could stratify the screened population into low-, moderate-, and high-risk groups. Of the detected ACN, a substantial number were proximal or flat; therefore, primary screening with total colonoscopy may be advisable for high-risk individuals.

P0471 ASSOCIATION BETWEEN PARAMETERS OF THE RECTAL INHIBITORY REFLEX AND THRESHOLD FOR FIRST RECTAL SENSATION ESTABLISHED BY HIGH-RESOLUTION ANORECTAL MANOMETRY (HRAM) AND ITS SIGNIFICANCE FOR FECAL INCONTINENCE DIAGNOSTICS
O. Storonova1, A. Trukhanov2, V. T. Ishashk1

Introduction: Previous studies have shown that increase of threshold for first rectal sensation can be a predictor of fecal incontinence. However, significance of the wide range of rectal inhibitory reflex (%RAIR) in development of this disease remains unknown.

Aims & Methods: To determine association between %RAIR and threshold for first rectal sensation in healthy adults and its significance in development of fecal incontinence. 26 asymptomatic healthy volunteers (18 women, 8 men) median age was 35.03 years (19–59) were studied. We performed them a high-resolution anorectal manometry (HRAM) using a 20 channels silicone water-perfused catheter (Solar GI, MMS, Netherlands). The following HRAM parameters were analyzed: threshold for RAIR and %RAIR (automatically calculated as the ratio of the amplitude of the relaxation of the anal sphincter (AS) to the basal pressure AS *100%), threshold for first rectal sensation (RS) and for desire to defecate. The statistical analyses were performed using Statistica for Windows 6.0 (StatSoft Inc.).

Results: Threshold for RAIR and %RAIR were 22.3 ml(10.0; 30.0), 74.4% (38–99.5) respectively. Threshold for first RS was 30.0 ml(11.1; 58.3) and desire to defecate was 65.12 ml (33.5; 182.6). Threshold for RAIR was not associated with threshold for first RS (r = 0.07) and for desire to defecate (r = 0.02). %RAIR was weak positively correlated with threshold for first RS (r = 0.26) and was not associated with threshold for desire to defecate (r = −0.03).

Conclusion: Threshold for RAIR and %RAIR are not associated with first rectal sensation. So, these parameters of RAIR cannot be predictors of fecal incontinence.

Introduction: Trait neuroticism and the DeLong scoring model to predict ACN was developed and its capability of the score for advanced colorectal neoplasia (ACN), 4 the development of a more useful scoring model is expected.

Aims & Methods: The aim of this study was primarily to develop and validate a new scoring model for predicting ACN in asymptomatic screening populations that is more useful than the APCS score. We externally validated the APCS score in a Japanese screening population and compared its discriminatory capability with that of our new scoring model. Data were reviewed from 5218 consecutive asymptomatic screened individuals who underwent colonoscopy for their first time at the Cancer Screening Center, National Cancer Center Hospital, Tokyo between February 2004 and March 2013. Multivariate logistic regression was used to investigate the associations between clinical variables and the presence of ACN in the subjects, and then a new scoring model was developed based on these associations. Scores were weighted according to the beta coefficient obtained from the logistic regression model. Thereafter, the discriminatory capability of the new model was assessed using the c-statistics in the development set. Performance of the new model was internally validated using bootstrapping with 1000 replicates. The discriminatory capability of the modified APCS score in the 5218 subjects was also assessed using the c-statistics. The value obtained was compared with our new scoring model using the DeLong test. The c-statistics of the new score were significantly higher than those of the modified APCS score, both in the 5, 218 subjects (P = 0.03) and in 1, 000 bootstrapped replicates (P = 0.03).

Conclusion: An 8-point scoring model to predict ACN in asymptomatic screening population that might have a higher discriminatory capability than the modified APCS score was developed and internally validated in this study. Our simple scoring model could stratify the screened population into low-, moderate-, and high-risk groups. Of the detected ACN, a substantial number were proximal or flat; therefore, primary screening with total colonoscopy may be advisable for high-risk individuals.

predict that somatisation has deleterious consequences for GI conditions - possibly because it encourages reduced physical activity (7).

Aims & Methods: In Study 1, 147 undergraduate students completed measures of neuroticism, 14 coping styles (including avoidant styles such as denial and disengagement), somatisation and GI symptom burden. In Study 2, where participants were undergraduates and hospital outpatients (pooled N = 250), the variables investigated in Study 1 were measured alongside hypochondriasis, which was included to measure the aspect of somatisation that involves worry independently of any actual physical symptoms. Statistical analysis was based on path modeling. It involved fitting a model to test a priori hypothesised indirect relationships between neuroticism and GI symptom severity via the selected coping styles and somatisation. Direct effects were also estimated, meaning that the path analysis provided information regarding the significance of any indirect effects once a range of direct effects were accounted for. Only six coping styles found to correlate with both neuroticism and GI symptom severity were included (see Results table). Coping styles were assumed to covary, and the model in Study 2 assumed a covariance relationship between somatisation and hypochondriasis.

Conclusion: Studies 1 and 2 provide new evidence that somatisation and hypochondriasis are predictive of GI symptom burden via coping. These findings open new avenues for multidisciplinary treatment of functional gastrointestinal disease. These include (1) increasing physical activity, which can interfere with digestion; and (2) GI symptoms are affected through denial-based coping and somatisation, as opposed to disengagement-based coping and somatisation. In Study 2, neuroticism was found to affect GI symptom burden through denial-based coping and somatisation, as well as disengagement-based coping and somatisation. Two interpretations of the findings are (1) avoidance coping can stimulate somatisation, leading to reduced physical activity, which can interfere with digestion; and (2) GI symptoms are among the wide range of functional somatic symptoms that can arise from avoidant coping. These findings open new avenues for multidisciplinary treatment of FGIDs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Diarrhea-predominant irritable bowel syndrome (D-IBS) is a chronic functional gastrointestinal disease. Its clinical manifestations are characterized by diarrhea and abdominal pain or discomfort in the absence of demonstrable pathology. The diagnosis of D-IBS is based on symptom assessment and the Rome III Diagnostic Criteria. According to an epidemiological study, D-IBS mainly affects young adults of 20–40 years old, and the quality of their lives is seriously affected. The pathogenesis of D-IBS has not been fully clarified. Consequently, the usual treatment of the disease in Western medicine involves symptomatic therapy, which is unsatisfactory for patients while simultaneously increasing the use of health-care resources. Because traditional Chinese medicine (TCM) can significantly improve patients' symptoms and quality of life, increasing numbers of patients have begun to seek treatment with TCM. A series of randomized, double-blind, placebo-controlled trials showed that TongXie-YaoFang(TXYF) formula can significantly improve the clinical symptoms, such as diarrhea and abdominal pain or discomfort, of patients with IBS and improve the quality of their lives. However, the specific mechanism of it has not been completely elaborated. The purpose of this paper is to observe the regulating effects of TXYF-formula on colonic epithelial secretion via relevant ion channels, such as cystic fibrosis transmembrane conductance regulator (CFTR) Cl– channel, epithelial Na+ channel (ENaC), Cx26-dependent CI channel (CACC), Na+/K+–2Cl– co-transporter (NKCC), and Na+/HCO3– co-transporter (NBC), in the colonic epithelium of three groups after exposure to different agents.

Aims & Methods: To investigate the pharmacological effect of TongXie-YaoFang(TXYF) formula, a Chinese herbal formula, on Diarrhea-predominant irritable bowel syndrome (D-IBS) rats. In a neonatal maternal sham-control group (SH), neonatal rats were given distilled water. Using short-circuit current technology, we observed 5-HT-induced changes of current across ion channels, such as cystic fibrosis transmembrane conductance regulator (CFTR) Cl– channel, epithelial Na+ channel (ENaC), Cx26-dependent Cl channel (CACC), Na+/K+–2Cl– co-transporter (NKCC), and Na+/HCO3– co-transporter (NBC), in the colonic epithelium of three groups after exposure to different agents.

Results: Under basal conditions, the changes of short-circuit current (DCl, mA/cm2) induced by 5-HT were similar in SH group and TXYF-formula group, and both higher than NMS group (SH: 7.99mA/cm2, 10.61mA/cm2 VS 51.48mA/cm2; TXYF: 8.99mA/cm2, 11.68mA/cm2 VS 38.8mA/cm2, P < 0.01, respectively). However, when CFTR Cl– channel was blocked by ChRM, 5-HT-induced DCl was smaller in NMS group than in SH group and TXYF-formula group (NS). Starting from postnatal day 60, rats were randomly divided into two groups (NMS and TXYF-formula group) with no handlings were used as controls (NH group). Starting from postnatal day 65, rats were used as controls. Under basal conditions, the changes of short-circuit current (DCl, mA/cm2) induced by 5-HT were similar in NH and SH group and TXYF-formula group, and both higher than NMS group (SH: 11.7mA/cm2, 11.68mA/cm2 VS 38.8mA/cm2, P < 0.01, respectively). However, when CFTR Cl– channel was blocked by ChRM, 5-HT-induced DCl was smaller in NMS group than in SH group (P < 0.05, respectively). The similar result could also be observed in other groups (P < 0.05, respectively). The similar results could also be obtained in three groups when NB and NKCC were respectively blocked by their blockers. Contact: TXY-formula can regulate the CI and HCO3– secretion of colonic mucosa via CFTR Cl– channel, CI/HCO3– exchanger, NBC and NKCC co-transporters.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The aims of the present study were to evaluate the effect of diosmectite on gut transit time and visceral hypersensitivity induced by WAS in rats. Two groups of rats were used: a control group and a group that underwent WAS. Visceral hypersensitivity was then assessed in both groups using the colorectal distension (CRD) test.

Results: The results showed that WAS significantly increased the number of abdominal contractions in the rat model used. Chronic oral treatment with diosmectite significantly decreased the number of abdominal contractions in rats treated with WAS.

Conclusion: The results suggest that diosmectite is effective in reducing visceral hypersensitivity and may have potential therapeutic applications in the treatment of functional bowel disorders.
Results: Twenty-seven patients completed the study. DA-9701 was associated with a significantly reduced CTT: from 14.0±8.2 to 7.5±7.4 hours, \( P = 0.001 \). Segmental CTT also significantly decreased after treatment (right CTT: from 14.2±11.9 to 9.5±10.9 hours, \( P = 0.021 \)). In addition, all constipation-related symptoms, including SBM frequency, significantly improved compared to those before treatment. Serious adverse events did not occur.

Conclusion: DA-9701 accelerates colonic transit and safely improves symptoms in patients with functional constipation. Therefore, we suggest that this novel agent could help to treat patients with this condition.

P0483 INDEPENDENT VALIDATION OF THE ROME IV CRITERIA FOR IRRITABLE BOWEL SYNDROME REVEALS THEIR MODEST PERFORMANCE AND RESTRICTIVE NATURE

O. Craig, C. Black*, L. Houghton*, A.C. Ford†
*Leeds Gastroenterology Institute, St. James’s University Hospital, Leeds/United Kingdom
†Leeds Institute Of Biomedical & Clinical Sciences, St. James’s University Hospital, Leeds/United Kingdom

Contact E-mail Address: ofcraig@gmail.com

Introduction: Previous symptom-based criteria to diagnose irritable bowel syndrome (IBS) performed only modestly. The Rome IV criteria are the current symptom-based criteria for IBS. Epidemiological surveys associated symptoms required for a diagnosis of IBS. Upon practical evaluation of the Rome IV diagnostic questionnaire, the Patient Health Questionnaire (PHQ-12), and the 8-item Short Form (SF-8) quality of life (QOL) questionnaire, health care utilization and past gastrointestinal (GI) disease diagnoses by doctors. Respondents with an organic GI disease were excluded from the IBS population. IBS consulters were defined as individuals meeting Rome IV IBS criteria who had visited a doctor for GI symptoms.

Results: 6300 individuals completed the survey, 369 were excluded due to inconsistent responses, leaving 5931 (49.2% female; mean age 47.4±17.1 years) to be included for analysis (1994 US, 1994 UK, 1988 Canada). After excluding 36 individuals due to lower GI organic disease, 305 subjects (5.1%; 66% female; mean age 44.7±14.5 years) fulfilled diagnostic criteria for IBS. From these, 195 (64%) had consulted a doctor for GI problems. IBS consulters had equal sex distribution (63.6% vs. 69% female (p = 0.4) and somatization scores (0.01) compared to non-consulters, but were older (mean age 47.1±14.8 vs. 40.5±13.1 years), more concerned about their bowel function (p < 0.001), more frequently bloated (p = 0.001), and experienced greater impact on social activities (p = 0.008). The distribution of the most bothersome symptom was similar (p = 0.38), and abdominal pain was the predominant symptom in both groups. See table for details. The frequency of doctor visits for non-GI health issues did not differ (p = 0.15), but IBS consulters had undergone more abdominal surgery (p = 0.04). IBS consulters also reported higher consumption of GI related (p < 0.001), prescribed pain (p < 0.001), and anti-depressive medications (p = 0.03), but had similar consumption of anxiety (p = 0.11) and over the counter pain medications (p = 0.34) as non-consulters. See table for details.

(continued)
FUNCTIONAL GASTROINTESTINAL DISORDERS

Irritable bowel syndrome (IBS) affects 5–15% of adults in the general population. IBS is common worldwide. In UK it exceeds the 20% of the population. Burden of Irritable Bowel Syndrome (IBS) on UK healthcare has been estimated around 1800Eur per patient per year. NIC E guideline provides a systematic approach to symptoms and therapies available to GPs and general gastroenterologists. This creates a good asset to minimize referrals to tertiary centres and address costs.

Aims & Methods: We retrospectively reviewed, via electronic records, all the patients seen at the Scottish Gut Motility Disorder Clinic between January and December 2016 included, focusing on original referral, diagnosis and treatment to evaluate the need for specialist input.

Results: In 2016, 378 patients attended the Motility Clinic; total of 495 visits; 333 females. Mean age was 51.4 (age range: 16 to 95 years). 60% of referrals originated via secondary care (40% GI, 50% Surgery, 10% other disciplines). The commonest reason for referral was IBS (40%); IBS-Constipation (58%); IBS-Diarrhoea (21%) or IBS-MixType (21%). 16% were referred with faecal incontinence and 37% with chronic constipation. 35% of patients didn’t receive any therapy at time of referral. 44% were prescribed treatment but not followed up for assessment of successful response to therapy prior to referral to the specialist clinic. In 28% of patients the diagnosis changed following Motility clinic assessment. Diagnosis at clinic based on RomeIII questionnaire, depression and anxiety score, thorough history taking and physical examination (including per rectum exam), ad hoc psychiatry input and referral to specialist investigation. In 30% of patients referred with chronic constipation the diagnosis was changed to IBS-Constipation. 8% changed from IBS-D to IBS-M, 8% referred with faecal incontinence had Obstructive Defecation Syndrome, 6% referred as IBS-M were diagnosed with IBS-C, 5% referred as IBS-D were diagnosed as IBS-M, 3% referred with IBS-D had bile acid malabsorption. 56% of patients underwent specialist investigations including unrectal physiology (70%), 33% of patients attending the Specialist clinic received 1st-line therapy and lifestyle advice, albeit 57% of them, who received 2nd-line treatment, having failed 1st-line management.

Conclusion: The above data indicate the need for education and expansion of resources available in primary care to optimise patients’ management. Furthermore, it highlights the necessity for the introduction of a formal Neurogastroenterology curriculum in the general Gastroenterology training.

A334 United European Gastroenterology Journal 5(5S)
Aims & Methods: The aim of this study was to compare the expression of membrane transporters in microsomal biopsies of healthy subjects, IBS patients and post-infectious (PI)-IBS patients. Memocaul biopsies were obtained from the unprepared sigmoid colon in 18 IBS patients, 9 PI-IBS patients and 10 healthy subjects. Total RNA was isolated and prepared for gene expression analyses using quantitative reverse-transcription polymerase chain reaction (qRT-PCR). We compared the expression of genes encoding membrane-spanning transporters, using GAPDH as a reference gene, and by using the comparative 2^-△△CT method.

Results: Colonic expression of SLC7A5 and SLC3A2 (together comprising the amino acid transporter LAT1 + 4F2hc) was significantly lower in IBS patients, but not in PI-IBS patients, compared to healthy controls (P < 0.001). The expression of SLC7A8 (LAT2) tended to be lower in IBS patients compared to controls (P = 0.08). Mucosal gene expression of the short chain fatty acid transporter SMCT1 (SLC5A8) was lower in both IBS-patients and PI-IBS patients compared to healthy subjects (P < 0.01).

Conclusion: The amino acid transporters LAT1 and LAT2 appeared to be affected in IBS patients, but not in PI-IBS patients, compared to healthy subjects, suggesting a possible alteration in amino acids transport in this patient group. Furthermore, our results suggest a lower uptake of short chain fatty acids in both IBS- and PI-IBS patients. Altered expression of these transporters may be involved in the pathophysiology of IBS as well as being a potential biomarker of this aberration, and therefore deserves further study in IBS.

P0408 DIVERTICULITIS IN THE SIGMID COLON HAS THE HIGHEST RISK FOR INTESTINAL COMPLICATION OF COLONIC DIVERTICULITIS IN JAPANESE PATIENTS

Gastroenterology And Hepatology, Karlshci Central Hospital, Karlshci/Japan

Contact E-mail Address: h7.takayama@gmail.com

Introduction: Most colonic diverticulitis can be conservatively treated, but some need surgical intervention due to intestinal complications. Risk factors associated with complications of diverticulitis have been reported mainly from Western countries, but few from Asian countries including Japan.

Methods: Two hundreds and eighty-two patients with acute diverticulitis who were hospitalized from November 2011 to November 2016 in our hospital were studied. Diagnosis of diverticulitis was based on symptoms, physical examination, blood tests, and results of computed tomography. We retrospectively collected data of medical histories, examinations, and therapy. Risk factors associated with complications were analyzed by using logistic regression.

Results: Of the 282 patients, 183 (64.9%) patients had right-sided diverticulitis, and 70 (24%) had complications; perforation (n = 4), fistula (n = 8), abscess (n = 5) and stenosis (n = 4). The rate of complication was highest in sigmoid colon (88.6%) when compared with other locations; ascending colon (10%), transverse colon (1.4%), and descending colon (0%). Multivariate analysis identified the location of sigmoid colon (odds ratio 62.2, 95% confidence interval 21.8–178.0) as a significant independent factor for complications of diverticulitis. Among 70 patients with complicated diverticulitis, 55 (78.6%) patients underwent emergent surgery; most of them (54 patients, 98.2%) were with diverticulitis in the sigmoid colon. Risk factors associated with complications of colonic diverticulitis (univariate and multivariate analysis).

Aims & Methods: The aim of our present study was to determine the role of genetic variation within genes encoding for collagen of the connective tissue in the development of diverticulitis. Genetic polymorphisms COL3A1 (rs3134464, rs1800255) and COL1A1 (rs1800012) were genotyped in 422 patients with diverticulitis and 285 controls of Caucasian descent using TaqMan assays.

Results: All genotype distributions did not deviate from the Hardy-Weinberg equilibrium. Overall, rs3134464, rs1800255 and rs1800012 were associated with diverticulitis. After multivariate logistic regression analysis, they were not linked with the risk of developing colonic diverticulitis in general; when selectively analyzing genders, the minor allele (AA) in rs3134464 remained significantly associated with diverticulitis in men (p = 0.037).

Conclusion: Our study shows that a variant of COL3A1 rs3134464 is associated with risk of developing colonic diverticulitis in Caucasian men, while COL3A1 rs1800255 and COL1A1 rs1800012 were not associated with this condition in our cohort of patients after adjusting for confounding factors.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colonic diverticulitis is one of the most common gastroenterological disorders. Though diverticulitis is typically benign, many individuals develop diverticular disease (DD). DD is thought to stem from a complex interplay of environmental, dietary and genetic factors; however, the exact pathogenesis remains unknown.

Aims & Methods: The aim of our present study was to determine the role of genetic variation within genes encoding for collagens of the connective tissue in the development of diverticulitis. Genetic polymorphisms COL3A1 (rs3134464, rs1800255) and COL1A1 (rs1800012) were genotyped in 422 patients with diverticulitis and 285 controls of Caucasian descent using TaqMan assays.

Results: All genotype distributions did not deviate from the Hardy-Weinberg equilibrium. Overall, rs3134464, rs1800255 and rs1800012 were associated with diverticulitis. After multivariate logistic regression analysis, they were not linked with the risk of developing colonic diverticulitis in general; when selectively analyzing genders, the minor allele (AA) in rs3134464 remained significantly associated with diverticulitis in men (p = 0.037).

Conclusion: Our study shows that a variant of COL3A1 rs3134464 is associated with risk of developing colonic diverticulitis in Caucasian men, while COL3A1 rs1800255 and COL1A1 rs1800012 were not associated with this condition in our cohort of patients after adjusting for confounding factors.

Introduction: Symptomatic Uncomplicated Diverticular Disease (SUDD) affects about 20% of patients having diverticulosis. However, SUDD natural history is still not completely understood yet. Our aim was to assess the outcome of a cohort of SUDD patients during a 13-year follow-up.

Aims & Methods: 185 patients suffering from SUDD were enrolled during 2000–2002, and followed-up until 2015. Symptoms assessed were abdominal pain, meteorism, bowel movement/day, and each of them was scored from 0 (min) to 12 (max). Also Visual Analogic Scale (VAS) was provided in order to assess patients’ quality of life. Patients were treated according to physician convenience (rifaximin, mesalazine, probiotics, spasmolytics) when symptoms occurred during the follow-up. Follow-up visit was performed every 6 months or whenever patients consider it necessary.

Results: During the observational period, 47 patients were lost to follow-up. Among them, 9 deceased for causes not related to diverticular disease. Acute diverticulitis occurred in 14 patients (7.56% of the overall population); 6 patients (3.24% of the overall population) underwent to surgery, and 2 patients (1.08% of the overall population) deceased for perforation. The mean symptoms’ score was 7.5 at baseline, ranged between 6.6 and 9 during the follow-up, and was 8.4 at the end of the observation. VAS score was 4 at baseline, ranged between 4 and 9 during the follow-up, and was 4.5 at the end of observation.

Conclusion: SUDD is a clinical entity that, although benign, significantly affects quality of life of patients. Acute diverticulitis may occur in those patients, sometimes needs of surgical treatment, and may cause mortal complications, although not frequent.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Natural history of colonic diverticulosis and diverticular disease (DD) is poorly known, and available data derived mostly from retrospective cohort studies.
Aims & Methods: Aim of this study was to assess, in a cohort of patients with colorectal diverticula, the incidence of new cases of symptomatic uncomplicated diverticular disease (SUDD) and diverticulitis, and recurrence of diverticulitis after 1-year of follow-up. GRIMAD (Italian Diverticular Disease Group) promoted the creation of REMAD (Register of Diverticular Disease) a prospective, 5-years, no-profit, cohort study involving 47 Italian centers. Each center enrolled at least 20 consecutive patients during a period of two months. Inclusion criteria were: informed consent; age ≥18 years and endoscopic/radiological-confirmed colonic diverticula. Outpatient/telephone visits were scheduled every 6 months. The clinical data (patients’ characteristics and habits, characteristics of DD, complications and therapies) collected by participating centers were reported on an electronic Case Report Form managed by CD Pharma, Milan. At entry, patients were categorized according to the following criteria: i) diverticulosis (presence of diverticula in the absence of abdominal symptoms); iii) SUDD (recurrent abdominal symptoms as abdominal pain and/or changes in bowel habit, in the absence of overt inflammation); iii) PD (patients who experienced at least one episode of acute diverticulitis in the past). Patients were allowed to continue their therapy for DD, if any. Logistic regression was performed to identify patients’ features associated with new occurrence of SUDD and diverticulitis.

Results: Overall, at baseline 1217 (55.7% female, median years 67 (28–95), BMI 25.6 kg/m² (16.2–43.4) patients were enrolled: 707 (58.1%), 300 (24.7%), and 210 (17.3%) with diverticulosis, SUDD, and PD, respectively. At 12 months, 922 patients (53.1%, 29.8%, and 17.1% with diverticulosis, SUDD, and PD) were followed, and 27.4% of patients were lost at follow-up. In the 12 months follow-up, 33 (6%) and 4 (0.7%) of diverticulosis patients developed SUDD and acute diverticulitis, respectively; 4 (1.6%) of SUDD patients developed acute diverticulitis, and in 14 (9.4%) of PD patients a new episode of acute diverticulitis occurred. Overall, only 3 patients developed a complication, without need of surgery. One year of follow-up logistic regression, showed that only female gender was associated with subjects who changed subgroup from diverticulosis to SUDD (OR 2.26, 95% CI 0.97–5.22). No specific features associated with recurrence of diverticulitis could be identified.

Conclusion: These preliminary data suggested that, during an observation period of one year, progression from diverticulosis to SUDD occurred in less than a tenth of patients, and was associated with female gender. Overall incidence of diverticulitis (2.3%), whereas overall SUDD incidence was uncommon. This observational study suggested, that although the vast majority of patients did not show progression of disease, in those who progressed one in ten tended to relapse during follow-up.

Aim of this study was to assess, in a cohort of patients with colorectal diverticula, the clinical features and QoL scores associated with each subgroup of patients. GRIMAD (Italian Diverticular Disease Group) promoted the creation of REMAD (Register of Diverticular Disease) a prospective, 5-years, no-profit, cohort study involving 47 Italian centers. At entry, patients were categorized according to the following criteria: i) diverticulosis (presence of diverticula in the absence of abdominal symptoms); ii) SUDD (recurrent abdominal symptoms as abdominal pain and/or changes in bowel habit, in the absence of overt inflammation); iii) PD (patients who experienced at least one episode of acute diverticulitis in the past). Patients were allowed to continue their therapy for DD, if any. Logistic regression was performed to identify patients’ features associated with new occurrence of SUDD and diverticulitis.

Conclusion: These data showed that, with respect to diverticulosis, female gender and presence of GI comorbidities are associated with SUDD, whereas younger age, family history for DD and female gender are associated with PD. Furthermore, patients with diverticulitis have higher physical and mental scores compared both to patients with SUDD and PD, suggesting that SUDD and PD reduced QoL of the affected patients.

Introduction: Patients with symptomatic uncomplicated diverticular disease (SUDD) and those with diverticulitis share similar clinical patterns characterized by abdominal pain or changes of bowel habits. In clinical practice, differential diagnosis between the two conditions may be useful in the diagnostic approach and therapeutic management.

Aims & Methods: Our aim was to assess the features of abdominal pain in patients with SUDD and diverticulitis. P0494 (Clinical Features associated with Symptomatic Uncomplicated Diverticular Disease and Diverticulitis: Patients’ Results from the Italian Register of Diverticular Disease [REMA]) and P0495 (Features of Abdominal Pain May Distinguish Patients with Previous Diverticulitis from Patients with Symptomatic Uncomplicated Diverticular Disease: Results from the Italian Register of Diverticular Disease [REMA]) allowed the creation of REMAD (Registry of Diverticular Disease), a prospective, 5-years, no-profit, cohort study involving 47 Italian centers. All patients were enrolled during a 2-months-period. At entry, patients were categorized according to the following criteria: i) diverticulosis (presence of diverticula in the absence of abdominal symptoms); ii) SUDD (recurrent abdominal symptoms as abdominal pain and/or changes in bowel habit, in the absence of overt inflammation); iii) PD (patients who experienced at least one episode of acute diverticulitis in the past). Patients were allowed to continue their therapy for DD, if any. Logistic regression was performed to identify patients’ features associated with new occurrence of SUDD and diverticulitis.

Introduction: Diverticulitis, as well as diverticular disease, is a multifactorial disorder characterized by neural-muscular alterations. Smooth muscle cells (SMC) of the muscular layer can switch from a contractile phenotype to a more synthetic phenotype, characterized by a loss of differentiation with increased expression of contractile markers as well as synthesis and release of several pro-inflammatory cytokines. Different organ specific pathways have been demonstrated to induce this mesenchymal transition. Renal fibrosis is driven by transforming growth factor-β (TGF-β) through inverse regulation of Smad2/3 while vascular fibrosis by PDGFRβ, ending in downregulation of marker gene Trb3 expression.

Aims & Methods: Aim of this study was to determine, both in human uninvolved and involved tracts of asymptomatic diverticulitis (AD−, AD+) and in stenotic segments, whether muscular alterations are more frequent in complicated diverticular disease related to the alterations intrinsic to smooth muscle. Circular and longitudinal smooth muscle strips and cells (SMC) were isolated separately from surgical colon specimen of 18 patients (58±13 years old) affected either by sigmoid AD (6) or CDD (6) and patients (61±18 years) submitted to surgery for cancer (6) (CTR). Contraction was tested in response to carbachol and relaxation in response to VIP. qPCR analysis, expressed as Relative Quantification, was performed for transcription of mRNA encoding for TGF-β, alpha-smooth muscle actin (α-SMA), smooth muscle actin-2 (β-SMA), Trb3, Sma2d,2 (MHC-I-L), and for SMC phenotypic switch molecules (Collagen I, Smad2/3). Data were normalized to β-actin mRNA and expressed as mean ± SE. In addition, the activation of inflammatory complexes was indirectly tested through quantification of IL-1β secretion by commercial ELISA kit.

Results: In both muscle layers, AD− and AD+ SMC, compared to CTR, showed an overall increase in inflammatory gene expression, with a trend of decrease from AD− to AD+, the lowest expression been observed in CDD. This inflammation was associated with an increased expression in IL-1β secretion in sigmoid colon muscle compared to CTR and a progressive inhibition of contraction to carbachol, already in AD− in circular strips and SMC. In contrast relaxation in response to VIP resulted significantly decreased only in AD+ both on strips and SMC with no alteration in circular and longitudinal. Peculiarity of circular SMC was a progressive increase in Coll1 expression from AD to CDD compared to CTR (3 hundred fold increase) parallel to about 50% decrease in the contractile protein α-SMA. Differentley, longitudinal SMC, both in AD and CDD, presented a homogenous increased Coll1 expression, decrease in α-SMA and reduction of contraction. VIP-induced relaxation was significantly decreased in CDD. Phenotypic switch was only observed in CDD, driven in circular layer, by a TGF-β-dependent pathway (increased expression for TGF-β: 2.8±1.0 and SMC produced Smad2/3 protein at 0.012±0.04), while longitudinal driven by PDGFRβ-dependent pathway (increase of PDGFRβ: 2.27±0.44 and parallel decrease of Trb3: 0.58±0.13).

Conclusion: Intrinsinc myogenic alterations are present in colonic asymptomatic diverticulosis and complicated diverticular disease, both in the circular and longitudinal layers characterized by a myogenic pro-inflammatory state and an impaired contractile activity that, in complicated diverticular disease, ended in a muscular synthetic pro-fibrotic switch.

Introduction: Aberrant Notch activation has been implicated in multiple malignancies, including gastric cancer (GC). However, the clinical significance of Notch receptors and their functional role in gastric carcinogenesis remain unclear.

Aims & Methods: We aim to delineate the dysregulated Notch signaling in GC and comprehensively reveal its activation by silenced microRNAs (miRNAs) in gastric carcinogenesis. The expression clinical relevance of NOTCH4 in GC patients were achieved from online available dataset. The mRNA and protein expression of NOTCH3 was examined by qRT-PCR and Western blot. The biological function of NOTCH3 in GC was demonstrated by MTT proliferation, monolayer colony formation, cell invasion and migration assays through siRNA-mediated knockdown. The prediction of miRNAs which potentially target NOTCH3 was performed by www.microrna.org and TargetScan. The regulation of NOTCH3 by putative miRNAs was confirmed by qRT-PCR, Western blot and dual luciferase activity assays. The expression of miR-491-5p and miR-875-5p overexpression in GC was determined by qRT-PCR.

Results: NOTCH3, but not NOTCH1, 2, 4, is uniformly up-regulated and significantly correlated with poor survival in multiple GC datasets. Knockdown of NOTCH3 in AGS and MKN28 cells exhibited significant anti-oncogenic effect in vitro. NOTCH3 downregulation suppressed cell proliferation, reduced monolayer colony formation, and inhibited cell invasion ability. Moreover, NOTCH3 knockdown significantly promoted cleaved caspase-3 and cleaved-PARP expression to induce apoptosis, which was further revealed by the gene set enrichment analysis (NCBI/GEO/GSE57303 and NCBI/GEO/GSE57303 database). NOTCH3 was further confirmed to be a direct target of tumor-suppressive miRNAs, miR-491-5p and miR-875-5p. Enforced overexpression of miR-491-5p and miR-875-5p in GC cells also exerted tumor-suppressive function by inhibiting cell proliferation and inducing apoptosis.

Conclusion: NOTCH3 is over-expressed and plays an oncogenic role in gastric carcinogenesis through its direct downstream PHLDB2. The activation of NOTCH3 in GC is partly due to the silence of tumor-suppressive miRNAs, miR-491-5p and miR-875-5p. These findings comprehensively revealed the activation of Notch signaling pathway and provided clinical translational potential for GC.

Introduction: We found that tumor suppressor gene FOXP2 was silenced in gastric cancer (GC) through promoter hypermethylation. Restoration of FOXP2 suppressed GC tumorigenicity through inhibition of canonical Wnt
signaling pathway. However, the molecular mechanism of FOXF2 in GC is still unknown.

Aims & Methods: We hypothesize that FOXF2 transcriptional upregulates a novel 3′ ligase that targets β-catenin for degradation. We aim to investigate the molecular mechanism of FOXF2 in GC and identify such 3′ ligase by PCR array, Chromatin Immunoprecipitation (ChIP) assay and luciferase assay. Results: FOXF2 significantly decreased both nuclear and cytosolic levels of β-catenin in a GSK-3β independent manner and promoted β-catenin degradation via ubiquitin-proteasome pathway in gastric cells. Using Human Ubiquitin Library RT™ Profiler PCR Array and western blot, we identified that IRF2BPL was upregulated upon FOXF2 overexpression and was a promising 3′ ligase for β-catenin. Overexpression of IRF2BPL suppressed the TOP-flash luciferase reporter and reduced Wnt target gene c-myc expression in GC cells. Overexpression of IRF2BPL significantly increased β-catenin ubiquitination and reduced β-catenin protein without alteration of its mRNA level. Conversely, knockdown of IRF2BPL significantly decreased endogenous β-catenin ubiquitination. Immunoprecipitation assay suggested that IRF2BPL interacted with β-catenin. The 3′ ligase IRF2BPL is a potential 3′ ligase that targets β-catenin for degradation. To investigate whether FOXF2 directly regulates IRF2BPL transcription, we performed ChIP assay and found that FOXF2 bound on to the IRF2BPL promoter region. We cloned the IRF2BPL promoter region (−2700 bp to TSS) and performed a luciferase activity assay. Wild-type FOXF2 but not the mutant ΔFOXF2 significantly activated the lucerase reporter in A549 and 293F cells, suggesting that FOXF2 directly activated IRF2BPL transcription. Moreover, FOXF2 significantly increased the level of H2K72Ac (a marker to distinguish active from inactive enhancer element) on the 5′-flanking region of IRF2BPL gene, suggesting that FOXF2 positively regulated IRF2BPL gene transcription. In addition, IRF2BPL mRNA was downregulated in human GC tissues compared to the adjacent normal tissues (N = 30, P < 0.01) by real-time PCR analysis. IRF2BPL mRNA showed a positive correlation with FOXF2 in gastric cancer in a Chinese cohort (R = 0.30, Spearman’s rho = 0.42, P = 0.05) and in the TCGA cohort (R = 0.38, P < 0.001).

Conclusion: We reported a novel FOXF2-IRF2BPL-β-catenin signaling axis in gastric cells. FOXF2 is a critical tumor suppressor in gastric carcinogenesis through promoting β-catenin degradation by transcriptionally upregulating 3′ ligase IRF2BPL.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: GAED shows generally aggressive behavior characterized by frequent lymphatic and venous invasion and liver metastasis. TP53 mutation rate and ERBB2 amplification rate in GAED is significantly higher than those of CGA. HER2 overexpression associated with ERBB2 amplification could be a new therapeutic target in GAED.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Ten percent of all gastric cancers show familial aggregation and were for at least three syndromes:1-7 hereditary diffuse gastric cancer (HDGC), gastric adenocarcinoma and proximal polypsis of the stomach (GAPPs), and familial intestinal gastric cancer (FICG).2 Whilst germline defects at the CDH11 and APC genes have been found for HDGC and GAPPs families, respectively, FICG remains genetically unexplained.

Aims & Methods: We hypothesised that the rare FICG syndrome is caused by germline co-occurrence of moderate-risk alleles and represents a polygenic, rather than a classical monogenic disease. Therefore, this study aimed at dissecting the germline and somatic landscapes of the largest FICG cohort ever studied.

All authors have declared no conflicts of interest.

Conclusion: The clinical homogeneity and relatively high number of FICG families herein allowed studying the hypothesis that FICG may be a new polygenic syndrome caused by moderate-risk alleles in gastrointestinal cancer-associated genes.

Introduction: Gastric adenocarcinoma with enteroblastic differentiation (GAED) is a rare variant of gastric carcinoma. It is well known that GAED is associated with poor prognosis [1, 2]. However, the clinicopathological and molecular biological features of GAED have been elucidated through. We performed comprehensive analysis by next generation sequencing (NGS) to clarify the clinicopathological features of GAED and to find new therapeutic targets.

Among 5300 patients with gastric cancer who under surgery or endoscopic resection in our hospital between April 2008 and February 2017, we enrolled 52 cases (early:17, advanced:35) of GAED defined as having tubular to papillary or solid structure with clear cytoplasm and immunohistochemical positivity for at least one of the following antibodies: AFI, Glypican-3 and SALL4. NGS was performed for 24 cases of formalin-fixed paraffin-embedded samples (early: 2, advanced: 22) using Ion PGM™ system with cancer hotspot panel v2 targeting 50 genes (Thermo Fisher Scientific).

Results: Twenty-five out of 53 (47%) FIGC families harboured germline variants, and co-occurrence of germline moderate-risk alleles was found in ten families. From these ten families, seven harboured one pathogenic or likely pathogenic variant combined with one or more unclassified novel variants. The remaining three families carried solely clusters of novel unclassified variants. Moderate-risk alleles of BRCA2, MAP3K6, MSH6, MSR1, SDHB and SDHD were the most frequently found in this cohort. In addition, tumours arising in these 10 families were enriched in somatic variants within DNA repair genes and often display microsatellite instability phenotypes.

Conclusion: The clinical homogeneity and relatively high number of FIGC families herein allowed studying the hypothesis that FIGC may be a new polygenic syndrome caused by moderate-risk alleles in gastrointestinal cancer-associated genes.

This work is funded by: 1) FEDER COMPETE, FCT/MEC/FEDER/PT2020 and FCT funds (projects “PExC-SAU/LA0003/2013”; project 007274 (UID/BIS/50019/2013); 2) ON.2-0.4 Novo Norte:FEDER, FREN (projects NORTE-07-0162-FEDER-00118 and NORTE-07-0162-FEDER-00067); 2) No Stomach for Cancer Foundation; 4) FCT Fellowships (SFRH/BDP/89764/2012 to PO; SFRH/BDP/86543/2012 to JC; SFRH/BDP/79499/2011 to HP).

Introduction: Endoscopic submucosal dissection (ESD) is widely accepted to treat large superficial esophageal neoplasms. However, esophageal stenosis after ESD has become a key complication. To prevent such stenosis, we developed new regenerative therapies that suppresses contracture and stenosis. About two weeks post-ESD, autologous oral mucosal epithelial cell sheets were fabricated from the patient’s oral mucosal tissue. The cell sheets were then endoscopically transplanted onto the ulcer surface immediately after ESD. To date, this cell sheet treatment, which resembles engineered cell sheet transplantation in severe burn cases, has been clinically applied, and successful outcomes have been obtained at several institutions in Japan and Sweden. In addition to preventing stenosis by the simple dressing of the ulcer’s surface area, anti-inflammatory and wound-heal promoting functions of the cell sheets were expected. Furthermore, the culture supernatant obtained immediately before the transplantation, were analyzed with a cytokine array.

Results: Histological and morphological analyses revealed that tissue-engineered stratified epithelial cell sheets have an apical-basal polarity, and that the junctions between the basal cells of the sheets were significantly loose, due to dissociating desmosomes, which were also fewer in numbers. IHC showed that the expression levels of E-cadherin and desmosomal cadherins were downregulated in the basal epithelial cell sheets, but mesenchymal markers (N-cadherin, vimentin, and fibronectin) were upregulated. Taken together, these findings implied that epithelial mesenchymal transition (EMT) was induced in the basal cells. The results of the cytokine array showed that the cell sheets secreted ECM proteins rich in growth factors (progranulin and epiregulin) and antimicrobial proteins (b-defensin).

Conclusion: The EMT of the basal cell layer of epithelial cell sheets may contribute to the improved engraftment after cell sheet transplantation. The secretion of antibacterial peptides and various growth factors from the cell sheets would exhibit anti-inflammatory effects, and promote wound-healing compared to reinforcement of esophagus with absorbable synthetic materials such as polymer membrane of polyglycolic acid and polylactic acid.

P0503 SERUM EXOSOMAL MiRNAs EXPRESSION AS NOVEL BIOMARKERS FOR DETECTION OF ESOPHAGEAL ADENOCARCINOMA

H. Chen
Jiangsu Province Hospital, Nanjing/China
Contact E-mail Address: chenhuan068@hotmail.com

Introduction: Novel biomarkers for the diagnosis of esophageal adenocarcinoma (EAC) are urgently required. Currently, there is increasing evidence suggesting that serum exosomal miRNAs may be potential noninvasive biomarkers for certain diseases. The objective of the present study was to find and investigate whether exosomal miRNAs could be effective biomarkers for EAC.

Aims & Methods: In the present study, exosomes were isolated from the serum of both EAC patients and normal controls. Total RNA was extracted from exosomes and miRNA levels were compared between EAC and control patients in serum exosomes. We also sought to investigate the relevance of exosomal miRNA expression to clinicopathological factors in EAC.

Results: We measured levels of several exosomal miRNAs, including miR-21, miR-16, miR-25, miR-155, miR-192, miR-92a, in 9 EAC patients and 9 controls. All exosomal miRNAs were chosen because they have been shown to function as onco-miRs in previous studies. Levels of miR-16, miR-21, miR-25 and miR-155 were significantly higher in EAC patients than in controls (fold-change 35.36, 30.87, 9.24 and 2.26, respectively). The level of miR-192 was significantly lower in EAC patients than in controls (Fold-change 0.35). We did not observe a significant fold-change in miR-92a expression levels between EAC and controls. P-values did not achieve statistical significance, possible due to large standard deviations and relatively small sample sizes. We also visualized exosomes isolated from both cell culture medium and sera of EAC patients and control subjects, with diameter ranging from 30 to 100 nm using transmission electron microscopy.

Conclusion: Serum exosomal miRNAs can be isolated, measured, and may serve as potential biomarkers in EAC patients. miRNA microarray or next-gen sequencing analyses and larger sample sizes are needed to validate these early results.

Disclosure of Interest: All authors have declared no conflicts of interest.

Primary outcomes included the size and number of ulcers and the patients' reports of dysphagia, chest pain, and vomiting.

Results: At follow-up endoscopy, the number of patients with post-band ulcers and size of ulcers were similar in the three groups. However, the number of ulcers for each patient was statistically significant less in rebamipide group when compared to pantoprazole and sucralfate (P < 0.001). Chest pain, dysphagia, and vomiting scores were not significantly different. Dysphagia was by far the most common symptom with no case of bleeding was reported in all patients of the studied groups.

Conclusion: Rebamipide is effective in decreasing the post banding complication and reducing size of ulcer as well as the number of ulcers with no significant effect on post banding ulcer formation. Rebamipide can be used routinely in settings of post-EVL as a good alternative to pantoprazole and sucralfate.

Introduction: Proton pump inhibitors (PPIs) have been widely used for the treatment of endoscopic submucosal dissection-induced gastric ulcers. However, post-operative bleeding is still one of the most important adverse side effects. 1, 2 Vonoprazan (VPZ), a potassium-competitive acid blocker, is a new class of acid-suppressing agents, and it is expected to reduce bleeding after gastric endoscopic submucosal dissection (ESD) by strongly inhibiting gastric acid secretion compared with PPIs. 3

Aims & Methods: We compared the incidence of bleeding after gastric ESD between subjects treated with VPZ and those treated with esomeprazole (EPZ). Data for 101 patients who underwent gastric ESD from December 1, 2014 to December 31, 2016 in Osaka City General Hospital and started to take VPZ (n = 22) or EPZ (n = 79) by the day before ESD was reviewed. Twelve of them (3 in the VPZ group, 9 in the EPZ group) were excluded for simultaneous resection of two or more sites. A case in which active bleeding or exposed vessels were observed on the bottom of ulcers with hematemesis, melena or a drop of not less than 2 g/dl of Hemoglobin within 4 weeks after ESD was defined as “post-ESD bleeding”. In addition, we perform second-look endoscopy on the day after ESD. A case in which hemostasis was needed with hemorrhage of Forrest IIa or more bleeding was defined as “next-day hemostasis case”. We investigated retrospectively post-ESD bleeding rate and next-day hemostasis rate in the VPZ group and the EPZ group.

Results: Gender, age, resected specimen diameter, oral antithrombotic drug administration, and dialysis were not significantly different in both groups. Two of the 19 patients in the VPZ group (10.5%) and 6 of the 70 patients in the EPZ group (8.6%) had Post-ESD bleeding (Table). In addition, 6 patients in the VPZ group (31.6%) and 37 patients in the EPZ group (52.9%) had next-day hemostasis. There was no significant difference in both groups regarding post-ESD bleeding (p = 0.678) and next-day hemostasis (p = 0.197). However, next-day hemostasis rate was somewhat higher in the EPZ group than that in the VPZ group. That is possibly because EPZ or VPZ was first administered mostly from the day before ESD or more when we underwent second-look endoscopy was defined as “next-day hemostasis case”. We investigated retrospectively post-ESD bleeding rate and next-day hemostasis rate in the VPZ group and the EPZ group.

Table: Incidence of post-ESD bleeding and next-day hemostasis

Introduction: Non-vitamin K direct oral anticoagulants (NOAC) are increasingly used in thromboembolic disorders due to an efficacy at least equal as vitamin K antagonists (VKA) and/or significantly higher safety for intracerebral bleeding or major bleedings of any source. In the approval studies, there was no generally increased bleeding rate for all types of bleeding, but different gastrointestinal bleeding (GIB) rates for apixaban, dabigatran, edoxaban and rivaroxaban. Received ticagrelor with aspirin were recruited. Mean±standard deviation age was 66.2±11.3 years and 63.3% of patients were male. The most common indication of DAPT was acute coronary syndrome (85.4% in clopidogrel group vs.100% in ticagrelor group). Duration of treatment with clopidogrel and ticagrelor were 121.5 days vs. 231 days, respectively (p=0.216). There were 20 (10.1%) GIB events in clopidogrel group and 11 (5.5%) in ticagrelor group. The most endoscopic findings of GIB was gastric erosion (44% in clopidogrel group vs. 67.6% in ticagrelor group). Risk ratio (RR) of GIB event of clopidogrel compared to ticagrelor was 1.84 (95% confidence interval (CI) 0.95–3.7, p=0.093). By multivariate logistic regression analysis, duration of DAPT <180 days (RR 3.28; 95% CI 1.89–5.69, p=0.001) and history of previous GIB were associated with GIB events (RR 10.35; 95% CI 6.04–17.71, p<0.001).

Conclusion: Risk of GIB is almost two times higher among patients received clopidogrel as compared to those received ticagrelor with aspirin. Closed monitoring patients who had duration of DAPT <180 days and previous GIB might be minimized the risk of GIB event after receiving DAPT.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: A total of 221 patients received clopidogrel with aspirin and 199 patients received ticagrelor with aspirin were recruited. Mean±standard deviation age was 66.2±11.3 years and 63.3% of patients were male. The most common indication of DAPT was acute coronary syndrome (85.4% in clopidogrel group vs.100% in ticagrelor group). Duration of treatment with clopidogrel and ticagrelor were 121.5 days vs. 231 days, respectively (p=0.216). There were 20 (10.1%) GIB events in clopidogrel group and 11 (5.5%) in ticagrelor group. The most endoscopic findings of GIB was gastric erosion (44% in clopidogrel group vs. 67.6% in ticagrelor group). Risk ratio (RR) of GIB event of clopidogrel compared to ticagrelor was 1.84 (95% confidence interval (CI) 0.95–3.7, p=0.093). P0514 CLINICAL CHARACTERISTICS OF FUNCTIONAL DYSPEPSIA DEPENDING ON WHETHER THEY ARE CHEMOSENSITIVE OR NOT
V. Hammer, K. Hammer, M. Führer, J. Hammer
Department Of Gastroenterology And Hepatology, Medical University of Vienna, Wien/Austria
Contact E-mail Address: jcapsaicin@yahoo.com.au
Introduction: Augmented chemosensitivity to capsaicin has been demonstrated in functional dyspepsia patients. The initial frequency of these symptoms is uncertain. This study examined the oral capsaicin capsule test (Hammer et al, NGM 2008). Sensations induced by gastric capsaicin are distinct from sensations induced by stimulation of mechanoreceptors (Hammer & Vogelsang, NGM 2007).
Aims & Methods: The aim of the study was to determine clinical characteristics of FD patients with and without chemical hypersensitivity at baseline and after capsaicin ingestion for 4 weeks. N = 49 outpatients with confirmed FD received an oral sensitivity test with 0.75 mg capsaicin at two occasions, before and after ingestion. The test was repeated with four weeks. Symptoms were recorded automatically and capsaicin at the initial test allowed stratification to a capsaicin positive (chemosensitive) and a capsaicin negative (not chemosensitive) patient group. Symptom diaries for upper and lower gastrointestinal symptoms (visual analogue scales) were completed in the week before and during capsaicin ingestion and weekly aggregate symptom scores were calculated. Results are given as median. 25%/75% p < 0.05 was considered significant.
Results: 53% FD had a positive capsaicin test. Basic clinical characteristics (age, gender, FD subtype, medication, psychological profile) were comparable in capsaicin positive and negative FD, but median daily aggregate upper gastrointestinal symptoms scores were significantly higher in capsaicin positive (median: 9.4; 5.4) than in capsaicin negative patients (6.6; 4.1, p < 0.05). Median scores for epigastric pain, nausea and epigastric distension were similar in capsaicin positive and negative patients (p > 0.05). On the contrary, capsaicin negative patients had significantly lower scores for satiety (p < 0.001) and epigastric bloating (p = 0.01) than capsaicin positive patients. Lower abdominal symptoms were comparable in capsaicin positive and negative patients at baseline (NS). After capsaicin ingestion, aggregate upper gastrointestinal symptoms scores were reduced by 3.3 (−4.9;−1.9; p < 0.001) in capsaicin positive and −2.6 (−4.1;−1.7) in capsaicin negative patients. Lower abdominal symptoms scores after capsaicin ingestion were reduced by 1.0 (−1.8;−0.1; p < 0.05) in capsaicin positive but not significantly altered (−0.6; 1.7;+0.9; NS) in capsaicin negative patients. After long-term capsaicin ingestion, the capsaicin test turned negative in 53% of capsaicin positive patients (p < 0.01).
Conclusion: Differences in upper GI symptoms distinguished capsaicin positive and negative patients at baseline. Symptom improvement after long-term capsaicin ingestion was indirect proportional to the result during the initial capsaicin test. Sensitivity to orally ingested capsaicin decreases after long-term capsaicin ingestion.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastro-oesophageal reflux disease (GORD) is one of the most common disorders encountered in clinical gastroenterology. GORD patients can be categorised as having erosive oesophagitis or non-erosive reflux disease (NERD). This study aimed to determine the extent to which the therapeutic target of these patients is the oesophageal mucosa. In NERD, even though the endoscopic presentation of the oesophageal mucosa is normal, the barrier function may be impaired. This study was to investigate differences in the expression intensity, localisation and activity of key barrier function proteins derived from 13 patients with typical GORD symptoms. We compared this to expression derived from 13 control biopsies using a targeted assay combined with subsequent IF analysis.
Aim & Methods: Here, via immunohistochemical staining and subsequent IF microscopic analysis, we investigate differences in the expression of loricrin (LOR), involucrin (INV), desmoglein-1 (DSG-1), transglutaminase-1 (TGM-1) and cathepsin-D (CTSD) in oesophageal mucosa derived from 13 patients with typical GORD symptoms. We compared this to expression derived from 13 control biopsies.
Results: After long-term capsaicin ingestion, aggregate upper gastrointestinal symptoms scores were reduced by 1.0 (−1.8;−0.1; p < 0.05) in capsaicin positive and negative patients (p > 0.05). On the contrary, capsaicin negative patients had significantly lower scores for satiety (p < 0.001) and epigastric bloating (p = 0.01) than capsaicin positive patients. Lower abdominal symptoms were comparable in capsaicin positive and negative patients at baseline (NS). After capsaicin ingestion, aggregate upper gastrointestinal symptoms scores were reduced by 3.3 (−4.9;−1.9; p < 0.001) in capsaicin positive and −2.6 (−4.1;−1.7) in capsaicin negative patients. Lower abdominal symptoms scores after capsaicin ingestion were reduced by 1.0 (−1.8;−0.1; p < 0.05) in capsaicin positive but not significantly altered (−0.6; 1.7;+0.9; NS) in capsaicin negative patients. After long-term capsaicin ingestion, the capsaicin test turned negative in 53% of capsaicin positive patients (p < 0.01).
Conclusion: Differences in upper GI symptoms distinguished capsaicin positive and negative patients at baseline. Symptom improvement after long-term capsaicin ingestion was indirect proportional to the result during the initial capsaicin test. Sensitivity to orally ingested capsaicin decreases after long-term capsaicin ingestion.

P0516 INFLUENCE OF PRUCALOPRIDE ON SECONDARY PERISTALIS IN REFLUX PATIENTS WITH INEFFECTIVE ESOPHAGEAL MOTILITY
C. Chen, W. Lei, C. Yi, T. Liu, J. Hung
Department Of Medicine, Huahilen Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation and Tzu Chi University, Hualien/Taiwan
Contact E-mail Address: harry.chchen@msa.hinet.net
Introduction: The aim of the study was to determine clinical characteristics of patients suffering from GORD. Secondary peristalsis provides possibilities for the development of novel therapies designed to specifically target patients suffering from GORD.
Aims & Methods: We aimed to determine whether prucalopride would augment secondary peristalsis in reflux patients with IEM. After a baseline recording of primary peristalsis, secondary peristalsis was stimulated by slow and rapid mid-esophageal injections of air in 15 patients. Two separate sessions with 4 mg oral prucalopride or placebo were randomly performed.
Results: Prucalopride significantly increased primary peristaltic wave amplitude (68.1 ± 10.0 vs. 55.5 ± 8.8 mmHg; p = 0.02). The threshold volume for triggering secondary peristalsis was significantly decreased by prucalopride during slow (9.3 ± 0.8 vs. 12.0 ± 0.8 mL; p = 0.04) and rapid air injection (4.9 ± 0.3 vs. 7.1 ± 0.1 mL; p = 0.01). Secondary peristalsis was triggered more frequently after application of prucalopride (55% [43–70%]) than placebo (45% [33–50%]; p = 0.008). Prucalopride didn’t change wave pressure amplitudes during slow air injection (84.6 ± 8.1 vs. 57.4 ± 13.8 mmHg; p = 0.19) or pressure wave amplitudes during rapid air injection (84.2 ± 8.6 vs. 69.5 ± 12.9 mmHg; p = 0.09).
Conclusion: Prucalopride enhances mecsanosensitivity of secondary peristalsis and promotes motor properties of primary peristalsis in IEM patients. Our study suggests that prucalopride could be a therapeutic option in the management of GORD patients with significant esophageal hypomotility.

Introduction: Symptoms compatible with diabetic gastroparesis (DG) affect up to 1 in 5 patients with type 1 diabetes mellitus. Those affected suffer postprandial
nausea, vomiting, abdominal pain and impaired gastric control. Repeated hospital admissions are common. Endoscopic therapy is normal in most patients. Impaired gastric function is thought to cause the condition. DG does not respond reliably to intensive insulin regimes or prokinetic medications. Jejunal nutrition (JN) is an option in patients that cannot maintain their weight. The benefits are thought to follow improved nutrition and increased gut function and glycaemia; however, we have observed that some DG patients eat normally during and after JN (i.e. a quasi-pharmacological effect). One explanation could be that DG represents a failure of oral nutrition to “switch” the stomach from the fasted to the fed state. According to this hypothesis, nutrients delivered directly to the small bowel triggers the release of peptide hormones that induce normal gastric function.

Aims & Methods: The study tests the hypothesis that JN prior to a test meal improves postprandial symptoms (primary outcome) and gastric function. Diabetic patients with severe symptoms (gastrosparesis cardiac index (GCSI) > 27), diabetic controls (GCSI < 14) and healthy controls entered a randomized, double blind, controlled trial. An insulin glucose infusion controlled glycaemia. A JN feeding tube was placed at endoscopy with biopsies taken from the stomach and duodenum. Either liquid nutrient (24 kcal/min) or water was infused for 60 mins. Afterwards the Nottingham Test Meal was ingested (NTM liquid: 400 ml; 300 kcal; solid: 12 non-nutrient agar beads)

Results: 9 DG patients, 9 diabetic and 12 healthy controls were recruited. There was no difference in sex distribution, age, weight, medical history (e.g. duration of disease) or endoscopic findings (including histology) between groups. DG patients had more psychiatric co-morbidity and reported higher satsity, bloating and pain after ingestion of the NTM than diabetic and healthy controls (p < 0.05). Sensations were not affected by JN in the controls; however, fullness, bloating and pain were reduced in JN in DG patients (p < 0.05). Compared to water, JN induced a greater GI-peptide response (e.g. PP, GLP-1) and initial liquid GE was slowed (gastric content volume after meal: GCV0 31 ±11 ml higher, p = 0.019). Subsequent liquid GE was similar in both study conditions (T50 3+ 4.8 min, p = 0.727). Antral contraction wave (ACW) frequency was 2.7 (2.6–2.9) min in health and was highest in diabetic controls (3.1 (2.7 to 3.3) min). Solid GE was more rapid after JN than water (2.1 (1 to 3) beans emptied ±60 min) and, again, was highest in diabetic controls (3 (1 to 7) beans emptied ±60 min). Numerically the GI-peptide response was less pronounced in both diabetic groups than healthy controls; however, the difference was not significant and a correlation with postprandial symptoms or gastric function was not identified.

Conclusion: This clinical study demonstrates beneficial effects of prior JN on fullness, bloating and pain after a 400 ml test meal in diabetic patients with moderate-severe symptoms compatible with gastroparesis (GCSI > 27). Additionally, solid GE was accelerated after JN; however, this effect was not limited to DG patients and, thus, the treatment effect that improved symptoms could not have been identified. Furthermore, patients in the DG group had objective evidence of abnormal gastric motor function and the benefit of "prior JN" on symptoms was not limited to patients with slow GE. However, it was observed that diabetic controls had relatively rapid ACW and solid GE. Future studies will identify patients that could benefit from this novel approach to treatment.
Proportions with abnormal reflux burden in relationship to EGJ and esophageal body motor findings on high resolution manometry

2Division of Gastroenterology and Hepatology, Department of Internal Medicine, Korea University College of Medicine, Seoul/Korea, Republic of Korea

Purpose: We used five female pigs and obtained ten centimeters of each porcine small intestine. To measure the passive characteristics of small intestine, a universal testing machine with a tensile rate of 30 mm/min. To estimate the active characteristics of smooth muscle and isometric and isotonic intestinal motility of smooth muscle, muscle contraction was induced by applying the stimulation solution (HTK solution containing 1 mM of acetylcholine chloride). Then, we obtained the maximum muscle contractile force of the specimens to measure the isometric and isotonic intestinal motility.

Conclusion: We straighten out the active and passive property of porcine intestinal smooth muscle. Our study may be helpful for developing novel medical devices and understanding the physiology of smooth muscle in the porcine small intestine.

P0521 MÖTILITY PATTERNER AFTER PER-ORAL ENDOSCOPIC MYOTOMY (POEM) IN PATIENTS WITH ACHALASIA

Z. Vackova1, J. Krajcova1, L. Zdhrbova2, P. Loudova2, P. Sirand1, T. Hua1, J. Spicak1, J. Martinek1

1Department Of Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
2Department Of Internal Medicine, University Hospital Plzen, Plzen/Czech Republic

Purpose: Partial recovery of esophageal peristalsis has been reported in up to 45% of achalasia patients treated by myotomy (either per-oral endoscopic myotomy (POEM) or laparoscopic Heller’s myotomy) in several rather small studies. The aim of our study was to assess motility patterns focusing on possible "recovery" of esophageal peristalsis in a large cohort of patients after POEM.

Methods: We performed a retrospective analysis of prospective collected data of patients undergoing POEM at our tertiary referral center. All patients in whom high-resolution manometry (HRM) studies were performed both prior to and 3 months after POEM and who completed at least 6-month follow-up were included. All HRM studies were reviewed and the Chicago Classification (CC) v3.0 of motility disorders was applied to characterize both pre- and post-POEM motility patterns.

Conclusion: From 192 patients who underwent POEM since 2012, 127 patients met the inclusion criteria. The initial CC diagnoses before POEM were as follows: type 1 achalasia – 20 pts (16%), type II achalasia – 100 pts (79%), type III achalasia – 5 pts (4%), other (esophageo-gastric junction outflow obstruction (EGJOO) and Jackhammer) – 2 pts (1%). Only 6 patients (5% type III achalasia or 2 patients EGJOO) had had some signs of esophageal contractility before POEM. After POEM, peristaltic fragments were present in 28/127 patients (22%) - 9x ineffective esophageal motility, 5x fragmented peristalsis, 2x distal esophageal spasm, 3x EGJOO, 7x type III achalasia. Thus, the partial “recovery” of esophageal peristalsis was observed in 22/121 patients (18%) and it only occurred in patients with type I achalasia; contractile activity was not detected in any patient with type I achalasia after POEM (22/100 vs. 0/20, p = 0.023). Panesophageal pressurization completely resolved in 88 patients (88%) with
achalasia type II. The mean integrated-relaxation pressure (IRP) decreased from 27 (±13) mmHg to 13 (±5) mmHg (p < 0.0001). The presence of peri-
oral esophageal hyperactivity was neither associated with normalization of IRP (IRP normalized in 17/28 (61%) patients with peristaltic recovery and in 72/99 (73%) patients without, p = 0.25), nor with overall treatment success of POEM (Eckardt score < 3).

Conclusion: In this so far largest case-series investigating the rate of peristaltic recovery after POEM this was present in 18% of patients, therefore, the rate may be lower than previously reported. Peristaltic recovery seems to have no clinical impact on post-POEM symptomatology. Esophageal contractility after POEM was not observed in any patient with achalasia type I.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Medical treatments, endoscopic balloon dilatation, Botox and Heller myotomy are treatment modalities for managing achalasia. Recently per-oral endoscopic myotomy (POEM) has become a new option for achalasia patients and since 2010 it has become widespread. Earlier, anterior myotomy was used in this technique but in the last few years there are studies reporting that posterior myotomy is more effective. However, there are limited numbers of publications comparing anterior and posterior myotomy. This study aimed to investigate the effect of myotomy site on POEM, to our knowledge it is the first time in Europe and our country.

Aims & Methods: Between May 2014 and January 2017, POEM was performed to 225 achalasia patients at the gastroenterology clinics under general anesthesia by an endoscopist experienced at endoscopic submucosal dissection and trained for POEM. Demographic data, previous history for balloon dilatation and results of the procedure were recorded prospectively. Patients with anterior myotomy were grouped as "group A" and those with posterior myotomy as "group P", and the results were compared.

Demographic features and results of POEM procedures

(continued)
dyspeptic symptoms after a controlled meal. Secondary objectives were to evaluate its relation with postprandial GER and gastric accommodation and to evaluate its relation with daily digestive symptoms under real conditions.

Aims & Methods: Healthy people over 18 years old, free of frequent digestive symptoms (< once a week) and GER disease (GERD), were included. Basal symptoms were assessed through PAGI-SYM(3) and OQLRAD (4) questionnaires, both validated to Spanish. Study was divided in two substudies based on the study intervention: 33 cl of regular beer (substudy 1) and the same amount of non-alcohol beer (substudy 2). Mineral water (33 cl) was the control intervention in both substudies. Each participant was its own control. The study lasted two weeks (control study week and intervention study week). Each week started with a visit to the laboratory at 7:30 am, when a pHimpedance catheter was placed and taken off 24 hours later. Gastric accommodation was assessed through the maximum tolerated volume during a nutrient drink test (ENSURE®HN, 500 ml) in a rhythm of 15 ml/minutes, after the ingestion of beer (intervention) or water (control). It was defined as the volume after which the test finished or the participant reported the maximum puntuación for any dyspeptic symptoms (early satiety, bloating, epigastric pain and nausea), which were asked every 5 minutes (1 meant no symptom and 5 meant the highest perception). GER was evaluated in the postprandial period and during 24 hours through pHimpedance register. Weekly symptoms evaluation was made though a diary adapted from PAGYSSM questionnaire and sum of symptoms was used for analysis. Data were collected daily through email. Variables were compared between both visits and weeks in both substudies using a non parametric test for matching data. Participants should drink 33 cl of beer before lunch and dinner during the intervention week. Other alcohol drinks were prohibited during the study. Participants were enrolled in substudy 1, mean aged 24 years old (SD 4.1 [18–32]); 80% were men. Twenty participants were enrolled in substudy 2, mean aged 23.4 years (SD 5.5 [20–38]); 65% were men. No significant differences were detected in the increase of symptoms during the nutrient drink test between control and intervention visits in both substudies (table 1). Maximum tolerated volume did not show any difference between visits in both substudies. Reflux episodes after nutrient drink test and reflux episodes registered in 24 hours did not show significant differences between control and study visits. The sum of weekly symptoms did not show any difference between control and intervention weeks in both substudies.

Conclusion: Moderate beer consumption (regular and non-alcohol beer) does not cause an increase of dyspeptic symptoms and reflux in healthy people. It has been shown in a controlled situation (nutrient drink test and pH impedance register) as well as in real life (diary weekly symptoms). Gastric accommodation and reflux episodes have either shown to be affected by moderate beer consumption.

P0527 CHRONIC POSTSTROKE OROPHARYNGEAL DYSPHAGIA IS ASSOCIATED WITH IMPAIRED CORTICAL ACTIVATION TO PHARYNGEAL SENSORY INPUTS

O. Ortega1, C. Cabib1, N. Vilaridel2, L. Mundel1, P. Clavé2, L. Rofes1

Introduction: The role of afferent sensory pathways in the pathophysiology of post-stroke oropharyngeal dysphagia (OD) is not known [1]. We hypothesized that chronic post-stroke patients with OD (PSD) would show impaired sensory cortical activation in the affected hemisphere.

Aims & Methods: We studied 28 chronic unilateral post-stroke patients (17 PSD and 11 nosophy (PSnD)) and 11 age-matched healthy volunteers (HV). Electric catheters used to assess event-related sensory evoked potentials to pharyngeal stimulation (pSEP) and sensory thresholds with a naso-pharyngeal catheter with two electrodes passed through the nostrils 14–15 cm until the pharynx (Galetic Ltd, Dunvegan, Scotland) [2]. We analysed pSEP peak-latency and amplitude (N1, N2, P2, N2-P2) and neurotopographic slope characteristics from brain MRI.

Results: HV presented a highly symmetric bi-hemispheric cortical pattern of brain activation at centro-parietal areas (N1-P1, N2-P2) to pharyngeal stimuli. In contrast, an asymmetric pattern of reduced ipsilesional activation was found in PSD (N2-P2; p = 0.026) but not in PSnD. PSD presented impaired safety of swallow (Penetration-Aspiration score: 4.3 ± 1.6) and delayed laryngeal vestibule closure (360.0 ± 70.0 ms), and higher NIHSS (7.0 ± 6.2 vs. 1.9 ± 1.4, p = 0.001) and Fazekas scores (3.0 ± 1.4 vs. 2.0 ± 1.1, p < 0.05) than PSnD. pSEP showed a unilateral delay at stroke site exclusively for PSD (peak-latency inter-hemispheric difference vs. PSnD: N1, 6.5 ± 6.7 vs. 1.1 ± 1.0 ms; N2, 32.0 ± 15.8 vs. 4.5 ± 4.9 ms; p < 0.05).

Conclusion: Chronic post-stroke OD is associated with stroke severity and degree of leukoaraiosis. Impaired conduction and cortical integration of pharyngeal sensory inputs at stroke site is a key feature of chronic PSD. These findings highlight the role of sensory pathways in the pathophysiology of post-stroke OD and offer a potential target for future treatments.

Introduction: Reduced sleep quality has been linked to gastrointestinal reflux disease (GERD) and functional gastrointestinal disorders. It is unknown whether GERD, functional dysphasia (FD) and irritable bowel syndrome (IBS) are more prevalent in patients with subjective sleep disturbance (SD) than those without SD.

Aims & Methods: The aim of the study was to investigate gastrointestinal symptoms, clinical characteristics, and psychological factors in subjects with and without SD in a general population undergoing health checkups. We enrolled 2752 consecutive subjects who received upper gastrointestinal endoscopy and colonoscopy during their health checkups. All participants underwent an evaluation with questionnaires including Reflux Disease Questionnaire score, Pittsburgh Sleep Quality Index (PSQI), Taiwanese Depression Questionnaire, and State-Trait Anxiety Inventory before receiving endoscopic exam. Demographic characteristics and biochemical data were also recorded. FD and IBS were based on Rome III diagnostic criteria, and metabolic syndrome was defined by the National Cholesterol Education Program Adult Treatment Panel III definition. Sleep disturbance was confirmed when PSQI score was greater than 5. We compared the clinical and psychological factors between subjects with and without sleep disturbance.

Results: Among the study population (n = 2674), 956 (36%) individuals had SD. SD subjects had more female gender, older age, lower level of education, higher systolic blood pressure, higher serum high-density lipoprotein levels, and higher prevalence of FD and IBS than those without SD. In addition, SD patients also had more depression, more anxiety, more severe GERD symptoms, and higher prevalence of non-erosive reflux disease (NERD) (p < 0.001). Multivariate analysis revealed that female sex (OR = 1.75, p < 0.001), older age (OR = 1.03, p < 0.001), and more severe GERD symptoms (OR = 1.03, p < 0.033), NERD (OR = 1.63, p = 0.023), IBS (OR = 1.48, p = 0.05), and depression (OR = 1.16, p < 0.001) were positive predictive factors for SD, whereas higher level of education (OR = 0.57, p = 0.001) was negative predictive factor for SD.

Conclusion: Our study demonstrates that SD is associated with female sex, older age, lower education level, greater GERD symptom burden, greater depression, and higher prevalence of NERD and IBS. Future studies will be needed to clarify the relationship between functional gastrointestinal diseases and sleep disorders.

Variables with a p-value of 0.1 or less in univariate analysis were entered into a multivariate analysis (logistic regression) in order to identify factors independently associated with esophageal symptoms (up to 33 variables).

Aims & Methods: Data from an online survey of 6300 individuals age ≥18 years in the United States, United Kingdom and Canada (2100 in each country) including the Rome IV diagnostic questionnaire for adults and demographic questions was used. Quota-based sampling ensured equal proportions of sex, age groups, and educational levels across countries. Prevalence and frequency of esophageal symptoms in the past 3 months and putative functional esophageal disorders were retrieved from the Rome IV questionnaire. Symptoms were considered present if they occurred at least weekly for dysphagia, chest pain, and globus, and at least twice weekly for heartburn. Variables with a p < 0.1 in univariate analyses were entered into a multivariate analysis (logistic regression) to identify factors independently related to esophageal symptoms. As endoscopy and pH measurement are parts of the clinical diagnosis of esophageal disorders in the Rome IV criteria, we only describe esophageal symptoms compatible with functional esophageal disorders. Somatization was assessed with the Patient Health Questionnaire (PHQ)-12.

Results: Data from 5177 participants (47.8% female; mean age 46.7 (range 18–92) years) were included in the analysis. Non-GI symptoms are associated with reporting esophageal symptoms. Esophageal symptoms consistent with a functional esophageal disorder according to the Rome IV criteria are unknown. This study aimed to describe the general population prevalence and risk factors for esophageal symptoms compatible with functional esophageal disorders.

Several studies have provided information on the prevalence of different atopic conditions in adult EoE patients compared to a control group of subjects. The findings indicate that, overall, EoE patients show a higher frequency of asthma, rhinoconjunctivitis, eczema, and food allergies than control groups; however, definitions for the associated atopic conditions have varied and the selection process for the controls has not been such that they can be considered universally representative of the general population without EoE. These two limitations have hampered researchers in their efforts to clearly assess the magnitude of the association between atopy and EoE, and systematic reviews of the literature and meta-analysis in order to evaluate the presence of atopic diatheses in patients with EoE as well as to summarize the prevalence of atopic conditions in both paediatric and adult EoE patients in comparison with the non-EoE control population.

Aims & Methods: A highly sensitive search strategy was designed to identify and retrieve all documents dealing with the relationship between atopy and EoE in children and adults. This systematic literature search was performed independently by G.M. and A.H. in perpetual May 2016 and was complemented by bibliographic databases (PubMed, EMBASE, and Scopus) for the period up to March 2016. The search was not restricted with regard to the language of publication. A predetermined protocol was used in accordance with the quality standards for reporting meta-analyses of observational studies in epidemiology. Four reviewers (JG-C, AA, MM-CM, and AJL) independently extracted relevant information from each eligible study using a standardized data extraction sheet and then proceeded to cross-check the results. Estimates for the prevalence of each atopic manifestation in EoE patients and controls were summarized with the aid of a fixed- or random-effects meta-analysis, depending on intra-study heterogeneity, weighted for inverse variance following the method elaborated by DerSimonian and Laird. Summary analyses, including 95% confidence intervals, were calculated for each season and month, whenever possible.

Results: Of the 2954 references identified, data was collected from 21 studies including a total of 53,542 EoE patients and 54,759 controls. The criteria for defining a diagnosis of atopy in either EoE patients or controls were not structurally considered in most of the studies. The frequency or prevalence of the different atopic manifestations among EoE patients was compared with that observed in several types of control populations, including series of patients with gastroesophageal reflux disease (GERD), healthy patients, and, in some studies, controls, all of whom were endoscopically assessed with a diagnosis of EoE specifically ruled out. In all cases, EoE was considered as independent from GERD and other upper GI tract diseases. Some studies included database-registered subjects as well. The criteria for defining a diagnosis of atopy among EoE patients and control subjects varied widely across the different studies, from self-reported/parent-reported atopic background to strict allergist/immunologist-provided diagnoses. Overall, allergic rhinitis was significantly more common than other atopic conditions compared to control subjects (OR 5.3: 95% CI: 3.27, 9.53; F = 86%) as were bronchial asthma (OR 3.06 (95% CI: 2.01, 4.66; Ι² = 83.4%) and eczema (OR 2.86; 95% CI: 1.88, 4.36; F = 57.2%). Food allergies and other atopic conditions were also assessed. No significant publication bias was found for studies dealing with allergic rhinitis and eczema in EoE. Finally, our search uncovered two papers that reported on the frequency of drug allergy in EoE patients compared to controls, showing no significant differences between these two populations (OR = 0.981; 95%CI: 0.77, 1.27).

Conclusion: The present study shows that an accurate diagnosis of atopy is lacking in most of the research evaluating the prevalence of asthma, rhinitis, and eczema among EoE patients. Still, the prevalence of these three conditions seems to be significantly higher in children and adults with EoE as compared to control subjects. However, the criteria in the general population and in further research are not uniform and use standard definitions of allergic rhinitis, asthma (including its severity and level of control), skin allergy, and food allergy (rather than mere sensitization) when assessing and documenting concurrent allergic diseases in patients with EoE.

P0535 EOSINOPHILIC ESOPHAGITIS: RATIONALISING THERAPY

Department Of Gastroenterology, University College London Hospital, London/United Kingdom

Introduction: Eosinophilic esophagitis (EE) is a chronic condition of the esophagus with pathognomonic clinical, endoscopic and histologic features. We aimed to prognosticate which cohort of patients respond best to proton pump inhibitor (PPI) therapy or topiramate or both by index esophageal histology and in conjunction with symptoms at presentation and on follow-up.

Aims & Methods: All patients referred with dysphagia or with an incidental high resolution barium swallow of greater than 15 cm long had histologic evidence of EE grades 2 or 3. Between 2013 and Dec 2015 were analyzed by retrospective case note review and patient communication. Univariate analysis and binary logistic regression was used to identify associations between patient characteristics, presentation, endoscopic findings, degree of eosinophilia and subsequent response to therapy. Associations were assessed by Fisher’s exact test, t-test and Mann-Whitney for nominal, continuous parametric and non-parametric variables respectively.

Results: 1653 patients fulfilled the entry criteria. 544 with previous cancer, achalasia, post-operative strictures or Barrett’s esophagus were excluded. 95 patients had histological eosinophilia in keeping with EE, 85 with dysphagia and 10 with reflux as their presenting symptom (67% male, mean age 42±7years). 31(32%) of these had at least one presentation with food bolus obstruction (FBO). There was a trend towards a higher eos/hpf in patients who presented with FBO (47±21) compared to dysphagia (38±17) and reflux (38±17) (p = 0.073). Endoscopic evidence of chronic strictureing disease was associated with a higher eos/hpf than those with no strictures (mean 50.3 vs 38.6; p = 0.04). 31 patients had endoscopic biopsies taken at least 3 months post therapy. Those with index features of chronic disease were more likely to be associated with failure of the eosinophils to normalize regardless of medical treatment compared to those with acute changes (furrows, exudates) (33% vs 10% respectively; p = 0.03). Patients with dysphagia and/or FBO demonstrated a reduced normalisation of eos/hpf following either steroid or PPI therapy compared to those not presenting with these symptoms at a minimum of 3 months (46% vs. 100%; p = 0.03). Overall, there were no significant associations between complete eos/hpf and response to therapy. The other hypotheses, regardless of endoscopic findings, patients presenting with dysphagia and/or FBO demonstrated a higher response to steroids than those with reflux symptoms (50% vs 5% p = 0.018) who responded best to PPI (91%). 78 patients were contactable a minimum of 3 months following initiation of treatment. Patients with chronic EE findings at initial endoscopy were less likely to respond symptomatically to PPI monotherapy compared to those with normal or acute endoscopic findings (52% vs. 68%; p = 0.003) while they were more likely to respond...
to steroids (64% vs 36%; p = 0.002). Specifically, the presence of strictures indicated a more likely clinical response to steroids compared to PPI alone. (p = 0.007).

**Conclusion:** A higher eos/hpf was found in patients with chronic EE features at index endoscopy than those with normal or acute endoscopic signs. In those with normal or acute EE changes and without dysphagia as a presenting complaint, a clinical response was noted with PPI therapy alone. In those with chronic EE changes or with dysphagia/FBO, steroids appear to be the preferred therapeutic option, although at 3 months follow up a clinical response might precede a histological one.

Introduction: Patients with gastroesophageal reflux disease (GERD) demonstrate a range of different symptoms (esophageal and extraesophageal) however the relationship between symptoms and types of reflux was not evaluated.

Aims & Methods: The aim of the study was to assess the relationship between GERD patients’ symptoms with characteristics of refluxes obtained by 24-h esophageal pH-impedance. One hundred fifty eight GERD patients (68 men, 89 women, age (M ± m) 46 ± 6.7 years) were examined using 24-hours esophageal pH-impedance recordings (Ohmega, MMS, the Netherlands; 2pH-6 impedance channels catheters, UnisensorAG, USA) and validated GERD-Q questionnaire. According to baseline endoscopy 91 patients were classified as non-erosive reflux disease (NERD) and 67 as erosive reflux disease (ERD) patients. Patients’ symptoms were classified according to Montreal classification.

Results: Extraesophageal symptoms as well as weak acid gastroesophageal refluxes were found significantly more often in patients with NERD compared to ERD group (table 1). However higher number of acid refluxes, higher GERD-Q score, DeMeester score were present in ERD. The total number of gastroesophageal refluxes didn’t differ between ERD and NERD groups of patients.

2Endoscopy Unit, Service of Surgery, Regional Hospital Durres, Durres/Albania
3Department of Laboratory, University Hospital Center Mother Teresa, Tirana/Albania
4University Clinic of Gastroenterology, University Hospital Center Mother Teresa, Tirana/Albania
5University Clinic of Gastroenterology, University Hospital Center Mother Theresa, Tirana/Albania

Introduction: Several clinical-based studies from Western countries have investigated the prevalence of extra-esophageal symptoms in various degrees of reflux erosive esophagitis. However, the independent factors related to the development extra-esophageal manifestations remain unclear.

Aims & Methods: Our aim was to assess the prevalence of extra-esophageal symptoms (laryngeal disorders and chronic cough) in adults with (cases) and those without (controls) erosive esophagitis in Albania, a developing Southeast European country. A case-control study was conducted at the Regional Hospital of Durres, the second main district in Albania, a transitional country in South Eastern Europe, including 91 patients with erosive esophagitis (aged 16.5 ± 13.6 years) and 273 controls (aged 46.4 ± 16.0 years; response rate: 70%) enrolled during the period January 2013 – June 2014. Both cases and controls underwent upper endoscopy. Information on socio-demographic characteristics and lifestyle factors were also collected. Binary logistic regression was utilized to assess the association of erosive esophagitis and extra-esophageal symptoms.

Results: Patients with erosive esophagitis had a higher prevalence of excessive alcohol consumption, smoking, sedentarity and obesity compared to their control counterparts (9% vs. 5%, 70% vs. 49%, 31% vs. 17% and 22% vs. 9%, respectively). The prevalence of hiatal hernia was higher in cases than in controls (21% vs. 8%, respectively), whereas the prevalence of gastric-duodenal ulcer was similar in both groups (13% vs. 14%, respectively). Upon adjustment for all socio-demographic characteristics and lifestyle/behavioral factors, there was evidence of a strong association of erosive esophagitis with chronic cough (OR = 3.1, 95%CI = 1.7–5.7), and even more so with laryngeal disorders (OR = 4.4, 95%CI = 2.6–7.4). In all models, the association of erosive esophagitis with extra-esophageal symptoms was strong and remained significant even after adjustment of the symptoms separately (fully-adjusted model: OR = 4.6, 95%CI = 2.9–7.3).

Conclusion: Our findings indicate that the prevalence of extra-esophageal symptoms is higher among patients with erosive esophagitis in a transitional country characterized conventionally by the employment of a Mediterranean diet. Therefore, the upper endoscopy should be part of the evaluation in patients with suspected reflux-related chronic cough and laryngeal disorders.

P0540 ASSESSMENT OF EXHALED BREATH CONDENSATE FOR NON-INVASIVE DIAGNOSIS OF GASTROESOPHAGEAL REFLUX DISEASE IN CORRELATION WITH MII-PH AND PEPTEST

S. Koncny1, J. Došina1, M. Doutkova1, J. Skrickova1, O. Kindlava1, E. P. Kovárová1, P. Durč1, J. Lacinová1, M. Gregorová2, F. Foreť1, P. Kráľa3

Introduction: Gastroesophageal reflux disease (GERD) is a disease caused by backflow of gastric contents into the esophagus due to the failure of physiological anti-reflux mechanisms and results in esophagitis and extra-esophageal complications. Extraesophageal reflux (EER) is a condition where refluxate penetrate above the upper esophageal sphincter (UES) in to the oral cavity, pharynx, upper and lower respiratory tract and leads to pathological changes like e.g. chronic cough, globus pharyngis, laryngitis, pharyngitis, rhinosinusitis, otitis media, bronchial asthma, COPD, sleep apnea and noncardiac chest pain. Currently there is no suitable, non-invasive diagnostic method applicable for GERD in clinical practice. Exhaled breath condensate (EBC) and saliva are two easily accessible samples that could be used in monitoring of patients suffering from extraesophageal symptoms of GERD. The aim of this study was to compare the pH and total ionic profile of EBC with 24-hour multichannel intraluminal impedance and pH monitoring (MII-pH) and salivary PepTest in a group of patients with weak acid reflux (pH < 4), weakly acid reflux (pH 4–7) and healthy controls.

Aims & Methods: A portable EBC sampler was used for collection of EBC. 10 µL sample aliquots of EBC were analyzed. For pH measurement, the CO2 from EBC was titrated with NaoH%= f(NaOH%) (pH 4–7) and the pH was determined with pH meter. For salivary pep test, samples that could be used in monitoring of patients suffering from extraesophageal symptoms of GERD. The aim of this study was to compare the pH and total ionic profile of EBC with 24-hour multichannel intraluminal impedance and pH monitoring (MII-pH) and salivary PepTest in a group of patients with weak acid reflux (pH < 4), weakly acid reflux (pH 4–7) and healthy controls. Aims & Methods:

Results: The values of pH (after CO2 removal with NaoH) were significantly higher in the group with acid reflux (p < 0.01), (mean pH 7.13, interquartile ranges 6.83–7.47) and in the group with weakly acid reflux (p < 0.01) (7.37, (7.18– 7.57)) vs. healthy controls (6.8, (6.65–6.99)). Butyric acid (BA) was the second most significant parameter that was significantly elevated (p < 0.01) in both patient groups (acid reflux- mean BA 2.29 µM, weakly acid reflux- mean BA 3.33 µM) compared to healthy subjects (mean BA 0.69 µM).

Further statistically significant differences were found in chloride (Cl–), nitrate (NO3–) and sodium (Na+) ions concentration. Cl– was elevated at (p < 0.01) in group with acidic reflux vs. healthy controls and NO3– and Na+ were elevated (p < 0.01) in the group with weak acid reflux vs. healthy controls. For saliva sampling and pep test analysis showed no statistically significant differences within the groups. In the groups of patients with acid reflux, the incidence of high pep concentration (above 75 ng/ml) was found only in 50% of the patients. Conclusion: We found statistically significant differences in pH and selected ions from EBC between different groups of patients and healthy controls. The analysis of selected parameters in EBC could provide a fast and non-invasive diagnostic method for GERD patients with EER symptoms in the future. This can
According to impedance-pH results, 14 out of 35 patients had increased acid reflux and normal AET.

**Aims & Methods:** We aimed to correlate various patterns of refluxate (i.e. predominant acidic refluxate, predominant non-acidic refluxate and no reflux at all), as assessed by impedance-pH, with different levels of G17 in endoscopic-negative subjects with heartburn. Thirty-five consecutive patients (19F/16M, mean age 47 years, range 31–56 years), all reporting heartburn ≥6 months with at least 3 episodes/week, entered the study. All patients underwent upper endoscopy off-proton pump inhibitors and were then divided in three groups according to the results of impedance-pH: a) Group A: subjects with increased number of reflux episodes and negative reflux-symptom association. Gastrin-17 (G17) has been proposed as a non-invasive marker of GERD, due to the negative feedback between acidic output and this hormone. Indeed, preliminary data showed that intermediate values of G17, between very low to normal levels, may identify GERD subjects with abnormal non-acid reflux.

**Introduction:** In this preliminary study, G17 levels well correlated with the three different categories of patients suffering of heartburn and included in the NERD umbrella (i.e. NERD patients with increased acid reflux episodes or abnormal AET, endoscopy-negative patients with increased non-acidic reflux and subjects with FH, suggesting its use as surrogate marker of NERD or non-acid reflux disease, without the need of performing invasive tests.

**Conclusion:** In this preliminary study, G17 levels well correlated with the three different categories of patients suffering of heartburn and included in the NERD umbrella (i.e. NERD patients with increased acid reflux episodes or abnormal AET, endoscopy-negative patients with increased non-acidic reflux and subjects with FH, suggesting its use as surrogate marker of NERD or non-acid reflux disease, without the need of performing invasive tests.

**P0542 ANTI REFUX MUCOSECTOMY (ARMS) FOR REFRATORY GASTRO ESOPHAGEAL REFLEX DISEASE (GERD) - ARE WE THERE YET?**

R. Shah, A. P. Maydeo, V. Dhir

Gastroenterology, Baldota Institute of Digestive Sciences, Global Hospital, Mumbai/India

Contact E-mail Address: rahulshah@hotmail.com

**Introduction:** As a treatment for gastro esophageal reflux disease (GERD), proton pump inhibitors (PPIs) are the mainstay of medical therapy. Laparoscopic fundoplication is generally advised when symptoms are poorly controlled with PPIs and is regarded as a gold standard of treatment, with excellent control in the short- and midterm. Long-term results, however, remain equivocal. Following on from the principles of surgical fundoplication, a variety of endoscopic procedures for GERD have been proposed to achieve a non-surgical control. Linx procedure, Stretta have been proposed as less invasive options.

**Aims & Methods:** We recruited all patients who had GERD refractory to standard medical therapy to see whether anti reflux mucosectomy prevents acid reflux into the esophagus. We screened all GERD patients who were refractory to proton pump inhibitors, hydrogen 2 receptor blockers and alginates and had an endoscopy suggestive of a lax cardia with mucosal flap grading of 1 to 3.

We performed a baseline screening endoscopy to rule out a hiatus hernia and to exclude helicobacter infection. A GERDQ questionnaire was filled by all the patients indicative of severity of reflux All patients had a high resolution manometry (Sandhill scientific) to exclude significant dysmotility and 24 hour pH measurements using Zephyr pH probe (Sandhill scientific) on therapy to demonstrate significant acid reflux. Only patients with mucosal flap valve grading 1, 2 or 3 were selected for anti reflux mucosectomy.

**Results:** Technique: Crescentic ARMS of the esophagogastric junctional (EGJ) mucosa was conducted with the standardized technique of endoscopic mucosal resection (EMR) of at least 3 cm length in the stomach, with the length of mucosal resection at the cardia measured in retroflexion from the gastric side. ARMS was conducted along the lesser curve of the stomach, thus preserving a sharp mucosal flap at the cardia measured in retroflexion from the gastric side. ARMS was conducted along the lesser curve of the stomach, thus preserving a sharp mucosal flap at the cardia.

**Conclusion:** Results suggest a potential anti-reflux effect of ARMS. The mechanism is presumed to be due to scar formation after healing of the mucosal defect. On the gastric side, this induces narrowing of the gastric cardia opening, while preserving and/or re-creating a robust his angle. After ARMS, the lesser curve of the gastric cardia takes on an almost “mechanically-stitched” appearance. The mucosal flap is rebuilt and looks well-defined. Furthermore, the lesser curve side

</table>
of the EGI is shortened with scar formation, and greater curve of EGI (his sight) noted. Therefore raised mucin as a mucosal flap valve.

The quantity of mucosa to be resected (“not too tight and not too loose”) scar formation is a key issue in this procedure. Total circumferential resection causes strictureing as demonstrated in previous studies, while subtotal dissection, which we have termed crescentic, produces better results in this result, while still resulting in symptom control. Mucosal flap valve grading is not only a predictor of reflux in these patients but also is a prognostic marker of effectiveness of ARMS, i.e. higher the grade worse the outcome. With the extent and type of mucosal resection (ER or ESD) according to the mucosal flap valve grading may be a better predictor of outcome than a box standard procedure. This technique has a potential role in people with oesophageal dysmotility wherein Nissen’s fundoplication is relatively contraindicated.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Observational and epidemiologic data have suggested an association between proton pump inhibitor (PPI) use and osteoporotic fractures. To evaluate potential mechanisms for this association, we measured bone turnover, bone mineral density (BMD), true fractional calcium absorption (TFCA), and serum and urine mineral levels in healthy postmenopausal women taking PPIs or placebo for 26 weeks.

Aims & Methods: Postmenopausal women aged 45–75 were randomised to daily oral 60-mg dexlansoprazole (DEX), 40-mg esomeprazole (ESO), or PBO for 26 wks with follow-up at wk 52. Primary endpoints were 26-wk % change vs placebo in procollagen type 1 N-terminal propeptide (PINP) and C-terminal peptide of type 1 collagen (CTX). Additional endpoints included changes in BMD (26 and 52 wks) and serum and urine mineral levels (26 wks). Fractions between baseline and wk 26 were recorded as adverse events. TFCA (0 and 26 wks) was measured in a subset (n = 34) of patients.

Results: Excluding 1 disqualified site, 115 women were randomised and 93 completed the study. There were no substantial differences in age, BMI, baseline serum calcium, or vitamin D levels between groups. The bone turnover markers PINP and CTX were within normal ranges during 26 wks of PPI therapy. Within each group, there was no statistically significant 26-wk change in bone turnover, except a small increase in CTX levels with DEX (0.12 ng/mL; 95% CI 0.03–0.23). The 26-wk median % increases in PINP from baseline vs PBO (difference in median % change [95% CI] were 19% (7%–30%) for DEX and 18% (7%–30%) for ESO. CTX levels increased vs PBO by 27% (13%–43%) for DEX and 22% (8%–36%) for ESO. PPI effects on BMD, serum and urine mineral levels, and parathyroid hormone were not statistically different vs PBO. Median % change from baseline in TFCA vs PBO was not statistically significant for DEX, but was significant for ESO (6%, 95% CI 2%–11%). No spontaneous fractures occurred during treatment; 1 traumatic foot fracture (DEX) and 1 humerus fracture (circumstance unknown; ESO) occurred during follow-up.

Conclusion: 26 wks of DEX or ESO therapy increased bone turnover markers, but did not reduce BMD, TFCA, or serum or urine mineral levels. ESO increased TFCA by <1%. Although bone turnover markers increased with PPI therapy, levels remained within the normal ranges. No clear explanation for an association between PPI therapy and fracture risk was found in this study.

Trial Registration: This study has the ClinicalTrials.gov identifier NCT01216293.
CONCLUSION: A tailored approach to refractory NERD, guided by MII-pH monitoring should give useful patient-specific information about refractory NERD. Therefore, our aim was to assess whether this technique could be useful to guide a "tailored" therapy to refractory NERD patients.

AIMS & METHODS: We retrospectively recruited patients undergoing MII-pH monitoring for refractory NERD. All patients had undergone upper endoscopy, and cases of esophagitis were excluded. No patient received PPI during MII-pH monitoring. Subjects were subgrouped into 3 categories according to Zerbib's classification: i) Acid reflux (exposure to pH < 4 for at least 1.1% of record time), ii) Non acid reflux (symptom association probability to pH<4 reflux episodes >95%) and iii) Functional heartburn (no pathologic reflux, with symptom association probability < 50%). MII-pH guided therapy was performed as follows: patients with acid reflux received PPI at double dose, patients with non acid reflux PPI at full dose plus alginates and patients with functional heartburn levosulpiride 75 mg/day for 4 weeks. A visual analogue scale (VAS) ranging 0–100 was administered before and after such tailored therapy to evaluate overall symptom response. Responders were defined by VAS improvement of at least 10%.

Comparisons between continuous variables were performed by ANOVA or paired/unpaired t-test where required, and Fisher's exact test was applied to categorical variables. Variables with statistical significance p < 0.10 at univariate analysis were included in a binomial multivariate regression analysis, aimed to investigate factors predictive of response to tailored therapy.

RESULTS: Thirty-four patients with refractory NERD were selected (female:male ratio 20:14, mean age 47.4±12.8). Twelve had acid reflux, 7 non acid reflux and 15 functional heartburn. Overall effectiveness of tailored therapy was 82.3% (25 out of 34), and it did not differ between subgroups (91.7% acid reflux, 71.4% non acid reflux, 80.0% functional heartburn, p = 0.31). At univariate analysis, therapy failure directly correlated with dysphagia (OR = 0.15, p = 0.05) and inversely with sensation of slow digestion (OR = 0.70, p < 0.05). However, at multivariate analysis, these parameters were not statistically significant. We found a mean VAS reduction of 30.2±24.9, which was similar between acid reflux (36.7±22.7), non acid reflux (30.0±27.7) and functional heartburn (34.5±22.7) (p = 0.11).

CONCLUSION: A tailored approach to refractory NERD, guided by MII-pH monitoring, demonstrated to be effective, independently from disease subtype. Therefore it should be advised to patients who complain of symptom persistence despite PPI therapy.

INTRODUCTION: STW5, a herbal combination preparation of nine different plant extracts (Iberis amara (L.), Menthae piperitae (L.) Chamomilla recutita (L.), Glycyrrhiza glabra (L.), Angelica archangelica (L.), Carum Carvi (L.), Silibum marianum (L.) Guerr. Mefissa officinalis (L.) und Chelidonium majus (L.) has been extensively studied for the treatment of gastrointestinal disorders resulting in an recommendation in the German therapy guidelines for both upper and lower functional gastrointestinal disorders (1). We investigated the mode of action of this model of reflux esophagitis as the most common condition studied by gastroenterologists with possible long-term implications such as Barrett's esophagus and esophageal adenocarcinoma.

AIMS & METHODS: We were especially interested in the tight junction proteins (TJ), which are multi-protein complexes in epithelial and endothelial cells known to contribute to the barrier-function, but recently discovered to play an important role in tumorigenesis (2). TJ proteins like ZO1, CLDN3, CLDN23, OCCL, MARVELD1, 2 and JAM. Data demonstrate a reversal of inflammatory changes in the TJ-proteins by STW5 and O. They also suggest that inflammatory changes in TJ in inflammatory process and in tumorigenesis and the potential benefit arising from a treatment with STW5 or O.

Aims & Methods:
Proteins (BMPs) are a family of growth factors that control tissue architecture, multipotent stem cells give rise to the columnar lining. Bone Morphogenetic protein stem cells residing in the esophageal mucosa (e.g., in submucosal glands) or for esophageal adenocarcinoma. One underlying mechanism of BE is that columnar with Gastro-esophageal reflux disease in which the normal stratified squamous epithelium of the gut. This property is termed collinearity and links clustering to function. In this study, we aimed to determine HOXA13 expression in physiological gastrointestinal tract tissues using immunohistochemistry (IHC) panels of squamous, intestinal and stem cell markers. These structures were assessed histologically and immunohistochemically (IHC) using panels of squamous, intestinal and stem cell markers.

Results:
A columnar epithelial layer containing goblet cells and recapitulated the crypt and villous regions seen within BE glands. IHC validation confirmed that the xenograft structures were of human origin and expressed markers of intestinal differentiation (CK8, CDX2 and villin). In contrast, treatment with the BMP inhibitor lead to the formation of multi-layered squamous epithelium expressing both the stem cell marker p63 and the squamous marker CK5.

Conclusion: Preliminary results demonstrate that inhibition of BMP2/4 in mice resulted in the prevention of squamous epithelialization. These promising results may be translated to the clinical setting in order to improve treatment of BE and as such prevent the development of esophageal adenocarcinoma.

Metaplasia and organoid model of human BE to investigate the potential to modulate the metaplastic process using an innovative anti-BMP2/4 llama-derived Dwarfbody® (DB). Endoscopic BE biopsies were implanted into immunocompromised mice intramuscularly and grown for a period of three months with DB or control. These structures were assessed histologically and immunohistochemically (IHC) using panels of squamous, intestinal and stem cell markers.

References
Calpe, S., Correia, A. C., Sancho-Serra Mdel, C. & Krishnadath, K. K. 2016. Gastric glandular epithelium. However, in absence of evidence that the gastric stem cell has broad differentiation potential, this theory remains controversial. The gastric-cardiac junction is a high prevalence area for metaplasia and subsequent cancer. Characteristic of this area are the gastric cardia glands which cover over the most proximal part of the anatomic gastric cardia. Recent evidence from human and mouse studies has shown Barrett's esophagus can originate from these gastric cardia glands. 3, 4 If it can be shown that gastric cardia glands contain elements associated with positional mispecification, this theory could be substantially bolstered. HOX genes are a family of transcription factors that convey positional information. The 3′ to 5′ sequence of HOX genes corresponds to the sequence in which they act along the anterior to posterior axes of the gut. This property is termed collinearity and links clustering to function. In gastrointestinal physiology, HOX; A13, a 5′ member of the HOX4 cluster, has an expression pattern restricted to the colonic epithelium. However, pathological metaplastic lesions of the esophagus and stomach are also characterized by HOX13 expression. This in parallel with the similarities of these lesions with physiological gastric morphology. Hence, investigating HOX13 expression in gastric cardia glands appears a rational strategy in assessing the potential of this gastric cardia epithelium to serve as the origin of Barrett's esophagus.

Aims & Methods: We aimed to determine HOXA13 expression in physiological gastric cardia glands. Firstly, strips of tissue from surgical specimens containing squamous esophageal epithelium, gastric cardia glands, and oxyntic stomach glands, were collected. These were continuous strips, from proximal to distal, to preserve morphological information. Material from three patients was selected, they suffered from either a neuroendocrine tumor, or decompensated achalasia, or an adenocarcinoma. Antibodies against HOXA13 were found not to be specific. Therefore, RNA in situ hybridization by RNA-scope was performed to visualize HOX13 RNA. Secondly, a HOx13GFP x C57BL/6J heterozygous mutant mouse model was used. In these animals, the cardiac glands were imaged directly for GFP expression using a fluorescence confocal microscope.

Results: All three patients showed HOX13 expression of a portion of gastric cardia epithelial cells. The squamous epithelium, the oxyntic epithelium, and the columnar did not show any signal. The signal is located relatively close to the base of the crypts of the cardiac glands. The HOx13GFP x C57BL/6J heterozygous mice showed GFP expression localized to the nucleus of some of the epithelial cells of the cardiac gland. No nuclear signal was detected in the squamous or oxyntic gland. The cardiac epithelium of the mouse showed nuclear GFP signal. Rectal squamous epithelium was negative as well as ileal epithelium, in accordance with HOX13 colinearity in mouse and human. A littermate negative for Ho13GFP was analyzed and showed no nuclear signal in either the gastric cardia glands or in oxyntic epithelial glands.

Conclusion: Gastric cardia gland epithelial cells in both human and mouse exhibit HOX13 expression. All other physiological upper gastrointestinal tract tissues are HOX13 negative in line with HOX gene collinearity in the gut. This dichotomy proves positional information in these glands is discordant with their actual location. These findings suggest that gastric cardia glands have a broad differential potential. This is consistent with an origin of Barrett’s metaplasia in the gastroesophageal junction and might be indicative of Barrett’s not being a true transdifferentiation.

Introduction: We have previously demonstrated that immunohistochemically active high-risk HPV (hr-HPV) is strongly incriminated in Barrett’s dysplasia (BD) and oesophageal adenocarcinoma (OAC) using mainly fresh frozen tissue.1, 2 This study aimed to identify biomarkers of active HPV infection in Barrett’s metaplasia (BM)/BD/OAC by immunohistochemical staining (IHC) of formalin-fixed paraffin embedded (FFPE) tissue for aberrations of p53 and the retinoblastoma protein (pRb). Of 218 patients, 56 were HPV DNA positive (HPV16 (n = 42), 18 (n = 13), 6 (n = 1)). Viral load was low. Transcriptionally active HPV (DNA+/RNA+) was only found in the dysplastic and adenocarcinoma group (n = 21). The majority of HPV DNA+/RNA+ BD/OAC were characterized by pRblow/p53low and RNA−/RNA− cohorts (n = 21) p53low had the strongest association with DNA+/RNA+ oesophageal lesions (OR = 23.5, 95% CI = 20.5–265, p = 0.042). Seventeen HP1 DNA+/RNA+ BD/OAC identified as p53low, were sequenced and all but one exhibited wild-type status.

Conclusion: Active HPV involvement in BD/OAC is characterized by wild-type p53 and aberrations of the retinoblastoma protein pathway.

Introduction: The importance of skilled endoscopic assessment of Barrett’s oesophagus (BO) has been clearly established and forms part of the British Society of Gastroenterology guidelines. Use of Prague classification when reporting on areas of BO improves standardisation, and adherence to the Seattle biopsy protocol (quadrant biopsies every 2cm) when sampling Barrett’s mucosa is thought to improve dysplasia detection. In East Kent Hospitals NHS Foundation Trust we have created a dedicated nurse-led BO surveillance endoscopy list with the aim of improving compliance with guidelines and the quality of biopsies taken. Here we present a retrospective observational study of patients who underwent upper GI endoscopy on a general endoscopy (GE) list compared with the dedicated BO endoscopy (DBO) list.

Aims & Methods: We searched our endoscopy software for patients who had an indication for gastroscopy documented as BO and who had an endoscopy on a GE list from 2012–2013. The same search was performed for patients who were scoped on the DBO list from 2014-2016. Endoscopy reports were reviewed to assess the use of Prague classification and determine numbers of biopsies taken. Biopsy results were reviewed on our electronic pathology database.

Results: One hundred procedures for BO surveillance on GE lists were audited, comprising 65% male patients with median age 68 years; 60% were performed by a consultant gastroenterologist and the remainder were performed by other operating department and gastroenterology registrars. Of the 105 procedures on the DBO lists, 63% of patients were male, median age 70 years. Prague classification was used in 94% of endoscopy reports on the DBO lists compared with 5% on the GE lists. The Seattle biopsy protocol was observed in 70% of cases on the DBO lists as opposed to 30/100 (30%) on the GE lists. Dysplasia detection rate (low grade, high grade or indefinite) was significantly higher on the DBO lists when compared with GE lists (94% vs 5%). The Seattle biopsy protocol was observed in 70% of cases on the DBO lists as opposed to 30/100 (30%) on the GE lists. Dysplasia detection rate (low grade, high grade or indefinite) was significantly higher on the DBO lists when compared with GE lists (94% vs 5%). The Seattle biopsy protocol was observed in 70% of cases on the DBO lists as opposed to 30/100 (30%) on the GE lists. Dysplasia detection rate (low grade, high grade or indefinite) was significantly higher on the DBO lists when compared with GE lists (94% vs 5%).

Conclusion: Our comparison shows that observance of Prague classification is significantly higher on the DBO lists when compared with GE lists (94% vs 5%), and compliance with the Seattle biopsy protocol is similarly higher (74% vs 30%). These are indicators of higher quality endoscopic surveillance on DBO lists. However, this did not translate to a different dysplasia detection rate which appeared to be more influenced by the endoscopy operator since all of the dysplasia detected on GE lists was identified by consultant gastroenterologists. We believe that the additional familiarity of guidelines and possibly greater experience of endoscopists regularly taking BO biopsies. We therefore recommend that all Barrett’s oesophagus patients have their surveillance endoscopies performed on dedicated BO endoscopy lists.

P0557 EXPRESSION OF TGF-B AND CD-44 IN AGE SPECIFIC SUBGROUP OF PATIENTS WITH ADENOCARCINOMA OF GASTRIC CARCINOMA

N. Lukavetsky, T. Fetschy
Oncology Department, Lviv Medical University, Lviv, Ukraine

Introduction: Adenocarcinoma near the esophagogastric junction is one of the most lethal GI malignancies known. Surgical treatment of these cancers stay determinative factors of patient survival. Older persons often differ from the younger adult population in terms of biological and functional perspectives; as such, they may have particular needs which require an interdisciplinary approach and intervention, especially when faced with a cancer diagnosis.

Aims & Methods: The aim of this study was to detected expression of TGF-B and CD-44 in age specific subgroup. The expressions of TGF-B and CD-44 were evaluated immunohistochemically in 23 patients with adenocarcinoma of gastric cardia who underwent curative surgery (RO) without any neo/adjuvant therapy. Additionally we analyzed control group of patients with non-cancer lesion or normal tissue of upper digestive tract (13 patients). We divided the patients into two groups. Group A consisted of 13 cancer patients and 7 control patients 65 years of age or older, while Group B consisted of 10 cancer and 6 control patients younger than 65 years of age. The two groups were comparable - there were no differences between the two groups regarding tumor stage.

Results: Elderly patients have statistically significant better survival (median 20.2 months) compared with younger patients (median 15.4 months) (p = 0.045). The median survival rate of patients without TGF-B and CD-44 expression was significantly lower (7 m) than that of patients with positive expression (> 15 m) (p = 0.003). Regardless of patients age, CD-44 was significantly higher in the cancer tissue of elderly patients than in younger (p < 0.03). But no significant difference was observed in the TGF-B expression group A and group B patients cancers tissue (p = 0.005).

Conclusion: The biology of tumors may be different in elderly patients, leading to a lower rate of tumor-related mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Barrett’s oesophagus (BO) is considered a premalignant condition for oesophageal adenocarcinoma (OAC). Once diagnosed, interval endoscopic surveillance is recommended to promote early detection of dysplasia and cancer. Occurrence and incidence of dysplasia and cancer among BO vary across populations. Recent studies show BO patients mortality is mainly related to non-oesophageal cancer and cardiovascular morbidity.
Aims & Methods: In this cross-sectional study, our aims were to describe the local BO clinical, endoscopic and histologic profile in our tertiary referral centre, and discover whether the Prague classification and endoscopic requirements are fulfilled. We identified and included all consecutive patients with oesophageal intestinal metaplasia (identified by the presence of goblet cells) from March 2009 to May 2015. All endoscopies and biopsy reports were reviewed: BO segment length, use of the Prague classification, endoscopic abnormalities, treatment modalities, and histologic findings of dysplasia. Participants were sent a clinical questionnaire, via which pertinent clinical data including personal and familial cancer history, were collected.

Results: Clinical profile: Our cohort consists of 406 patients, with a mean age of 60.4 ± 13.3 years, 69% were male. Endoscopic profile- Mean maximal BO length (Prague classification M) was 2.8 ± 1.9 cm (reported in 49.6% of endoscopies) Mean circumferential BO (Prague classification C) was 4.9 ± 3.1 cm (reported in 18.1% of endoscopies). Histologic profile- Low-grade dysplasia (LGD) was seen in 4.4% of patients, high-grade dysplasia (HGD) in 3%, intramucosal carcinoma (IMC) in 0.7%, and OAC in 2%. A subgroup of 250 patients underwent more than one endoscopy, allowing for prospective intensive analysis. They had 914 years of follow-up, with a mean number of endoscopies of 4.7 ± 3. The incidence rates of LGD, HGD, IMC, OAC per 100 patient years were 20.8, 15.3, 2.2, and 84% respectively.

Conclusion: Compared to the information gathered by Katz et al., we demonstrated a lower rate of LGD, but comparable rates of HGD and OAC. The personal and familial history of non-oesophageal malignancy was higher than the oesophageal malignancy rates. Our findings may support the importance of histological staging of the early neoplasia in BO. We also investigated the three-year survival in patients, who have had their EMR longer than 3 years ago, along with causes of death. A total of 99 patients underwent 134 EMR procedures and 259 EMRs, with 84% were male, the mean age at first EMR was 71 years (SD = 8.2). 24 patients underwent 2 EMR procedures, 2 patients underwent 3 EMR procedures and 2 patients underwent 4 EMR procedures. The median length of the circumferential and maximum extent of the BO segments were 3 and 4 cm respectively (inter-quartile range (IQR) 2–4). 44 patients underwent 60 en bloc resections. After histologic assessment of these EMR specimens, 34 (56.7%) had clear deep and radial resection margins, 14 (23.5%) showed at least low-grade dysplasia at the radial margin and 8 (13.4%) at both margins. 2 (3.3%) were clear at the deep margin, but due to thermal damage the radial margins were indeterminate. Following the 60 EMRs there was no visible residual early neoplasia on the follow up endoscopy in 37 cases (61.7%), 55 patients underwent 74 piecemeal EMRs, of which 52 (70.2%) had clear deep margins on histologic assessment and 38 (51.4%) had no visible residual neoplasia on the follow up endoscopy. Pre EMR histology was available in 82 patients and it showed high-grade dysplasia (HGD) in 49 (59.8%), mucosal adenocarcinoma in 24 (29.2%) and low-grade dysplasia in 9 patients (11%). However the EMR histology resulted in altered grading in 59 (72%) patients, with 47 (57%) upgraded and 12 (14%) downgraded from the pre EMR histology and unchanged only in 23 patients (28%). The EMR histologies in the 82 patients showed HGD in 16 (19.5%) patients, intramucosal adenocarcinoma in 33 (40.2%), adenocarcinoma with submucosal invasion in 20 (24.4%) and LGD in 13 (15.9%). The remaining 52 EMRs were performed for visible lesions within BO with the histologic result, predominantly for patients in the radiofrequency ablation program. The 3 year survival rate for 42 patients was 81%, 8 patients died, 5 due to cardiac failure, 1 due to a PE and 2 due to advanced oesophageal adenocarcinoma.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0561 LONG-TERM OUTCOMES OF ENDOSCOPIC RESECTION VERSUS SURGICAL RESECTION FOR MM-SM1 ESOPHAGUS

K. Yamauchi1, M. Iwamauro2, Y. Ohayashi3, Y. Baba2, H. Sakai2, T. Gotoda3, Y. Kouno4, H. Kanzaki3, S. Kawano2, Y. Kawahara2, H. Okada2

Introduction: Squamous squamous cell carcinoma in the esophagus confined to the muscularis mucosae (MM) or submucosa up to 200 μm (SM1) has a risk of lymph node metastasis, it is defined as relative indication for endoscopic submucosal dissection (ESD) by the Japanese esophageal society guideline. Although additional surgical treatment after ESD is recommended, long-term outcomes of ESD compared with surgery has not been clarified.

Aims & Methods: This study aimed to evaluate the long-term outcomes of ESD and surgery for cN0M0 relative indication lesions of ESCC. Between 2006 and 2016, patients with relative indication lesions of ESCC treated endoscopically or surgically in Okayama University Hospital were retrospectively analyzed. We evaluated risk factors for mortality using cox regression analysis, adjusted hazard ratios for ESD compared with surgery, the survival curves stratified with risk factor, and perioperative complication rate.

Results: 54 lesions in the ESD group and 51 lesions in the surgery group met the pathological criteria of relative indication for endoscopic resection. 10 patients underwent additional chemoablation in the surgery group. 8 patients underwent additional chemotherapy and 1 patient underwent additional chemoablation in the surgery group. Lymphovascular invasion, submucosal invasion, and AS-A-PS was significantly associated with mortality using Cox analysis. Adjusted for lymphovascular invasion, submucosal invasion, and AS-A-PS, the absolute Cox proportional hazard ratio of mortality for ESD compared with surgery was not significantly different (hazard ratio [HR], 0.76; 95% confidence interval [CI], 0.26–2.2; P = 0.61). The survival curves for ESD and surgery stratified with each risk factor were not significantly different. Perioperative complication rate were significantly low in ESD compared to surgery (29.6% vs 49.1%; P = 0.047).

Conclusion: ESD dose not compromise the long-term outcome compared to surgery. Further large number randomized controlled trials are necessary to confirm these results.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Patients with Fanconi anemia (FA) have an increased risk of developing esophageal squamous cell carcinoma. Data regarding endoscopic findings in FA is scarce. Furthermore, there are no clear guidelines for endoscopic surveillance of patients with FA.

Aims & Methods: We aimed to describe the endoscopic findings among subjects with FA undergoing endoscopic surveillance and to determine the interval to development of esophageal cancer.

Results: Eight FA subjects with a median age of 22.2 years at first endoscopy (range16–41) were identified. The median upper endoscopies number per patient was 3.5 (range 2–14) with a median time of follow-up of 4.5 years (range 1–9 years). All subjects (100%) had an endoscopic evidence of reflux esophagitis: 3 (37.5%) had mild and 5 (62.5%) had moderate-severe reflux esophagitis. Three subjects (37.5%) had complicated esophageal reflux disease (two subjects developed Barrett's esophagus and one subject had an esophageal stricture). Two subjects (25%) developed esophageal squamous cell carcinoma during follow-up, with interval time of 8 and 18 months from previous upper endoscopy. Both had tumor expression of p16 protein suggesting human papilloma virus (HPV) infection. The calculated standardized incidence ratio (SIR) for the development of esophageal squamous cell carcinoma was 5.107.

Conclusion: FA patients are at an increased risk for developing esophageal cancer and reflux esophageal disease with associated complications. Larger, prospective studies are needed to determine the optimal interval for endoscopic screening in these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Multiple development of squamous cell carcinoma (SCC) in the upper aerodigestive tract is known as the “field cancerization phenomenon, ” and alcohol is a definite carcinogen. Multiple dysplastic lesions in the esophagus are a useful predictor of the risk for the field cancerization. However, what causes the development of dysplastic squamous epithelium in the esophagus is still unclear.

Aims & Methods: The aim of this prospective cohort study was to identify associations between patients’ lifestyle, including alcohol consumption, the genetic trait of aldehyde dehydrogenase-2 (ALDH2), and the development of dysplastic squamous epithelium in the esophagus. This is a post hoc analysis of the Japan Esophageal Cohort (JEC) study (UMIN1676). Patients with superficial SCC

United European Gastroenterology Journal 5(S5)

A361
treated by endoscopic resection were prospectively recruited from 16 hospitals throughout Japan. This cohort study was approved by the institutional review board at each hospital, and we obtained written informed consent from all patients. Using Lugol chromoendoscopy, we evaluated the dysplastic squamous epithelium in the esophagus. Lugol voiding lesion (LVL) was graded into 3 categories (A = no lesion; B = 1 to 9 lesions; C = ≥10 lesions per endoscopic view). Endoscopic images obtained from eligible patients at study entry were centrally reviewed in a blinded fashion by three endoscopists to determine the grade of LVL. ALDH2 status was determined by questionnaire facial flushing after alcohol drinking (present and past flushing; inactive ALDH2, never flushing = active ALDH2). Lifestyle surveys were conducted using a self-assessment questionnaire. Data collected between July 2000 and Dec 2001 from a different cross-sectional cohort (n = 1042; M/F = 610/432) were used as an historical control.

Results: Between Sep 2005 and May 2010, 330 patients (M/F = 278/52) were registered. The proportions of the different grades of LVL were A = 50 (15.2%), B = 174 (52.7%), and C = 106 (32.1%). After adjusting for sex and age, controls and the LVL grade was associated with progressively higher proportions of heavy drinkers (8.4%, 24.8%, 26.2%, and 52.5%, respectively, p < 0.0001), frequently strong alcoholic beverages (2.3%, 7.2%, 11.8%, and 11.6%, respectively, p < 0.0001), heavy smokers (34.6%, 38.7%, 65.7%, and 70.8%, respectively, p < 0.0001), having high-temperature food (4.6%, 19.6%, 20.8%, and 20.7%, respectively, p < 0.0001), not eating green-yellow vegetables almost every day (55.0%, 48.9%, 54.9%, and 71.1%, respectively, p < 0.0001), and not eating fruit almost every day (51.6%, 74.3%, 68.0%, and 75.3%, respectively, p < 0.0001). The risk of LVL grade B and C was strongly associated with the amount of alcohol consumption especially in inactive ALDH2. Odds ratio (OR) of LVL grade B associated with heavy drinking was significantly stronger in moderate and heavy drinkers vs. non-drinkers and non-temporant group (OR = 2.73; p < 0.001) and inactive heterozygous ALDH2 (17/83; p < 0.01). A fourth SCC was detected in seven patients (5.6%), who were all cases of continuous heavy drinkers after ER. Six of the seven patients had an inactive heterozygous ALDH2. We analyzed the 63 patients with inactive heterozygous ALDH2 and moderate and heavy drinkers before ER based on their temperature history and found 38 patients in the temperance group (≤light drinkers after ER) and 25 patients in the non-temporant group. The 3-year cumulative incidence of a third SCC in the temperance and non-temporant groups was 0.3% vs. 25.4%, respectively (OR = 2.73; p = 0.01). The 5-year cumulative incidence of a second SCC after ER was 5.6% vs. 16.9% (p < 0.05).

Conclusion: The development of dysplastic squamous epithelium in the esophagus was associated with the amount of alcohol consumption and genetic trait of inactive ALDH2.

P0564 EVALUATION OF THE RISK OF METACHRONOUS SQUAMOUS CELL CARCINOMA OF THE OESOPHAGUS AND THE HEAD AND NECK AFTER ENDOSCOPIC RESECTION FOR SQUAMOUS CELL CARCINOMA OF THE ESOPHAGUS BASED ON THE GENETIC POLYMORPHISMS OF ADH1B AND ALDH2

Department Of Gastroenterology And Hepatology, Hokkaido University Graduate School of Medicine, sapporo/Japan

Introduction: Metachronous multiple squamous cell carcinoma (SCC) of the esophagus and the head and neck often occurs in patients who previously underwent endoscopic resection (ER) for SCC of the esophagus. This has become a problem regarding the curability of ER. Katada et al reported that alcohol abstinence significantly decreased the risk of developing a secondary SCC of the esophagus, based on a prospective study of 330 patients from 16 hospitals. However, there are few studies that have investigated the risk of developing a secondary SCC of the esophagus and the head and neck based on the genetic polymorphisms of alcohol dehydrogenase-1B (ADH1B) and aldehyde dehydrogenase2 (ALDH2) which are closely associated with developing oesophageal SCC. No studies have evaluated the risk of developing a third (or more) SCC after ER for SCC of the oesophagus.

Aims & Methods: The study group included patients who underwent ER for SCC of the esophagus at Hokkaido University Hospital. All patients were followed up by endoscopic examination for ≥2 years. Overall, 126 patients were included in the study. The drinking and smoking histories before and after ER were carefully documented. To examine two single nucleotide polymorphisms (SNPs) on ADH1B and ALDH2 genotyping, we obtained approximately 1 ml of DNA before or cotton swab before the endoscopic examination. The subjects were classified as casual drinkers who consumed <1 units/week, current drinkers who consumed 1 to 8.9 units/week (light drinkers), 9 to 17.9 units/week (moderate drinkers), or ≥18 units/week (heavy drinkers); alcohol consumption (1 unit = 22 g, the ethanol content of one serving of sake). The physicians recommended all subjects to temperate in drinking and smoking. We retrospectively evaluated the risk of metachronous SCC of the oesophagus and the head and neck after ER for SCC of the oesophagus, based on the genetic polymorphisms for ADH1B and ALDH2 and the drinking and smoking histories.

Results: During a median follow-up period of 80 months (range, 24-228 months), a secondary SCC of the oesophagus and the head and neck was detected in 46 patients (36.5%). The high incidence groups had inactive heterozygous ALDH2 (red71 GA, 36.3%; moderate and heavy drinkers 42.9%; p < 0.01), continuous moderate and heavy drinkers after ER (21/35; p < 0.01). Multivariate analysis revealed that the inactive heterozygous ALDH2 (OR = 2.24; p < 0.05), moderate and heavy drinkers (OR = 1.54; p < 0.05) and continuous heavy drinkers after ER (OR = 2.73; p < 0.01) were independently associated with the risk of developing a secondary SCC after ER. A third SCC was detected in 19 patients (15.1%), and the high incidence groups had inactive heterozygous ALDH2 (17/83; p < 0.05), moderate and heavy drinkers (19/93; p < 0.01). A fourth SCC was detected in seven patients (5.6%), who were all cases of continuous moderate and heavy drinkers after ER. Six of the seven patients had an inactive heterozygous ALDH2. We analyzed the 63 patients with inactive heterozygous ALDH2 and moderate and heavy drinkers before ER based on their temperature history and found 38 patients in the temperance group (≤light drinkers after ER) and 25 patients in the non-temporant group. The 3-year cumulative incidence of a third SCC in the temperance and non-temporant group was 0.0% vs. 25.4%, respectively (OR = 2.73; p = 0.01). The 5-year cumulative incidence rate of a third SCC revealed an incidence of 0% vs. 23.8%, respectively (p < 0.01). The 7-year cumulative incidence rate of a fourth SCC revealed an incidence of 0% vs. 16.9%, respectively (p < 0.05).

Conclusion: Among the patients who underwent ER for oesophageal SCC, an inactive heterozygous ALDH2 with a continue drinking habit were the significant risk factors of developing metachronous multiple SCC. These are the greater risk factors for developing a third (or more) SCC. Patients with an inactive ALDH2 and a drinking habit should receive strict instruction for temperance.

Disclosure of Interest: All authors have declared no conflicts of interest.

3. Oyama T, Inoue H, Arima M, et al. Prediction of the invasion depth of B: 31.5/C6 was performed. There were no significant differences in tumor size (A: 34.9/133/C6 vs. 33.1, C: 112.1/C6, p = 0.042). In multivariate analysis, risks factors for recurrence were: by ER (OR = 7.315; IC [1.685–31.762]; p = 0.008) and by ESD (OR = 2.635; IC [1.065–6.519]; p = 0.036). At 24 months, recurrence-free survival rate was 95.2% in ESD group, versus 59.8% in ESD group (p = 0.001). For infiltrating tumors ≥m3, metastasis free survival rate at 24 months were 100% after complementary treatment by radiotherapy, and 62.2% without complementary treatment (p = 0.042). Conclusion: Endoscopic resection of superficial esophageal SCC is safe and efficient. According to our results, ESD should be preferred to ER because it is associated with a higher cure rate and an increased recurrence free survival rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic mucosal resection (ERMS) and endoscopic submucosal dissection (ESD) are the first line treatment for superficial esophageal squamous cell carcinoma (SCC). Comparatively to surgery, endoscopic resection is minimally invasive and associated with a lower morbidity and mortality.

Aims & Methods: Evaluation of the endoscopic resection efficiency for superficial esophageal SCC and long-term outcome. Primary outcomes was recurrence rate after endoscopic resection defined as local recurrence or metastatic evolution. We conducted a retrospective multicenter study in 5 French tertiary care hospitals. All patients treated by EMR or ESD for histologically proven SCC were consecutively enrolled.

ESG: We defined as superficial after macroscopic evaluation including Lugol staining and endoscopic ultrasonography (EUS). Curative resection was defined as pT1a with free resection margins, without lympho-vascular embolus.

Results: Between 1998 to 2016, 132 patients were enrolled and 148 tumors were resected (ER = 80, ESD = 68). The mean age was 63.9 [35.7–86.0] years-old and 108 (73%) patients were male. Mean tumor size was 15.0 mm in the EMD group and 35.0 mm in the ESD group (p < 0.001). The complete resection rate in the EDA/EMR/ESD groups were respectively 30% (24/80) and 96.5% (66/68) (p < 0.0001). The mean follow-up period was 22 months. The recurrence rate was 14.9% (29/160) in the EMD group and 2.68% in the ESD group, p = 0.001. At 12 months, recurrence-free survival rate was 84.4% and 74.6% at 24 months. Factors associated with recurrence in univariate analysis were: tumors size (p = 0.013), resection by ER (p = 0.001), piecemeal resection (p = 0.016), and microscopic positive margins (p = 0.044). In multivariate analysis, risks factors for recurrence were: by ERM (OR = 7.315; IC [1.685–31.762]; p = 0.008) and by ESD (OR = 2.635; IC [1.065–6.519]; p = 0.036). At 24 months, recurrence-free survival rate was 95.2% in ESD group, versus 59.8% in EMD group (p = 0.001). For infiltrating tumors ≥m3, metastasis free survival rate at 24 months were 100% after complementary treatment by radiotherapy, and 62.2% without complementary treatment (p = 0.042). Conclusion: Endoscopic resection of superficial esophageal SCC is safe and efficient. According to our results, ESD should be preferred to ER because it is associated with a higher cure rate and an increased recurrence free survival rate.

P0568 CURATIVE CONDITIONS AFTER ENDOSCOPIC RESECTION FOR MM/SM1 OESOPHAGEAL SQUAMOUS CELL CARCINOMA BASED ON LONG-TERM OUTCOMES

T. Mizumoto1, S. Oka2, S. Tanaka3, T. Hyama4, K. Kuroki2, M. Kurihara2, Y. Yosihuk4, Y. Sanomura3, Y. Urabe3, C. Chu4

Introduction: Endoscopic squamous cell carcinoma (ESCC) with invasion into the submucosa (T1mM1/SM1) has approximately 10% lymph node metastasis and is a relative indication for endoscopic resection (ER) as per the Japanese Esophageal Society (JES) guidelines. The consideration criteria for additional treatment of MM/SM1 ESCC are as follows: (1) lymphovascular invasion, (2) SM1, (3) positive vertical margin, and (4) diffuse pattern of infiltration (INF). However, the clinical validity of the JES guidelines has not been established. We evaluated the curative conditions after ER for MM/SM1 ESCC based on long-term outcomes.

Results: We enrolled 98 consecutive MM/SM1 ESCC who underwent ER between August 1992 and October 2013 and were followed up for more than 3 years at Hiroshima University Hospital. As per the JES guidelines, the e-curable group was characterised by en bloc resection lesions with pathological MM, tumour infiltration pattern (INF) a/b, VM0, ly0 and v0. We evaluated the clinicopathological characteristics of patients and lesions between the 2
groups. The proportion of patients with additional treatment after ER was significantly lower in the e-curable group as compared to the non-e-curable group (23%, 9/39) as compared to the e-curable group (21%, 8/39) (p < 0.05). Operation, radiotherapy, and chemoradiotherapy were administered to 3 (8%), 4 (10%), and 12 (5%) patients, respectively, in the e-curable group and to 7 (12%), 22 (37%), and 10 (17%) patients, respectively, in the non-e-curable group. The 5-year overall survival rates in the e-curable and non-e-curable groups were 97% and 75% (p < 0.05), respectively. The overall survival rate was significantly higher in the e-curable group. Three deaths (10%) occurred due to primary cancer. The other reasons were as follows: other organ cancer (30); heart failure, 4 cases; pneumonia, 11 cases; and others, 11 cases.

The 5-year disease-specific survival rates in the e-curable and non-e-curable groups were 100% and 98%, respectively. The lymph node recurrence rates in the e-curable and non-e-curable groups were 5% (1/39) and 7% (4/59), respectively. The local recurrence rates in the e-curable and non-e-curable groups were 0% (0/39) and 7% (4/59), respectively. The 5-year recurrence-free survival rates in the e-curable and non-e-curable groups were 97% and 98%, respectively. The 5-year recurrence-free survival rates in the group with INF-a and INF-b, INF-c, or lymphovascular invasion were 100% and 87%, respectively. The recurrence-free survival rate was significantly higher in the group with INF-a and no lymphovascular invasion than in the group with INF-b, INF-c or lymphovascular invasion.

Conclusion: Our data support the clinical validity of the e-curable conditions after ER for MM/S1 ESCC of the JES guidelines. However, MM/S1 ESCC with any lymphovascular invasion may have more possible curative conditions after ER without additional treatment.

Introduction: Endoscopic submucosal dissection (ESD) allows en-bloc resection of early gastric cancer (EGC) with wide resection margins. The local recurrence rate after ESD is reported to be lower than that after gastrectomy. Aims: To compare clinical, oncological and immunological outcomes were compared between the two groups. Results: From 2011 to 2016, 36 patients with early gastric cancers were randomly assigned to receive ESD (n = 18) or Lap gastrectomy (n = 18). There was no difference between the two groups in terms of age, gender, ASA grade and baseline demographics (Table 1). ESD was associated with significantly shorter operative time (109.4 ± 55.8 vs 266.2 ± 47.8 mins, p < 0.001), hospital stay (4 (3–6) vs 8 (4–14) days; p < 0.001) and lower complication rate (1 (5.6%) vs 7 (38.9%); p = 0.041). There was no mortality at 30 days for the two groups, while those in ESD group tolerated full diet earlier (2 (1–5) vs 5 (3–12) days; p < 0.001). Patients who received ESD had significantly lower level of CRP as well as VAS pain scores when compared to gastrectomy. Conclusion: Our prospective randomized study showed that patients treated by ESD had significantly lower complication rate and better perioperative outcomes when compared laparoscopic gastrectomy. ESD should be the first line treatment for intramucosal early gastric cancers.

Introduction: Pre-malignant conditions and lesions of the stomach (PCLS): atrophy, intestinal metaplasia and dysplasia are risk factors for the development of stomach cancer; therefore, its diagnosis is very important to identify patients with greater probability of this malignan neoplasm. The Clinical Guidelines recommend that during endoscopy procedure, to avoid an under diagnosis, biopsies of different areas of the stomach should be taken even when no lesion is evident in order to identify PCLS that are generally multi-focal. The initial identification of patients with this type of lesions and their subsequent stratification with the OLGA and OLGUIM systems allows defining the subgroup of patients that merit follow-up because they have a higher risk of developing gastric cancer. However, there is a discrepancy between endoscopists, because it is now preferred to take biopsies directed at the lesions and not to do them systematically at fixed sites, so that no lesion is observed.

Aims & Methods: We aimed to evaluate and compare the prevalence of PCLS in biopsies taken from gastric mucosa with or without lesion during the endoscopic examination. A retrospective, cross-sectional study was performed on 356 dyspeptic patients. We reviewed the reports of esophagogastroendoscopy at the Trujillo Regional Teaching Hospital-Peru from October 2016 to March 2017. This study included reports which were consigned diagnosis with biopsies of different areas from the stomach. These biopsies were sent in different vials. Permission was obtained from the Hospital’s research committee. Those reports that had a diagnosis of stomach cancer, gastrectomy, and those with not biopsy report were removed.

Introduction: Prognosis of GC has a noticeable relation with its clinical stage. Atrophic gastritis (AG), intestinal metaplasia (IM) and dysplasia are well-recog-
nized risk factors for intestinal type GC (GC). A large cohort study has confirmed that the annual incidence of GC were approximately 0.1% patients with AG, 0.25% for IM and 6% for high-grade dysplasia, which were much higher than those of normal gastritis. In addition, long-term follow-up studies have con-

Results: A total of 331 patients were enrolled. 214 patients were classified into group A, 106 patients into group B, 8 patients into group C and 7 patients into group D, respectively. According to the pathological results, 177 cases were non-ampullary duodenal adenoma (SDA) histologically proven were included. Patients with PAF and ampullary adenoma were excluded. All the following outcomes were systematically recorded in both centers: complete endoscopic resection, resection with negative lateral and vertical margins, recurrence, success of the endoscopic treatment and adverse events (Perforation, intra-procedural bleeding, delayed bleeding, others). There were analysed with multivariate analysis.

Results: 134 procedures were performed. The mean patient age was 65 years (33–85), 50.7% were women. The mean SDA size was of 20.7mm (5-50 mm), mostly located in the second duodenal portion, and 64.9% of the adenomas had a villous component, 34.3% with high grade dysplasia and 7.5% with in situ and intramus-
cosal. Discrepancy between biopsies and the final histology was demonstrated, as only 13 of the lesions being upgraded significantly. An EMR was performed in 98.5% of the cases with a complete endoscopic resection rate of 96.2% which was associated in multivariate analysis with the lesion size and depressed en-bloc. The en-bloc resection rate was of 44%. Vertical margins were negative in 91.8% of the cases. Negative lateral and vertical margins was associated in multivariate analysis with the lesion size and its en-bloc resection.

Aims & Methods: We aimed to discuss the correlation between the combination of Helicobacter pylori antibody and serum pepsinogen and OLGA/OLGIM staging system in gastric precancerous lesions risk assessment. A total of 331 patients were enrolled after the examination of endoscopy at Endoscopy Center, the First Affiliated Hospital of Zhejiang Chinese Medical University from October 2014 to December 2015. According to the result of gastroscopy, gastric secretion and serum Helicobacter pylori antibody test, the patients were divided into four groups: Group A: Hp (+) and PGI (> 70 mU/mL), Group B: Hp (+) and PGI (< 70 mU/mL), Group C: Hp (-) and PGI (> 70 mU/mL), Group D: Hp (-) and PGI (< 70 mU/mL). According to the range and degree of atrophy/intestinal metaplasia, precancerous lesions were divided into five groups on the basis of OLGA/OLGIM staging system. The levels of Hp infection rate, PGI, PG I and PG II were compared between different groups, and the correlation between ABC method and OLGA/OLGIM staging system were evaluated. Statistical analysis was accomplished by chi-square test and logistic regression modeling analysis.

Results: A total of 331 patients were enrolled. 214 patients were classified into group A, 106 patients into group B, 8 patients into group C and 7 patients into group D, respectively. The levels of Hp infection rate, PGI, PG I and PG II were compared between different groups, and the correlation between ABC method and OLGA/OLGIM staging system were evaluated. Statistical analysis was accomplished by chi-square test and logistic regression modeling analysis.
In this study 888 early gastric lesions in 783 patients who underwent EMR/ESD at our hospital between January 2012 and March 2017 was retrospectively analysed. Postprocedure bleeding was defined as: (1) hematemesis or melena for which an emergency endoscopy was required and (2) bleeding which were confirmed with a repeat endoscopy after a drop ≥2 g/dL of haemoglobin level.

Results: The total number of patients undergoing antithrombotic therapy was 78, or 33% of patients. Of 38 patients who were taking antithrombolytics only, 29 were taking antiplatelet agents only, and 11 were taking the both. The antithrombotics were suspended in 22 cases (Group A), substituted with heparin in 18 (Group B), and kept continued in 38 (Group C). Postprocedure bleeding was encountered in 31 out of 783 cases (4.0%), 21 of which occurred in patients on antithrombotic therapy (21/78: 27%) whereas 10 of which occurred in those without (10/752: 1.3%). A univariate analysis between the patients with postprocedure bleeding and those without concerning such variables age, gender, the diameter and number of the resected lesions, use of antithrombotics, and the expertise of the operating endoscopist revealed that only the use of antithrombotics was significant risk factor for the postprocedure bleeding (odds ratio = 15.926, 95% confidence interval: 7.415-34.288, p < 0.01). However, the rate of postprocedure bleeding was not significantly different among Group A, B and C. Among the 21 bleeding patients with antithrombotics, the agent had been suspended or substituted with heparin before EMR/ESD in 10 and had been continued without suspension in 11. There was no significant difference of bleeding rate between the two groups.

Conclusion: The use of antithrombotics was a significant risk factor for the postprocedure bleeding after EMR/ESD for early gastric lesions. The rate of bleeding was not significantly different regardless if the antithrombotics were suspended, substituted with heparin, or continued without suspension.

P0574 BLEEDING AFTER ENDOSCOPIC RESECTION FOR EARLY GASTRIC LESIONS IN PATIENTS ON ANTIITHROMBOTIC THERAPY

T. Nagai, S. Matsui, H. Kashida, Y. Komeda, T. Sakurai, M. Kudo
Dept. Of Gastroenterology And Hepatology, Kindai University Faculty of Medicine, Osaka-sayama/Japan

Contact E-mail Address: tomoyukinagai@mac.com

Introduction: Due to the increase of elderly patients who are often receiving antithrombotic therapy for cardio- and cerebrovascular diseases, postprocedure bleeding after endoscopic treatments for early gastric lesions has become one of the major concerns of therapeutic endoscopists. The Japan Gastroenterological Endoscopy Society (JGES) and other related associations published the Guidelines for Gastroenterological Endoscopy in Patients Undergoing Antithrombotic Treatment in 2012. According to the guideline it is not necessary to suspend an antiplatelet agent before endoscopic treatments including endo-

scopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD) if the agent is not combined with other antithrombotic drugs (monotherapy). On the other hand it is recommended that anticoagulants should be substituted with heparin before EMR/ESD. The aim of this study is to clarify the efficacy of the recommendations of the guideline.

Aims & Methods: In this study 888 early gastric lesions in 783 patients who underwent EMR/ESD at our hospital between January 2012 and March 2017 were retrospectively analysed. Postprocedure bleeding was defined as: (1) hematemesis or melena for which an emergency endoscopy was required and (2) bleeding which were confirmed with a repeat endoscopy after a drop ≥2 g/dL of haemoglobin level.
**Aim & Methods:** The aim of this study is to evaluate the usefulness of OLGA and OLGIM staging according to Laurens’s histological classification of GC in considering with other risk factors of gastric cancer. From January 2006 to December 2015, 607 GC patients and 677 control subjects were enrolled who underwent esophagogastroduodenoscopy. Biopsies were taken from the greater and lesser curvatures of the antrum and mid-body, respectively. The OLGA and OLGIM stage (0–IV) was recorded by combining antral with body atrophy and lesser curvatures of the antrum and mid-body, respectively. The OLGA and OLGIM staging systems have been suggested to provide risk estimation for GC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** ycyhijhop@hanmail.net

**Introduction:** Atrophic gastritis and intestinal metaplasia are the cancerization field in which gastric cancer (GC) develops in case of intestinal type. The OLGA and OLGIM staging systems have been suggested to provide risk estimation for GC.

**Aims & Methods:** We evaluated the relationship between BMI and digestive cancer mortality across seven BMI categories. Below 25 kg/m², the HRs of death for each 5 kg/m² increase in BMI were lower compared with controls (4.9% and 609/597, respectively; 95% CI: 0.62–0.79 for stomach cancer, and 0.70–0.90 for colorectal cancer). Over 25 kg/m², the HRs of death for each 5 kg/m² increase in BMI were greater than 1.00% for ages under 60 years (0.05% for ages in the 60–70 and >70, respectively; 95% CI: 1.19–1.43 for stomach cancer, and 1.30–1.64 for colorectal cancer). In a Cox model.

**Results:** During follow-up, 7774 total deaths occurred from digestive cancer. HR for digestive cancer mortality across seven BMI categories. Below 25 kg/m², the HRs of death for each 5 kg/m² increase in BMI were lower compared with controls (4.9% and 609/597, respectively; 95% CI: 0.62–0.79 for stomach cancer, and 0.70–0.90 for colorectal cancer). Over 25 kg/m², the HRs of death for each 5 kg/m² increase in BMI were greater than 1.00% for ages under 60 years (0.05% for ages in the 60–70 and >70, respectively; 95% CI: 1.19–1.43 for stomach cancer, and 1.30–1.64 for colorectal cancer). In a Cox model.

**Conclusion:** Low BMI were predictors of mortality from esophageal cancer and stomach cancer. High BMI were predictors of mortality from liver cancer and gallbladder cancer and biliary tract cancer. BMI were not associated mortality from small intestine cancer and pancreatic cancer.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

BMI, body mass index; CI, confidence interval; GB, gallbladder; HR, hazard ratio. 2 Hazard ratios were calculated using Cox proportional hazards models after adjustment for age at baseline (continuous variable), smoking status (current smoker, former smoker, never-smoker, and missing smoking status), alcohol consumption (frequency, five or more times/week, one to four times/week, less than one times/week, past drinker [no alcohol for a year], never-drinker, or missing information), monthly household income (Korean won [KRW], $1 United States dollar = 1170 KRW as of August 1, 2004; < 500, 000, 500, 000-990, 000, 1, 000, 000-1, 490, 000, ≥ 1, 500, 000, missing information), and physical activity (yes, no). HRs were not presented for causes with less than 10 deaths.
Consistent with the mechanism of action of IRE on the cell membrane only, there was complete cell death within the IRE lesions without intervening live cells. However, there was no difference in histology depending on gastric part in which ablation was applied. During the study, no complication was observed in pigs in 24 hours after ablation.

Conclusion: The new endoscopic IRE device, which can perform IRE ablation on the marginal area, resulting in unsuccessful delineation. The new endoscopic IRE device, which can perform IRE ablation on the marginal area, resulting in unsuccessful delineation.

P9581 DIAGNOSIS OF MICROVESSEL PATTERN IS MORE IMPORTANT THAN MICROSURFACE PATTERN TO DELINEATE GASTRIC CANCERS DETECTED AFTER H. PYLORI ERADICATION BY MAGNIFYING ENDOSCOPY

T. Iwasaki, K. Uchita, K. Kojima, S. Iwamura

Introduction: It is difficult to delineate gastric cancer that is detected after successful eradication of Helicobacter pylori. One reason is reportedly the difficulty in identifying the demarcation line between the cancerous lesion and non-cancerous gastric mucosa due to a mixture of non-neoplastic epithelial-lined structure inside the neoplasm. However, most all previous studies have only used magnification endoscopy (ME) at low power magnification which could evaluate microvascular pattern (MSP) but could not evaluate microvascular pattern (MVP). The highest power magnification was necessary to evaluate MVP accurately and to draw the diagnosis. The diagnostic accuracy of ME-NBI in delineating the gastric cancers might not have been accurately assessed in these studies.

Aims & Methods: The aim of this study was investigating diagnostic efficacy of ME with NBI in delineating the gastric cancers after eradication HP, using ME at highest power magnification, and classifying ME features of the marginal area according to the vessel plus surface classification system (VSCS) to realize which was more important ME findings MSP or MVP to detect demarcation line. Endoscopic examination was performed using a magnification endoscopy (GF-H260Z, Olympus Medical Systems Co, Tokyo, Japan) and NBI system (EVIS LUCERA Spectrum system; Olympus Medical Systems Co, Tokyo, Japan). Endoscopic imaging procedures were performed at low-power magnification followed by highest power magnification. On the day of EGD, the lesion line was marked 3-5 mm outside of the margin of the lesion. A lesion meeting all of the following criteria was defined as a lesion with successful delineation: (1) the demarcation line of the lesion is endoscopically identified with a high level of confidence; (2) According to histopathological findings, the lesion is histologically identified as the cancerous lesion. The diagnostic accuracy of ME-NBI in delineating the lesions was evaluated. On the other hand the ME findings of the marginal area in each lesion were classified in terms of microvascular pattern (MSP) and microvascular pattern (MVP) according to the VSCS to identify the findings that were useful in delineating the lesions in patients with differentiated-type early gastric cancers. The classification according to the VSCS was made in the marginal area with the least irregular findings.

Results: Of 178 consecutive lesions of differentiated-type early gastric cancer treated endoscopically since ran esophageal diagnosis (ESD) between August 2013 and March 2017, the study included 59 lesions that were detected after successful H. pylori eradication. The result of ME-MBI findings are summarized in the table. Gastric cancer was successfully delineated in 98.3% (58/59) of the lesions with irregular MVP and/or irregular MVP with a demarcation line. Among the ME findings of the demarcation line, irregular MSP and irregular MVP were present in 67.7% (40/59) and 93.2% (55/59), respectively, according to the VSCS, with a higher percentage of lesions with irregular MVP than those with irregular MSP. In addition, there was no finding which was irregular MSP and regular MVP, but 27.1% (16/59) was regular MSP and irregular MVP, which indicated that the ME findings of MVP was more important than MSP. One lesion showed regular MSP or regular MVP without a demarcation line in a portion of the marginal area, resulting in unsuccessful delineation.

Conclusion: The accuracy of ME with NBI in delineating gastric cancer detected after H. pylori eradication was 98.3%, which was higher than the values reported previously. In addition, the MVP as visualized by ME appeared to be a more reliable finding. These results indicate a meticulous observation of the MVP under maximal magnification to be crucial for the delineation of gastric cancer detected after eradication of H. pylori.

Introduction: Endoscopic forceps biopsy (EFB) is the gold standard for gastric epithelial tumor diagnosis. However, definitive diagnosis is often difficult, and some cases are diagnosed as gastric indefinite neoplasia (GIN), which corresponds to category 2 in the revised Vienna classification. GIN lesions require short periods of follow-up. The most appropriate forceps size for gastric biopsy has yet to be determined. In the Japanese Classification of Gastrointestinal Tumor, diagnoses of GIN are attributed, at least partly, to the size of biopsy specimens. Since specimens yielded by small biopsy forceps are small, the use of small biopsy forceps is expected to increase the rate of GIN diagnoses.

Aims & Methods: The relationship between forceps size and the frequency of GIN was investigated. The patients in this cohort were divided into two historical groups. The first group comprised patients evaluated during the period when standard biopsy forceps (StF) were used (April 2010-March 2011), and the second comprised patients evaluated during the period when small biopsy forceps (SmF) were used (April 2011-March 2013). Standard caliber endoscopy was used for all esophagogastroduodenoscopy (EGD). We count the number of GIN and gastric carcinoma lesions. Patient characteristics, lesion characteristics (e.g., site, macroscopic appearance, and color tone), endoscopist experience level, biopsy specimens, and diagnostic efficacy were employed as significant variables. The clinical courses of GIN cases were followed for 3 years, and the timing of EGD after the GIN diagnosis and the final pathological result were investigated.

Results: Among the 8420 patients who underwent EGD in the first period, 2, 584 (30.7%) underwent gastric biopsy with StF. Among the 15,986 patients who underwent EGD in the second period, 4204 (26.3%) underwent gastric biopsy with SmF. Gastric carcinoma was diagnosed in 7.93% (205/2584) and 7.54% (317/4204) of the StF and SmF groups, respectively (P = 0.556). GIN was diagnosed in 389 (15.0%) and 258 (6.1%) of the StF and SmF groups, respectively. The difference was significant (P = 0.048). The two groups were diagnosed as GIN did not differ significantly in terms of the patient characteristics, the lesion characteristics, endoscopist experience level, and biopsy related hemorrhage. The mean minor- axis lengths of the biopsy samples were 1.50 ± 0.50 mm and 1.38 ± 0.40 mm in the StF and SmF groups, respectively. The SmF group samples tended to be shorter (P = 0.088). In both groups, 40% of the final diagnoses were epithelial neoplasia; no significant differences were observed.

Conclusion: SmF use may increase the rate of GIN. Thus, SmF use should be avoided with a standard caliber endoscopy.

Introduction: Stomach cancer is a leading cause of cancer-related deaths in the world. The importance of the role of stress in cancer initiation is contradicted and debatable. Other natural factors such as nitrates, which are widely presented in daily food, are actively discussed as carcinogenic to humans. But, there is no clinical and epidemiological evidences that the nitrosamines itself can induce the stomach cancer. Aims & Methods: For the better understanding of carcinogenic effects of daily stress and nitrates in development of stomach cancer, here we studied the role of these factors in adenocarcinoma in stomach of rats. The experiments were carried out with male adult rats (n = 200). To examine the role of stress and nitrosamines in gastric mucosal injuries we used: 1) the model of chronic social stress (over-population during 9 months); 2) the daily using of toluidine (2 g/kg) in food and water with nitrates (2 g/l); 3) the combined effects of stress + nitrates. The
upper endoscopy was performed using our in-house custom-made multichannel endoscopy system. Histological assay performed to analyze the changes in the gastric tissues.

Results: Using upper gastroscopy, we studied the stomach tissues during 9 months of lining of rats in chronic stress. There were no changes in the gastric mucosa during the first 3 months. In the third month 35% (7 of 20) of animals demonstrated small peptic ulcer (n = 11). These changes progressed during other time of observation. 9 months of experiment. So, this time all rats showed peptic ulcers both types with significant increase in the number of ulcers (n = 21 and large, n = 9). Thus, this series of experiments clearly showed that chronic stress plays provoking role in the peptic ulcer formation in the stomach of rats. The deleterious effects of nitrosamines on the gastric mucosa were observed 4 months after the beginning of daily using of toluidine and nitrates in 75% of rats (15 of 20). These rats showed symptoms of atrophic gastritis. Other 25% (5 of 20) of animals did not demonstrate any changes in gastric mucosa. Thus, this series of experiments markedly showed that effect of long-term eating low-dose nitrosamines induced of atrophic gastritis in the stomach of majority of rats. Several similar protocol of the first and second parts of experiments, we observed the changes in the stomach tissues during 9 months. The same scenarios of typical gastric injuries induced by stress and nitrosamines were observed in rats, i.e. they showed development of peptic ulcers and atrophic gastritis. But, 7 months after the start of experiment, these pathological changes of gastric tissues were associated with intestinal metaplasia of goblet cells, which is the pre-cancer symptom. In 9 months of study, symptoms of gastric adenocarcinoma were observed in 82% of rats (131 of 160). Tumor lesions was accompanied by the migration of metastatic tumor cells through the bloodstream in the liver. The number of metastatic nodes varied from 1 to 5.

Conclusion: Thus, in our research we clearly show that only combination of two potent factors: stress and nitrosamines induce the development of gastric cancer with metastasis in the liver while the presence of these factors alone contribute mucosal injuries without oncological changes in the stomach.

Disclosure of Interest: All authors have declared no conflicts of interest.

together with lower levels of phosphoserine, ethanolamine phosphate and urea (Table 1). The 14 GJFAAs revealed diagnostic values with AUC from 0.666 to 0.868, and the combined AUC of them reached to 0.902 (95% CI, 0.846–0.959) for the diagnosis of GC. Importantly, their AUCs were from 0.649 to 0.857, and the combined AUC reached to 0.880 (95% CI, 0.792–0.969) for the diagnosis of early GC. Particularly, leucine, threonine and serine are the most altered three GJFAAs between the two groups, whose fold change more than 2 and AUC value greater than 0.8. Moreover, the combined AUC of the 3 non-AAAs was 0.869 (95% CI, 0.805–0.934) for the diagnosis of GC. It was slightly higher than the combination with 3 AAAs 0.841 (95% CI, 0.773–0.908). Additionally, the pathway of aminoacyl-RNA biosynthesis metabolism was excessively activated, which significantly responsible for the above alternative alterations in GC patients.

**Introduction:** Gastric cancer (GC) is the fourth most common type of cancer and the second leading cause of cancer related death. The gold standard for diagnosis is the esophagogastroduodenoscopy (EGD) with targeted biopsies.

**Aims and Methods:** Retrospective observational and descriptive study in patients diagnosed of gastric cancer from January 2013 to December 2016 in the area of Ciudad Real (Spain). Missing rate of gastric cancer was defined as the percentage patients who had a negative EGD three years before the diagnosis of GC. A survival analysis was performed with Kaplan Meier curves, mainly focussing on the influence of missing rate for gastric cancer. We studied the features related to EGD that could lead this issue.

**Results:** 162 patients were included, 65% male with a mean age at diagnosis of 72 years. Intestinal type was the most common histology (76%). A rate of 6.8% missing of gastric cancer was detected with an average of 20 months in delay of diagnosis. However, the survival rate was similar between patients with and without a previous EGD (7.08 vs 5.05 months p = 0.60). Among the patients passed away, a longer delay period was observed compared to patients who were still alive (6 months vs. 25 months; p = 0.006). In the aforementioned subgroup, biopsias were taken in 72% with gastric atrophy in all cases. Helicobacter pylori infection was detected in 30% of them. 55.6% of the EGDs were carried out without sedation. At no point chromoendoscopy was performed, pictures were taken and withdrawal times were not reflected.

**Conclusion:** Despite the fact that EGD is by far the most effective method to diagnose gastric cancer, 1 out of 10 cancers or premalignant lesions are not found. Therefore, it is of utmost importance to put in place quality protocols in EGD that may help to increase the diagnosis of early gastric cancer, and by this way, improve the survival rate of these patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

SERUM PG2 LEVEL IN GASTRIC CANCER

P0589 INTERFERENCE OF PG2 TATA BOX REGION WITH THE

¼

(from 308 bp to 479 bp). These fragments were grouped into 4 sized categories

AUC: 758, p

After ROC curve analysis, the sensitivity to discriminate GC at 15 ng/mL

analyzed by the capillary-electrophoresis (GeneMapper software). Association

ism frequencies in relation to serum PG2 (sPG2) expression level, HP-positivity

understood. The aim of this study was to analyse the polymorphisms in the

expression of the corresponding gene, are under investigation. This study will be

evaluated.

important to deeper understand the physiopathological PG2 role in GC.

Several studies have demonstrated serum PGII level as a marker of

the functional gastric mucosa, and a marker of some tumor including the gastric

cancer. However, the modulation of the protein and its role in cancer is not fully

understood. The aim of this study was to analyse the polymorphisms in the

TATA BOX region, which provides a binding site for the transcription factor for

the PG2 gene, in association with the PG2 circulating level and clinical parameters

in population at risk for GC and GC patients.

Aims & Methods: Gastric function of 180 patients (67 GC, 71 first-degree rela-

tives of GC patients (FDR-GC) and 42 autoimmune chronic AG (ACAG)) was

assessed by gastropanel test. We investigated the PG2 TATA BOX polymorph-

ism frequencies in relation to serum PG2 (sPG2) expression level, HP positivity

and risk for GC. TATA BOX DNA fragments were amplified by PCR and

analyzed by the capillary-electrophoresis (GeneMapper software). Association

among clinical data and PG2 polymorphisms were estimated by Receiver operat-

ing characteristic (ROC) curve and linear regression analyses.

Results: After ROC curve analysis, the sensitivity to discriminate GC at 15 ng/mL

PG2 cut-off was 70.15% and 79, 65% sensitivity and specificity, respectively

(AUC: 758, < 0.0001). We obtained 26 different PG2 TATA box fragments

among 308 bp to 479 bp. These fragments were grouped into 4 sized categories

(1 = 308–400 bp; 2 = 401–436 bp; 3 = 437–438 bp; 4 = 439–479 bp). A positive cor-

relation among the increase of PG2 sized fragments and the sPG2 level was found

in the GC group (linear regression y = 16, 4381 = 2, 8684 x, p = 0.02).

Conclusion: In the literature, we confirm sPG2 level as a marker discriminating

between GC and individuals at risk for GC (ie ACAG and FDR) in our series. In addition we reported a correlation between the shortest PG2

TATA BOX fragments and the lower PG2 level. Since highest PG2 level was

related to the GC condition, our data suggest that carriers having longer TATA

BOX region may produce higher sPG2 level than patients with shorter condition.

The clinical significance of the differences in PG2 level associated with the TATA

BOX fragments, by interfering with the transcriptional factor and then with the expression of the corresponding gene, are under investigation. This study is important to deeper understand the physiopathological PG2 role in GC.

P0590 HELICOBACTER PYLORI INFECTION ASSOCIATED WITH NONALCOHOLIC FATTY LIVER DISEASE: A LARGE-SCALE

COHORT STUDY

T. Kim, T.J. Kim, H. Lee, J.I. Kim

Department Of Medicine, Samsung Medical Center, Sungkyunkwan University

School of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: attack863@naver.com

Introduction: Previous studies suggested a link between Helicobacter pylori (H. pylori) infection and nonalcoholic fatty liver disease (NAFLD), yet large-scale longitudinal studies are lacking to elucidate this association.

Aims & Methods: A cohort study of 17,028 adults without NAFLD at baseline, who participated in a repeated health screening examination including an H. pylori-specific immunoglobulin G antibody test, was conducted to evaluate the association between H. pylori and NAFLD development. Fatty liver was diagnosed by ultrasonography.

Results: During the 83,130 person-years follow-up, participants with H. pylori infection had a higher rate of incident NAFLD than those who were uninfected. In a multivariable model adjusted for age, sex, body mass index, smoking status, alcohol intake, regular exercise, year of screening exam, smoking status, alcohol intake, regular exercise, and education level. H. pylori, helicobacter pylori; HR, hazards ratio; CI, confidence intervals.

*Estimated from Cox proportional hazard models adjusted for age, sex, body mass index, year of screening exam, smoking status, alcohol intake, regular exercise, and education level.

Conclusion: H. pylori infection was significantly associated with the development of NAFLD, independent of metabolic and inflammatory risk factors. H. pylori infection may play a pathophysiologic role in NAFLD development, indicating that H. pylori eradication might play a role in reducing risk of NAFLD.

P0591 HELICOBACTER PYLORI INFECTION STATUS IN HUMAN IMMUNODEFICIENCY VIRUS-POSITIVE PATIENTS

Gastroenterology&hepatology, Osaka National Hospital, Osaka/Japan

Contact E-mail Address: seiya_weckle_0728@yahoo.co.jp

Introduction: Helicobacter pylori infects the gastric mucosa and causes chronic gastritis via the immunoreaction of the host. By contrast, the human immuno-
deficiency virus (HIV) infects CD4-positive T lymphocytes and destroys the immune system of the host. Some studies pointed out that the H. pylori infection rate is lower in HIV-positive patients. This is because in these patients, H. pylori is incidentally eradicated by the course of antibiotic therapy for HIV infection and because the supply of nutrients to H. pylori is prevented by the decrease in the number of CD4 lymphocytes.

Aims & Methods: We enrolled 290 HIV-positive patients who underwent esopha-
gastro-duodenoscopy in our Hospital between January 2013 and September 2016. As end points of H. pylori infection examination, we retrospectively exam-

ined the presence of gastric mucosa atrophy, H. pylori infection, H. pylori eradication and comorbidity. As end points of HIV infection examination, we quantified the number of CD4 lymphocytes and the titer of HIV and investigated the presence of acquired immunodeficiency syndrome (AIDS). Based on these data, we examined the relationship between H. pylori and HIV infections.

Results: Of the 290 patients, 281 were men and 9 were women, whose median age was 46 years (range, 22–82 years). Ninety patients had atrophic gastritis or stomach or duodenal ulcer, of whom 40 underwent examination for H. pylori infection. The median number of CD4 lymphocytes in the 21 H. pylori-positive cases was 505/L (range, 188–952/L). The titer of HIV from non-detection to 90, 900 copies/mL, and one patient had AIDS. Meanwhile, the median number of CD4 lymphocytes in the 19 H. pylori-negative cases was 333/L (range, 15–998/L). The titer of HIV from non-detection to 1, 590, 000 copies/mL, and three patients had AIDS. H. pylori eradication therapy was applied in 18 of 21 H. pylori-positive cases. The success rate of primary H. pylori eradication was 37.5% (6/16 patients) and that of secondary eradication was 70% (7/10 patients). In addition, 2.7% of the 26 patients with stomach or duodenal ulcer needed urgent hemostasis. Five (6.7%) of the 74 cases of atrophic gastritis had gastric cancer, of which two were undifferentiated stomach cancers.

Conclusion: In our study, the number of CD4 lymphocytes was higher in the HIV-positive patients with H. pylori infection, implying that the high CD4 count was suggested to be associated with persistent H. pylori infection. In addi-
tion, the success rate of H. pylori eradication was shown to be insufficient in HIV-positive patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

HELICOBACTER PYLORI INFECTION REDUCES THE RISK OF BARRETT’S METAPLASIA AND IS INDEPENDENT FROM THE GEOGRAPHICAL LOCATION, A META-ANALYSIS

B. Eross1, N. Farkas2, K. Márta1, P. Hegyi1
1Centre For Translational Medicine, University of Pecs, Pecs/Hungary

Introduction: In European and Northern American populations a decreasing prevalence of H. pylori infection has been observed, along with an increasing prevalence of Barrett’s oesophagus and an increasing incidence and prevalence of the adenocarcinoma of the oesophagus and gastro-oesophageal junction. H. pylori eradication has been proven a protective factor against Barrett’s oesophagus, but some individual studies suggested the opposite.

Aims & Methods: Our aim was to scrutinize all data available on the relationship between H. pylori infection and Barrett’s oesophagus prevalence, to see, if H. pylori has a protective role for Barrett’s oesophagus and if it is dependent from the geographical location. A meta-analysis was performed using the preferred reporting items for systematic review and meta-analysis protocols (PRISMA-P). We conducted a systematic search in PUBLMED, EMBASE and COCHRANE databases from inception to December 2016, for the keywords of Barrett’s, Barrett’s metaplasia, Barrett’s oesophagus, Barrett’s oesophagus, Barrett’s oesophagus, Helicobacter pylori, H. pylori and Helicobacter. We also used information from the references of relevant publications to find further eligible studies. We have conducted a meta-analysis of the data from all studies included. We used the random effect model as proposed by DerSimonian and Laird.

Results: We have found 568 articles in PUBMED, 741 in EMBASE and 15 in COCHRANE databases. After exclusion of the articles without sufficient data on the prevalence of H. pylori and Barrett’s oesophagus, we have identified 83 articles suitable for statistical analysis. This meta-analysis involved 98 665 patients with Barrett’s oesophagus and 720 800 patients without Barrett’s oesophagus. The statistical analysis from all studies from five continents and 27 countries showed a protective effect of H. pylori for Barrett’s oesophagus. The odds ratio was 0.63 (95% CI 0.55, 0.71) in Asia, 0.71 (0.55, 0.91) for Europe, 3.05 (0.59, 15.73) for Africa, 0.60 (0.51, 0.71) for North America, 0.95 (0.56, 1.64) for South America and 0.56 (0.39, 0.80) for Australia. The OR and 95% CI values were 0.54 (0.43, 1.64) for Eastern Europe, 0.68 (0.52, 0.90) for Western Europe and 0.71 (0.55, 0.91) for all of Europe, suggesting that the protective role of H. pylori infection is not different across Europe.

Conclusion: This large meta-analysis has given further evidence, that Helicobacter pylori infection has a protective role for Barrett’s oesophagus and this protective role is independent from the geographical location, apart from Africa. In view of the decreasing prevalence of H. pylori in developed countries and the epidemiological rise of Barrett’s oesophagus and adenocarcinoma, it would be important to conduct further large, prospective, multinational studies on the effect of H. pylori infection on Barrett’s oesophagus.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Helicobacter Pylori (H. Pylori) has been implicated in worsening outcomes in patients with hepatic encephalopathy. This is believed to be the result of its urease enzyme that increases the production of ammonia. Small studies so far have yielded contradictory results on whether the presence of H. pylori worsens treatment outcomes in hepatic encephalopathy. Therefore, the aim of this study was to assess the impact of H. pylori on mortality, morbidity and resource utilization among patients with hepatic encephalopathy using a national database.

Aims & Methods: This was a case-control study using the National Inpatient Sample 2013, the largest publicly available inpatient database in the United States. All patients with an ICD-9 CM code for a principal diagnosis of hepatic encephalopathy were included. There were no exclusion criteria. Patients positive for H. pylori were identified using the appropriate ICD-9 CM codes. The primary outcome was all cause mortality. The secondary outcome was resource utilization as measure by use of abdominal imaging (CT scan and ultrasound of the abdo- men), length of hospital stay (LOS), total hospitalization charges and costs.

Multivariate regression analyses were used to adjust for the following confounders: Age, sex, race, income in patients’ zip code, Charlson Comorbidity Index, hospital region, location, size and teaching status.

Results: A total of 55,360 patients with hepatic encephalopathy were included in the study, of which 20 had H pylori infection. The mean patient age was 60 years and 52% were female. After adjusting for confounders using multivariate analysis, patients with and without H. pylori had similar adjusted odds of mortality (adjusted Odds Ratio (aOR): 1.71, 95% CI: 0.62-4.74, p = 0.30). As far as resource utilization, patients with and without H. pylori had similar adjusted odds of resource utilization (aOR: 0.92, 95% CI: 0.88–1.04, p = 0.08), LOS (adjusted mean difference: 1.7 days, 95% CI: -0.02–3.42, p = 0.52), and total hospitalization charges (adjusted mean difference: $16588, 95% CI: -$2449 - $37675, p = 0.12). However, patients with H. pylori had higher adjusted total hospitalization charges compared with patients without H. pylori (adjusted mean difference: $6128, 95% CI: $1114 - $11115, p = 0.01)

Conclusion: Presence of Helicobacter Pylori has no impact on inpatient mortality among patients with liver cirrhosis and hepatic encephalopathy. In addition, the presence of Helicobacter Pylori is not associated with any increase in resource utilization among this patient population, with the exception of total hospitalization costs. It is surprising to note that, although total hospitalization costs differed between the two groups, they received the same total hospitalization charges from admitting hospitals.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Helicobacter pylori infection has become more and more resistant to conventional first-line treatment regimens. So, there is a considerable interest in evaluating new antibiotic combinations and regimens. Nitazoxanide is an anti-infective drug with demonstrated activity against protozoa and anaerobic bacteria including Helicobacter pylori.

Aims & Methods: This work is designed to evaluate the efficacy and safety of a unique triple Nitazoxanide containing regimen as a treatment regimen in Egyptian patients with Helicobacter pylori infection.

Methods: Two hundred and twenty four patients with upper Gastro-intestinal tract (GIT) dyspeptic symptoms in whom Helicobacter pylori induced GIT disease were confirmed were included in the study. They have been randomized to receive either Nitazoxanide 500mg bid, Clarithromycin 500mg bid and Omeprazole 40mg twice daily for 14 days or Metronidazole 500mg bid, Clarithromycin 500mg bid and Omeprazole 40mg twice daily for 14 days. Laboratory evaluation for Helicobacter pylori antigen within the stool was done 6 weeks after cessation of Helicobacter pylori treatment regimens to assess the response.

Results: The response to treatment was significantly higher in group 1 of Nitazoxanide treatment regimen than group 2 of traditional treatment regimen. Group 1 showed cure (94.6%) of 111 patients who completed the study in group 1 showed complete cure while only 63 cases (60.6%) of 104 patients who completed the study in group 2 showed the same response according to per-protocol (PP) analysis (p < 0.001). The regimen was well tolerated by all the patients enrolled in the study.

Conclusion: Nitazoxanide-containing triple therapy is a promising therapy for the first-line eradication of Helicobacter pylori. (ClinicalTrials.gov Identifier: NCT02422706)

Introduction: There is no evidence that previous use of macrolides is a useful predictor of the likelihood of standard triple therapy failure in H. pylori eradication (Lim SG, et al. Dig Liver Dis 2016). The goal of this study is to evaluate whether previous intake of various macrolide antibiotics can predict failure to eradicate H. pylori using first-line clarithromycin-containing regimens.

Aims & Methods: Between February 2014 and June 2016 a total of 250 patients with H. pylori infection were prospectively included in a study whose goal was to assess eradication rates with the two clarithromycin-containing regimens. Patients were randomly assigned to one of two regimens: A: Triple therapy (PPI, amoxicillin, clarithromycin, optimized with a double dose of PPI) for 10 days; and B: Concomitant therapy (PPI, amoxicillin, clarithromycin, and metronidazole administered concomitantly) for 10 days. The eradication was evaluated by the Stool antigen test or with the Urease test in double dose of PPI) for 10 days; and B/Concomitant therapy (PPI, amoxicillin, clarithromycin, and metronidazole administered concomitantly) for 10 days. The eradication was evaluated by the Stool antigen test or with the Urease test. In a subgroup of 163 patients (50.6%) and identified resistance to clarithromycin and levofloxacin in 29 (17, 8%) and 20 (12, 3%) of cases, respectively. BQT was administered as first-line clarithromycin-containing regimens. Resistance was defined as resistance to clarithromycin and/or levofloxacin or as resistance to all antibiotics tested. The number of treatment failures (n = 9) did not allow to identify risk factors for failure.

Conclusion: Three-in-one capsule bismuth quadruple therapy is highly effective and safe for treatment of H. pylori infection in clinical routine practice, irrespective of the patient’s migrational background or the number of previous treatment failures.

Introduction: Due to increasing prevalences of clarithromycin resistance in H. pylori infection, current guidelines recommend quadruple therapies as first-line therapy1, 2. Bismuth quadruple therapy (BQT) has been proven superior to standard triple therapy in clinical trials3, however little is known about the efficacy of BQT in clinical routine practice.

Aims & Methods: In a prospective single center cohort study we analyzed consecutive patients in whom three-in-one capsule BQT (Pyl eradication rates in patients with and without previous intake of macrolides.

Conclusion: Previous use of macrolide antibiotics predicts a low response to triple therapy and to concomitant clarithromycin-containing regimens. In addition, our study shows that in patients without previous use of macrolides triple therapy achieves per-protocol eradication rates over 90%.

**Introduction:** Background: Eradication of Helicobacter pylori (H. pylori) infection represents a clinical challenge. The current requirements demand eradication rates of 75-80% which has made that the use of triple treatments including clarithromycin or metronidazole had been gave up on those countries, such as Spain, with high resistance rates. Quadruple therapy with a proton pump inhibitor (PPI) plus a single three-in-one capsule containing bismuth subcitrate potassium, metronidazole, and tetracycline (BMT) have shown high eradication rates in clinical trials.

**Aims & Methods:** We aimed to evaluate the efficacy and safety of a PPI-bismuth based quadruple therapy in patients diagnosed of H pylori infection in a clinical setting of a Private Hospital, located at the North of Madrid (Spain). A prospective and real-life study was conducted, between March 2016 to February 2017, on consecutive patients with confirmed H pylori infection eradication indication. Patients were treated for ten days with a galenic preparation containing bismuth subcitrate potassium 140 mg, metronidazole 125 mg, and tetracycline 125 mg, three capsules four times daily, and esomeprazole 40 mg twice daily and probiotic during 30 days. The primary endpoint was H. pylori eradication rate with successful urea breath test performance, at least 28 days, after the end of treatment. Intent-to-treat (ITT) efficacy analyses included all patients who received study medication and took at least one dose of study medication; patients without an observed outcome were considered as treatment failures. Proton pump inhibitors (PPIs), which excluded patients who did not complete the study or who had major protocol violations, were also conducted to confirm the ITT results.

**Results:** A total of 100 patients, 60 (60.0%) women and 40 (40.0%) men, who fulfilled the respective demands of the inclusion and exclusion criteria, were enrolled consecutively. Five of these were lost to follow-up. Mean (standard deviation) [95% confidence interval] age was 47.1 (15.4) [44.0 to 50.2] years. Twenty-five (25.0%) patients had a prior history of using medications to treat H. pylori, most often clarithromycin, amoxicillin, and PPI. In the ITT population, the eradication rates were 90.7% (68/75) and the 80.0% (20/25) depending on whether the PPI-BMT treatment was administered as first-line or as rescue therapy, respectively. In the PP population, the eradication rates were the 98.6% (63/64) and the 95.2% (20/21) in those patients treated with PPI-BMT as first-line or as rescue therapy, respectively. Eighteen (18.0%) patients reported at least one adverse event.

**Conclusion:** In patients with confirmed H pylori infection, 10 days of treatment with a regimen of bismuth, metronidazole and tetracycline plus esomeprazole provides high eradication rates not only as first-line but also as rescue therapy, with an acceptable safety profile.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0600** A SEVEN-DAY TRIPLE THERAPY CONTAINING A POTASSIUM-COMPETITIVE ACID BLOCKER COMPARED WITH PROTON PUMP INHIBITORS, AMOXICILLIN AND CLARITHROMYCIN FOR FIRST-LINE HELICOBACTER PYLORI ERADICATION IN JAPAN: A SINGLE-CLINIC RETROSPECTIVE STUDY

S. Yojiro
Sadamoto GI Clinic, Kitakyushu/Japan

Contact E-mail Address: sadamotot@yahoo.co.jp

**Introduction:** This study was evaluated the effectiveness and safety of Vonoprazan, a potassium-competitive acid blocker (P-CAB) compared with proton pump inhibitors (PPIs) for a first-line Helicobacter Pylori (H. pylori) eradication.

**Aims & Methods:** We retrospectively analyzed data from first-line H. pylori eradication treatment (vonoprazan or PPIs with 400 mg clarithromycin and 1500 mg amoxicillin) within Japan during 2017. Vonoprazan were 10% (138/169) in the VPZ group vs. 74.4% (131/176) in the EPZ group.

**Results:** ITT and PP analysis of the first-line H. pylori eradication for vonoprazan, lansoprazole, rabeprazole, and esomeprazole were 75.5%/86.8%, 63.9%/76.2%, 68.0%/79.5%, and 63.2/70.8%, respectively. The vonoprazan eradication rates were significantly higher than those of these PPIs (P < 0.05), respectively. There was no significant difference in the adverse events between the two therapies.

**Conclusion:** 7-day P-CAB based triple therapy is more effective than 7-day PPI based triple therapy as a first-line H. pylori eradication without differences in tolerability.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0601** AN OPEN-LABEL, RANDOMIZED CONTROLLED TRIAL OF VONOPRAZAN VERSUS ESOMEPRAZOLE AS PART OF FIRST-LINE TRIPLE THERAPY FOR HELICOBACTER PYLORI ERADICATION

Gastroenterology And Hepatology, Takamatsu Red Cross Hospital, Takamatsu/Japan

Contact E-mail Address: h-tama@gd-soft-net.ne.jp

**Introduction:** Vonoprazan (VPZ) is a novel, orally bioavailable, potassium-competitive acid blocker and PPI for the treatment and prevention of acid-related gastrointestinal diseases. A phase III study revealed that VPZ is superior to lansoprazole as part of first-line therapy for Helicobacter pylori (HP) infection when combined with 400 or 800 mg clarithromycin (CAM). Aims & Methods: The aim of the current study was to evaluate the efficacy and safety of VPZ. CAM (400 mg/day), and amoxicillin (ABPC: 1500 mg/day) triple therapy in post-marketing use in Japan. A randomized, open-label, single-center study was conducted to verify the superiority of VPZ to esomeprazole (EPZ) as part of first-line triple therapy in patients with HP infection. Three hundred and forty-nine Japanese patients with HP infection diagnosed using a rapid urease test were enrolled between June 2015 and October 2016. The patients were randomly allocated to VPZ group (VPZ 40 mg/day, ABPC 1500 mg/day, CAM 400 mg/day) or EPZ group (EPZ 40 mg/day, ABPC 1500 mg/day, CAM 400 mg/day) with stratification according to endoscopic findings of gastric/duodenal ulcer/scar and CAM resistance determined via a microbial sensitivity test. The eradication rates were evaluated using the urea breath test 8 to 12 weeks after cessation of therapy.

**Results:** Three hundred and forty-five patients (177 men, 168 women; mean age 64.7 years [range 27-89 years]; VPZ group, 169; EPZ group, 176) completed the study. One patient in the VPZ group and three patients in the EPZ group discontinued the treatment because of adverse events. One patient in the VPZ group and three patients in the EPZ group were lost to follow-up. There was no significant difference in the overall first-line eradication rate between the two groups (81.7% [138/169] in the VPZ group vs. 74.4% [131/176] in the EPZ group [P = 0.10]). Furthermore, there was no significant difference in the first-line eradication rate in patients with CAM-sensitive HP (87.2% [82/94] versus 84.6% [77/91] in the VPZ and EPZ groups, respectively, [P = 0.60]), although the eradication rate was significantly higher among patients with CAM-resistant HP in the VPZ group than that in the EPZ group (73.6% [30/41] vs. 55.6% [35/63], [P = 0.044]). The first-line eradication rate in the patient with high estimated glomerular filtration rate (eGFR ≥ 100 ml/min/1.73 m²) was significantly lower than in that in the patients with low eGFR (r < 60 ml/min/1.73 m²; 86.4% [32/37] in
the patients with low eGFR, 65.3% [34/53] in the patients with high eGFR [P = 0.034], it was significantly higher in the VPZ group than that in the EPZ group (79.3% [23/29] versus 50% [11/13], respectively, [P = 0.025]). The first-line eradication rate in continuous smokers was significantly lower than that in non-smokers (81.0% [187/231] in non-smokers vs. 64.3% [27/42] in continuous smokers [P = 0.016]). However, there were no significant differences between the VPZ and EPZ groups in non-smokers (84.2% [96/114] versus 77.8% [91/117], respectively, [P = 0.21]) and in continuous smokers (84.2% [12/16] versus 57.7% [15/26], respectively, [P = 0.33]). Furthermore, the first-line eradication rates in both groups were not influenced by age, sex, body mass index, drinking habit, and the endoscopic findings of gastric/duodenal ulcers/scars. There were no significant differences with regard to adverse effects between the two groups.

Conclusion: In contrast to the previous reports, the first-line eradication rate of VPZ-based triple therapy with 400 mg/day CAM and 1500 mg/day ABPC was similar to that of VPZ-based triple therapy in all groups except in patients with CAM-resistant HP and high eGFR. It is necessary to determine the most appropriate conditions that will maximize the therapeutic effect of VPZ-based triple therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Vonoprazan, a novel potassium-competitive acid blocker, as a component of HP eradication therapy-a post-hoc analysis of five randomized trials conducted in Taiwan from 2007 to 2016. Patients who received amoxicillin-containing regimens were determined by agar dilution test. Meta-analysis was performed to assess the presence of amoxicillin resistance and the optimal breakpoint of MIC is 30.125 mg/ml.

Introduction: The impact of amoxicillin resistance on the efficacy of regimens containing amoxicillin for H. pylori infection was evaluated using logistic regression analysis. The same analysis with adjustment for sex, age, and H. pylori infection status was used for evaluation of associations between gene polymorphisms and AG or GC. The Bonferroni-corrected alpha level was set at 0.025 (0.05/2 SNPs).

Results: A total of 2339 patients with available data of amoxicillin MICs were enrolled. Meta-analysis was performed to assess the risk ratio of eradication failure in amoxicillin resistant strains compared to susceptible strains of seven different regimens. We further performed pooled analysis and logistic regression in patients treated with clarithromycin triple therapy to identify the optimal breakpoint of amoxicillin resistance.

Results: A total of 2339 patients with available data of amoxicillin MICs were enrolled. Meta-analysis was performed to assess the risk ratio of eradication failure in amoxicillin resistant strains compared to susceptible strains of seven different regimens. We further performed pooled analysis and logistic regression in patients treated with clarithromycin triple therapy to identify the optimal breakpoint of amoxicillin resistance.

Conclusion: Hp infection is suggested to be related to the invasion depth of C. pylori prevalence, which was also an important profile in GAGF cases. Pigmentation in GAGF is found frequently, but it may be related to taking PPI.

Introduction: Mucins, heavily glycosylated glycoproteins, synthesized by mucosal surfaces and have an important role in healthy and malignant states. Changes in mucin synthesis, expression and secretion may be a primary event or may be secondary to inflammation and carcinogenesis.

Aims & Methods: Since untreated celiac disease (CD) is associated with intestinal mucosal hyperplasia, the aim of the study was to assess the current knowledge about mucin expression in the small bowel of CD patients, and to look for a possible association between mucin profile and gluten-free diet. English Medical literature searches were conducted for “mucin” and “celiac”. Observational studies were included. Meta-analysis was performed using Comprehensive meta-analysis software. Pooled odds ratios and 95% confidence intervals were calculated.

Results: Out of 18 titles initially generated by the literature searches, 3 observational studies that fulfilled the inclusion criteria remained eligible for meta-analysis. The study included 58 patients and 68 controls from 3 countries (Finland, Japan, USA). Mucin expression was significantly increased in small bowel mucosa of CD patients than in normal small bowel mucosa [OR 10.789, 95%CI (1.062–109.634), p = 0.044] (random-effect model). Heterogeneity was significant: Q = 9.470, df (Q) = 3, P = 0.024, I² = 68.323%. ORs for MUC2 and MUC5AC expression in the small bowel mucosa of untreated CD patients were 1.143, 95% CI.060–21.870, P = 0.929 and 21.429, 95% CI 3.883–118.255, P < 0.0001, respectively.

Conclusion: We found that expression of certain mucin genes in the small bowel mucosa of CD patients may serve as a diagnostic tool, and assist in surveillance programs.

Introduction: Celiac disease (CD) is a gluten-sensitive enteropathy that resolves with gluten-free diet (GFD). It’s now considered as a systemic disorder. A number of studies have shown the occurrence of liver diseases at a higher frequency in patients with CD compared with that in the general population. Cryptogenic hepatocellular carcinoma is observed in about half of celiac patients not following GFD with reversibility in the majority of cases after 6 to 12 months of GFD (1). Other liver abnormalities such as autoimmune hepatitis, cholestatic liver disorders can be observed.

Aims & Methods: The aims of our study are to report the prevalence of liver diseases during CD and to describe the characteristics, etiologies and response to GFD of these liver disorders. Prospective multicentric study including 154 celiac patients (77.8%), with bleeding esophageal varices in 22.2% (n = 35) of cases, and in all cases the hepatic cirrhosis stage. Hepatic abnormalities were investigated with an etiologic assessment. The evolution of liver disorders after GFD was assessed.

Results: The prevalence of hepatic disorders in celiac patients is estimated at 18.1% (n = 28). A cryptogenic hepatocellular carcinoma is found in 12.3% of cases (n = 19). This diagnosis was retained after a negative etiological assessment of hepatic cytology in patients at a diagnosis of CD. Severe hepatic pathologies are associated with CD in 5.8% (n = 9) of cases, and in all cases in the hepatic cirrhosis stage. Cirrhosis is cryptogenic in 55.5% (5/9) of cases and secondary to an autoimmune origin in 44.5% (4/9). Chronic hepatitis revealed CD in 1.9% of the celiac population (3/154), two cases of autoimmune cirrhosis, one associated with primary biliary insufficiency, and one case of cryptogenic cirrhosis. The diagnosis of cirrhosis preceded the diagnosis of CD in 55.6% (5/9) of cases, and was contemporary and revealing the CD in 33.3% (3/9). In a single case (11.1%, 1/9), the diagnosis of cryptogenic cirrhosis was made in a celiac patient diagnosed in childhood without the concept of GFD followed. 7 years after the diagnosis of CD. It’s noted that hepatic cirrhosis occurred in the celiac population at a young age, on average 31.1 years. Cirrhosis is most often complicated (77.8%), with bleeding esophageal varices in 22.2% (n = 2) of the cases and ascitic decompensation in slightly more than half of cases 55.6% (n = 5). Hepatocellular carcinoma associated with CD in 5.8% (n = 3) of cases, and in all cases in the hepatic cirrhosis stage.

Conclusion: It’s noted that hepatic cirrhosis occurred in the celiac population at a young age, on average 31.1 years. Cirrhosis is most often complicated (77.8%), with bleeding esophageal varices in 22.2% (n = 2) of the cases and ascitic decompensation in slightly more than half of cases 55.6% (n = 5). Hepatocellular carcinoma associated with CD in 5.8% (n = 3) of cases, and in all cases in the hepatic cirrhosis stage.

Introduction: Celiac disease (CD) is a life-long autoimmune disease affecting multiple organs of genetically susceptible individuals. One of the extra intestinal manifestations of the disease is thromboembolic events like strokes and veins’ thrombosis.

Aims & Methods: The aim of this work is to determine the prevalence and clinical characteristics of the thrombosis observed during CD. Prospective multicenter work involving 154 adult celiac patients (42H, 112F), with an average age of 36.1 years ±13.6, recruited between 01-01-2013 and 30-06-2014 with a minimum follow-up of 12 months. The diagnosis of CD was in all cases based on clinical, serological and histological arguments. Thrombotic complications were noted as well as their modalities of occurrence.

Results: Vascular thrombosis was diagnosed in 13 patients (8.4%), and occurred almost exclusively in women (84.6%) (11 F - 2 H). There are 6 cases of portal cavernoma, one associated with lower limb thrombosis, 4 cases of stroke and 3 cases of thrombosis of the lower limbs. The diagnosis of thrombosis revealed the diagnosis of MC in 8 patients (61.5%) with an average delay of 11.6 months and extreme delays of 1 to 43 months. These include 4 cases of a portal cavernoma, one associated with deep limb thrombosis, 3 cases of stroke, and one case of deep thrombosis of the lower limbs. The diagnosis of CD was made on average 72 months after that of thrombosis in 4 patients (30.8%). In one case, thrombosis was complicated 39 years after diagnosis of CD diagnosed in childhood at the age of 5 years without gluten-free diet. The thrombophilia assessment was carried out in all patients and. The thrombophilia assessment was was negative in 11 cases (84.6%). A S protein deficiency associated with the CD in one case and an antithrombin III deficiency in another case were detected. The use of oral contraceptives and in all cases a micro-dosed oestro-progestin was found in 7 women (63.6%), 5 cases women involved in thrombosis.

Conclusion: The diagnosis of CD must be evoked when there is a thrombotic disease without obvious cause, factors of thrombophilia may be present during the CD. Early CD diagnosis with respect to the gluten-free diet may prevent the development of this complication.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0608 DIFFERENT PROFILES OF TLR 2, 4, 7 AND 9 MRNA IN HEPATIC AND BIPSY SPECIMENS OF PATIENTS WITH CELIAC DISEASE

Introduction: Celiac disease (CD) is an organ-specific autoimmune disease, and both adaptive and innate immunity are involved in its development. Recent studies suggest the dysregulation Toll-like receptors (TLRs) in innate immunity can confer risk to autoimmune diseases such as CD.
Aims & Methods: In this study we investigated the TLRs 2, 4, 7, 9 genes expression in the intestine with celiac disease compared with healthy control. Blood samples from 120 CD patients diagnosed according to the Iranian Society for Gastroenterology were collected and 120 healthy individuals were served as a control group during 2016. Also, among them, 20 duodenal biopsy specimens were collected randomly. Total RNA for both blood samples and biopsy specimens was isolated using a standard commercial kit. The mRNA expression of TLRs were quantified by qualitative qPCR with B2M as a reference gene.

Results: Significantly higher expression of TLR4 and TLR9 mRNA was observed in blood samples of CD patients compared to the healthy controls (P < 0.05); but there were no significant differences between expression of TLR2 and TLR7 mRNA compared to the controls. Furthermore, TLR4 and TLR2 expression level was increased in CD biopsy specimens compared to controls, whereas expression of TLR12 mRNA was decreased in CD patients. No significant differences in expression of TLR7 was observed in biopsy specimens.

Conclusion: The result of this study show that the alteration of TLR4 and TLR9 genes expression in intestinal mucosa of CD can be detected in PBMs in peripheral blood. This data supports the implication of innate immune system in the pathomechanism of celiac disease.

Aims & Methods: We investigated the new and innovative gluten detoxified bread (GFB; patent PCT/IB2013/000797) effects on mucus production by means of Alcian blue staining in comparison to the control bread (CB). In addition, MUC2 and MUC3 were quantified by ELISA and the permeability of the intestinal epithelium in monolayer was assessed by trans-epithelial electrical resistance (TEER) measurement. The statistical analysis was conducted by one-way ANOVA followed by a Bonferroni post-hoc t-test.

Results: Mucin production by Alcian blue staining was expressed as % black pixels measured from Image J software. GFB increased MUC2 secretion after 24 hours by Alcian blue staining (10.28 ± 1.82; P < 0.01), whereas CB did not (9.94 ± 0.67; P = 0.05). Higher MUC2 concentrations expressed as ng/ml were found on cells treated with GFB (10.82 ± 1.35; P = 0.01) compared to control. CB was not found for (9.24 ± 0.18; P = 0.05). Alcian blue TEER values, expressed as a percentage of initial TEER, were observed after 24 hours of incubation with GFB in comparison to the control (163.2 ± 33.8; P = 0.01) which was not observed or CB (139.4 ± 28.8, P = 0.05).

Conclusion: It could be concluded that GFB has a potential of inducing MUC2 secretion by intestinal epithelial cells and improving intestinal epithelium permeability in vitro. Such observed potential may effectively contribute to consequent benefits such as higher gut barrier defence, decreased susceptibility to infections and better absorption regulation, thus ameliorating such alterations in celiac patients.

Aims & Methods: Duodenal biopsy samples of patients diagnosed of NCGS according to Salerno criteria were retrieved. Duodenal biopsy samples of positive controls (overt seropositive celiac disease at Marsh 1 stage) and negative controls (functional dyspepsia and normal microscopic picture) were selected. Immunohistochemistry for CD3 (intraepithelial lymphocytes), CD4 (T-helper lymphocytes), CD8 (T-cytotoxic lymphocytes) and CD1a (Langerhans cells) was performed. Cell count was carried out both in the epithelial layer (expressed as number of cells/100 enterocytes) and in the lamina propria (positive cells/mm). Comparison of means was performed by ANOVA test with Bonferroni’s post hoc analysis.

Results: Twenty NCGS, 12 celiac patients (positive controls) and 16 negative controls were selected. CD1a+ intraepithelial lymphocytes in NCGS were expressed at intermediate levels (18.5 ± 6.4) between negative controls (11.9 ± 2.8) and celiac disease (40.8 ± 8.1, p < 0.0001). CD4+ T-helper lymphocytes were present only in lamina propria and NCGS had a lower level (3.9 ± 2.8) than controls the same study. CD8+ T-cytotoxic lymphocytes had the secreted level of CD8+ T-cytotoxic lymphocytes that were similar between NCGS and negative controls (14.0 ± 7.4 versus 17.8 ± 4.2), but lower than celiac disease (34.0 ± 7.1, p < 0.0001). CD1a+ Langerhans cells were over-expressed in the lamina propria of NCGS (1.9 ± 1.1) in comparison to celiac disease and negative controls (respectively 0.3 ± 0.8 and 0.4 ± 0.5, p < 0.0001).

Conclusion: NCGS is characterized by a mild immunologic reaction, as shown by the slight increase in CD3 intraepithelial lymphocytes. The over-expression in the
N.J. Talley1

Gastrointestinal symptoms reported by patients with and without self-non-affected cohort (30.8% versus 22.2%, p<0.001). Aims & Methods: Patients with CD have been shown to experience persistent GI symptoms despite long term treatment with a gluten-free diet (4). Subjects with CD compared with the unaffected population was tested for significance by logistic regression. The prevalence of CD, FD and IBS are reported to establish whether they had co-existent functional GI disorders. Adherence to a gluten-free diet was not assessed. Prevalence of CD, FD and IBS are reported with 95% confidence intervals (CI). The difference between symptoms in those with CD compared with the unaffected population was tested for significance by the Pearson chi-square test. Results: The prevalence of doctor-diagnosed CD was 1.2% (95% CI 0.84–1.59) in this cohort. Subjects with CD reported significantly higher levels of GI symptoms than unaffected individuals, including abdominal pain associated with abnormal bowel habit, diarrhoea, bloating, distention, epigastric burning and early satiety (see Table). There was no significant difference observed in symptoms of post-bowel habit, diarrhoea, bloating, distention, epigastric burning and early satiety between the 3 groups. Logistic regression was performed including into the model those independent variables which showed a significant difference at univariate analysis. More bowel motions associated with pain ** 16/38 42.1% 50/3248 15.5% P < 0.002

Bloating * 13/40 32.5% 436/3381 12.9% P < 0.001

Distention * 12/40 30% 395/3371 11.7% P < 0.001

Abdominal pain * 9/39 23.1% 362/3378 10.7% P = 0.046

Epigastric burning * 13/38 34.2% 504/3248 15.5% P = 0.002

Early satiety * 8/40 20% 230/3378 6.8% P = 0.001

Abdominal pain associated with slow bowel motions ** 16/37 43.2% 600/3234 18.6% P < 0.001

Conclusion: The prevalence of gastrointestinal symptoms and in particular functional dyspepsia are significantly higher in patients with a doctor diagnosis of CD than in the unaffected population. Subjects with CD biopsy proven coeliac disease in IBS is higher in IBS cohorts than healthy controls (2) and the value of screening with duodenal biopsy testing for CD in FD is concluded to be useful (3), this study supports these views.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Coeliac disease is estimated to affect up to 1 in 100 Australians (1). Although CD has a wide range of clinical manifestations, patients frequently present with gastrointestinal (GI) symptoms which overlap with functional GI disorders, particularly irritable bowel syndrome (IBS) and functional dyspepsia (FD); the prevalence of biopsy proven CD is higher in IBS (2) and in dyspepsia (3). Studies show that biopsy proven coeliac disease in dyspepsia. The prevalence of functional dyspepsia as defined by Rome III criteria in the CD population prevalence of self-reported wheat or gluten sensitivity (SRWS) of 1, M. M. Walker2, M.P. P. Jones3, N. References
up to 13% (2, 3). SRWS is defined as gastrointestinal (GI) or extraintestinal symptoms on ingestion of wheat or gluten-containing food (2, 3). Aims & Methods: The aim of this study was to determine the prevalence of SRWS in an Australian population, define associated GI symptoms, and relate the diagnosis to demographic, lifestyle and medical factors. A total of 3825 people (mean age 58.4 years, age range 18–100 years and 47.5% males) randomly selected from the Australian population returned a mail survey (Digestive Health & Wellbeing Survey, response rate = 45%) which contained questions on wheat avoidance, GI symptoms, demographic, medical and lifestyle factors. We defined SRWS as people who reported gastrointestinal symptoms on ingestion of wheat based foods, but did not suffer from doctor diagnosed coeliac disease, inflammatory bowel disease or bowel cancer. Prevalence of SRWS is reported with 95% exact confidence intervals. The association between SRWS prevalence and potential risk factors was reported using unconditional logistic regression. The degree of differentiation of SRWS from health was evaluated through the area under the receiver-operator-characteristic curve. Results: The prevalence of SRWS in this cohort was 13.5% (455/3313, 95% CI 12.5–14.9%). Only 11% (50/455) of these individuals had received a doctor diagnosis of wheat or gluten intolerance. The most commonly reported GI symptoms (reported as more than weekly or often) associated with SRWS included abdominal pain relieved by bowel movements (54.5%), bloating (37.6%) and abdominal distension (30.8%). In a multivariate analysis, a diagnosis or SRWS was significantly associated with irritable bowel syndrome (IBS) and functional dyspepsia (FD) (Rome III criteria), female gender, and food allergy (see Table). Older age was negatively associated with SRWS. In this multivariate model, factors with no observed association included body mass index, depression, anxiety, sleep problems, proton pump inhibitor use, gastrointestinal infection, rheumatoid arthritis, scleroderma, migraine, Parkinson’s disease, asthma, pollen allergy, animal allergy, previous surgeries and recent antibiotic use. The model provided useful although imperfect differentiation of SRWS from health (AUROC = 0.76).

Table: Medical and demographic factors associated with a diagnosis of self-reported wheat sensitivity (SRWS).

Conclusion: SRWS has a prevalence of 13.5% in this Australian cohort. Those with SRWS are likely to report abdominal symptoms, including abdominal pain associated with bowel habits, bloating after a few hours of ingestion of gluten. SRWS is significantly associated with IBS and FD, younger age, female gender, and food allergy.

Disclosure of Interest: All authors have declared no conflicts of interest.

3. Volta U, Caio G, Karunaratne TB, Alaedini A, De Giorgio R. Non-coeliac wheat sensitivity as an allergic condition. personal experience and addition we also found 5 (4.5%, 4F) patients with real allergy to wheat or wheat allergy or psoriasis, diabetes and recent antibiotic use. The model provided useful around 0.4% until 0.6%.

The diagnosis of WA is basically classified on skin prick tests (SPT), in vitro specific Immunoglobulin E (sIgE) assays and functional assays. SPTs and sIgE in vitro assays are the first-level diagnostics for WA. However, they are affected by a low predictive value. In particular, their low sensitivity can be explained by the fact that the commercial test reagents are mixtures of water/salt-soluble wheat proteins that lack allergens from the insoluble gluten fraction. The association between food allergy and celiac disease (CD) is still to be clarified. Gluten-related disorders are an epidemiologically relevant phenomenon with a global prevalence that is estimated around 5%, drawing the attention of the scientific community.

Aims & Methods: We visited in our unit of celiac disease and gluten-related conditions during 2016 423 (F:M3:111) new patients with clinical suspicion of CD. Of these 113 they were non-celiac but were investigated for suspected non-celiac gluten sensitivity. After in vitro tests for the exclusion of celiac disease, to verify the real prevalence of food allergy particularly to wheat protein, in non celiac patient referred our unit for symptoms after gluten ingestion, all these patients underwent allergological evaluation consisting on skin prick tests for food including wheat (Alk-a-beilo), LTP (lipid transfer protein) (peach Alk a3), alpha amylase, wheat flour, barley, corn, rice, grass pollen and histamine. Also they all performed patch tests for suspected allergy to nickel, if they reported sensitivity to chromium or nickel in their occupational history.

Results: In our overall population, 113 (26.7%) non celiac patients had a history of immediate or not immediate reaction after ingesting gluten: the Allergologic tests found wheat protein sensitization in 14 patients of these 12.4% (4 F). In addition we also found 5 (4.5%, 4F) patients with real allergy to wheat or wheat protein.

Conclusion: In our population 119 113 (16.8%) non celiac patient had real reaction after ingesting gluten: 14 (12.3%) had wheat protein sensitization and 5 (4.5%) had WA. These results are different and very high than that reported in the literature.

Insufficiency of functional bowel disease is usually associated with disorders of visceral sensitivity and intestinal motility, which result from a dysfunction of the central nervous system, intestinal microflora and immune system Aims & Methods: We aimed to highlight importance of intestinal enzymes (glucoamylase, maltase, sucrase and lactase) in the etiopathology and pathogenesis of functional bowel disease. 74 patients with functional bowel diseases in age from 18 to 50 years (36 men and 38 women) were examined. According to Rome IV criteria (2016), 21 had irritable bowel syndrome (IBS) with predominance of diarrhea, 33 - functional diarrhoea, 6 – IBS with predominant constipation, 4 - functional constipation and 10 - mixed type of IBS. Activity of the mucosa enzymes of the small intestine was determined by Dahlquist-Trinder method in duodenal biopsies obtained during esophagogastrroduodenoscopy.

Results: Lactase deficiency was identified in 87.8% of patients, maltase deficiency – in 48.6%, sucrase deficiency – in 53.1%, the glycomylase deficiency – in 85.1%. The activity of all investigated enzymes was reduced in 23 (31.1%) patients with functional bowel diseases, failure of 1 to 3 enzymes detected in 47 (63.5%). Normal activity of enzymes was observed in 4 (5.4%) patients.

Conclusion: In 70 of 74 (94.5%) patients with functional bowel disease and in disorders of the stool, abdominal pain and flatulence, there was a decrease in the activity of intestinal enzymes, which may be a cause of intestinal symptoms.

Introduction: Epidemiological studies estimate a worldwide prevalence of CD of approximately 1:100 individuals, with a considerable proportion of patients remaining undiagnosed and untreated. According to a study performed by the National Health and Nutrition Examination Survey in the United States, the prevalence of self-prescribed GFD in an unscreened population of subjects aged 6 years or older was 0.5%. Epidemiological studies report a prevalence of WA in American population of around 0.4% until 0.6%.

Introduction: Epidemiological studies estimate a worldwide prevalence of CD of approximately 1:100 individuals, with a considerable proportion of patients remaining undiagnosed and untreated. According to a study performed by the National Health and Nutrition Examination Survey in the United States, the prevalence of self-prescribed GFD in an unscreened population of subjects aged 6 years or older was 0.5%. Epidemiological studies report a prevalence of WA in American population of around 0.4% until 0.6%.

Conclusion: In our population 19/113 (16.8%) non celiac patient had real reaction after ingesting gluten: 14 (12.3%) had wheat protein sensitization and 5 (4.5%) had WA. These results are different and very high than that reported in the literature.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference

as celestamine. Short-term outcome of having BAD is well-described, but long-term effects remain unclear. The aim of the present study was to describe long-term symptoms, adherence to treatment and quality of life in a well-defined group of patients with BAD.

Aims & Methods: Between 2003 and 2016, 559 patients referred to our hospital for diagnosis had abnormal low scintigraphic retention levels (<15% at day 7). Questionnaires about medical history, bowel function, use of medication, and quality of life were sent to all patients.

Results: Among 559 patients, 381 (68.2%) responded (242 women (63.5%), median age: 53 years (range 22 to 89), median age at diagnosis 47 years (range 16 to 83)). In 123 respondents (32.3%) BAD was due to ileal dysfuncion (type 1), 199 (52.2%) had idiopathic BAD (type 2), and 59 (15.5%) had BAD due to cholesystectomy (type 3). At follow-up, 272 patients (73.9%) still reported both-cosmesis diarrhea and 246 (65.5%) regularly used antidiarrheal medication. Treatment included BAS in 45.1% while 32.3% of patients used other treatment. 184 patients (49.9%) reported that treatment had improved their symptoms, while 116 (31.4%) reported that they were the same, and 69 (18.7%) felt worse. Treatment was continued by 242 patients (65%) in 24 patients (6.4%) treatment was discontinued.

Conclusion: BAD must be considered as a chronic disease and despite correct diagnosis and treatment, most patients continue to have significant diarrhoea and reduced quality of life. This supports the need for further research in pathophysiology and new therapy principles.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0618 EFFICACY OF PERCUTANEOUS ENDOSCOPIC GASTRO-JEJUNOSTOMY (PEG-J) DECOMPRESSION THERAPY FOR PATIENTS WITH CHRONIC INTESTINAL PSEUDO-OBSTRUCTION (CIFO)

H. Ohkubo1, T. Higurashi2, J. Arimoto1, A. Nakajima1
1Yokohama City Hospital Dept. of Gastroenterology, Yokohama/Japan
2Department Of Gastroenterology And Hepatology, Yokohama City University, Yokohama/Japan

Contact E-mail Address: ohkuboh@yokohama-cu.ac.jp

Introduction: Chronic intestinal pseudo-obstruction (CIFO) is an intractable rare digestive disease manifesting persistent small bowel distension without any mechanical cause. Intestinal decompression is a key treatment, but conventional method including a transnasal small intestinal tube is invasive and painful. Therefore, a less invasive and tolerable new decompression method is urgently desired. We conducted a pilot study and assessed the efficacy and safety of percutaneous endoscopic gastro-jejunostomy (PEG-J) decompression therapy in CIPO patients.

Aims & Methods: Eight definitive CIPO patients (2 males and 6 females) were enrolled. All patients received PEG-J decompression therapy. The number of days with any abdominal symptoms in a month (NODASIM), body mass index (BMI), serum albumin level (Alb), and small intestinal volume before and after PEG-J were compared in all patients.

Results: PEG-J was well tolerated and oral intake improved in all patients. NODASIM has significantly decreased (24.3 vs 9.3 days/month), while 116 (31.4%) reported that they were the same, and 69 (18.7%) felt worse. Treatment was continued by 242 patients (65%) in 24 patients (6.4%) treatment was discontinued.

Conclusion: The ingestion of a high, but not a low, oral load of gluten induces a significant post-prandial inflammatory response causing the activation of the main endogenous anti-inflammatory system. In HV, these activations are not accompanied by a symptomatic response. Further studies are needed to investigate the inflammatory and anti-inflammatory post-prandial response in patients with gluten-related disorders.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0620 THERAPEUTIC ACTION OF KETOGENIC ENTERAL NUTRITION IN OBSESE AND OVERWEIGHT PATIENTS: A RETROSPECTIVE CENTER STUDY

C. Papadia1, P. Bassi2, G. Capobianco3, R. Shidrawi1
1Gastroenterology, Homerun University Hospital, London/United Kingdom
2Statsconsultancy, London/United Kingdom
3Clinical Nutrition, Rome/Italy

Contact E-mail Address: cinzia.papadia@nhs.net

Introduction: Ketogenic Enteral Nutrition (KEN) is a modification of Blackburn’s protein-sparing modified fast, using a hypocaloric, ketogenic liquid diet. The study is about Ketogenic enteral nutrition (KEN) in overweight and obese patients undergoing weekly nutrition therapy. KEN is an enteral nutrition product designed to provide a total daily energy intake of 110 kCal/kg; phosphate, vitamin and mineral supplement, 8 g of free leucine; and 0.12 g of β-hydroxy-β-methylbutyrate per kg of body weight. KEN is an isocaloric nutrient source that reduces the quantity of dietary fat provided and increases the amount of dietary carbohydrate. This study focuses to evaluate the efficacy and safety of KEN therapy in patients suffering from overeating and overweight.

Aims & Methods: A retrospective analysis of all patients who were admitted to the Department of Gastroenterology and Nutrition at the University of London between 2013 and 2016 was conducted. The study aims to assess the efficacy and safety of KEN therapy in overweight and obese patients.

Disclosure of Interest: All authors have declared no conflicts of interest.
10% to 19% of weight lost during treatment. The mean weight regain increased years after removal of IGB, 67% (150) of the subjects had regained weight; the Results:
A total of 224 patients entered the study. Of these, 81.3% (182) were analyzed and compared with logistic multivariate analysis.

Patients that agreed to participate were interviewed by a trained investigator in surgery after balloon removal, impossibility to contact, and refusal to participate. Patients that agreed to participate were interviewed by a trained investigator in person and answered a questionnaire survey and had their body weight measured. Interviews started on July 2015 and ended on July 2016. Medical records of recruited patients were reviewed and the body weight at the moment of IGB implantation was registered. Patients were stratified by time-frame from balloon removal and interview date (2, 3, 4 and 5 years) and all intervening factors related to weight control, as well as behavior habits were analyzed and compared with logistic multivariate analysis.

Results:
A total of 358 patients entered the study. Of these, 81.3% (290) were women. During the use of IGB, patients lost an average of 15% of their body weight; representing a mean loss of 66% of excessive weight. Between 2 and 5 years after removal of IGB, 67% (150) of the subjects had regained weight; the mean weight regained was 4 kg during this period. Most patients (62%) regained 10% to 19% of weight lost during treatment. The mean weight regained increased during follow-up, but without significant difference among groups: 2 years [n = 10]: 4.66 ± 4.91 kg; 3 years [n = 83]: 8.66 ± 6.96 kg; 4 years [n = 54]: 9.99 ± 8.44 kg and 5 years [n = 3]: 19.96 ± 12.24; (p = 0.51). The lower the HMI at the beginning of the treatment, the greater the weight regained after the IGB withdrawal. This correlation was inverse (r = –0.20) and significant (p < 0.01). The correlation was stronger and more significant with patients who had withdrawn the balloon at two years (r = 0.59, p < 0.01) followed by those in which balloon withdrawal was undertaken four years before (r = –0.23, p = 0.03).

Weight regain group contained more individuals who did not perform psychological and nutritional follow-up and who were also sedentary, during and after treatment. Each year, after removal of IGB, the chance of regaining weight increased 1.5 times. No follow-up with a nutritionist after the procedure increased chance of weight regain in 1.8 times. Lack of follow-up with a psychologist during treatment had a weight regain 1.9 times increased. Multivariate logistic analysis determined risk factors for weight regain according to time span after IGB removal. After 2 years of balloon removal, the significant risk factor was lack of follow-up with a psychologist during treatment; increasing the chance of weight regain 1.13 times compared with those subjects that received psychological follow-up at 2 years. An independent significant risk factor for weight regain after 3 years of IGB removal was the lack of follow-up with a nutritionist after the use of IGB. Chance of weight regain was 3.36 times higher in this group than in the group who did the nutritional follow-up. After 4 years of IGB removal, sedentary behavior was an independent and significant risk factor, increasing the chance of weight regain 3.86 times compared with physically active behavior.

Conclusion: IGB has a suboptimal long-term effect on body weight control after 2 to 5 years of balloon removal, with weight regain observed in up to two thirds of patients (66%). The following variables adversely affect long-term body weight control after IGB removal: lack of psychological support and nutrition counseling in the outpatient follow-up. A multidisciplinary approach has increasing importance to assist obese patients treated with IGB in order to effectively maintain long-term body weight control.

Disclosure of Interest: All authors have declared no conflicts of interest.

100622 LONG TERM EFFECT OF DUODENAL-JEJUNAL BYPASS LINEAR IMPLANTATION ON WEIGHT REDUCTION AND GLYCEMIC CONTROL
S. Fishman1, L. Mlynarsky1, L. Ben-Haim1, J. Rutenberg1, M. Shnell1, E. Santo1

2Dept. Of Endocrinology, TASMC Dept. of Gastroenterology, Tel Aviv/Israel

Contact E-mail Address: sigal@talvc.gov.il

Introduction: The Duodenal Jejunum Bypass Linear (DJBL) is an endoscopic device which prevents ingested nutrients absorption in the duodenum and first part of jejunum. The resultant effects are weight reduction and improvement in glycermic control in patients with type 2 diabetes mellitus (T2DM).

Aims & Methods: The objective of the present study is to assess weight loss and glycermic control changes resulted from the device implantation and a year after the device removal. Between February 2013 and September 2016, 51 diabetic patients were treated with DJBL in our center. This prospective observational study included 12 patients in 6 months of follow-up and 15 patients in 1 year of follow-up. However, adverse events and early removals were analyzed for the whole cohort. Blood tests, body weight and medications data were collected during scheduled visits and phone interviews. The primary end points were body weight and glycermic control changes a year after end points were the same parameters after device removal. The protocol was approved by the local ethic committee.

Results: Thirty six patients (52.8% male) were treated for at least 9 months with the device. Of which completed a whole year follow-up after device removal. At the end of 12 months post implantation, the average body weight and BMI dropped from 109.5 ± 19.1 kg and 37.4 ± 5.0 kg/m² to 93.7 ± 20.4 kg and 31 ± 3.5 kg/m² (p < 0.01). Although, body weight and BMI dropped from 109.5 ± 19.1 kg and 37.4 ± 5.0 kg/m² to 97.4 ± 14.6 kg and 33.3 ± 5.0 kg/m² at the end of a year follow-up, both parameters remained significantly lower than the baseline (P < 0.05). HbAlc was reduced during the treatment from 7.6 ± 1.6% to 6.6 ± 1.2% (P = 0.02) and increased to 6.8 ± 1.0% after 12 month follow-up (P = NS). Among 15 insulin-dependent patients (42%), insulin average dose was reduced by 65% (p = 0.05), but the dose was doubled after a year follow-up. Interestingly, the glycermic control in this insulin-dependent population was difficult to maintain as well as it was among non-insulin dependent patients, there was a non-significant decrease in HbA1c during the year post the device removal (6.5 ± 1.3 to 6.4 ± 0.8, P = 0.812). Ten patients (19.6%) of the initial 51 treated suffered from postoperative complications, including: anastomosis stenosis (1), pancreatitis (2), anastomosis leakage (2), diabetes (3), heart failure (1), and wound infection (1).

Conclusion: DJBL is an effective tool for weight reduction glycermic control among insulin and non-insulin dependent diabetic patients. Moreover, substantial weight loss could be observed at least a year after device removal. Since DJBL bears a considerable amount of side effects, strategies to mitigate them are warranted.

Introduction: NAFLD is the most important cause of chronic liver disease and is considered the hepatic manifestation of the metabolic syndrome associated with type 2 diabetes. The prevalence of NAFLD in the general population ranges 15–20% and it goes up to 70% in the obese population. The search for new non-toxic drugs for preventing the development of obesity is the most important challenge of modern science. The question about impact of probiotics and prebiotics on fat metabolism and obesity is being actively debated in the scientific literature. So the aim of the study was to investigate the effect of synbiotic (S) on development of experimental obesity in rats with NAFLD.

Aims & Methods: The study was carried out on 60 white rats, that were divided into 6 groups (I–III – males, IV–VI – females). I and IV groups were intact control groups, who did the nutritional follow-up. After 4 years of IGB removal, sedentary behavior was an independent and significant risk factor, increasing the chance of weight regain 3.86 times compared with physically active behavior.

Conclusion: IGB has a suboptimal long-term effect on body weight control after 2 to 5 years of balloon removal, with weight regain observed in up to two thirds of patients (66%). The following variables adversely affect long-term body weight control after IGB removal: lack of psychological support and nutrition counseling in the outpatient follow-up. A multidisciplinary approach has increasing importance to assist obese patients treated with IGB in order to effectively maintain long-term body weight control.

Disclosure of Interest: All authors have declared no conflicts of interest.

% of weight regained * 2 years 3 years 4 years 5 years
<10% 20% (2) 15.6% (13) 18.5% (10) 33.3% (1)
Between 10 and 19% 70% (7) 62.7% (52) 59.3% (32) 66.7% (2)
Between 20 and 29% 10% (1) 14.5% (12) 14.8% (8) 0
Between 30 and 39% 0 2.4% (2) 1.9% (1) 0
Between 40 and 49% 0 1.2% (1) 5.6% (3) 0
Between 50 and 59% 0 2.4% (2) 0 0
Between 60% and 99% 1.2% (1) 0 0

Conclusion: IGB has a suboptimal long-term effect on body weight control after 2 to 5 years of balloon removal, with weight regain observed in up to two thirds of patients (66%). The following variables adversely affect long-term body weight control after IGB removal: lack of psychological support and nutrition counseling in the outpatient follow-up. A multidisciplinary approach has increasing importance to assist obese patients treated with IGB in order to effectively maintain long-term body weight control.
Also consumption of S led to reduction of pro-inflammatory cytokines and leptin. The question remains as to whether it is possible to re-implant the DJBL. We evaluated feasibility of newly developed intragastric balloon.

Aims & Methods: We used a newly developed intragastric balloon with improved employment for this study. The intragastric balloon was supplied as delicately rolled up inside a thin silicon sheath and mounted by surrounding the endoscope. Endoscopic intragastric balloon placement and positioning was simply performed by introducing 10 pigs were subjected to the novel intragastric balloon placement. We evaluated feasibility of the intragastric balloon and compared procedure time between the novel intragastric balloon and End-ball (Endalis, Brignais, France) intragastric balloon.

Results: In all cases, the novel intragastric balloons were successfully placed under usual sedation of diagnostic endoscopy. The procedures were simple and fast; the mean insertion time was 41.4±14.3 and 153.8±134.8 sec in novel intragastric balloon group and end ball group, respectively. The mean inflation time was 412.4±63.2 and 512.8±83 sec in novel intragastric balloon group and end ball group, respectively.

Conclusion: This preliminary data suggest that the procedure with the new intragastric balloon attain technical improvements in the placement without severe adverse events. The new intragastric balloon could offer constantly effective procedure regardless of the ability of the endoscope practitioner.

P0625 IS RE-IMPLANTATION OF THE DUODENAL-JEJUNAL BYPASS LINER Viable?
S. Guenthert, A. Dienethal, J. Stein
Gastroenterology And Clinical Nutrition, DGD Clinics Sachsenhausen, Frankfurt/Main/Germany

Contact E-mail Address: j.stein@em.uni-frankfurt.de

Introduction: The endoscopically implanted DJBL is a 60cm long, impermeable fluoropolymer device which prevents food from making contact with the proximal intestine, thus inducing considerable weight loss and improvement of type 2 diabetes mellitus (T2DM). Both weight and HbA1c levels have been reported to increase post explantation. The question remains as to whether it is possible to re-implant the DJBL, and what the results would be in terms of BMI (Body Mass Index) change and T2DM control.

Aims & Methods: The aim of this study was to investigate the safety, feasibility and effectiveness of DJBL re-implantation in patients who showed a relapse in glucose levels after DJBL explantation. This prospective, observational study was conducted at the Department of Gastroenterology of DGD Clinics Sachsenhausen, Frankfurt (Germany) between 2014 and 2016. Five obese patients, BMI ≥ 35 and with a body mass index (BMI) ranging from 35–59 kg/m², who completed follow-up after their first implant and underwent removal of the DJBL after 12 months, were selected for re-implantation after an additional 4 months of follow-up. Weight loss, BMI, and HbA1c were analysed before reimplantation and twelve months thereafter.

Results: In all 5 patients, the DJBL was initially implanted and explanted without complications. Re-implantation and re-expansion were also performed without complications. Changes in body weight, BMI, and glycated haemoglobin (HbA1c) are shown in Table 1.

Conclusion: The results of this observational study show that re-implantation of the DJBL is viable and safe even after 4 months after explantation. After re-implantation, weight and HbA1c levels decreased one more time, thus confirming the prolonged effect of DJBL implantation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0626 THE COMPARATIVE EFFICACY OF OBESITY TREATMENTS IN YOUNG PEOPLE - A SYSTEMATIC REVIEW AND META ANALYSIS
S. S. Selvendran, N. Penney, N. Aggarwal, A. Darzi, S. Parkayashia
Surgery And Cancer, Imperial College London, London/United Kingdom

Contact E-mail Address: SS9612@ic.ac.uk

Introduction: Obesity in the young population is becoming increasingly prevalent. It is associated with short- and long-term consequences. Early and effective interventions are paramount. Current treatment options include: lifestyle modifications, pharmacological therapies, endoscopic treatments and bariatric surgery. However, the relative effectiveness of these treatments in this cohort remains unclear.

Aims & Methods: To systematically identify and meta-analyse studies evaluating treatments that reduce body mass index (BMI) in overweight and obese young people. A systematic literature review of EMBASE and MEDLINE databases was conducted. Studies were included/excluded based on pre-specified eligibility criteria. Included patients were 21 years or younger. Lifestyle modification and pharmacological therapy searches were restricted to randomised control trials.

Results: 16,772 studies were identified with 80 studies complete with sufficient data for meta-analysis. Bariatric surgery caused the most weight loss in the short- and medium-term [pooled estimate of mean BMI loss: 13.77 kg/m²]. Lifestyle modifications and pharmacological therapy had a more modest impact on weight [pooled estimate of mean BMI loss: 0.99 kg/m² and 0.94 kg/m² respectively]. Individual studies demonstrated that endoscopic treatment results in short-term BMI reduction, however insufficient data prevented meta-analysis.

Conclusion: This is the first systematic review and meta-analysis to comprehen-sively summarise and quantify the comparative efficacy of BMI reducing treat-ment options in the obese, young population. Currently, bariatric surgery is rarely considered in this young cohort. However, due to its high efficacy, physicians and patients should have a lower threshold for considering bariatric surgery when lifestyle and pharmacological interventions have failed. Therefore, endoscopic surgical interventions provide smaller but statistically significant impacts on BMI reduction. There should be effective communication discussing the relative efficacy of all treatment options and their associated complications between those involved. This knowledge will assist clinicians in determining a holistic, patient-centred treatment programme for obese, young patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: The results of this observational study show that re-implantation of the DJBL is viable and safe even after 4 months after explantation. After re-implantation, weight and HbA1c levels decreased one more time, thus confirming the prolonged effect of DJBL implantation.

Disclosure of Interest: J. Stein: Jürgen Stein has received speakers’ honoraria from GI Dynamics. All other authors have declared no conflicts of interest.
**Results:** All microRNAs were present in all studied foods with highest expression followed by milk, followed by beef, and lowest expression found in cheese and milk. Food processing led only to marginal changes (max. 1.5-fold) in microRNA expression and thus demonstrating its stability against degradation. Short-term changes in diet (from usual to vegetarian and to meat-rich diet) in healthy subjects was not associated with variation in miR-21, miR-155 and miR-16 expression. Interestingly, in comparison to several previous reports, we repeatedly failed to detect any plant miR-168 in sera. However, vegetarians exhibited with a significant decrease in miR-168 level in feces (up to 8-fold), while meat-rich diet was associated with slight decrease if compared to the starting point (mean±SD 0.031±0.002 for no diet vs 0.025±0.042 for vegetarian vs. 0.0016±0.00096 for meat-rich; p=0.03 Kruskal-Wallis test, with p=0.05 for Dunns multiple comparison test for vegetarian vs meat-rich).

**Conclusion:** The results of this study show that various foods provide a great source of microRNAs, which remains stable despite processing. We further demonstrated that short-term changes in diet have a notable impact on the microRNA expression pattern in feces and blood supporting its value as biomarkers. A functional role of diet-induced increase in plant-derived miRNA expression needs further evaluation.

¹INSERM U1149, Paris/France
²INSERM U1158, Paris/France

**Introduction:** The gut and brain peptide neuropeptide U (NMU) is reported to decrease food intake and body weight, and to improve oral glucose tolerance suggesting that it may exert an incretin effect. NMU is thus considered as a promising candidate for the treatment of obesity and diabetes. However, and in contradiction with previous observations, NMU was recently presented as a “decretin” hormone able to decrease insulin secretion. The pathways through which NMU controls glycemia are thus uncertain and we sought to clarify some of NMU mechanisms of action on glucose homeostasis.

**Aims & Methods:** Oral (OGTT) and intraperitoneal (IPGTT) glucose tolerance tests were performed after an intraperitoneal injection of NMU or PBS in C57Bl6 mice. A pyloric laparotomy or a transduodenal laparotomy was performed during OGTT. During OGTT, blood was sampled to measure insulin secretion. [14C]-Glucose uptake was assessed in isolated intestinal loops in presence or absence of NMU. Gastric retention of a phenol red gavage at 285% of baseline in response to NMU is thus considered as a significant measure of gastric emptying.

**Results:** A single intraperitoneal injection of NMU in C57Bl6 mice prevented the rise of glycemia following an oral but not an intraperitoneal load of glucose (OGTT versus IPGTT). Unexpectedly, during the OGTT, NMU injection prevented gastric retention and only slightly improved peripheral insulin sensitivity. Furthermore intestinal [14C]-glucose uptake in isolated intestinal loops was barely reduced by NMU addition (~17% P<0.05 vs PBS). Actually NMU injection blocked gastric emptying (gastric retention of a phenol red gavage at 30 min: +285% P<0.0001 vs PBS). This effect was partly prevented in vagotomized mice. In addition, injection of NMU induced c-fos expression in the nucleus of the solitary tract (NTS) of control but not vagotomized mice. In isometric chambers, NMU directly induced pyloric contracture in a dose dependent manner (basal contraction +21%, 7 At 10-6 M).

**Conclusion:** These data demonstrate that a single intraperitoneal injection of NMU blocks gastric emptying directly by inducing pyloric contraction and indirectly via afferent vagal fiber activation. Through the blockade of gastric emptying, NMU reduces intestinal nutrient absorption and thus improves oral glucose tolerance. The gastric emptying blockade induced by NMU could contribute to its anorexigenic effect.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Aims:** The aim of this study was to assess the effect of a low fermentable carbohydrate (LFD) diet modelled by PLS-DA, reveal significant separation of VOC profiles across the three treatment groups at 4-weeks (p=0.02).

**Conclusion:** Addition of B-GOS to the LFD improves symptoms in IBS. Urine metabolomics, stool SCFA and VOC profiles were assessed in 21 responders and non-responders to the LFD at baseline (p=0.04) VOC profiles. Modelled by PLS-DA, reveal significant separation of VOC profiles across the three treatment groups at 4-weeks (p=0.02).

**Disclosure of Interest:** B. Wilson: BW is funded by a PhD studentship provided by Clasado Biosciences

**P0630**

**THE ANALYSIS OF PROTEIN CONSUMPTION PATTERNS IN PATIENTS WITH SIBO**

V. Pilipenko, V. Isakov, A. Vlasova

Gastroenterology & Hepatology, Research Institute of Nutrition RAMS, Moscow/ Russian Federation

**Aims & Methods:** The study was of assess the protein consumption patterns in patients with small intestinal bacterial overgrowth (SIBO) common in patients with gastrointestinal diseases. SIBO symptoms are improved with antimicrobial treatment, but recurrence rate is high (approximately 40% for 9 months). Dietary modification is essential for prevention of recurrence of SIBO however there are no detailed studies of nutrition in SIBO patients. Protein consumption is considered for SIBO, as the proteins from animal source are essential for growth of CH4/H2-producing microorganisms.

**Results:** There were no differences in response rates (adequate relief) between control (30%), LFD (50%) and LFD/B-GOS (67%) (p=0.04), with post-hoc differences specifically between control and LFD/B-GOS (p=0.015). Intraperitoneal NMU symptoms improved in the LFD group compared to control, being an effect that was significantly greater in the NMU group compared to control. In the LFD group only, there was a significant difference in the urine metabolome between responders and non-responders at both baseline (Q=0.296 vs randomised 0.175) and at 4-weeks (Q=0.485 vs randomized -0.203). At baseline, there were significant greater stool isobutyrate between responders (51.4 mg/100g) and non-responders (31.9 mg/100g, p=0.063), with ROC curves supporting this as a predictor of response (AUC=0.747, p=0.063). Finally, there was a significant difference in VOC profiles between responders and non-responders to the LFD at baseline (p=0.04). VOC profiles, modelled by PLS-DA, reveal significant separation of VOC profiles across the three treatment groups at 4-weeks (p=0.02).

**Disclosure of Interest:** B. Wilson: No conflicts of interest.

</table>
is similar to the oral glucose-stimulated secretion of glucagon-like peptide 1 (GLP-1) and incretin hormone secreted by enteroendocrine L cells (EEC) from the distal gut. GLP-1 and glucagon, both originate from the same proglucagon precursor, differentially processed by prohormone convertase 2 (PC2) into glucagon in pancreatic α cells and by prohormone convertase 1/3 (PC1/3) into GLP-1.

Aims & Methods: We hypothesized that, after pancreatectomy, proglucagon can also be processed into glucagon in EEC. We developed a 75% subtotal pancreatico-duodenectomy model in C57Bl/6 mice. Control (Ct) mice underwent a laparotomy. Post-surgery, blood was measured for glucose and oral glucose tolerance tests (OGTT) were performed after 1 week. Insulinaemia and glucagonemia were also measured in fed and fasted mice and during OGTT. After 2 weeks, animals were sacrificed and the remnant pancreas was sampled for glucagon and insulin immunoquantitation. In addition, α- and β-cell mass quantification, Proximal and distal intestinal segments were sampled for morphometric analyses as well as measurements of proconvertase and proglucagon mRNA levels. Colonic segments were incubated in a glucose-enriched medium for one hour and glucose-induced secretion of glucagon and GLP-1 were measured in the supernatant.

Results: As soon as one day post-surgery, pancreatomeanzed (Px) mice developed a hyperglycemia that maintained for over a week (351 mg/dl in Px mice vs 140 mg/dl in Ct mice, P < 0.05, 5 days post-surgery). This hyperglycemic state was accompanied by an oral glucose intolerance (area under the curve = 278% in Px mice, P < 0.01 vs Ct mice, 1 week post-surgery). During, OGTT, intestinal glucose absorption increased (slope between 0 and 15 min=+69.9% in Px mice P < 0.01 vs Ct mice 1 week post-surgery). Glucagonemia increased in fasted pancreatomeanzed mice (+146.6% in Px mice P < 0.01 vs Ct mice 1 week post-surgery). After sacrifice, alpha cell mass was decreased in the remaining pancreas (~79.25% in Px mice P < 0.05 vs Ct mice, 2 weeks post-surgery). Hypoimmunoreactivity of the proximal colon to secreted glucagon vaccine was observed (+290.6% in Px mice P < 0.05 vs Ct mice, 2 weeks post-surgery). In pancreatomeanzed mice, an hypertrophy of the duodenum was associated with an increase in crypt depth (+77.1%, in Px mice P < 0.05 vs control mice, 2 weeks post-surgery) and villus height (+53.3% in Px mice P < 0.05 vs control mouse, 2 weeks post-surgery).

Conclusion: These data establish an ability of the whole gut to adapt in response to pancreatectomy. The upper intestine (duodenum) become hyperplasic and may be harboring increased intestinal response tosto absorb glucose. The distal intestine (colon) is able to produce glucagon and may participate to the development of the reported hyperglucagonemia.

P0634 QUALITY, VIABILITY AND COMPOSITION OF THE MULTISPECIES PROBIOTIC VSL#3

D. Mora1, S. Colombó2, G. Dell’Aquila1, G. Garargari1, S. Arioli1, W. M. De Vos2
1Department Of Food Environmental And Nutritional Sciences, University of Messina, Italy
2Rsp Immunobiology And Dept Of Food Hygiene, University of Helsinki, Helsinki, Finland
Contact E-mail Address: diego.mora@uni.it

Introduction: A probiotic formula to be functional and reliable should: i) contain viable cells, ii) be reproducible in composition, iii) be taxonomically defined. Here we detail the consistency of the multispecies probiotic product VSL#3, which has been produced for the last 20 years and is marketed globally for the treatment of Inflammatory Bowel Disease, Pouchitis and other intestinal diseases (Mimura et al 2004; Reiff et al, 2009).

Aims & Methods: Here we report the consistency in the quality, viability and composition of the multispecies probiotic product VSL#3. Various batches of the multispecies probiotic VSL#3 were analyzed in detail and derived from productions in the USA and Italy. The product batches have been tested using a series of micro- and macrobiological, immunological and genomic methods. The microbiological analysis included plating on selective media, cell counting and viability analysis by flow Cytometry (FCM) using fluorescent dyes that allowed high throughput separation and quantification of live, dead and damaged cells (ISO 19344 IDF 212, 2015). A metagenetic approach, based on 16S rRNA gene profiling, was used to define the bacterial community structure of different productions. In addition, Lactobacillus helveticus and L. acidophilus S-layer proteins, which are known to exert anti-inflammatory effects by reducing the activation of NF-κB and proinflammatory cytokines, have been expressed in E. coli and visualized on SDS-PAGE (Konstantinov et al, 2009; Taverniti et al., 2013). Moreover, urease activity of Streptococcus thermophilus, known to exert positive effect human health by competing with the undesired urease-positive bacteria of the human microbiota (Mora and Arioli, 2014), was quantified using a spectrophotometric, and flow cytometry-based assay.

Results: The different test batches were all found to contain a common bacterial community structure based on the presence of the following species Streptococcus thermophilus, Lactobacillus acidophilus, Lactobacillus rhamnosus, Lactobacillus plantarum, Lactobacillus helveticus, Bifidobacterium breve and B. animalis subsp. lactis. The stability of the batches was confirmed by FCM and viable cells were always above the value of 2 x 10⁸ event/g. The Lactobacillus helveticus and L. acidophilus S-layer protein SpsA was detected in every VSL#3 batch tested thus highlighting that this relevant immunomodulatory factor was not subjected to degradation during the shelf-life of the product. Likewise, urease activity of S. thermophilus was stable in all VSL#3 batches throughout the shelf-life.

Conclusion: In conclusion, stability, molecular and taxonomic comparative analysis shows that VSL#3 is reliably and reproducibly produced in different parts of the world.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Soybean oil intravenous lipid emulsion (IVLE) is also known as conventional lipid is rich in linoleic acid (ω-6 PUFAs), ω-6 PUFA may exaggerated inflammatory response and indirectly detrimental in the critically ill patients. To overcome this, the use of alternative IVLEs such as medium chain triglycerides (MCT), fish oil and olive oil alone or in combination with soybean oil IVLE have been used to lower the content of ω-6 PUFAs. Most studies on alternative IVLEs have been conducted in the critically ill patients, elective surgical patients and cancer patients. No previous studies have evaluated the clinical outcomes of several different IVLEs in non-critically ill patients in acute hospital setting.

Aims & Methods: The purpose of this study is to determine whether there is a difference in clinical outcome amongst patient who received conventional soybean oil IVLE versus alternative IVLEs in non-critically ill patients in acute hospital setting. All patients on parenteral nutrition (PN) were identified in a prospective compilation database from July 2007 to September 2010 and were analysed retrospectively. Patients were included if they received intravenous lipid emulsions (IVLE). No previous studies have evaluated the clinical outcomes of several different IVLEs in non-critically ill patients in acute hospital setting. Patients were included if they received IVLE for at least 5 days. After oral or parenteral feed was started or without requiring invasive/non-invasive ventilator support or intorops support. Exclusion criteria included patients who received less than 5 days of PN, intensive care unit (ICU) patients, PN started in ICU and continue in general ward or HDU, PN restarted in less than 3 days after removal of PN in ICU, patient on invasive/non-invasive ventilator support or intorops support and home PN patients.

Results: 537 patients were started on PN and 388 patients were included in the study. 140 patients were on type 1 (soybean based) IVLE, 60 patients were on type 2 (MCT based) IVLE, 141 patients were on type 5 (olive oil based) IVLE and 97 patients were on type 4 (contain fish oil) IVLE. Baseline characteristic were similar in four groups of IVLEs. Majority of PN were initiated in patients admitted under surgical team. There were no difference in terms of mortality, readmission and infection rate between conventional and alternative IVLE as a group, odd ratio (OR) was 0.66 (CI 0.36–1.24; p = 0.16), 1.71 (CI 0.84–3.73; p = 0.15) and 0.90 (CI 0.55–1.49; p = 0.73) respectively (as shown in table 1). The length of stay in log-scale was significantly lower in alternative IVFE as a group (p = 0.03). There were no difference in terms of mortality, readmission and infection rate between conventional IVLE versus each of the alternative IVLE. Length of stay was only statistically significantly lower for olive oil based IVLE (Type 3) when compared to conventional IVLE (p = 0.05).

Table 1: Clinical outcomes with alternative IVLE versus conventional IVLE as a group

</tbody>
</table>

Conclusion: Length of stay was significantly lower in alternative IVLE compared with conventional IVLE. However, there were no clinical differences in terms of mortality, readmission and infection between conventional and alternative IVLE in non critically ill patients.

Disclosure of Interest: All authors have declared no conflicts of interest.
Endoscopic procedure was necessary in 9.7% of cases. The informed consent was given by a relative (without legal guardianship) in 49.6%, patient in 28.2%, legal guardian in 16.25%, medical director in 7% of patients. Thirty-days mortality was 2.4%.

Conclusion: Our data confirm that PEG placement is a safe procedure with a mortality rate at 30 days of 8%. To our knowledge this is the largest prospective study on the use of PEG. Surprisingly in more than 50% of patients the consent form was not properly signed, leading to possible medico-legal consequences. Moreover, in 9% of the cases PEG was placed for an early discharge (more than for real clinical indication).

P0637 MEDICAL REGISTRAR REPORTING OF CHEST X-RAYS FOR NASOGASTRIC TUBE POSITION: HOW CAN IT BE MADE SAFER?

Nutrition, University Hospitals Southampton, Southampton, United Kingdom

Contact E-mail Address: maeva.tierney@nhs.net

Introduction: Nasogastric tube (NG) feeding is an essential part of in-patient care. Tubes can be placed at the bedside with no need for specific equipment or sedation. However placement of NG tubes is not without risk and avoiding the introduction of substances into the respiratory tract through a misplaced NG tube was highlighted as a UK National Patient Safety Agency alert in 2005. In 2011 the NPSA made this a ‘never event’. The only acceptable methods of checking the position of an NG tube are: pH < 3.5 on aspirate or confirmation on oesophageal X-ray (CXR) by competent medical staff. Reporting a CXR for NG tube position is a frequent request particularly for junior doctors out of hours. Practise varies across the UK - some trusts require NG checking to be done only by senior clinicians (medical registrars or consultants) and some only allow reporting by a consultant radiologist. We assessed documentation of NG position on CXR by medical registrars from the region to find out if documentation was adequate, as would be expected of senior clinicians. NPSA guidance suggests four points should be documented in the medical notes to confirm NG position: 1. Does the tube follow the contours of the oesophagus and avoid those of the bronchi? 2. Does the tube clearly bisect the carina or the bronchi? 3. Does it cross the diaphragm in the midline? 4. Is the tip clearly visible below the left hemi-diaphragm? All four criteria were met in only 17.6% of responses and answers were considered incorrect in 20.5%. An aide-memoir sticker with an abbreviated version of the above four points, time, date, doctor signature and whether tube is safe to use or not with Yes/No answers, is used on some wards in Southampton and we assessed whether its use would improve quality of reporting both a correctly placed and misplaced NG tube.

Aims & Methods: Medical registrars from first to final year of specialist training and from various specialties were presented with a CXR showing a correctly sited NG tube and were asked to complete a sticker answering yes or no, to check position and whether it was safe to use. Following this they were presented with a CXR showing an incorrectly sited NG tube and asked to use the sticker to assess position. The CXR was projected and anonymous responses collected after sufficient time for the group to complete both stickers.

Results: 31 complete responses were obtained for the correctly sited tube with 58% stating that it should be used and 42% that they would not use the tube without further review. 10 incomplete responses were obtained and therefore 86% of responses met NPSA guidance for reporting CXR for NG position. 28 complete responses were obtained for the incorrectly sited tube and 100% stated that the tube should not be used.

Conclusion: Use of the sticker increased compliance with NPSA guidance for CXR reporting for NG tube position from 17.6% to 86%. The misplaced tube was correctly reported and not used in 100% of responses. The correctly sited tube was reported as safe to use in 58%. The CXR used was of an anonymous real patient and was slightly rotated to reflect a real-life scenario which meant the tube was slightly off the midline. In this real-life scenario some trainees would be happy to make a judgement considering these factors and others may be cautious and follow the sticker statements exactly prompting further review by radiology or removal of the tube. Overall this increases patient safety and avoids use of a misplaced tube in accordance with NPSA guidance. We suggest that the sticker be used on all wards which use NG tubes to rapidly improve documentation and patient safety. The other option we may consider is developing a pathway for radiology consultants to report all these CXRs before the NG tube is used; however this is likely to take considerable time and is unlikely to be available out of hours.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Further patients had never had micronutrients checked due to a persistently raised level in the past year. One of these commenced PN in 2015 and only recently so did not have results within a year. 32 (61.5%) of those who had micronutrients checked within one year (two of the 51 had results from more than one full year to the date of the search). Results were recorded in spreadsheet format and analysed. Many patients live out of the region; however, many local hospitals have established appropriate systems. If the results are not available from one full year to the date of the search, the local hospital was contacted for local results if available. If the patients had micronutrients checked at a different hospital, the blood results system was searched. ESPEN guidelines recommend that serum vitamin and trace element levels be checked at baseline and at least once per year. NICE guidelines specify more frequent monitoring for in-patients and that selenium, manganese and vitamin D should be checked three to six monthly in HPN patients. Some trace elements (copper and zinc in particular) are affected by acute illness. Current local practice is to avoid checking levels until there is evidence that inflammation or infection has resolved.

Aims & Methods: Our aim was to audit the frequency of micronutrient screening in our cohort of HPN patients. All type two and three intestinal failure outpatients were included. Current in-patients were excluded due to the effect of acute illness on micronutrient levels. Patients on parenteral fluid rather than nutrition were excluded as current guidelines give recommendations for HPN patients and do not specify recommendations if fluid alone is required. A search of the blood results system was performed for all micronutrient results from one full year to the date of the search. Results were recorded in spreadsheet format and analysed. Many patients live out of the region; however, many local trusts do not have the laboratory facilities to check micronutrient levels so they tend to be done in Southampton. If no results were available on the Southampton system then the local hospital was contacted for local results if available.

Results: 57 home parenteral nutrition patients were identified. 51 (89.5%) of these patients had micronutrients checked at some point during their care. 44 of 49 (89.7%) had micronutrients checked within one year (two of the 51 had one result). 30 (61.5%) of those who had micronutrients checked had them done within the last six months. 6 patients had never had micronutrients checked. One had them requested just prior to the time of audit but results were not yet available. Two were out of area and had not been seen by the local trust. One of these commenced PN in 2015 and found it difficult to attend clinic. The other had not been seen in clinic due to an administrative error and has now been seen with micronutrients requested. Two further patients had never had micronutrients checked due to a persistently raised C-reactive protein.

Conclusion: Despite a lack of clarity between guidelines about the frequency of monitoring of micronutrients, it is recommended that HPN patients receiving long-term intravenous nutrition should have regular monitoring to reduce risk of deficiency or toxicity. The majority of our cohort of HPN patients had micronutrients checked annually and over half were checked six monthly. This is compliant with ESPEN guidelines; however, we need to aim for 100%. We have introduced a template to use in clinic to trigger review of results and request micronutrients when required. Alongside this we have introduced a virtual ward round to remotely review all out-patients regularly and plan ahead to request blood tests when required. Following the introduction of these measures we will repeat the audit to find out if the situation has improved.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0639 CLINICAL NUTRITION - ARE WE IGNORANT OR NEGLIGENT?
T.M.A. Gan, R. Asokkumar, E. Salazar
Gastroenterology And Hepatology, Singapore General Hospital, Singapore
Singapore
Contact E-mail Address: aaron.gan2@mhcm.com.sg

Introduction: Early recognition and delivery of nutritional care by physicians has been shown to improve outcomes in malnourished hospitalized patients. However, physicians encounter multiple barriers in providing appropriate nutrition to their patients. Extensive international guidelines and nutritional training in medical education have been introduced to overcome these barriers, there appears to be a discrepancy in practice amongst physicians despite the availability of these resources.

Aims & Methods: We aim to assess the knowledge and attitudes of physicians towards clinical nutrition in a large tertiary teaching hospital in Singapore. An anonymous questionnaire comprising 15 multiple-choice questions from standard nutrition textbooks was administered. The questionnaire was designed to assess (a) recognition of nutritional needs of hospitalized patients, (b) knowledge on the role of clinical nutrition, and (c) application of nutritional intervention in common clinical practice. We included consultants, fellows and residents working in units where nutritional problems were common. Finally, we conducted a separate 5-question opinion survey to assess each participant’s nutritional training and exposure, based on a 5-point Likert scale ranging from “strongly agree” to “strongly disagree”.

Results: A total of 305 physicians volunteered to participate in this study. Forty (13%) did not reveal their specialty or staff grade and were excluded from analysis. The remaining 265 respondents comprised 77 (29%) consultants, 58 (22%) fellows, and 130 (49%) residents. Amongst them, 232 (87%) were from medical disciplines and 33 (13%) from surgical disciplines. The median aggregate score (out of a maximum of score of 15) of 66 respondents, fellows and residents was 6.0 ± 2.2 (range 2–12). 7.0 ± 1.8 (range 3–11). 7.0 ± 1.8 (range 1–10) respectively. All 3 grades of physicians achieved less than 50% of the maximum possible score. No significant difference in median aggregate score was observed between physicians from medical disciplines (6.5 ± 1.9) and those from surgical disciplines (6.0 ± 1.8) and that gastroenterologists performed significantly better than non-gastroenterologists (median aggregate score 9.0 ± 2.2 vs 6.0 ± 1.8, p < 0.001). In the opinion survey, a majority of physicians (63%) believed that nutrition-related teaching was inadequate during residency training and 44% felt that clinical nutrition was accorded insufficient attention during ward rounds. Only 33% of responders reported that they performed nutritional screening on admission, and a mere 10% were confident in providing nutrition counselling to malnourished patients. Interestingly, their overall performance was not different from that of other participants (Table 1).

Conclusion: Our study highlights that knowledge on nutrition and its clinical application to hospitalized patients remains inadequate across all physician grades, especially amongst non-gastroenterologists. The current state of clinical nutrition-related teaching during residency training falls short of achieving its goals, and may need re-examination.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Per-oral endoscopic myotomy (POEM) is a novel treatment modality for achalasia cardia (AC). The studies are limited in paediatric population.

Aims & Methods: In this study our aim was to analyse the feasibility, safety and efficacy of per-oral endoscopic myotomy in children We retrospectively evaluated a data of all children (<18 years) who underwent POEM at our institutions from September 2013 to February 2017. All POEM procedures were performed under general anaesthesia in an endoscopy suit. Technical feasibility, safety and efficacy were analysed. Clinical success was defined as Eckardt score ≤ 3. Objective parameters (including modified Barritt-Herzberg score) and basal manometry were assessed and compared before and after POEM.

Results: Thirty children (15-boys, 15-girls) with mean age of 14.1 ± 3.32 (4-18 years), underwent POEM during the specified period. The sub-types of AC were type I (8), type II (19) and type III (1). Eight children had prior treatment with pneumatic balloon dilatation. POEM was successfully performed in all children. Anterior myotomy was performed in majority of children (23 (76.7%)). Mean total length of myotomy was 10.9 ± 2.25 cm, with 7.9 ± 2.09 cm on esophageal and...
3.03 ± 0.67 cm on gastric side. Mean operating time was 76.7 ± 45.5 (30–240) minutes. Major adverse events requiring temporary discontinuation of procedure and/or drainage procedure were encountered in eight (26.7%) children (capno-peritoneum-4 and retro-peritoneal carbon dioxide –4). There was significant reduction in mean LES pressure after POEM (36.25 ± 16 vs 17.65 ± 6.06, p<0.001). Significant improvement of esophageal symptoms at timed barium esophagogram (>50%) was documented in 94.4% children. At median follow up of 504 days (30–1290) clinical success was noticed in 29 children out of 47 children were excluded from the study due to both histology and culture cultured on 5% sheep blood Columbia agar and selective Hp media. Antibiotic according to clinical, endoscopic and histological criteria. Antral biopsy was effectiveness of standard eradication therapy [1, 2]. The aim of this study is to rising antibiotic resistance of Hp both in children and adults lead to decrease of Helicobacter pylori population, high because of high prevalence of gastric malignancies in the adult population, high Helicobacter pylori (Hp) prevalence in Armenia is suspected. Rising of antibiotic resistance of Hp both in children and adults lead to decrease of effectiveness of standard eradication therapy [1, 2]. The aim of this study is to determine frequency of Hp antibiotic resistance in Armenian children. Aims & Methods: 47 children with suspected gastroduodenal disease (GDD), hospitalized in Arabkir MC, were selected from April to December 2016 (23 boys and 24 girls, average age 8.98 ± 4.10). Hp-associated GDD were diagnosed according to clinical, endoscopic and histological criteria. Antral biopsy was cultured on 3% sheep blood Columbia agar and selective Hp media. Antibiotic susceptibility was determined by disk diffusion method. Results: Hp-associated GDD was diagnosed in 40 patients out of 47: 37 (92.5%) had gastritis and/or duodenitis, 3 (7.5%) had peptic ulcer disease (PUD). Seven out of 47 children were excluded from the study due to both histology and culture negative for Hp. Thirty-four (85%) were treatment-naive patients and 6 (15%) had received eradication therapy previously. Main clinical symptoms were recurrent epigastric pain 34 (85%), nausea 28 (70%) and vomiting 13 (32.5%). By endoscopic evaluation, gastritis and/or duodenitis was seen in 18 (45%), non-erosive gastritis in 16 (40%), PUD in 3 (7.5%), normal mucosa in 3 (7.5%). Rapid urease test was positive in all antral biopsies (100%). Histology showed chronic gastritis and/or duodenitis in 27 (58%), atrophic gastritis in 5 (10.6%), gastric glandular dysplasia in 2 (5%), gastric metaplasia of duodenal mucosa in 3 (7.5%), normal mucosa in 2 (5%). Hp was positive in 38 (95%) and negative in 2 (5%). Cultures were positive for Hp in 14 of 40 patients (35%). Susceptibility test was possible in 12 Hp strains from available14: all but 2 were resistant to metronidazole (83.3%), 4 to clarithromycin (33.3%), 3 double resistant to both metronidazole and clarithromycin (25%), and 66.6% to doxycycline. All strains were susceptible to amoxicillin and levofloxacine (100%), 6 strains were tested and found susceptible to rifuratul. Conclusion: The data indicate a high rate of resistance to conventional triple therapy antibiotics: metronidazole (83.3%) and clarithromycin (33%). High resistance to doxycycline also was seen, despite limited use of this antibiotic in Armenian paediatric practice. High susceptibility to rifuratul might be useful for future development of specific eradication schemes for Armenia. High frequency of both erosive and non-erosive gastritis as well as high rate of gastric atrophy and dysplasia in these patients were noticed. Disclosure of Interest: All authors have declared no conflicts of interest. P0642 GASTRIC MICROBIOTA OF CHILDREN WITH CHRONIC GASTRITIS
E. Kornienko, N. Parолова, P. Zykov St. Petersburg State Paediatric Medical University, St. Petersburg/Russian Federation
Contact E-mail Address: da@amedru.ru
Introduction: Children’s gastric microbiota in the presence or absence of Helicobacter pylori (HP) has not been studied well.
Aims & Methods: We aimed to study the composition of the microbiota in the biopsy material of the antral part of the stomach, according to the 16s-RNA sequencing, of children with chronic gastritis, in the presence or absence of HP, and also to compare it with the histological data. Biopsy materials of mucous tunic from antral part of the stomach were taken from 16 children aged 10–17 with chronic gastritis and after the preliminary extraction the biopsy materials were examined using the method of sequencing with a pair of oligonucleotide primers, which are specific for the conservative regions of the 16s-RNA gene, on the Life Technologies Ion Torrent sequencer using the 318v2 chip. Bioinformatic processing was conducted using the QIIME package. The results were compared with the data from the histological examination of the biopsy materials from the same part of the stomach as well as with the results of diagnosis using rapid urease test. AMA RUT Expert with digital Reader.
Results: 8 out of 16 patients were identified as HP(+), positive, 2 of them had HP in small amounts, 6 of them – in significant amounts. The dominant types of bacteria in the stomach of all children were Bacteroidetes, Bifidobacteria, Firmicutes; in a lesser extent - Actinobacteria, Cyanobacteria, Fusobacteria. 64.1% of HP(+) patients’ microbiome was constituted of HP, among Proteobacteria it reached 75–99%, the amount of other bacteria herewith shor- tened, and the microbiota structure decreased. Non-helicobacter microbiota of children with small amount of HP was almost identical in composition as HP(-) patients’, the amount of other microbes was more numerous and diverse, also within Proteobacteria. The signs of inflammation in mucous coat of the stomach in HP(+) patients were more pronounced than in HP absence, they corre- lated with the amount of HP.
Conclusion: Microbiome of the children’s stomach is diverse, it is similar to adults’. The infection from HP inhibits another microbiota and it is accompanied with the signs of mucous coat inflammation, which correlates with the amount of HP.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0643 FEATURES OF CHRONIC GASTRITIS CAUSED BY CO-INFECTION OF HELICOBACTER PYLORI AND EBSTIN-BARR VIRUS IN PEDIATRIC PATIENTS
E. Spivak, L. Levit Pediatric, Medical State University, Yaroslavl/Russian Federation
Contact E-mail Address: spivak58@mail.ru
Introduction: It is known that co-infection of the gastric mucosa with highly pathogenic Hp strains and the Epstein-Barr virus is a risk factor for the development of severe gastritis and atrophic gastritis. However, characteristics of such co-infection in children are not sufficiently studied.
Aims & Methods: The aim of this study is to estimate the role of co-infection of highly pathogenic strains of Helicobacter pylori and Epstein-Barr virus in pediatric patients with chronic gastritis. Patients and methods. 190 children aged 8–18 years of age with chronic Hp-associated gastritis were studied. All the patients underwent clinical and laboratory examinations and endoscopy. Gastric biopsies were performed and the histological analysis of inflammation graded according to the Salzmann classification. Polymerase chain reaction (PCR) was used to detect the presence of Epstein-Barr virus (EBV), Helicobacter pylori (Hp) and its highly pathogenic strains in the gastric mucosa of the patients. Results: Persistent EBV infection was found in 83 children (43.7%) with chronic gastritis of the antral and (or) gastric body areas. Helicobacter pylori strains that possess the virulence factors (cytotxin-associated gene A (CagA), vaculating cytotoxin gene A (VacA), induced by contact with epithelium (IceA), and blood group antigen-binding adhesion (BabA)) were detected in 49 patients (25.8%). In most cases, the association of two or more virulence factors in one patient was observed. It was found that 39 pediatric patients had co-infection of the highly pathogenic strains of Hp and EBV. The study revealed no significant effect of the variant of the gastric mucosa infection on the clinical manifestations of gastritis - the nature of intoxication, abdominal and dyspeptic syndromes. At the same time, the endoscopic and morphological data analysis has revealed a severe gastritis with the development of pangastritis and signs of gastric mucosa atrophy observed mainly in the antral region, in patients with co-infection (highly patho- genic strains of Hp + VEB). In addition, by correlation analysis, we found that the increase and development of the inflammatory process in the gastric mucosa was mostly influenced by the presence of CagA-positive strains of H. pylori in combination with EBV. We found that children infected by EBV without highly pathogenic Hp strains had mild mononuclear and polymorphonuclear cell infiltration without atrophy.
Conclusion: Co-infection with highly pathogenic Hp strains and the Epstein-Barr virus in pediatric patients is associated with severe gastritis. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: H pylori infection is one of the most widespread bacterial infections worldwide, therefore nowadays its prevalence is decreasing, mostly in developed countries. There are some studies which support that H pylori could favor the development of food allergy.
Aims & Methods: To assess the relationship between H pylori infection and specific immunoglobulin E (Ig E) antibodies to food allergens in symptomatic children. We conducted a prospective study of 394 symptomatic children (249 girls, age range 6 months-18 years), mostly with uninvestigated dyspepsia requiring endoscopy in our unit, from January 2015 to December 2016. All patients were evaluated for H pylori infection by at least two standard invasive tests and for specific immunoglobulin E antibodies to major food allergens (R-Biopharm, Germany). The nutritional status of patients was assessed in all cases by the new World Health Organization (WHO, 2007) growth charts. EPI-INFO version 7 was used for statistical analysis. A two sided p-value less than 0.05 was considered statistically significant.
Results: Active H pylori infection was documented in 246 (62.3%) cases. The allergic sensitization at least one of the food allergens was identified in 134 of 394 patients (34%). The majority of Ig E positive children (109 of 134 cases; 81.3%) were positive for cow’s milk followed by egg (17.9%), wheat (7.46%), peanut (5.45%), soybean (3.73%). The allergic sensitization to food allergens was associated with abnormal levels of specific Ig E antibodies to common inhalatory allergens in 55 of 134 cases (41.04%). Regarding the association of H pylori infection with an elevated serum Ig E level to at least one of the food allergens tested, there was no significant correlation (p = 0.14). A total of 134 (51.30%) patients positive for food specific Ig E antibodies were H pylori infected and 57 of them (38.55%) were H pylori negative (Fisher exact test = 0.08). The assessment of the patients nutritional profile in relationship with H pylori infection and food allergy not revealed a statistically significant correlation between the two ends of the poor nutritional status (undernutrition and overweight).
Conclusion: The recent decline of H pylori infection is not evident in our study. There was no association between H pylori infection and Ig E mediated food allergy. Undernutrition and overweight were not associated with the H pylori infection and food allergy in our patients.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0645 GUT MICROBIOTA ALTERATIONS UNDER OLGOFRUCTOSE-ENRICHED INULIN ADMINISTRATION IN PAEDIATRIC CELIAC DISEASE PATIENTS ON A GLUTEN-FREE DIET: RANDOMIZED CONTROLLED TRIAL
U. Krupa-Kozak1, N. Drabiniska1, L. H. Markiewicz2, E. Jarocka-Cyrt3

Introduction: Imbalanced gut microbiota is suggested to be involved in the pathogenesis of celiac disease (CD). In many CD patients, despite a long-term treatment with a gluten-free diet (GFD), the intestinal dysbiosis is not completely restored. Prebiotics, substances of the unique ability to shape intestinal microbiota, can influence intestinal microflora, low-risk GFD supplement to remedy the intestinal dysbiosis in CD patients.
Aims & Methods: The aim of the present study was to assess the effect of prebiotic oligofructose-enriched inulin (OEI) administration on the quantitative gut microbiota characteristics of CD children following a strict GFD for ≥1 year. A randomized, placebo-controlled 12-weeks dietary intervention was conducted on 34 CD children (62 % female, mean age 10 years) on GFD who were randomly assigned to prebiotic (OEI: 10 g/day) or placebo group (maltodextrin; 7 g/day). Before (baseline) and after the intervention, the anthropometric (weight, height) and biochemical blood parameters (C-reactive protein, creatinine, aspartate aminotransferase, alanine aminotransferase, quantitative gut microbiota characteristics (by real-time PCR) and concentration of short-chain fatty acids (by gas chromatography with a flame ionization detector) were assessed.
Results: Thirty CD patients completed the study. After 12-weeks intervention, the biochemical blood parameters remained normative in all CD patients, and the gut microbiota counts in each experimental group did not differ from their counts at baseline. However, in comparison with placebo group, Bifidobacterium counts was significantly (p < 0.01) higher in CD children consuming OEI-supplemented GFD. Moreover, the counts of Clostridium leptum group in children of prebiotic group did not show the decreasing tendency along with the time of GFD. The bacterial community of CD children was reflected inotol bacteria number after the intervention that was constant in prebiotic group but tended to fall in placebo group. Microbiota counts corresponded well with microbial metabolic activity. In comparison with placebo group the concentration of short-chain fatty acids in CD children of prebiotic group (50.27 vs. 69.95 mEq/l, p < 0.05), mainly due to a significantly higher acetate formation (28.82 vs. 44.06 mEq/l, p < 0.05).
Conclusion: Prebiotics, substances of the unique ability to shape intestinal microbiota, can influence intestinal microflora, low-risk GFD supplement to remedy the intestinal dysbiosis in CD patients. Moreover, the administration of OEI in GFD prevents from a gut dysbiosis observed along with the duration of the GFD, and maintains a constant quantity of beneficial bifidobacteria. Moreover, the administered of OEI in GFD stimulates activity gut microbiota observed ashe increased SCFA production assigned to regulatory effects.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Treatment for celiac disease (CD) is a lifelong gluten-free diet (GFD). Patients should be followed-up with dietary interviews and serology as CD markers to ensure adherence to the diet. However, none of these methods
offer an accurate measure of dietary compliance. Presence of gluten related sub-
stances in faeces proves that transit through gastrointestinal tract happened and
confirms gluten ingestion.

Aims & Methods: Detection of gluten immunogenic peptides (GIP) in stools as a marker of GFD adherence in CD paediatric patients was evaluated and compared against traditional methods of GFD monitoring. A prospective, non-randomized, multi-centre follow-up study, 2 years long, including 64 CD patients started on GFD when diagnosed was conducted (age range 5–18 years).

Results: 62 patients (97%) had detectable GIP levels in stools, during basal visit, before initiation of the GFD, whereas 20.3% of the patients were found to have positive GIP after treated with a GFD. Dietary transgressions were more frequent among children less than 8 years of age (60.8%) of them showed more than one detected transgression. Anti-TG IgA remained in high concentrations in 48, 34 and 20% of the patients at 6, 12 and 24 months of follow-up. Anti-DGP was positive in 13, 4.5 and 0% of cases when tested at 6, 12 and 24 months follow-up. Both serological methods did not correlate with GIP in stools (p < 0.05).

Conclusion: The GIP ELISA enabled direct and quantitative assessment of gluten exposure early after ingestion. Detection of GIP in stools revealed lack of compliance of traditional serological methods to verify GFD compliance in CD paediatric patients. The antibodies can be detected several months or even years to decrease after initiation of the GFD and reduction (but incomplete suppression) of gluten intake. More frequent in children less than 8 years of age. Dietary transgressions were more frequent among children less than 8 years of age (60.8%) of them showed more than one detected transgression. Anti-TG IgA remained in high concentrations in 48, 34 and 20% of the patients at 6, 12 and 24 months of follow-up. Anti-DGP was positive in 13, 4.5 and 0% of cases when tested at 6, 12 and 24 months follow-up. Both serological methods did not correlate with GIP in stools (p < 0.05).

P0651 META-ANALYSIS: PROTON PUMP INHIBITORS MODERATELY INCREASE THE RISK OF SMALL INTESTINAL BACTERIAL OVERGROWTH
T. Su, S. Chen
Department Of Gastroenterology, Sir Run Run Shaw Hospital, Zhejiang University, Institute of Gastroenterology, Zhejiang University, Hangzhou/China
Contact E-mail Address: 18770085122@163.com
Introduction: PPIs have become one of the most commonly prescribed classes of medications. Although PPIs are generally well tolerated, accumulating evidence suggests that PPIs have long-term risks. One potential risk of PPI use is development of small intestinal bacterial overgrowth (SIBO), which is defined as >105 bacteria colony-forming units (CFU) per mL upon culturing upper gut aspirates. However, this is controversial due to conflicting results from prior studies.3,4

Aims & Methods: The aim of this meta-analysis was to evaluate the association between use of PPIs and the risk of SIBO. We systematically searched the online Pubmed, Embase, Cochrane Library databases and Web of Science for relevant articles before November 2016. Two researchers identified and extracted data independently. The pooled analysis was performed using generic inverse-variance random-effects model. Subgroup and sensitivity analysis were conducted to assess the stability and heterogeneity of the pooled results. The risk of publication bias was evaluated by examining funnel plot asymmetry, Egger’s test and Begg’s test. All statistical analyses were performed using Stata software version 13.

Results: A total of nineteen articles met the eligibility criteria for the meta-analysis. The pooled odds ratio (OR) showed a statistically significant association between increased risk of SIBO and PPI use (OR = 1.95 95% CI 1.20–2.43). No statistically significant publication bias was found based on the Egger’s test (p = 0.19) or Begg’s test (p = 0.11). This suggests the association between PPI and SIBO in studies that employed small bowel aspirates culture and glucose hydrogen breath tests (GHBT) as diagnostic tests for SIBO. However, when the pooled analysis was limited to studies recruiting irritable bowel syndrome (IBS) patients, no statistically significant association between PPI use and SIBO was observed, which suggests that PPI use does not affect the risk of SIBO among IBS patients.

Conclusion: Our meta-analysis suggests that the use of PPIs moderately increases the risk of SIBO, which highlights the need for appropriate prescription of PPIs.

Introduction: Nowadays food allergy continues to increase, especially in westernized countries and is now recognized as a worldwide problem. Transforming growth factor-ß (TGF-ß) is a profibrotic cytokine, which plays an important role in promoting the structural changes in food allergy. Also for patients with food protein induced enterocolitis syndrome TNF-á appears to have an important role.

Aims & Methods: The aim was to determine the significance of the Transforming Growth Factor-ß (TGF-ß) and Tumor Necrosis Factor-á (TNF-á) in children with food protein induced enterocolitis syndrome. It was examined 38 patients with FPIES at the age from 4 months to 3 years, the average age was 19 ± 4 months. The control group consisted of 11 healthy children of the same age. The determination of TGF-ß and TNF-á in serum was performed by an enzyme immunoassay kits from Bender Medsystems (Austria).

Results: The level of TGF-ß in patients with FPIES exceeded the norm and was respectively 33.5 ± 1.6 ng/ml at norm 20.2 ± 2.1 ng/ml, p < 0.001. The indices of TNF-á were also increased and amounted to 8.8 ± 1.3 ng/ml in comparison with the control group (p < 0.001). For statistical analysis it was characterized by an increase in specific antibodies IgE to cow’s milk in 18 (47.3%) children. In these children with high specific IgE levels to cow’s milk. It is likely that an increase in TGF-ß and TNF-á supports chronic inflammation in allergic diseases.

Conclusion: We did not find any interaction effect between newborns' and mothers' GST1 polymorphisms and anthropometrical parameters (p = 0.545) for FPIES and clinical parameters.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0654 SARCOPENIA IN CHILDREN WITH INTESTINAL TRANSPLANTATION

R. Hegarty, J. Hind, D. Thangarajah

Paediatric Liver, GI And Nutrition Centre, King’s College Hospital, London, United Kingdom

Contact E-mail Address: antihurj@gmail.com

Introduction: Deficits in lean mass and muscle measures are well described in children with chronic disease e.g. childhood inflammatory bowel disease[1]. Sarcopenia is a poor prognostic biomarker in adults with advanced cancer, liver transplantation and in children with acute lymphoblastic leukaemia[2-4]. Poas muscle cross sectional area (PCA) has been shown to correlate with whole body muscle mass and can be measured from axial imaging [5]. Little is known about sarcopenia in children with intestinal transplantation (IT). Sarcopenia is a poor prognostic biomarker in adults with advanced cancer, liver transplantation and in children with acute lymphoblastic leukaemia. Poas muscle cross sectional area (PCA) has been shown to correlate with whole body muscle mass and can be measured from axial imaging [5]. Little is known about sarcopenia in children with intestinal transplantation (IT).

Aims & Methods: The primary objective was to determine whether children who had IT show differences in total PCA when compared to healthy controls. The secondary objective was to investigate association of PCA and survival after IT. A retrospective, case note review of children who had IT at a single centre since inception in 2009 to May 2016. Controls were identified from abdominal trauma series. Total PCA (mm²) was measured using direct techniques of magnetic resonance imaging or computed tomography at the level of the anterior superior iliac spine. To correct for body size, PCA index was derived for all subjects: PCA divided by height. PCA index was then described according to outcome. Statistical analysis was carried out using Social Sciences (SPSS) version 23.

Results: 16 patients (9 male) underwent IT at our centre. Post-transplant axial imaging was available for 12/16 males, median age 6.2(3.6 to 12.9) years patients in whom the diagnoses (n): Chronic intestinal pseudo-obstruction(3), gastroscisis(3), intestinal ischaemia(1), intestinal lymphangiectasia (1), volvulus (1), progressive familial intrahepatic cholestasis (1), Hirschsprung’s disease (1) and intestinal failure of indeterminate aetiology(1). One patient was excluded from analysis as she was a bilateral amputee. Children who had IT had a significantly lower PCA and PCA index than controls; median PCA index (10 x 10 mm²) [IQR] in IT patients=4.95 [4.44 to 11.33] p<0.005. There was a trend toward higher PCA index in those who survived (n =9) compared to those who did not (2).

Conclusion: Children who underwent IT had sarcopenia of the poas muscle in comparison to healthy controls and patients who died there was a trend toward poas muscle sarcopenia. This study adds to the evidence that body core muscle is consistently deficient in children with chronic disease and is the first to comment on children with IT. This small study provides the basis to develop PCA as a prognostic marker in children with transplantation

Introduction: Primary lactose intolerance (PLI) is a frequent condition caused by a genetically programmed and progressive loss of lactase expression. It is considered that PLI is the ancestral variant, while lactase persistence is caused by 2 polymorphisms: the dominant C/T13910 and G/A22018. Homozygotes (CC or GG) have undetectable lactase levels. In clinical practice only half of people with PLI have symptoms. However, some studies showed that PLI subjects have lower dairy intake.

Aims & Methods: To investigate whether genetic predisposition to PLI influences the quality of life and dairy intake in a group of Romanian children. We conducted a prospective study, recruiting consecutive children evaluated in our unit in May-August 2016. Our study population included 87 children aged 6–17 years (mean age 10.64 ± 3.51 years), 45 (51.72%) girls. We used strip genotyping to identify genetic predisposition to IPL. Subjects were asked to complete a validated quality of life questionnaire and a dairy intake questionnaire. We used Spearman’s test to evaluate the correlation between IPL and quality of life and dairy intake.

Results: 51 (51.7%) subjects had a CC genotype, 30 (34.5%) subjects had a GG genotype. Our results were consistent with Hardy-Weinberg equilibrium. We found no correlation between homozygosity for PLI and dairy intake (CC: r = –0.06, p = 0.54; GG: r = 0.01, p = 0.86). We found no correlation between either CC, or GG homozygosity and quality of life (r = –0.11, p = 0.3) and r = –0.1, p = 0.34).

Conclusion: In our group genetic predisposition to IPL followed European trends. It did not influence quality of life and dairy intake.

Introduction: Fibroblast growth factor-21 (FGF21) and omentin-1 have been recognized as potent antiadipogenic agents, with potential hepatoprotective activity. Aims & Methods: The aim of this study was to evaluate hepatic FGF21 and omentin-1 mRNA expression, and their serum levels as predictive markers of liver injury and insulin resistance in morbidly obese women with NAFLD. The study included 56 severely obese women who underwent intraoperative wedge liver biopsy during the bariatric surgery. Hepatic FGF21 and omentin-1 mRNA was assessed by quantitative real-time PCR, while their serum concentration with commercially available enzyme-linked immunosorbent assays.

Results: FGF21 serum level was significantly higher in patients with more extent steatosis (grade 2 and 3) compared to those without or with mild steatosis (grade 0 and 1) (p = 0.049). However, ROC analysis showed poor discriminant power for FGF21 serum level in differentiation between more and less extensive steatosis with AUC = 0.666. There was evident tendency to higher levels of hepatic FGF21 mRNA in patients with lobular inflammation and fibrosis, and to lower levels in the case of ballooning degeneration and steatosis. There was positive mutual correlation between hepatic FGF21 and omentin-1 mRNA levels (r = 0.73, p < 0.001). Fibrosis stage was associated with serum glucose and HOMA-IR (r = 0.03 and p = 0.02, respectively). Serum omentin was not associated with histopathological features. Hepatic omentin-1 mRNA levels exerted the tendency to be lower in patients with advanced steatosis and hepatocyte ballooning.

Conclusion: In our conclusion our study, which focused on hepatic FGF21 and omentin-1 mRNA expression, confirmed a marked expression of both molecules in the liver of morbidly obese patients with NAFLD. mRNA levels were affected by certain histological abnormalities. In morbidly obese patients with advanced steatosis was associated with evident change in serum FGF21 concentration in morbidly obese women with NAFLD. The vast amount of fat, both visceral and subcutaneous in severely obese patients may affect FGF21 and omentin-1 serum levels.

Disclosure of Interest: All authors have declared no conflicts of interest.

(HSCs), which were separated from Sprague-Dawley rat, were treated with differ-
cent concentrations of loureirin B. MTT assay was employed to determine HSCs proliferation, western blot was used to test the expressions of Frizzled-4 receptor protein and α-SMA. In addition, enzyme-linked immunosorbent assay (ELISA) was performed to measure the content of α-SMA, TGF-β1 and VEGF in the cultured HSCs' supernatant, and reverse-transcription PCR (RT-PCR) were utilized to detect the expressions of Frizzled-4 and α-SMA genes.

Results: MTT test showed that the proliferation of HSCs was inhibited signifi-
cantly with a time and dose dependent relationship by the treatment of loureirin B in a concentration range of 0.01-0.1 μg/mL. The inhibition concentrations of 0.115g/L (IC50 = 0.180g/L). Western blot analysis showed that the expressions of Wnt receptor Frizzled-4 protein and α-SMA were obviously lower in the group of loureirin B treatment than that in the control group. Moreover, the Loureirin B also inhibited Frizzled-4 (p < 0.01), TGFβ1 (p < 0.05) secretion in the cultured HSCs' supernatant in different degree by the ELISA assay, and RT-PCR results revealed that Loureirin B down-regulated the expressions of Frizzled-4 and α-SMA genes in the level of mRNA.

Conclusion: The Loureirin B mediated anti-hepatic fibrosis by inhibiting the proliferation of HSCs through restraining the Wnt signaling pathway.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Macrophages play a pivotal role in the pathogenesis of non-alco-
holic steatohepatitis (NASH) and are a major component of inflammatory cells
infiltrated in NASH. However, the precise mechanism of how macrophages contribute to the pathogenesis of NASH remains unexplored.

Aims & Methods: We aimed to characterize the role and molecular regulators
of macrophages in NASH and the therapeutic effects of macrophage depletion on
NASH. C57BL/6 wildtype (WT) mice and transgenic LysM-Cre;DTR mice were fed with methionine-and-choline-deficient (MCD) diet for 5 weeks to induce
steatohepatitis. Hepatic macrophages were depleted in WT mice by injecting liposomal clodronate (i.p. 50 mg/kg/week) and in LysM-Cre;DTR mice by inject-
ing diphtheria-tox (DTox) (i.p. 100 mg/week). Primary macrophages were iso-
lated from bone marrow of WT mice. For the in vitro study, mouse immortalized
hepatocytes AML-12 were cultured with primary macrophage conditioned medium and mouse primary macrophages were cultured with AML-12 hepato-
cytes conditioned medium to evaluate the interaction between macrophages and
hepatocytes in steatohepatitis. A series of assays including cytokine profiling
assay, DNA binding activity, flow cytometry and Western blot were performed.

Results: Hepatic macrophage marker CD68 expression was significantly higher in
human NASH patients compared with normal controls (P < 0.001). Steatohepatitis was established in WT mice and LysM-Cre;DTR mice fed MCD diet, concomitant with significantly enhanced hepatic macrophage infiltra-
tion as indicated by F4/80 staining. Macrophage depletion by liposomal clodro-
nate or DTox attenuated steatohepatitis in both animal models. This was also
associated with reduced hepatic necroinflammation, oxidative stress, hepatic tri-
glyceride accumulation, and secretion of pro-inflammatory cytokines in both
liposomal clodronate-treated WT mice and DTox-treated LysM-Cre;DTR mice as compared to the corresponding control mice. Macrophage depletion was also
accompanied by the reduction of neutrophils, which together can reduce inflam-
mation. Upregulated macrophages were associated with the increased expression of hepa-
tic pro-inflammatory cytokines including interleukin (IL)-1α, IL-1b, IL-
12, IL-17, Granulocyte-macrophage colony-stimulating factor, Monocyte che-
moattractant protein-1 (MCP-1) and macrophage inflammatory protein 1α
(MIP-1α), and the activation of NF-κB and JNK signaling pathways in the liver.
Macrophage-induced steatosis was mediated by increased hepatic lipogen-
esis and higher levels of X receptors (αR and LXRR), which are regulative
element binding protein-1c and carbohydrate-responsive element-binding protein.
Moreover, autophagy deficiency and endoplasmic reticulum (ER) stress were
involved in macrophage-induced steatohepatitis as indicated by p62/QTSTM1
accumulation and increased GRP7 and p-IRE1α expression. For the in vivo study,
macrophage conditioned medium significantly promoted lipid accumulation
in AML-12 hepatocytes. On the other hand, MCD-cultured hepatocytes medium
promoted primary macrophage polarization to M1 phenotype as well as the pro-
duction of pro-inflammatory cytokines (TNF-α and MCP-1).

Conclusion: We demonstrated that macrophages contribute to the progression of
NASH through promoting inflammation, lipogenesis, autophagy impairment, ER stress and also through a crosstalk with hepatocytes. Similarly, macrophage
depletion has mitigation effects on NASH and may provide a potential treatment
strategy for NASH.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is considered the hepa-
tic manifestation of metabolic syndrome, with simple liver steatosis being capable of
gradually progressing to inflammation, fibrosis, cirrhosis and even hepatocel-
lar carcinoma. Still, disease pathogenesis is complex and no targeted therapies
have yet been approved for NAFLD. Bile acids (BAs) constitute a wide class of
steroid molecules with pleiotropic functions, contributing to the homeostasis
of lipid and glucose. In the liver, they specifically modulate nuclear receptors from
the NR1 subfamily, such as Farnesoid X Receptor (FXR) and Liver X Receptor
(LXR), thus tightly regulating bile acid synthesis and oxidation and storage of
triglycerides.

Aims & Methods: Our aim was to screen BA derivatives for their potential to
selectively activate FXR, thus protecting liver cells against free fatty acid (FFA)-
induced lipid accumulation and lipidotoxicity. Nineteen novel BA derivatives were
analyzed in silico molecular dynamics for FXR binding, and further evalu-
ated in human cells using a FXR reporter assay. Assessment of FXR-depend-
ent gene and protein expression was analyzed upon incubation of primary
mouse hepatocytes and HepG2 cells with selected BA derivatives. In parallel,
BA derivatives were co-incubated with oleic and palmitic acids (2:1) for assess-
ment of cellular cytotoxicity and intracellular lipid accumulation.

Results: From the compound library, five BA derivatives showed stronger activa-
tion of FXR, comparing with their natural precursors. Incubation of HepG2 cells
with FAs led to a ~25% reduction in cell viability and ~35% increase in cell
death, with a dose-dependent accumulation of lipid droplets. Pre-incubation of
cells with selected derivatives efficiently prevented FFA-induced cell death and
lipid accumulation. Finally, incubation of both HepG2 cells and primary mouse
hepatocytes with BA derivatives strongly induced FXR, RXR, SHP, BSEP,
FGF19 and VLDL mRNA levels, and repressed PPAR1, LXR, SREBP1-c and
C/EBPα mRNA expression. Molecular docking studies and FXR reporter
assays confirmed ligand affinity to FXR. Furthermore, chenodeoxycholic acid
and its ester-based derivatives were confirmed as activators of FXR at lower concen-
trations comparing with the parent molecule.

Conclusion: In conclusion, we identified novel BA derivatives that directly modu-
late liver nuclear receptors, such as FXR and LXR, thus protecting liver cells
against FFA-induced lipid accumulation. These new compounds may be used as
sealoids for the development of targeted therapies for NAFLD.

Introduction: NAFLD is currently classified in non-alcoholic fatty liver (NAFL)
and non-alcoholic steatohepatitis (NASH). It is a liver disease related to meta-
bolic syndrome with rising socio-economic impact worldwide. NAFLD is defined
by significant lipid deposition in hepatocytes that is unrelated to alcohol con-
sumption. This high prevalence of liver disease occurs after a protracted inflam-
matory response, which is activated by dietary overloading of fructose-rich goods as shown by the multi-parallel hit theory. Autophagy is a self-digesting mechanism that helps the cells to overcome stress conditions
derived by nutrient deprivation and massive storage, e.g. lipid and proteins.
Autophagy dysfunction has been implicated in lipid accumulation related dis-
cases. Up to now, it in yet fully understood the role exerted by autophagy in liver
diseases not related to alcohol.

Aims & Methods: Here, autophagy has been analyzed in a mouse model of
NAFL/NASH and in human in vitro model. Liver specimens were collected from
24 weeks old FLS and FLS-oh/ob mice. Liver tissue was snap frozen and kept at −80°C. RNA and proteins were isolated. RTP-PCR and western bloting
was performed. HepG2 cells were incubated for 24h with 2mM oleic acid (OA)
P0662 MODULATION OF MITOCHONDRIAL DYNAMICS BY MIRNAS IN NAFLD

Introduction: Non-alcoholic fatty liver disease (NAFLD) pathogenesis associates with intracellular lipid accumulation in the liver. In addition, recent evidence supports a functional role for both mitochondrial dysfunction and microRNAs (miRNA/miRs) in NAFLD pathogenesis. In particular, deregulation of mitochondrial dynamics proteins, like mitofusin-2 (Mfn2) is frequently observed in obese and diabetic patients.

Aims & Methods: Our aims were to profile global liver miRNA expression changes during NAFLD progression and correlate them with the development of mitochondrial dysfunction in both experimental and human NAFLD. C57BL/6 mice were fed either a standard or a fast food (FF) diet for 25 weeks; or a methionine- and choline-deficient (MCD) diet for 2 and 8 weeks. miRNA profiling was performed using liver RNA from 8 weeks MCD-fed mice, in TigaMan MicroRNA arrays. qPCR array data was analyzed using a HTqPCR package in Bioconductor. Liver biopsies were obtained from patients with simple steatosis or NAFLD. mRNA and protein expressions were analyzed by qRT-PCR and immunoblotting, respectively. miRNA targeting was evaluated by dual-lucerase reporter assays.

Results: Both FF- and MCD-fed mice developed NAFLD-like features, including liver steatosis, inflammation and insulin resistance; as well as progressive steatohepatitis, severe liver damage and fibrosis. Strikingly, liver Mfn2 protein levels significantly decreased in both models (p < 0.05). Inversely, expression of Drp1, a mitochondrial fission protein, was found increased (p < 0.05). Other mitochondrial proteins, such as the voltage-dependent anion channel (VDAC), presented no expression changes. In human patients, Mfn2 protein levels decreased from steatosis to NASH (p < 0.05). Microarray profiling indicated that liver miRNAs are significantly modulated during NAFLD progression. Specifically, 25 miRNAs were found significantly increased in the liver of MCD-fed mice, while inversely, 27 miRNAs were decreased. Curiously, in silico analysis revealed that several of the up-regulated miRNAs could target Mfn2 in at least, one Mfn2 3’UTR binding site. Binding of miRNAs to Mfn-2, including miR-34a, was validated in HepG2 cells using a dual-lucerase reporter vector containing the Mfn2 3’UTR. Finally, overexpression of mir-34a in C2C12 muscle cells lead to Mfn2 inhibition and insulin resistance (p < 0.05).

Conclusion: In conclusion, mitochondrial dysfunction, particularly downregulation of Mfn2, plays a key role in human and experimental NAFLD and is targeted by miR-34a. A better understanding of the molecular network of miRNAs targeting mitochondrial proteins during NAFLD may help in the development of novel targeted therapies for metabolic diseases associated with mitochondrial dysfunctions. P0663 GRANULOCYTE COLONY STIMULATING FACTOR IN DECOMPENSATED LIVER DISEASE - OUR EXPERIENCE IN A TERTIARY HOSPITAL IN NEPAL

S. Thapaliya
Department Of Gastroenterology, Tribhuvan University Teaching Hospital, Institute of Medicine, Maharajgunj, Kathmandu/Nepal

Contact E-mail Address: sabinthapaliya@gmail.com

Introduction: Alcoholic Hepatitis, Decompensated Chronic Liver Disease and Acute-on-Chronic Liver Failure form a bulk of in-patients in Nepal. Mortality is quite high in these presentations despite all the medications currently available in our country. Prednisolone and Pentoxifylline are not up to the mark in terms of both short and long-term outcomes. The only option that remains is liver transplantation, which is not readily available in our country, and even if available it will be only in the near future, needs at least some months for planning and preparation and is also very costly. G-CSF (Granulocyte Colony Stimulating Factor) has shown both morbidity and mortality benefit in some studies in these groups of patients.

By comparing the outcomes in those receiving G-CSF and not receiving G-CSF, we can suggest G-CSF therapy to reduce mortality and morbidity in these patients. Although most of the studies done in the role of G-CSF in ACLF (Acute-on-Chronic Liver Failure) and decompensated CLD (Chronic Liver Disease) have used 4 μg/kg dose of G-CSF, our study has used fixed dosage of 300μg of G-CSF subcutaneously twice a day for a total of 3 days (6 doses).

Aim & Methods: We aimed to study the role of G-CSF in the treatment of alcoholic hepatitis, Decompensated CLD and ACLF. From January 2016 to December 2026, a total 49 patients with alcoholic hepatitis, decompensated chronic liver disease and acute-on-chronic liver failure admitted in TUTH (Tribhuvan University Teaching Hospital) were studied. Patients were randomized (in a 1:1 ratio) to either the ‘GCSF + SMT’ (Standard Medical Therapy) group (cases) or the ‘SMT-alone’ (control) group according to computer-generated random numbers. Patients in G-CSF group received G-CSF 300μg twice daily for 3 days (total 6 doses). Mortality rates at 1 month and CTP (Child Turcotte Pugh) and MELD (Model for End Stage Liver Disease) scores at enrollment and at Day 30 were compared in the two groups.

Results: A total of 49 patients [median age: 49 (range: 27-73), 70% males] were included in the study. 24 of them received G-CSF along with SMT and 25 received SMT alone. Baseline characteristics were similar in both the groups. The 3-day G-CSF therapy did not lead to any significant adverse effects. At one month, in GCSF+SMT group, 4 had died whereas in SMT alone group 15 had died and G-CSF survived with only 40% survived in control group (P = 0.02). Also significant improvement in CTP and MELD scores was seen in the group treated with GCSF at one month after therapy. Also, there were fewer complications of sepsis, hepatic encephalopathy and renal impairment in G-CSF group compared to the SMT alone group.

Conclusion: GCSF therapy improves survival and clinical outcome in patients with alcoholic hepatitis, decompensated chronic liver disease and acute-on-chronic liver failure. It may be useful in patients who do not have access to transplant services and also to the patients awaiting transplantation to prevent worsening during the waiting period. Further studies are needed to explore whether lower doses (total 6 doses) of GCSF are as effective as higher doses (total 10 doses).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cirrhosis and its complications are common causes of death among patients with end-stage liver disease. Liver transplantation as a definitive treatment is limited by shortage of donors and high cost. Autologous bone marrow
mononuclear layer containing stem cells is a novel approach for regeneration of liver. This therapy is not considered as a standard therapeutic option for patients.

Aims & Methods: To determine the outcome after intrasplenic or intrahepatic injection of autologous bone marrow stem cells (ABMSC) transplantation in patients with liver cell failure secondary to chronic hepatitis C infection. Sixty chronic hepatitis C patients with liver cell failure were prospectively enrolled. They were classified into 3 groups; group I: 20 patients underwent (ABMSC) injected intrahepatic. Group II: consisted of 20 patients underwent (ABMSC) injected intrahepatic after trans differentiation into hepatocytes with the double amount of growth factor. Group IIb: 10 patients underwent (ABMSC) injected intrahepatic after trans differentiation into hepatocytes using regular amount of growth factor. Group Ib: 10 patients underwent (ABMSC) injected intrahepatic after trans differentiation into hepatocytes using regular amount of growth factor. Group Ib: 10 patients underwent (ABMSC) injected intrahepatic after trans differentiation into hepatocytes using regular amount of growth factor. Group III: (Control Group) consisted of 20 patients received traditional supportive treatment for chronic liver cell failure and symptomatic treatment of ascites and bleeding abnormalities. All groups of patients were followed regularly for nine months clinically, biochemically and ultrasonographically. Fatigue was assessed by the modified fatigue impact scale questionnaire before, during and at end of the study.

Results: Our study included 60 patients (78.33% males) with mean age ±SD (49.9 ± 6 years). Patients who had ABMSC injection showed improvement in clinical parameters as bleeding tendency, ascites, lower limb edema and hepatic encephalopathy. There was statistically significant improvement in serum albumin, ascites, lower limb edema and hepatic encephalopathy. There was also statistically significant improvement in Child-Turcotte-Pugh in group I and II compared to group III. There was maintained till the end of the study. Fatigue improved in all patients who had ABMSC. There was improvement in serum albumin, ascites, lower limb edema, bleeding tendency and physical activity. Also there was improvement in MELD scores in all groups.

Conclusion: Stem cell transplantation has a beneficial effect on synthetic functions of the liver and possibly improves survival and quality of life of patients with end stage liver disease. Autologous bone marrow transplantation is safe and beneficial technique of treatment of patients with liver cell failure secondary to chronic hepatitis C infection.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
1. The prevalence of non-alcoholic fatty liver disease (NAFLD) has increased and several studies have shown that there is an association between NAFLD and insulin resistance (IR). The aim of this study was to determine how much impact the risk factors of metabolic syndrome has on ultrasonographic fatty liver, especially NAFLD.

Aims & Methods: A total of 41,258 adults who underwent routine comprehensive health evaluations, including abdominal ultrasonography, were selected. We calculated the adjusted prevalence ratios (PRs) for components of MetS (high blood pressure (BP), impaired fasting glucose, low high-density lipoprotein cholesterol (HDL-C), and high triglycerides) according to NAFLD.

Results: NAFLD was found in 13.8% of non-obese subjects and 52.3% of obese subjects. NAFLD was associated with most components of MetS in both obese and non-obese subjects. However, non-obese NAFLD patients had significantly higher PRs for certain components of MetS than did obese patients, especially among women. Body mass index, waist circumference, fasting blood glucose, triglyceride, HDL-C and aspartate aminotransferase, alanine aminotransferase, γ-glutamyl transpeptidase levels all affected NAFLD independently. The prevalence of metabolic syndrome was increased in mild (40.3%) and moderate (57.8%) NAFLD groups. When odd ratio (95% CI) for NAFLD group was compared to the contrast group, there was an increased risk of metabolic syndrome with odd ratio of 12.8 (95% CI, 9.1 – 17.0).

Conclusion: NAFLD and its components had a closer association with MetS and also with each risk factors of MetS. Therefore, assessment for concurrent MetS among NAFLD patients is considered to be necessary.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0668 THE USE OF THE FATTY LIVER INDEX TO DETERMINE THE PREVALENCE OF FATTY LIVER DISEASE (HEPATIC STEATOSIS) IN AN IRISH POPULATION

L. Reynolds, L. Rabbitt, C. Goulding
Acute Medical Unit, University Hospital Galway, Galway/Ireland

Contact E-mail Address: laurar3enol3@gmail.com

Introduction: Worldwide, the prevalence of fatty liver disease (FLD) is increasing, particularly in countries with rising obesity rates, such as Ireland. Studies suggest that up to 25% of those with FLD can progress to non alcoholic steatohepatitis (NASH) and be at risk of its sequelae, including cirrhosis and hepatocellular carcinoma. Indeed, NASH is now the second most common indication for liver transplantation in the US. Despite this alarming data, there is no prevalence data for Ireland in relation to FLD.

Aims & Methods: We aimed to use a simple screening tool, the Fatty Liver Index (FLI) to identify those at risk of having fatty liver disease (FLD) amongst all comers presenting to an Acute Medical Unit (AMU) and to use this data as an indicator of prevalence of FLD in Ireland.

Methods: In this prospective cohort study, all patients attending the Acute Medical Unit (AMU) were invited to take part. Their height, weight and waist circumference were measured, and triglycerides (TG) were added to their ‘routine AMU blood panel’, which also included measurement of gamma glutamyl transferase (GGT). Exclusion criteria were as follows: known liver disease, excess alcohol intake (>17 units per week for males, >11 units per week for females), age <18 years, pregnancy, active malignancy. The Fatty Liver Index (FLI), an algorithm to determine the risk of non-alcoholic fatty liver disease (NAFLD), was used to stratify patients into groups based on risk of having FLD. A FLI score of >60 is highly suggestive of having FLD, a score of 30–60 is indeterminate and a score of <30 is considered low risk for FLD. Ethical approval for this research was obtained from the local ethics committee.

Results: Data was completed on 316 participants; 58 were excluded, the majority due to either a history of alcohol excess or known liver disease. A total of 258 participants were therefore evaluated; 50% were male. One hundred and sixteen (45%) participants were >60 on the FLI; 57.3% of which were male. Only 16% of males had a FLI <30, compared with 44% of females. Males had a significantly higher FLI than females; 60.9 vs. 43.12 (p<0.0001). There was a statistically significant difference in all parameters measured between the 3 groups (p<0.0001), apart from height, although there was a trend toward lower height in the FLI <30 group, most likely due to the fact that it was 73% female. When overall participants, at there was no height difference between the 3 groups. Those with a FLI >60 were older than those with FLI <30, 54.6 vs. 48 (p=0.01).

Conclusion: In this study looking at prevalence of fatty liver in Ireland, 45% of participants were found to be at high risk, and 70% were at high or indeterminate risk. Worryingly, only 16% of males fell into this low-risk group. Apart from weight, GGT, TG and BMI this study also showed age and male sex to be significant risk factors for developing fatty liver. This group clearly needs follow up to further evaluate and manage their fatty liver.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0669 ROLE OF BISPHENOL A AS AN ENVIRONMENTAL MODIFIER IN THE PROGRESSION OF NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD)

Introduction: Bisphenol A (BPA) is an endocrine disrupting chemical, a heterocyclic group of chemicals usually found in food packaging or insecticide residues from multivariate logistic regression analysis. The probability was estimated with the equation: 0.627 + 0.640 * β + 0.593 * glucose (fasting glucose level) - cholesterol level + 0.361 * triglycerides + 0.458 * uric acid + 0.403 * serum lipase + 0.066 * platelet count in liver steatosis. According to the score values for different cut off levels, best ability in the prediction of severe FP has shown the score value above 6.5

Conclusion: Our study demonstrated that pancreatic fat infiltration due to its hormonal factor that plays a central role on mechanisms of MeSand manifestations, affects glucose metabolism and severity of NAFPD. Interestingly, significant association was registered among NAFPD patients

simulate human hyperglycemia, and at low (L-HepG2) glucose concentrations, for 48 h. In vitro, the proliferation of BPA-exposed HepG2 cells at two different concentrations (0.0025 and 0.005 μM) was evaluated, both at high (H-HepG2), in order to
with use of antidiabetic agents and the absence of highly fatty pancreas, indicating its potential protective role. Simple new noninvasive scoring system was designed from multivariate logistic regression analysis to estimate the occurrence of severely FP in NAFLD with best ability in the prediction in score values above 6.5.

P0671 SERUM THYROID STIMULATING HORMONE IS INDEPENDENTLY ASSOCIATED WITH HEPATIC STEATOSIS AND STEATOHEPATITIS IN EUTHYROID SUBJECTS

A. Eshraghian1, S. Nikghahboulian2, B. Geramizadeh3, S. Ali Malek-Hosseini4
1Gastroenterology And Hepatology, Shiraz University of Medical Sciences, Shiraz/Iran
2Transplant Research Center, Shiraz/Iran

Contact E-mail Address: eshraghiana@yahoo.com

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a rapidly growing disease worldwide. The pathogenesis of NAFLD is not well recognized. Thyroid is totally involved in regulation of lipid and carbohydrate metabolism, body weight, and energy homeostasis. Therefore, the role of thyroid hormones in pathogenesis of hepatic steatosis is anticipated.

Aims & Methods: This study aimed to investigate thyroid hormone abnormalities in euthyroid subjects with hepatic steatosis. A cross sectional study was conducted between September 2012 and September 2015 at Namazi hospital, Shiraz, Iran. Study subjects were healthy individuals who had undergone liver biopsy for evaluation of liver histology as a routine pre-transplant checkup before living related liver transplantation. Liver function tests, age, gender, weight, height, fasting plasma glucose, thyroid hormones, and lipid profile were recorded. Liver biopsy specimens were reviewed by an expert pathologist for hepatic steatosis and steatohepatitis. Individuals with a history of chronic liver disease, hepatitis B or C infection, hepatitis-biliary cancers, those with > 20 grams/day alcohol consumption, and individuals receiving medications causing hepatic steatosis were excluded from the study.

Results: A total of 210 individuals (130 women and 80 men) were included. Seventy six individuals (36.19 %) had hepatic steatosis and 19 individuals had steatohepatitis (9.04 %) in liver histology. Mean age of individuals with and without hepatic steatosis were 32.9 ± 6.69 and 31.8 ± 6.72 years respectively (P = 0.26). In univariate analysis higher weight, triglyceride, total cholesterol, alanine aminotransferase (ALT), alkaline phosphatase, fasting blood sugar (FBS) and thyroid stimulating hormone (TSH) were associated with hepatic steatosis (P < 0.05). Serum T4 and T3 were not associated with hepatic steatosis (P > 0.05). In regression analysis, higher alkaline phosphatase, higher ALT and higher TSH (OR = 1.36; 95 % CI: 1.02–1.80, P = 0.03) were independent predictors of hepatic steatosis. In regression analysis, higher serum TSH was independently associated with steatohepatitis compared to those without steatohepatitis (6.83 ± 6.04 mIU/L and 2.10 ± 1.27 mIU/L) (OR = 2.11; 95% CI: 1.45–3.07, p < 0.001). A cutoff value of 3.75 mIU/L for TSH was predictor of presence of steatohepatitis in liver biopsies (sensitivity = 73%; specificity = 89%; AUC = 0.754; P = 0.004).

Odds Ratio (OR) 95 % Confidence Interval (CI) P-Value

| Weight     | 1.05 | 0.96–1.16 | 0.245 |
| Triglyceride | 1    | 0.98–1.01 | 0.989 |
| ALT        | 1.007 | 0.93–1.08 | 0.867 |
| TSH        | 2.11 | 1.45–3.07 | <0.001 |

Conclusion: Higher serum TSH is associated with hepatic steatosis and steatohepatitis in euthyroid subjects. Thyroid hormones may have crucial role in hepatic steatosis and may be targeted for treatment of NAFLD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastroceidase II is part of the functional pathway of co-translational protein translocation and maturation in the endoplasmic reticulum. It is implicated in autosomal dominant polycystic liver disease (ADPLD) and autosomal dominant polycystic kidney disease (ADPKD). The β-subunit of gastroceidase II, encoded by GANAB, has been identified as one of the causative genes of ADPLD. Recent data suggest that the α-subunit of gastroceidase II (GHI), encoded by GANAB, is associated with ADPKD and ADPLD. We aimed to identify GANAB mutations in an independent cohort of patients with the primary phenotype of polycystic liver disease (PLD) and to predict the influence of these mutations on gastroceidase II function.

Aims & Methods: We identified genetic mutations in GANAB using molecular inversion probe (MIP) analysis in a cohort of PLD patients. Both patients with ADPKD and ADPLD were included for analysis. Mutations identified with MIP analysis were validated using Sanger sequencing. Bioinformatics prediction tools (PolyPhen-2, Align GVGD, SIFT, MutationTaster) were used to predict the functional significance of the mutations. YASARA&WHAT IF were used for analysis of the structural effects of the mutations. Primary cholangiocytes obtained from a patient with GANAB mutation (c.251SC > T) were used to study loss of heterozygosity.

Results: We identified and validated 6 new bona fide GANAB mutations in 7 patients. These are 2 frameshift (c.687delT and c.11_16delTAGGGG), 1 splicing (c.2691–28C > Gi), 2 nonsense (c.2590C > T and c.2656C > T) and 1 missense (c.1835G > C) mutation. In silico analysis showed c.687delT and c.11_16delTAGGGG are located in N-terminal domain of the protein. These mutations probably lead to a total defective protein, c.1835G > C is located in the active site of the protein. It is predicted to disrupt the composition of the active site and reduce enzymatic activity. The remaining mutations (c.2691–28C > Gi, c.2590C > T and c.2656C > T) are located in C-terminal domain, which interacts with PRKCSH. The mutations could result in early termination of this domain. It is speculated this disrupts the ability of the two subunits to interact. Western Blot showed no differences in GHI expression in an ADPLD patient with GANAB mutation (c.251SC > T) compared to primary cholangiocytes obtained from a patient without PLD. This indicates in this patient no loss of heterozygosity occurs in cholangiocytes lining the hepatic cysts.

Conclusion: We describe six novel GANAB mutations that can cause PLD in a mixed population of ADPKD and ADPLD patients. These mutations are found in functionally important domains of α-subunit of gastroceidase II, which may lead to impaired enzymatic activity of the complex. In contrast to other PLD related genes no loss of heterozygosity was found for GANAB in cyst epithelium.

Introduction: Steatohepatitis (NASH) is the most prevalent cause of chronic liver disease and is characterized by hepatic fibrosis and cirrhosis in about 25% of cases. Steatohepatitis is associated with the metabolic syndrome and type 2 diabetes mellitus and is the most common indication for liver transplantation. The natural history of NASH is characterized by a progression to advanced fibrosis and cirrhosis in 80% of patients with NASH, and the risk of developing these complications is similar to that of patients with chronic hepatitis C and significantly higher than that of patients with chronic hepatitis B. Importantly, up to 60% of NASH patients have advanced fibrosis or cirrhosis, which is associated with a decreased life expectancy and the need for liver transplantation. Despite the prevalence and severity of these complications, there are still no effective treatments for NASH, which highlights the importance of further research in this area.

Methods: We performed a systematic review of the literature to identify studies that evaluated the natural history of NASH. We searched PubMed, EMBASE, and Cochrane Library databases for relevant articles published between January 2000 and December 2019. We included studies that provided data on the progression of NASH to advanced fibrosis and cirrhosis. We also included studies that evaluated the impact of NASH on patient outcomes, such as survival and quality of life.

Results: We identified 123 studies that met our inclusion criteria. The studies included a total of 18,666 patients with NASH. The results of the studies showed that the progression of NASH to advanced fibrosis and cirrhosis is a significant clinical concern. The mean annual rate of progression to advanced fibrosis was 4.0% (95% CI: 3.2-4.8%), and the mean annual rate of progression to cirrhosis was 1.3% (95% CI: 0.9-1.7%). The studies also showed that the progression of NASH to advanced fibrosis and cirrhosis is associated with increased mortality and decreased quality of life. Importantly, the studies showed that the progression of NASH to advanced fibrosis and cirrhosis is influenced by lifestyle factors, such as diet and physical activity, and by medications, such as statins and thiazolidinediones.

Conclusion: The natural history of NASH is characterized by a progression to advanced fibrosis and cirrhosis, which is associated with a decreased life expectancy and the need for liver transplantation. Further research is needed to identify effective treatments for NASH that can prevent the progression of NASH to advanced fibrosis and cirrhosis and improve patient outcomes.

Disclosure of Interest: All authors declare no conflicts of interest.
Aims & Methods: Aim of our study was to compare two non-invasive methods: fibrosis (p and NAFLD-FS for significant fibrosis). FIB-4 correlated with TE for high degree statistic significant with TE (p < 0.0001). BARD score did not correlate with TE and NAFLD-FS for significant fibrosis. BARD-4 and TE can be used to evaluate the progression of fibrosis in NAFLD and to select the patients for liver biopsy. In our study BARD score was not useful in detection of high degree fibrosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0678 EFFECTS OF UDCA AND STATIN COMBINATIONS ON LIPID PROFILES IN NAFLD PATIENTS
S. S. Vyalov
Gastroenterology, Peoples Friendship University of Russia, Moscow/Russian Federation
Contact E-mail Address: sviialov@mail.ru

Introduction: Dyslipidemia has an important role in NAFLD and inflammation progress and insulin resistance development. The studies suggested the role of UDCA in lipid profile correction. UDCA replaced bile acid balance and improved triglyceride and cholesterol levels in NAFLD patients, has immunomodulatory action.

Aims & Methods: The aim of study was estimation of the efficacy of different dosage of ursodeoxycholic acid (UDCA) with statin combination treatment in patients with NASC and NAFLD. There are 180 patients with NAFLD. It was divided into two subgroups: fatty liver (90 subjects) – patients with normal level of ALT, and nonalcoholic steatohepatitis (NAS, 90 subjects) – patients with elevated level of ALT (the median is 78.5 U/l). All patients were divided in 3 groups. The blood test, liver enzymes, lipid profile, HOMA-IR, Fibroscan and stool test was checked every 2 weeks of treatment. First group was taken UDCA 10 mg/kg/day and the patients of first group continue treatment for 3 months. Second group was taken UDCA 15 mg/kg/day + Statin. Third group were fed the low-lipid and low-glycemic index diet only (900 kcal/day). After 3 months of treatment patients of third group (diet only) add UDCA 15 mg/kg/day to treatment for extra 3 months.

Results: The subgroups did not show any difference in terms of initial total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), and triglycerides (TG). The analysis of the lipid spectrum showed a more intense dynamics in the group of patients taken UDCA combined with statin. After 3 months of follow-up there was a significant reduction in TC to 4.2 mmol/l, LDL-C to 1.8 mmol/l and TG to 1.2 mmol/l in the fatty liver subgroup, and TC to 4.1 mmol/l, LDL-C to 1.8 mmol/l and TG to 1.2 mmol/l in the NAS subgroup. Changes were similar in the subgroups. The level of total cholesterol, triglyceride and liver enzymes were decreased faster in group taken UDCA and statin independent from UDCA dosage. There are no side effects or liver enzyme elevation in group treated with UDCA and statins. In the NASH subgroup there was a significant decrease in ALT to 35 U/l. At the end of the first month of statin therapy combined with UDCA in the NASH subgroup a significant positive dynamics of ALT was found in patients with NASH (initially 78.5 U/l; after treatment decreased to 42.8 U/l).

Conclusion: 3-month statin therapy in combination with UDCA showed significant lipid-lowering effects in patients with NAFLD, as well as normalization of ATR. UDCA and statin treatment was well tolerated. In the group who previously had not taken steatosis in the NASH subgroup, higher levels of TC and TG were observed. The studies suggested the role of UDCA in lipid profile correction. UDCA replaced bile acid balance and improved triglyceride and cholesterol levels in NAFLD patients.

difficult due to the unreliable history of alcohol consumption and lack of sensi-
ble markers. A new tool to overcome these difficulties: a ANI (alcoholic liver disease/nonalcoholic fatty liver disease index) was created for a non-invasive determination of fatty liver diagnosis.

Aims & Methods: The aim of this study was to evaluate the reliability of ANI as a non-invasive diagnostic tool in alcoholics. A retrospective study between 2010 and 2015 in patients with definite diagnosis of NAFLD and ALD based on clinical, biochemical and histological criteria was performed. ANI scor-
ing system in the differentiation of ALD and NAFLD was evaluated through the area under the receiver operating curve (AUROC). ANI score was calculated through Mayo Clinic formula.

Results: This study was carried out in 22 patients with ALD and 120 with NAFLD, 87 men (61.3%) with a median age of 51 ± 13 years. NAFLD patients presented a higher body mass index (BMI) of 28.9 ± 5.9 vs 23.9 ± 6 in ALD. ANI showed a sensitivity of 81% and specificity of 79% for the diagnosis of ALD with a cut-off value of -1.96 [AUROC 0.806 (0.715-0.898), p < 0.001]. ANI greater than -1.96 indicates a diagnosis of ALD whereas ANI less than -1.96 indicates a diagnosis of NAFLD.

Conclusion: ANI scoring system is a non invasive diagnostic and reliable tool that may be used to distinguish NAFLD from ALD, decreasing the need for liver biopsy. ANI greater than -1.96 suggests the diagnosis of ALD and ANI lesser than -1.96 suggest NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.
The CTCAE scale was used. Overweight was detected in 40 patients: BMI = 25–29.9 kg/m² (n = 40). In 30 (75%) patients with AL, the overload was more than 15 kg. Overweight presence the patients were divided into 2 groups: I (n = 44) – patients with AL and normal body weight, II (n = 40) – patients with AL and overweight.

Results: In AL patients of group I before the start of chemotherapy functional liver mass (%) was not significantly different from healthy people. In group II there was an increase of ALT activity in 1.5 times, AST – in 1.2 times, ALP and GGT in 1.4 times compared to the norm (p < 0.05) and reached grade I level, and no change in bilirubin and total protein levels. On the 28th day of treatment in 3 (6.8%) patients of group I the violation of the functional liver state was revealed, which was characterized by the increased activity of ALT in 2.3 times, AST – in 2.6 times respectively, GGT and ALP in 2.6 and 3.7 times respectively. In group II hepatotoxicity was detected in 26 (65%), which was characterized by the increased activity of ALT in 1.5 times, AST – in 1.3 times, GGT – in 1.9 times compared to normal levels, the bilirubin and total protein levels remained in the normal range, that consistent with grade I. In group II hepatotoxicity was detected in 26 (65%), which was characterized by the increased activity of ALT in 1.5 times, AST – in 2.3 times respectively, GGT and ALP in 1.9 and 2.4 times respectively, the level of total bilirubin increased in 2.1 times (p < 0.05), of which in 17 (42.5%) patients hepatotoxicity was of grade I and in 2 (5%) – of grade II level, with no statistically significant changes in protein synthesis liver function. On the 56th day of treatment in 7 (15.9%) patients of group I the violation of the functional liver state was revealed, which was characterized by the increased activity of ALT in 1.8 times, AST – in 1.3 times, ALP – in 1.6 times. GGT – in 1.9 times compared to normal levels, the bilirubin and total protein levels remained in the normal range, that consistent with grade I. In group II hepatotoxicity was detected in 26 (65%), which was characterized by the increased activity of ALT and AST in 2.6 and in 2.3 times respectively, GGT and ALP in 2.6 and 3.7 times respectively, the level of total bilirubin increased in 3.6 times (p < 0.05), of which in 10 (25%) patients hepatotoxic reactions were of grade I and in 16 (40%) – of grade II level.

Conclusion: The presence of the overweight results in a significant increase in the frequency and degree of hepatotoxic reactions in patients with AL during chemotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Binge drinking is a common pattern of alcohol consumption among young people. At present few data are available on the relationship between binge drinking and alcohol use disorder (AUD) in adolescents. The aim of this study was to assess drinking habits, patterns of alcohol consumption, smoking habits, use of illicit drugs, the prevalence of binge drinking and AUD among young students. The correlation between binge drinking and AUD was also investigated.

Aims & Methods: This study was performed on 2704 subjects attending high school. Questionnaires regarding socio-demographic data, anthropometric characteristics, pattern and amount of alcohol intake, smoking habits, use of illicit drugs, and physical activity were administered to students. Moreover Italian versions of AUDIT, STAI-Y1, STAY-Y2 and ZUNG scale were administered.

Results: Alcohol intake was reported by 2126 students (79%); among them 1278 (34%) in the last month. According to AUDIT questionnaires, a diagnosis of AUD was made in 165 (6%) subjects. The prevalence of AUD was higher in subjects that reported binge drinking behavior than in those that did not report binge drinking (p < 0.0001).

Conclusion: Alcohol consumption and abuse among young students is alarming. Binge drinking behavior among young students seems to be very common and it seems a risk factor for the development of AUD.

Introduction: Severe alcoholic hepatitis (SAH) remains a condition which bears high mortality and morbidity rates, as well as high healthcare costs. This is why adequate selection of patients who benefit the most from corticotherapy is of utmost importance. Although serum biomarkers are available (Maddrey Discriminant Function - MDF), the diagnostic of SAH relies on liver biopsy. Previous metabolomic studies have shown a core metabolic phenotype represented by decreased serum lysophosphatidylcholines (LPC) and increased serum bile acids that occurs relatively early in liver diseases regardless of etiology, and remains stable in their evolution, including liver cirrhosis and hepatocellular carcinoma (1). Our previous work also showed that decreased LPC levels are associated with alcoholic liver disease (ALD).

Aims & Methods: The aim of the study was to assess the metabolic profile of patients with ALD and to identify potential new biomarkers associated with severity. Between December 2015 and September 2016, 64 patients with biopsy proven AH were included (38 with SAH - MDF  32 and 24 with non-severe AH - MDF < 32). Fasting serum was stored at -80 degrees after centrifugation at 5000 rpm for 10 minutes. Specific purification protocol metabolic analysis was performed using Thermo Scientific UHPLC UltiMate 3000 system, equipped with a Dionex quaternary pump delivery system and a Bruker Daltonics Maxis Impact MS detection equipment (version 2012). Biostatistical analysis The chromatograms obtained were processed using CompassDataAnalysis 4.2 software (Bruker, Germany) and about 3000-4000 molecular masses were identified. Those data were further processed using ProfileAnalysis (Bruker, Daltonics): time alignment, normalization by sum of bucket values in analysis, 80% bucket filter, internal recalibration, etc. The matrix obtained was further processed through MetaboAnalysis, to analyze samples through univariate and multivariate statistical analysis.

Results: Univariate and multivariate statistical analysis by MetaboAnalysis identified 10 potential biomarkers. Among them, LPC (18:0) showed good discrimination for SAH (AUC = 0.804) with significantly lower values as compared with non-severe AH (0.38 fold change, p = 6 x 10^-11).

Conclusion: SAH appears to have a different metabolic profile, mainly due to changes in lysophosphatidylcholine metabolism. Targeted metabolomic studies are required in order to confirm the results and to evaluate the possible applications in current clinical practice.

P0688 APPLICATION OF THE ICA-AKI CRITERIA IN THE DIAGNOSIS OF ACUTE KIDNEY INJURY IN PATIENTS WITH ACUTE DECOMPENSATION OF CIRRHOSIS

R. Azevedo, J. Pinto, H. Ribeiro, F. Pereira, C. Leitão, A. Caldeira, E. Pereira, R. Sousa, A. Banhudo
Gastroenterology, Amato Lusitano Hospital, Castelo Branco/Portugal

Contact E-mail Address: richardazevedo13@gmail.com

Introduction: Acute kidney injury (AKI) is a common complication in patients with decompensated liver cirrhosis. Recently, the International Club of Ascites (ICA) defined new diagnostic criteria: the ICA-AKI criteria.

Aims & Methods: This study aims to identify patients hospitalized for acute decompensation of cirrhosis with AKI according to the ICA-AKI criteria, and to determine if its application leads to greater prognostic accuracy.

Methods: Retrospective analysis of hospitalized patients in a gastroenterology department for acute decompensation of cirrhosis, without acute-on-cronic liver failure, between January 2014 and December 2015. Identification of AKI patients according to ICA-AKI criteria. Analysis of the severity of liver diseases and in-hospital and short-term mortality among patients with and without AKI. Compared the accuracy of the conventional criteria vs. ICA-AKI criteria in the prediction of mortality.

Results: 161 patients included, 85.7% male, mean age of 65 ± 10.8 years. Average length of stay of 11.6 ± 9.5 days. 39.8% of patients had AKI on admission or during hospitalization according to the ICA-AKI criteria (50.9% in stage 1, 20.3% in stage 2 and 18.8% in stage 3). Patients with AKI according to ICA-AKI had longer hospitalizations (14.55 ± 9.75 days, p < 0.05), higher severity of hepatic disease quantified by the MELD and MELD-Na scores (17.62 ± 12.83 vs. 16.17 vs. 12.83 p < 0.05) and higher in-hospital, 28 and 90-day mortality when compared to patients without AKI (23.4 ± 6.2% vs. 9.3%, p < 0.05, 42.9 ± 23.7%, p < 0.05). There was a statistically significant association between the presence of infection and the development of AKI (p < 0.05). The ICA-AKI area under the curve (AUC) to predict in-hospital, 28 and 90-day mortality was significantly higher than the AUC of conventional criteria (0.682 ± 0.533 vs. 0.678 ± 0.588 vs. 0.618 ± 0.509, p < 0.001). ICA-AKI criteria in the prediction of mortality.

Conclusion: This is the first reported case-control study of HE in Taiwan. The study provides further evidence that infections are strongly associated with HE death. The study can be used to assist in the management of patients with HE. The study can be used to define the ICU population, since patients admitted to the ICU have higher rates of infection and HE. The study can be used to define the ICU population, since patients admitted to the ICU have higher rates of infection and HE. The study can be used to define the ICU population, since patients admitted to the ICU have higher rates of infection and HE. The study can be used to define the ICU population, since patients admitted to the ICU have higher rates of infection and HE.}

Aims & Methods: The aim of this study was to evaluate the efficacy of carvedilol versus propranolol on the prognosis of variceal bleeding in cirrhotic patients with occlusive portal vein thrombosis. Between January 2014 and December 2015, cirrhotic patients with occlusive non-malignant PVT were enrolled in a tertiary center. PVT was suspected by Doppler ultrasound and confirmed by computed tomography. Cirrhotic patients with esophageal varices and no previous variceal bleeding were randomized to carvedilol 6.125 mg daily or Propranolol 40 mg daily. End points were esophageal variceal bleeding or death.

Results: During the study period forty eight patients were evaluated. Twenty one and twenty seven patients were randomized in carvedilol and propranolol arms respectively. Mean age was 49 ± 12.2 years: 33 (68.7%) were males; 60.4% had viral cirrhosis; mean Child-Pugh score was 7.2 ± 2.6 and mean follow up was 12.3 ± 9.1 months (range 1–29 months). All the patients had occlusive non-malignant PVT, most of them involving only the trunk, and grade 2 or 3 esophageal varices. Both carvedilol and propranolol groups had comparable variceal bleeding rates (14.2% vs. 14.8%, P = 0.002), bile related mortality (9.5% vs. 11.1%, P = 0.027) and overall mortality (23.8% vs. 22.5%, P = 0.044) respectively. Adverse events in carvedilol group were hypotension (n = 2), requiring cessation of therapy, while and dyspnea (n = 3) resolved spontaneously. In the propranolol group there was 1 adverse event that required discontinuation of treatment (grade 2 atio-ventricular block).

Conclusion: Our study suggests that carvedilol is probably not superior to propranolol in preventing first variceal bleeding in cirrhotic patients with occlusive PVT, and they both can be used as primary prophylaxis.

Introduction: The ALBI score was recently developed to assess the severity of liver dysfunction, taking into account albumin and bilirubin levels. We aimed to assess its prognostic performance in patients with liver cirrhosis complicated with upper gastrointestinal bleeding (UGIB) while comparing it with Child-Pugh (CP) and MELD scores.

Aims & Methods: Retrospective uncenter study, including consecutive adult patients with cirrhosis admitted for UGIB between January 2011 and November 2015. Clinical, analytical and endoscopic variables were assessed and ALBI, CP and MELD scores at admission were calculated. Statistical analysis was performed using SPSS v21.0 and MedCalc v16.4.3, and a two-tailed p value < 0.05 was defined as indicating statistical significance.

Results: Included 111 patients with a mean age of 57.14 years, 76.6% were males. Liver cirrhosis was most frequently alcoholic (89.2%) and the most common etiology for UGIB was variceal hemorrhage, in 75.5% of patients. During the first 30 days of follow-up 12 patients (10.8%) died, and during the 1st year of follow-up another 10 patients died (1st year mortality of 19.8%). When comparing the three scores, regarding in-stay and 30 days mortality, only ALBI score showed statistical significant results, with an area under the curve (AUC) of 0.82 (p < 0.001) for both outcomes. Regarding 1st year mortality, AUC for ALBI, CP and MELD scores, were 0.71 (p < 0.02), 0.64 (p < 0.05) and 0.66 (p = 0.02), respectively, while for global mortality AUC were 0.75 (p < 0.01), 0.72 (p < 0.01) and 0.72 (p < 0.01), respectively. When comparing the AUC of the three scores, no significant differences were found regarding 1st year mortality and global mortality.

Conclusion: In our series, ALBI score accurately predicted both in-stay and 30 days mortality (0.82 (p < 0.001)), while CP and MELD scores weren’t able to predict these outcomes. All scores showed a fair prognostic prediction performance regarding 1st year and global mortality. These results suggest that ALBI score is particularly helpful in the assessment of short term outcomes, with a better performance than the most commonly used scores, and may assist the clinician in the stratification of care at admission and maybe even in the referral to liver transplant.

P0693 CARVEDIOL VERSUS PROPRANOLOL EFFECT IN THE PRIMARY PROPHYLAXIS OF VARICEAL BLEEDING IN CIRRHOTIC PATIENTS WITH PORTAL VEIN THROMBOSIS

1Gastroenterology, “Gr. T. Popa” University of Medicine and Pharmacy, Iasi/Romania
2Institute of Gastroenterology and Hepatology, Iasi/Romania

Contact E-mail Address: gilda_iri25@yahoo.com

Introduction: Portal vein thrombosis (PVT) is recognized as an independent factor of variceal bleeding. Beta blockers are the mainstay treatment to prevent variceal bleeding in cirrhotic patients. Carvedilol has been shown to be equal to propranolol in preventing first bleeding in cirrhotic patients, however, the efficacy of this policy in patients with PVT is unknown.

Introduction: Despite the progress in the treatment of cirrhosis, infections remain a common problem, being responsible for the great majority of morbidity and mortality in these patients.

Aims & Methods: The aim of this study was to identify predictive factors for infection in the first hospitalization for decompensated cirrhosis (DC).

Retrospective analysis of patients with the first hospitalization for DC between January of 2009 and March of 2016. Demographic, clinical and biochemical data was compared between patients with and without infection in the first hospitalization for DC.

Results: From the 179 patients with a first hospitalization for DC, 6% had ascites on admission, 45.8% had upper gastrointestinal bleeding, 38.5% had jaundice, and 28.5% had hepatic encephalopathy. Regarding medication, 29.6% of the patients were taking proton pump inhibitors (PPI), 22.3% had beta-blockers prescribed, and 1.7% were on prophylactic antibiotic. In those 53 patients with proven infection, spontaneous bacterial peritonitis was the most common infection (34%), followed by urinary tract infection (30.2%) and pneumonia (13.2%). Infected patients presented with jaundice (p = 0.03), severe ascites (p = 0.039), use of PPI (p = 0.003) and acute-on-chronic liver failure (p = 0.006) more frequently than those without infection. Additionally, infected patients presented with significantly increased values of C-reactive protein (p < 0.001), INR (p = 0.04), creatinine (p = 0.04), and MELD scores (p = 0.001). Mortality rates were higher in infected patients at 30-day (4.0% vs. 9.4%), 3 months (7.9% vs. 18.9%), 6 months (12.7% vs. 24.5%) and 1 year (22.2% vs. 26.5%). In the multivariate analysis, the use of PPI was independently associated with an increased risk of infections (OR = 2.3; 95% CI 1.052–5.173).

Conclusion: Almost a third of patients will develop infections right at the first hospital admission for decompensated cirrhosis, which are associated with higher short and long-term mortality rates. As PPI more than double the risk of infections, the indication for the use of these drugs should be strictly reviewed and their interruption considered in cirrhotic patients.

Introduction: Critical flicker frequency (CFF) values ≤39 Hz identify cirrhotic patients with minimal hepatic encephalopathy (mHE) and predict their risk of developing overt hepatic encephalopathy (oHE). However, these results have been obtained in cirrhotics with advanced liver disease suffering a previous episode of oHE. Cirrhotic patients should be routinely screened by CFF to identify patients at risk of oHE.

Contact E-mail Address: vincisentino@gmail.com

Introduction: Probiotics has been recently used to treat cirrhotic patients with any grade of acute or chronic hepatic encephalopathy (HE). Herein, we evaluated the efficacy of Lactobacillus Ruminans GG (LRGG) on the treatment of minimal HE (mHE) in compensated cirrhotics.

Aims & Methods: 134 patients were screened by critical flicker frequency (CFF) to diagnose mHE. Among them, 41 patients were CFF+ (≤39Hz) and were
randomized to placebo or LRGG treatment, for 2 months. In all intention to
treat analyses, the patient demographics, laboratory test, model for end-stage liver disease (MELD) score, and Child-Pugh class were evaluated.

Results: CFF value increased in both LRGG and placebo groups at the end of
study compared to baseline (p < 0.05). The same results was also reported in the male subpopulation as the same
allele was found to be significantly higher in both HCV spontaneous clearance (SVC) and control groups when compared to chronic HCV group [OR 0.42 (95% CI 0.21 to 0.82, Pc < 0.0372) and OR 0.40 (95% CI 0.23 to 0.71, Pc < 0.0054)] respectively. The same result was also reported in the male subpopulation as the same
allele was found to be significantly higher in both HCV spontaneous clearance (SVC) and control groups when compared to chronic HCV group [OR 0.42 (95% CI 0.21 to 0.82, Pc < 0.0372) and OR 0.40 (95% CI 0.23 to 0.71, Pc < 0.0054)] respectively.

Conclusion: The risk of development of chronic HCV infection was associated with T allele carriage of TLR3rs3775291 SNP. While the carriage of C allele of TLR7r3853839C allele was associated with spontaneous HCV clearance in both male and female subpopulations in Egyptian families.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Th17 cells are involved in liver fibrosis by activating hepatic stellate cells (HSCs). We aimed to investigate whether HSCs could regulate the function of Th17 cells and the relevant mechanism. Aims & Methods: Sixty-five patients diagnosed with chronic hepatitis B (CHB) were enrolled in this study. To unravel the effect of HSCs on T cells, naïve CD4+ T cells and Th17 cells were sorted from CHB patients and cultured with activated-HSCs. The expression of cytokines and genes transcription were analyzed. In addition, the regulatory mechanism of HSCs was also investigated.

Results: ELISA and qRT-PCR showed that Th17 cells from CHB patients were more pathogenic via the expression of IL-17A, IL-23R, RORC, CCL20 and CCR6, and meanwhile, they could activate the primary HSCs. The co-culture experiment indicated that activated HSCs dramatically promoted the proliferation of CD4+ T cells in a time- and dose-dependent manner. In addition, they could also induce the naïve CD4+ T cells into Th17 cells which had a more pathogenic phenotype. Moreover, activated-HSCs-mediated induction of Th17 cells might depend on IL-1β and IL-6 release as well as COX-PGE2 pathway. Conclusion: Th17 cells cooperated with HSCs in a proinflammatory feedback loop provide us a more understanding of the pathogenic role of Th17 cells in the chronicity of HBV infection.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Living donor liver transplantation (LDLT) has become the only life-saving treatment option for patients with end stage liver disease secondary to HCV infection in Egypt, unfortunately recurrence of infection is nearly universal,
resulting in cirrhosis and graft failure within 5 years after transplant. Different studies are studying the efficacy and safety of direct acting antiviral (DAI) drugs in treatment of HCV infection post-liver transplantation. We aimed to evaluate the efficacy and safety of treatment with DAA drugs early post-transplant period in LDLT recipients with HCV genotype 4.

Aims & Methods: This study was descriptive retrospective analysis on twenty-six LDLT patients with HCV genotype 4 treated with DAA drugs (fifteen patients received Sofosbuvir 400 mg and weight based Ribavirin dose for 24 weeks, eight patients received Sofosbuvir 400 mg and Daclatasvir 60 mg for 24 weeks and three patients received Sofosbuvir 400 mg and Simprevir 150 mg for 12 weeks) in the early post-transplant period who were transplanted during the period from January 2014 till December 2015 at Egyptian tertiary center for organ transplantation.

Results: Twenty-six patients completed the treatment course, sustained virological response (SVR) at week 12 was achieved in 80.8% (21/26) of recipients, 100% (11/11) for Sofosbuvir- Daclatasvir and Sofosbuvir- Simeprevir group versus 66.7% (10/15) for Sofosbuvir-Ribavirin group (p < 0.05). No major side effects had been reported, anemia developed in patients received ribavirin respond to treatment with erythropoietin and reduction of the ribavirin dose.

Conclusion: Use of Daclatasvir/Sofosbuvir or Simeprevir/Sofosbuvir in early treatment of HCV genotype 4 post living donor liver transplant recipient achieved higher rates SVR than Sofosbuvir/Ribavirin.

11Clinics of Infectious Diseases 3 would constitute the best option.

Twenty-four Italian centers were involved in this real-life study where HCV genotype 3 patients treated with DAA. To expand the number of cases, we conducted a systematic review of literature on the outcome of genotype 3 patients treated with DAA.

Results: A total of 233 patients with HCV genotype 3 were enrolled. Cirrhotic patients accounted for 83.7%. Overall, the SVR12 rate was achieved by 205 (88.4%) patients with compensated advanced chronic liver disease (cACLD), the meta-analytic approach suggests to extend therapy at 24 weeks.

for these patients appears to be the combination sofosbuvir/daclatasvir, adminis-
t ended over the cut-off point which has a Sensitivity of 0.76 and Specificity of 0.81. NPV = 78.12, PPV = 78.57. 32 patients with highly suggestive cACLD (LS > 15 kPa) underwent upper endoscopy (UE): 10 (32%) had varices (5 small EV and 5 big EV).17 (53%) fulfilled the Baveno VI criteria (3 with small EV and 4 with medium EV). There were only 3 cases of EV misdiagnosed by Baveno VI.

Conclusion: We did not find any significant differences in platelet levels or in the regression of varices. All authors have declared no conflicts of interest.

Characteristics

Main Cohort

n = 84

Age mean (st) 60 (9.8)

Male-sex (%) 49 (58.3%)

Aetiology of liver disease (%) HCV 100%

Platelet count × 103/mm3 Baseline mean (st) 149.21 (59.62)

Platelet count × 103/mm3 SVR 54 mean (st) 168.15 (60.33)

Fibrosis Stage F0–1 in SVR 54 n (%) 8 (12.7%)

Fibrosis Stage F2 in SVR 54 n (%) 12 (19.5%)

Fibrosis Stage F3 in SVR 54 n (%) 15 (23.8%)

Fibrosis Stage F4 in SVR 54 n (%) 30 (47.62%)

Liver Stiffness (kPa) Baseline [n = 84]mean (st) 23.86 (12.63)

Liver Stiffness (kPa) SVR 24 [n = 59] mean (st) 15.6 (12.14)

Liver Stiffness (kPa) SVR 54 [n = 63] mean (st) 16.18 (10.99)

Patients who underwent Upper Endoscopy n (%) 32 (38.01%)

Patients with varices (VE) (any size) [n = 32] n (%) 10 (31.25%)

Patients fulfilling Baveno criteria [n = 32] n (%) 17 (53.15%)

Patients with high-risk VE [n = 32] n (%) 5 (15.6%)

Patients fulfilling Baveno criteria with high-risk VE [n = 32] n (%) 4 (12.5%)

Conclusion: There is a significant improvement in LS data after treatment with DAA both at SVR24 and SVR > 54. This improvement seems to be more likely due to the early response of patients with lower TE values in our study 17.9 kPa. We did not have enough available data in our study to support that this improvement in LS measured by TE has a relevant impact on the clinical management of the patient. The Baveno VI criteria are a useful tool in daily practice to avoid unnecessary UE. Further investigation with larger samples is needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

2Epidemiology, Hospital Universitario Mostoles, Mostoles/Spain

Contact E-mail Address: miguelpeffer@gmail.com

Introduction: One improvement in liver stiffness (LS) measured by transient elastography (TE) has been observed in patients with chronic hepatitis C treated with direct action antivirals (DAA).1,2 The Baveno VI guidelines1,2 propose that patients with compensated advanced chronic liver disease (cACLD), LS measurement < 20 kPa and a platelet count > 1500000 can avoid screening endoscopy as their combination is highly specific for excluding clinically significant oeso-
phageal varices (EV). These patients have been validated recently.1,3

Aims & Methods: The aim of this study was to quantify LS regression both quantitatively (measured in Kilopascals) and qualitatively (Stages of F0-F4 fibrosis) in a stationary phase after the sustained virological response (SVR) in patients with cACLD (14). The secondary objective was to assess whether this improvement in LF measurements has a clinical correlation with changes in platelet numbers and the presence of varices according to Baveno VI criteria.

Results: 84 patients (49 men and 35 women) with cACLD were included in the study. Median TE on baseline (BL) prior to DAA treatment was [mean(range), 23.86 (12.5–75) kPa] and decreased to [mean(range), 15.6 (4.8–75) kPa] at SVR 24 and [mean range], 16.19 (3.627) kPa] at SVR > 54. Both were statistically significant showing a decrease in LS about 30% between BL and SVR 24 and about 33% between BL and SVR > 54. We did not find statistically significant differences between SVR 24 and SVR > 54. Regarding the probability of qualitative improvement of the LS (improve from F4 to F3 or less) the AUC was 0.8 with 17.9 kPa as the cut-off point, which has a Sensitivity of 0.76 and Specificity of 0.81. NPV = 78.12, PPV = 78.57. 32 patients with highly suggestive cACLD (LS > 15 kPa) underwent upper endoscopy (UE): 10 (32%) had varices (5 small EV and 5 big EV). 17 (53%) fulfilled the Baveno VI criteria (3 with small EV and 4 with medium EV). There were only 3 cases of EV misdiagnosed by Baveno VI.

Conclusion: We did not find any significant differences in platelet levels or in the regression of varices. All authors have declared no conflicts of interest.
P0705 8 VERSUS 12 WEEKS OF LEDIPASVIR/SOFOSBUVIR REGIMEN IN PATIENTS WITH CHRONIC HEPATITIS C GENOTYPE 1 INFECTION

Contact E-mail Address: joana.rita.carvalho@gmail.com

Introduction: The therapeutic regimens for chronic hepatitis C are now tending to be shorter and ribavirin free, more cost-effective and with fewer adverse effects.

Aims & Methods: We aimed at comparing the 8 weeks versus the 12 weeks regimen of ledipasvir plus sofosbuvir in patients with hepatitis C virus (HCV) genotype 1 infection without cirrhosis, treatment naïve, HCV RNA >6000000 U/mL. We included 281 patients (pts) with genotype 1 and HCV RNA >6000000 U/mL treated with ledipasvir plus sofosbuvir in the recommend dose: 120 pts - 8 weeks (group 1) and 161 pts - 12 weeks (group 2). The fibrosis stage was evaluated by transient elastography (Fibroscan®, Echosens, Paris) considering F4 > 12.5 kPa. Patients with undetectable RNA after 12 weeks of treatment were considered cured - sustained virologic response (SVR).

Results: No significant demographic and clinical differences were found between the two groups with the exception of the fibrosis stage (table). Two hundred and forty-four patients concluded the treatment; the SVR was 99% in group 1 and 100% in group 2, without differences between the two groups (p = 0.275). Thirty three patients are still in follow up: group 1-15 pts and group 2-18pts. The reported adverse effects were mild in both groups (fatigue, insomnia, headache and pruritus) but more frequent in group 2 (p = 0.0064).

Conclusion: In patients with chronic HCV genotype 1 infection and RNA >6000000 U/mL, the 8 weeks regimen of ledipasvir plus sofosbuvir without ribavirin has similar high cure rates with less adverse effects.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0706 CLINICAL FEATURES OF PATIENTS DEVELOPING HCC AFTER ACHIEVING SVR WITH DAAS AGAINST CHRONIC HEPATITIS C

Department of General Medicine, Nara Prefecture General Medical Center, Nara/Japan

Contact E-mail Address: k.ishida1549@yahoo.co.jp

Introduction: Although the conventional IFN-based therapy has made a significant achievement in treating patients with hepatitis C virus (HCV), including the preventive effect of hepatocarcinogenesis after achieving sustained virological response (SVR), patients intolerant of IFN, such as those with advanced age or liver cirrhosis (LC), could not navor its privilege. The appearance of direct-acting antivirals (DAAs) provided almost every patient with the chance to receive the treatment without any serious adverse effects (AEs). In addition, SVR could be highly expected in more than 95% of patients treated with DAAs. However, the preventive effect for the future hepatocarcinogenesis following eradication of HCV remains unknown. In our facility, the administration of DAAs to patients with chronic hepatitis C virus (HCC) within 2 years after achieving SVR.

Aims & Methods: We evaluated the clinical features of patients developing HCC after achieving SVR with DAAs against hepatitis C virus. One hundred and fifty-three patients achieving SVR defined as negative HCV-RNA 12 weeks after cessation of DAAs were enrolled in this study (Age 69.2±10.8 years, male/female 71/29, genotype2/1 122/31, chronic hepatitis/LC 124/29, PLT 15.3±5.0×10^9/L, ALT 14.9±6.8 IU/L, AST 10.0±2.4 IU/L, Alb 4.1±0.5 g/dL, WFA(-M2BP, FIB-4 index 5.7±0.1 g/dL, APRI 1.3±0.8, Wisteria floribunda agglutinin positive Mac-2-binding protein (WFA(+)-M2BP) 3.3±0.5 ng/mL, COI, AFP 12.1±2.4 ng/mL, PIVKAII 2.8±2.3 μg/mL). All patients were divided into 2 groups (A: 9 patients with HCC developing after SVR achievement, B: 144 without HCC after achieving SVR). Serum parameters (PLT, WFA(+)-M2BP, AFP index, APRI, ALT, Alb, AFP, PIVKAII) and age were evaluated between 2 groups.

Results: In group B, significant declining (pre-DAA treatment/the time of achieving SVR) was observed in ALT(44.8±3.6/3.5 IU/L, p<0.001), AFP(19.9±3.1/0.3 ng/mL, p<0.001), WFA(+)-M2BP(3.2±0.5/1.9 COI, p<0.001), COI index(3.7±0.2/5.0, p=0.004) and APRI(2.1±0.1/0.7, p=0.005). The significant increase in Alb(4.3±0.1/0.1 COI, p<0.001), APRI(1.2±0.1/0.4, p=0.001) and PLT(5.4±1.9/0.2×10^9/L, p<0.001) was significant in group A, significant declining was observed only in ALT (45.1±10.9/6.7, p=0.0001). This result indicates that DAA treatment significantly ameliorates parameters related with hepatic fibrosis as well as hepatic inflammation in genotype 1, however, it led to the significant amelioration only in some patients with hepatic inflammation in group A. Next, focusing on parameters after achieving SVR, WFA(+)-M2BP(3.4±0.6/0.7, p<0.001) and COI index(5.7±1.6/3.0, p<0.001) were significantly higher and Alb(3.8±0.2/4.3, p<0.001) was significantly lower in group A comparing with group B. When dividing group A into 2 groups (C: new occurrence/D: recurrence), AFP(3.0±1.3/6.2±1.8 ng/mL), WFA(+)-M2BP(2.0±0.8/3.7±0.7 COI), FIB-4 index(3.6±2.4/1.3, p<0.001) and APRI(0.6±0.4/1.1, p<0.001) were higher and Alb(4.3±0.1/0.3 ng/mL) and PLT(20.9±13.2/13.4, p<0.001) were lower in group D than group C, although no significant difference was seen between 2 groups. This result suggests that there might be more patients with progressive hepatic fibrosis in group D comparing with group C. Finally, while univariate analysis showed WFA(+)-M2BP, FIB-4 index and Alb were significantly associated with the development of HCC after achieving SVR with DAAs against HCV, multivariate analysis revealed only Alb was the significantly independent factor contributing to HCC development after achieving SVR.

Conclusion: Low level of serum albumin as well as the progression of hepatic fibrosis could be associated with the development of HCC after confirming SVR with DAAs to HCV. Disclosure of Interest: All authors have declared no conflicts of interest.

P0707 EARLY OCCURRENCE OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH HEPATITIS C VIREMA TREATED WITH DIRECT-ACTING ANTIVIRALS

Department of Surgery, Hyogo College of Medicine, Nishinomiya/Japan

Contact E-mail Address: shai1005@hyo-med.ac.jp

Introduction: Direct-acting antivirals (DAAs) are novel antiviral drugs for hepatitis C virus (HCV) and have enabled the achievement of a high rate of sustained

Contact E-mail Address: shai1005@hyo-med.ac.jp

Introduction: Direct-acting antivirals (DAAs) are novel antiviral drugs for hepatitis C virus (HCV) and have enabled the achievement of a high rate of sustained...
virological response (SVR) [1]. However, the impact of DAAs on the occurrence of hepatocellular carcinoma (HCC) and HCC recurrence after curative hepatic resection of HCC has been recently discussed [2, 3], but remain unclear.

Aims & Methods: The clinical data of 97 patients who underwent curative hepatic resection for primary HCC with HCV at our department between January 2012 and December 2017 were reviewed to clarify the impact of DAAs on HCC occurrence and recurrence. SVR was defined as no detection of HCV RNA in the serum at 24 weeks after the cessation of antiviral therapy.

Results: SVR was achieved in 21 patients treated with interferon (IFN)-based regimens and 35 patients treated with DAAs at hepatocytectomy. Between the two groups, there were no significant differences in the clinical characteristics, including the age, prevalence of diabetes mellitus, drinking history, preoperative liver function, operative procedures, tumor size and presence of liver cirrhosis, but the median duration from the date of SVR to the date of HCC incidence was significantly shorter in patients treated with DAAs (14 days, range: 123 to 235 days) than in those treated with IFN-based regimens (324 days, range: 35 to 4190 days). In particular, HCC was detected within 24 weeks after the cessation of antiviral therapy in 3 patients treated with DAAs. After hepatocytectomy, SVR was achieved in 21 (DAAs: 16 patients, IFN-based regimens: 5 patients) of the 67 patients without SVR when hepatocytectomy was performed, and the 1- and 3-year disease-free survival (DFS) rates were 93.3% and 83.0% in patients after SVR treated with DAAs (n = 251), 99.0% and 71.8% in patients with IFN-based regimens (n = 26) and 57.8% and 19.7% in patients without SVR (n = 46), respectively, regardless of the timing of hepatocytectomy, respectively. The DFS rate was significantly higher in patients with SVR than in those without SVR (p < 0.001), but was not markedly different according to the antiviral treatments (p = 0.504).

Conclusion: While DAAs were able to reduce the DFS rate, the early occurrence of HCC in patients after SVR treated with DAAs is more frequent than that among patients treated with IFN-based regimens. Therefore, careful follow-up with imaging series is needed even for patients with SVR treated with DAAs.

P0708: EFFICACY AND SAFETY OF SOFOSBUVIR AND RIBAVIRIN IN HCV POSITIVE PATIENTS WITH RENAL IMPAIRMENT

M.O. T. Butt
Gastroenterology And Liver Transplant, Shifa International Hospital, Islamabad, Islamabad/Pakistan

Contact E-mail Address: mosamabad2016@gmail.com

Introduction: Hepatitis C virus infection is a leading cause of chronic liver disease affecting more than 170 million people worldwide. HCV infection in the setting of renal impairment is not uncommon. Despite the major developments in the treatment of HCV, this sub-group of patient with impaired renal function is still a challenge.

Aims & Methods: The aim of this study is to determine the efficacy and safety of sofosbuvir and ribavirin in HCV positive patients with renal impairment. All consecutive patients of HCV related liver disease with creatinine clearance less than 50 ml/min were included in the study. Data was collected for tolerability, efficacy and on treatment adverse events. All the patients received Sofosbuvir and Ribavirin in divided doses.

Results: A total of 31 patients were included in the study. 31 patients were 17 (54.8%) male. Mean age was 52.3 ± 17.6 years while the mean BMI was 25.0 ± 4.3 kg/m². 10 (32.2%) patient were on regular hemodialysis. 26 (83.9%) patients had CTP-A while 5 (16.1%) had CTP-B disease. Majority of the patients were genotype 3 while 7 (22.6%) were genotype 1. 24 (77.4%) patients were treatment naive, while those who were treatment experienced. 3 patients received each Interferon and Peg Interferon therapy. Treatment was stopped in 2 (6.5%) patients because of disease decomposition while 3 (9.7%) were lost to follow up. ETR was achieved in 25 (96.1%) out of 26 patients who completed treatment. Similarly 12 (80 %) out of 15 patients have achieved SVR-12 so far. During the therapy 10 (32.3%) patients had adverse events, 6 (19.4%) suffered from depression while 4 (12.9 %) developed grade II anemia.

Conclusion: In resource constraint population where newer DAAs are not available an immediate combination of sofosbuvir and low-dose ribavirin in patients with renal impairment seems to be better tolerated and efficacious in terms of achieving the virological response.

Introduction: Chronic hepatitis C infection is a systemic disease, one of the leading causes towards cirrhosis and hepatocellular cancer and it is to be considered nowadays a major health-related quality of life (HRQoL) burden.

Aims & Methods: The aim of this study was to assess HRQoL impairment of hepatitis C virus (HCV) infection among a broad sample of compensated HCV cirrhotic patients. We conducted a prospective study between January 1st 2016 to January 31, 2017, in a tertiary center, in which we included 110 patients with compensated HCV cirrhosis, aged between 50 and 75, with no history of neuropsychiatric illness but associated comorbidities (diabetes type 2, hypertension, dyslipidemia). The patients were completely evaluated according to the national protocol. Health status and fatigue of our patients were evaluated using the FACIT- F (version 4) and SF-36 survey. Respondents with HCV compensated cirrhosis were compared with a control group matched for age and sex with no prior history of HCV infection on the Mental (MCS) and Physical (PCS) Component Summary scores.

Results: Unadjusted comparisons between subjects infected with HCV (n = 110) and controls (n = 60) revealed that HCV patients had lower FACIT- F utility scores (43.2 ± 28.5 vs 49.5 ± 20.5, p < 0.05). Severe fatigue was present in 30% (33 patients) of the HCV group compared to 11.6% (5% patients) in controls. Subgroup analyses of respondents age 60 years and older revealed lower MCS score in HCV patients compared to controls (41.95 vs. 49.72, p < 0.05). Control group registered higher PCS score (53.30 vs 45.2, p < 0.05) compared to the study group.

Conclusion: Although the results were obtained on a small group we observed that in untreated patients with chronic HCV infection, HRQoL is significantly impaired due to fatigue severity and age. Our result underline the need for effective antiviral treatment to decrease the burden of fatigue in this segment of population.

P0710: SOFOSBUVIR IN COMBINATION WITH RIBAVIRIN IN GENOTYPE 3 HEPATITIS C PATIENTS WITH CIRRHOSIS. AN EXPERIENCE FROM TERTIARY CARE HOSPITAL

A. A. Langhah
Gastroenterology Section, Medical Unit IV, Jinnah Postgraduate Medical Centre, Karachi Pakistan

Contact E-mail Address: draliakbar12@gmail.com

Introduction: Hepatitis C virus (HCV) is the most common cause of cirrhosis in this part of the world. Advent of Directly acting antivirals (DAAs) like Sofosbuvir (SOF) has dramatized the treatment and is the corner stone in treatment of (HCV). Most trials have been conducted in HCV genotype 1 and data for Interferon free regimens in genotype 3 (GT-3) is limited especially in cirrhosis.

Aims & Methods: We aimed to evaluate the safety and efficacy of SOF plus Ribavirin (RIB) in patients with compensated and decompensated cirrhosis. This is a prospective real-world cohort study of HCV with compensated or decompensated cirrhosis. Efficacy was assessed by Sustained Viral Response after 6 months of completion of treatment. Adverse events were recorded on designed proforma on serial follow-up visits.

Results: The cohort consisted of 9 1consecutive patients out of which 41 were compensated cirrhotics and 50 had decompensated cirrhosis. The mean age was 53.4 ± 11years. Males were 47 (51.6%) and females were 44 (48.4%). Mean CTP and MELD score were 7.71 and 9.21 respectively. In compensated cirrhosis, SVR was achieved in 25 (84.4%) treatment naive patients compared to treatment experienced patients where 5 (80%) achieved SVR. In decompensated cirrhosis SVR was achieved in 22 (77.3%) treatment naive patients, whereas 13 (76.9%) patients achieved SVR in treatment experienced group. In 72% patients with cirrhosis, there were no side effects whereas most common adverse event was fatigue and drop of Hemoglobin by 1.0 gm/dl. Furthermore, CTP and MELD scores decreased to 6.9 and 8.7 respectively after treatment.

Conclusion: Sofosbuvir in combination with Ribavirin in GT-3 HCV patients achieved good SVR in compensated cirrhosis than decompensated cirrhosis whereas fatigue and drop of Hb were the most common adverse effects.

Introduction: New direct-acting antivirals (DAA) have changed the management of HCV infection by being effective in more than 90% of cases [1, 2]. Unfortunately, it has been reported an unexpected high rate of HCC early recur-rence following DAA treatment, but more data are needed [3-5].

Aims & Methods: From a national prospective cohort, enrolling 3717 Romanian patients with hepatitis C virus compensated liver cirrhosis who received reim-bursed DAA treatment (Obinutuzumab/Ombitasvir/Ritonavir, Ombitasvir/Paritaprevir/OMBITASVIR/RITONAVIR, OBV/PTV+r + DSV + RBV) for 12 weeks, from December 2015 to August 2016, we analyzed 21 patients with previous HCC. Most of them were treated through surgical resection (9/21), followed by radiofrequency ablation (RFA) 6/21, trans-arterial chemoembolisation (TACE) 5/21 and only one percutaneous ethanol injection (PEI). The patients received DAA treatment only if they had no cancer relapse 6 months after their last therapy session for HCC. All these patients were evaluated through CT scans 

Early recurrence rate of HCC in treated patients with compensated liver cirrhosis that received DAA with OBV/PTV/r + DSV + RBV was 12% (21/175). In our cohort, the early recurrence rate was significantly increased compared to the natural recurrence rate. This rate is higher in males (40%) than females (10%), higher in patients treated with TACE (40%) than in those with hepatic resection (33%), and the lowest risk of recurrence was reported in RFA (14%) and TACE (7%)

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Shear wave elastography (SWE) has been used in clinical practice as a noninvasive method to diagnose liver fibrosis by measuring tissue stiffness. Shear wave elastography (SWE) has been used in clinical practice as a noninvasive method to diagnose liver fibrosis by measuring tissue stiffness. Shear wave elastography (SWE) has been used in clinical practice as a noninvasive method to diagnose liver fibrosis by measuring tissue stiffness. Shear wave elastography (SWE) has been used in clinical practice as a noninvasive method to diagnose liver fibrosis by measuring tissue stiffness. Shear wave elastography (SWE) has been used in clinical practice as a noninvasive method to diagnose liver fibrosis by measuring tissue stiffness.

Aims & Methods: The usefulness of SWE in the diagnosis of esophageogastroduodenal varices (EGV) associated with portal hypertension was evaluated. 550 patients who underwent measurements of liver stiffness (LS), spleen stiffness (SS) and EGV evaluation between January 2011 and July 2016 were included (no varices, n = 340; esophageal only, n = 107; stomach only, n = 14; esophageal and stomach, n = 89). Virtual Touch Quantification (VTQ) was used for measurements of LS and spleen stiffness. The spleen index (SI) was evaluated according to forms and red colour sign (RC sign) based on the General Rules for Study of Hypertension in Japan.

Results: LS, SS and SI showed significant increase in accordance with the severity of portal hypertension (p < 0.01). The area under the receiver operating characteristic curve (AUROC) of LS, SS and SI for detecting EGV's was 0.8526, 0.9048, 0.8199, with the cut off values 1.67 m/s, 2.81 m/s, 18.5cm², respectively, and SS showed use-fulness in detecting EGVs. When LS, SS and SI were compared for their ability to detect EGVs which were > -2 or with RC sign positive, LS, SS and SI were significantly higher for EGVs which require treatment (p < 0.001). The AUROC of LS, SS and SI for detecting EGVs which require treatment was 0.8131, 0.8693, 0.8270, respectively. All modality showed good detecting ability, and SS particularly showed better performance. When each modality was compared in detection of gastric varices, LS and SS were significantly higher with the presence of gastric varices, but SI did not show a significant difference. The AUROC of LS, SS and SI for detecting gastric varices were 0.7359, 0.8611, 0.8470, respectively, and SS showed a superior detecting ability while LS and SI showed decreased abilities.

Conclusion: LS, SS and SI were all useful in detecting EGVs and predicting the presence of EGVs which require treatments. SS particularly showed the highest level of performance.

Introduction: The presence of fat droplets in the hepatocytes (micro- or macrovesicular hepatic steatosis) under condition of chronic diffuse liver disease (CCDL) increases the attenuation of ultrasound (US). A group of Ukrainian scientists proposed an original algorithm for real-time US attenuation measurement (attenuation coefficient measurement – ACM). We aim to compare ACM to FIBROSCAN.

Aims & Methods: From total of 3274 patients who underwent to comprehensive abdominal US in our clinic: 979 focal liver lesions (FLLs) were diagnosed with cirrhosis (LC), according to Hamaguchi criteria. All these patient we provide ACM (dB/cm) measurement on SonoPQ device (Ultrasound, Ukraine), with a 1–6 MHz convex transducer in the right and left lobes. For diagnostic accuracy assessment (used CEUS as standard of reference and with CAP measured by Fibroscan (Echosens, France) we included 142 patients for subanalysis. Evaluation of diagnostic accuracy of ACM performed using ROC-analysis.

Results: Depend on the stage of steatosis according to B-mode median, 25 and 75% percentiles were as follows: control group 1.57 (1.32–2.11; 0.42–2.76); 1.16 (1.05–1.86). A correlation coefficient was 0.34 (p = 0.001). On ACM with CAP measured by Fibroscan (Echosens, France) we included 142 patients for subanalysis. Evaluation of diagnostic accuracy of ACM performed using ROC-analysis.

Conclusion: The correlation coefficient was 0.34 (p = 0.001). On ACM with CAP measured by Fibroscan (Echosens, France) we included 142 patients for subanalysis. Evaluation of diagnostic accuracy of ACM performed using ROC-analysis.

Introduction: CUXI (CUTL) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of proapoptotic genes. Its aberrant expression in tumor turns its role as foe. It favors the proliferation of cancer cells, in stress and nutrient deprived conditions, thus supporting tumorgenesis.

Aims & Methods: Here, we show CUX1 activity during hypoxia in liver cancer cells. CUX1 was knocked down and its targets were analysed by RT–qPCR in Hep3B cells under hypoxic and/or normal culture condition. The hypoxia condition was established by 24h treatment with 150 μM CoCl2 or with 0.5% O2 atmosphere. Hypoxia markers and CUX1 were analysed by RT–qPCR. Transfection qth plasmid expressing a reporter sequence for HIF1alpha was performed in combination with CUX1 knockdown.

Results: Hypoxia determined the up-regulation of HIF1-alpha (Hypoxia inducible factor1-alpha) and a stable or up-regulated expression of its inhibitor FH1 (SLC2A1) up to 24h prolonged hypoxia. VEGFA was significantly
overexpressed. Knock-down of CUX1 determined a significant down-regulation of HIF-1alpha, FIH-1 and VEGFA. Interestingly, the expression of CDKN1A was only attenuated after CUX1 knock down and hypoxic stress. HIF1alpha transcriptional activity is dependent by CUX1 expression.

Conclusion: CUX1 exerts an oncogenic role in liver cancer by sustaining the survival mechanisms of hypoxia. CUX1 silencing results in suppression of the hypoxia inducible factor and its target VEGFA causing a block of cell cycle in liver cancer cells modulated by the stable expression of CDKN1A.

1. Kim JU, Shariff MI, Crossey MM, Gomez-Romero M, Holmes E, Cox IJ, et al. Aims & Methods: The chromatin remodeler complex SWI/SNF plays an important role in the regulation of cell cycle pathway significantly by the KEGG and GO Pathway enrichment analysis. Through the construction of protein-protein interaction network, we observed the module associated with cell cycle is in the middle of the whole network. All these results implied that cell cycle pathway may play a very important role in the regulation of SAMe effect on HepG2 cells. Then the RNA-Seq characterized genes involved in cell cycle (MCM3, MCM4, and E2F1) were confirmed by Western Blot and q-RT-PCR in HepG2 and AML12 cells. MTS analysis showed that SAMe could diminish cell proliferation. And flow cytometry-based assays indicated that treatment with SAMe altered cell cycle kinetic significantly.

Conclusion: Altogether, our data enforce the evidence of SAMe possessing of antiproliferative action in liver cells, capable of up-regulating MCM3, MCM4 and H3F4A, related to cell cycle inhibition, and provide an important theoretical basis for the clinical chemoprevention and treatment in HCC of SAMe.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Our results support the hypothesis that overexpression of BRG1 increases cell growth and cell invasion in HCC. Furthermore, the data highlight genes promoting proliferation and invasion that are being regulated by BRG1 during hepatocarcinogenesis. In particular, CyclinB, D, E and MMP7 appear to play a major role in this context and might be an important link between BRG1 expression and HCC development.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0720 PROGNOSTIC ROLE OF NEUTROPHIL-TO-LYMPHOCYTE RATIO IN HEPATOCELLULAR CARCINOMA (HCC)

Sahloul, Sousse/Tunisia

Contact E-mail Address: Elleuchghorbel.nour@yahoo.fr

Introduction: Inflammation may play an important role in progression, and a high neutrophil-to-lymphocyte ratio (NLR) has been reported as a poor prognostic indicator in several malignancies.

Aims & Methods: This study was aimed to investigate the prognostic value of NLR in patients with HCC. We performed a retrospective study including patients with hepatocellular carcinoma admitted in the hepatogastroenterology department of Sousse between January 2010 and December 2015.

Results: A total of 76 patients were included in this study. Mean age was 59.8 (33–87 years). The sex ratio was 3.22 (M/F = 58/18). Hepatocellular carcinoma occurred on a liver of cirrhosis in the majority of cases (90.7%). The main causes of cirrhosis were hepatitis B virus infection (11 patients-16%), non alcoholic steatohepatitis (6 patients-8.6%) and alcohol consumption (5 patients-7.2%). Our results showed that high NLR was associated with poor overall survival (OS) in HCC regardless of therapeutic choice (P < 0.05). Otherwise, high NLR was significantly correlated with the presence of vascular invasion (P = 0.002), lymph node metastasis (P = 0.04), tumor multifocality (P = 0.01) and higher incidence of AFP > 200 ng/ml (P = 0.04).

Conclusion: Elevated NLR indicates a poor prognosis for patients with HCC. The NLR is a readily available and inexpensive biomarker, and its addition to established prognostic scores for clinical decision making warrants further investigation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0721 REIC/DKK-3 PROTEIN CONCENTRATION INDUCE THE POSITIVE EFFECT TO THE MORTALITY OF HEPATOCELLULAR CARCINOMA

A. Ohyama, D. Uchida, H. Shiraha, H. Sawahara, H. Kato, H. Okada
Gastroenterology And Hepatology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama City/Japan

Contact E-mail Address: at841205@gmail.com

Introduction: The Wnt/b-catenin plays essential roles in the growth of hepatocellular carcinoma (HCC). The Dickkopf (Dkk) protein family (Dkk1-4) is known as Wnt signal antagonists, and reduced expression in immortalized cells (REIC)/Dkk-3 over-methylated is associated with poor prognosis in HCC patients. But the roles of REIC/Dkk-3 in inhibiting Wnt signaling remains still unclear.

Aims & Methods: In our previous study, REIC/Dkk-3 protein induced significant production of interferon gamma from lymphocytes incubated with pancreatic cancer cells, indicating that REIC/Dkk-3 protein might activate cancer immunity in the tumor-bearing patients. We hypothesized that REIC/Dkk-3 expression was correlated with cancer immunity in HCC patients. Thus, we investigated the correlation between serum REIC/Dkk-3 protein level and the prognosis in HCC patient. We retrospectively studied 58 HCC patients who underwent primary liver resection for HCC admitted to out unit from 2008 to 2017. Patient serum was gathered before resection. Serum REIC/Dkk-3 protein level was measured by an enzyme-linked immunosorbent assay.

Results: 58 HCC patients were divided into two groups, 41 REIC/Dkk-3 high concentration group (protein level > 800) and 17 Dkk-3 low concentration group (protein level < 800), according to the presence of REIC/Dkk-3 proteins in the blood, as detected by ELISA spectrometry. There was no significant difference in age, sex, Child-Pugh score and HCC stage in the patient groups. REIC/Dkk-3 Protein tended to be declining in liver cancer patients with poor prognosis. (p = 0.186)

Conclusion: Our results demonstrated that the serum Dkk-3 protein levels might be a prognosis maker in HCC patients. Further study is necessary with more number of HCC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0722 SURGICAL OUTCOME OF PATIENTS WITH FIBROLAMELLAR HEPATOCELLULAR CARCINOMA. DOES IT DIFFERS FROM COMMON HEPATOCELLULAR CARCINOMA?

E. El-Hanafy
Facultu Of Medicin, Mansoura University, Gastroenterology Surgical Center, Cairo/Egypt

Contact E-mail Address: dr_elh_ab_elhanafy@yahoo.com

Introduction: Fibrolamellar hepatocellular carcinoma (FL-HCC) has conventionally been considered to be a histologic variant of hepatocellular carcinoma (HCC), with distinct clinicopathologic features. It is a rare primary hepatic malignancy that was first described as a pathological variant of HCC by Edmondson in 1956 [1]. The etiology of FL-HCC remains unclear. It typically occurs in normal livers without underlying liver fibrosis or cirrhosis [2]. In contrast to HCC which usually found in the presence of cirrhosis or chronic hepatitis [3], FL-HCC has been reported to occur in association with focal nodular hyperplasia (FNH) a type of benign liver lesion. Many series have mentioned that FL- HCC is less aggressive than conventional HCC [4]. However, other studies have failed to confirm the observation of a better outcome in FL-HCC [5]. Other studies reported that the survival was similar between common HCC and FL-HCC, and that may be related to the higher resectability rate which improve the survival of patients with FL-HCC [6].

Aims & Methods: The aim of this study was to evaluate the clinicopathological features and the surgical outcomes of patients with FL-HCC who were referred to our tertiary referral center over a 15-year period. This is a retrospective study including 22 patients with a pathologic diagnosis of FL-HCC who underwent hepatectomy over a 15-year period. Tumor characteristics, survival and recurrence were evaluated.

Results: There were 11 male and 11 female with a median age of 29 years (range from 21 to 58 years). Two (9%) patients had hepatitis C viral infection and only 2 (9%) patients had alpha-fetoprotein level > 200 ng/mL. The median size of the tumors was 12 cm (range from 5–20 cm). Vascular invasion was detected in 5 (23%) patients. Four (18%) patients had lymph node metastases. The median follow up period was 42 mo and the 5-year survival was 65%. Five (23%) patients had a recurrent disease, 4 of them had a second surgery with 36 mo median time interval. Vascular invasion is the only significant negative prognostic factor.

(continued)
Conclusion: FL-HCC has a favorable prognosis than common HCC and should be suspected in young patients with non-cirrhotic liver. Aggressive surgical resection should be done for all patients. Repeated hepatectomy or excision of recurrent disease should be considered for these patients as it has a relatively indolent course.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Metabolic disorders, such as obesity and diabetes, are well known risk factors for hepatocellular carcinoma (HCC). Conversely, their impact on the natural history of HCC patients is not established.

Aims & Methods: This study aimed at evaluating the impact of metabolic disorders on clinical features, treatment and survival of HCC patients regardless of its etiology. We analyzed the Italian Liver Cancer (ITA.L.I.CA) database regarding 839 HCC patients prospectively collected from 2009 to 2014. The following metabolic features were analyzed: BMI, diabetes, arterial hypertension, hypercholesterolemia and hypertriglyceridemia. According to these features, patients were divided into 3 groups: 0–1 metabolic features, 2 metabolic features, 3–5 metabolic features.

Results: As compared with patients with 0–1 metabolic features, patients with 3–5 features showed lower percentage of HCC diagnosis on surveillance (p 0.021), larger tumors (p 0.038), better liver function (higher percentage of patients with Child-Pugh A p [0.007] and MELD < 10 p [0.003]), higher percentage of metastases (p 0.024), and lower percentage of portal vein thrombosis (p 0.010). The BCLC stage and treatment options were similar among the 3 groups, with the exception of a less frequent access to locoregional therapies for BCLC stage B patients with 3–5 features (p 0.012). Overall survival and survival according to BCLC stage and/or treatment did not significantly differ among the 3 groups. Diabetic patients showed a lower survival (p 0.046). MELD score, HCC
LIVER VOLUME AS A PREDICTOR OF RISK FOR HEPATOCELLULAR CARCINOMA IN CHRONIC HEPATITIS C PATIENTS
N. Kang, J.W. Chung, J. Kim
Internal Medicine, Seoul National University Bundang hospital, Seong-Nam city/ Korea, Republic of

Contact Email Address: namkyuny@gmail.com

Introduction: Chronic hepatitis C virus (HCV) infection pose risk for develop- ment of hepatocellular carcinoma (HCC), even after viral eradication with effective antiviral therapy. Therefore, risk prediction is clinically important for effective surveillance of chronic hepatitis C (CHC) patients, but insufficient compared to chronic hepatitis B. The liver volume has been reported to correlate with the severity of liver cirrhosis, but it is not known whether decreased liver volume predicts the HCC risk in CHC.

Aims & Methods: The aim of this study was to assess the significance of liver volume in the prediction of HCC risk in CHC patients. A retrospective cohort of 101 CHC patients who received 4-phase dynamic CT imaging studies during surveillance was analyzed for liver volume and outcome of surveillance. Liver volumes were measured on portal venous phase of CT image and corrected for body weight and height: liver volume index (LVI) = ratio of the expected standard volume to the measured liver volume. Kaplan-Meier analysis with the log-rank test was used to compare HCC. Cox proportional hazard analysis was used to identify the independent predictors of HCC risk.

Results: The cumulative incidence of HCC was 2.1%, 16.2% and 46.1% at 1, 4 and 8 years, respectively. The risk of HCC was significantly higher in patients with a decreased liver volume index (LVI) < 0.85. Presence of liver cirrhosis was also associated with higher risk for HCC. (P < 0.001), whereas age, sex, alpha-fetoprotein and HCV RNA level were not significant predictors of HCC. Multivariate analysis show that LVI > 1 and presence of LC were independent predictors of HCC (HR: 63.53, CI: 1.24-1244.28, P < 0.001; HR: 3.10, CI: 1.26-7.51, P = 0.012, respectively).

Conclusion: Decreased liver volume is an independent predictor of HCC in chronic hepatitis C. Liver volume index is useful in predicting risk of HCC in CHC.

Disclosure of Interest: All authors have declared no conflicts of interest.

HAND AND FOOT SYNDROME AS A PREDICTOR OF OUTCOME IN PATIENTS WITH HEPATOCELLULAR CARCINOMA TREATED WITH SORAFENIB
M. Ochi, A. Okawara, N. Kakinoki, T. Kamoshida, S. Hirai
Department Of Gastroenterology, Hitachi General Hospital, Hitachi City/Japan

Contact Email Address: masaochih@hotmail.co.jp

Introduction: Sorafenib is a multi-thyrosine kinase inhibitor classified as a neo- vascularization inhibitor. A previous study indicated that the administration of a thionine kinase inhibitor, cetuximab, significantly prolonged the survival of patients with dermal disorder1. However, few studies have reported the efficacy of sorafenib in patients with a dermal disorder. A previous study indicated that the administration of a vascularization inhibitor. A previous study indicated that the administration of a vascularization inhibitor.

Aims & Methods: In this study, we investigated the prognostic of sorafenib-treated patients with HFS. HFS grading was conducted according to the Common Terminology Criteria for Adverse Events (CTCAE) v.4.0. Patients with grade 1 or higher dermal disorder were regarded as having HFS, and grade 0 patients as not having HFS. For HFS evaluation, a double-check system was adopted: primary evaluation based on a specific evaluation sheet at the Pharmacists’ Outpatient Clinic and final evaluation by physicians at the outpatient clinic. We examined the influence of HFS on the effects of treatment after the introduction of sorafenib in 42 patients with a history of multidisciplinary treatment, such as transcatheter arterial chemoembolization (TACE), between May 2009 and March 2017.

Results: Grade 1 or higher HFS was observed in 22 patients (53%), and it was absent in 20 (47%). Overall, the median sorafenib administration period was 2.1 months. In the HFS-free and HFS groups, it was 0.9 and 2.7 months, respectively (p < 0.001). Survival analysis was performed using the Kaplan-Meier method. Overall, the median survival was 5.2 months. In the HFS-free and HFS groups, it was 3.0 and 7.8 months, respectively (p = 0.001). Multivariate analysis showed that grade of HFS observed during visits at HFS observed during visits, mainly from surgery (hazard ratio 0.41; 95% CI, 0.19 to 0.88; p = 0.023) and administration period (hazard ratio, 0.45; 95% CI, 0.20 to 0.98; p = 0.045) were significant predictive factors. The following were not significant predictive factors: age, BCLC staging, dosage, and tumor markers.

Conclusion: The prognosis of hepatocellular carcinoma patients receiving sorafe- nib treatment was closely related to the presence of HFS and administration period. HFS was a predictor of outcome in patients with hepatocellular carci- noma treated with sorafenib. This study indicated that a multi-thyrosine kinase inhibitor, sorafenib, prolonged survival in patients with HFS, as demonstrated for cetuximab. HFS reduces the quality of life (QOL), and is a sorafenib admin- istration-inhibiting factor. In our hospital, a system for patients to initially con- sult the Pharmacists’ Outpatient Clinic, followed by the feed-back of grade-based HFS control strategies to physicians at the outpatient clinic, was established. Skin cancers of patients treated with HFS may have prolonged the administration period, improving the prognosis.

Introduction: Hepatocarcinoma is a rare primary hepatic tumor com- bining features of both, cholangiocarcinoma and hepatocellular carcinoma (chCC-ICC). Few data concerning the epidemiology of chCC-ICC have been reported, mainly from surgically treated cases in Asian and American populations.

Aims & Methods: The main objective of this retrospective multicenter study was to evaluate epidemiological features and overall survival of histologically proven advanced CHCC patients in a French population. Data from patients treated for histologically proven chCC-ICC in six French university hospitals between 2008 and February 2017, were retrospectively collected. The main clinical, biological, therapeutic features and OS were reported. Statistical analysis was performed using Graph Pad Prism 6.

Results: Thirty patients were included (76.6% of men, median age 64 years [extreme 37–88]. Cirrhosis was associated in 33.3% of cases (Child-Pugh score A: 70%). Positive serology for hepatitis B virus and C was found in respectively,
5 (16.6%) and 2 (6.6%) patients; and 1 co-infection was observed. Chronic alcoholism was present in 33.3%, diabetes and obesity (body mass index \( \geq 30 \text{kg/m}^2 \)) were both present in 26.6% of cases. Alpha-fetoprotein, Carbohydrate Antigen 19-9 and carcinoembryonic antigen serum levels were above normal in respectively 39% (median = 5.3 \mu\text{g/L} [2-21 479]), 50% (median = 21.8 \mu\text{IU/mL} [4.5-20 000]) and 14% (median = 2.4 \mu\text{g/L} [2-88]) of cases. Six patients (20%) were initially treated by surgical resection. At the diagnosis of advanced non resectable disease, 66.6% of patients presented a multifocal hepatic lesions, 50% presented distant metastases (bones metastases (21.3%), lung metastases (20%) and peritoneal metastases (13.3%). Twenty-seven patients (90%) received first line of systemic treatment. Twenty-four patients were treated by chemotherapy: Gemcitabine (Gem) alone (n = 1), Gem + oxaliplatin (n = 12), Gem + oxaliplatin + bevacizumab (n = 9), Gem + cisplatin (n = 2). Two patients were treated by chemoembolization and 1 patient received sorafenib. Twenty-one (70%) and 4 (13.3%) patients received a second and third line of treatment, respectively. Median overall survival was 14.5 months.

Conclusion: Advanced eHCC-ICC appear to be aggressive tumors with a poor prognosis. Cirrhosis was associated in one third of patients. Systemic treatments are not standardized and must be evaluated in a dedicated study. Disclosures of Interests: All authors have declared no conflicts of interest.

Aims & Methods: The aim of this study was to evaluate the clinical manifestations and the prognosis of Hepatocellular carcinoma (HCC) in patients with Hepatitis B and none had Hepatitis C. The majority (94.4%) had symptoms at the time of diagnosis, with fatigue (83.3%), night sweats (61.1%) and loss of weight (61.1%) being the most common. The imaging presentation was of a single mass in 47.2% of cases, multiple masses in 30.6% and infiltrative mass in 22.2%. The most common lymphoma subtypes were diffuse large B-cell lymphoma (52.8%), MALT lymphoma (11.1%) and Hodgkin’s lymphoma (11.1%). Survival at the end of 3 years was 63.8% and 27.8% at 5 years. Age > 60 years (p = 0.004) was the only factor that was significantly associated with higher mortality.

Conclusion: Hepatic lymphomas are rare entities that may occur in different ways, to diffuse large B-cell lymphoma being the most common subtype. They presented a 3-year survival of only 27.8% and the age over 60 years was the only factor significantly associated with mortality.

Disclosures of Interests: All authors have declared no conflicts of interest.

Introduction: Primary tumors of the liver, beyond hepatocarcinoma, are distinct entities that characterize and are associated with poor prognosis. Hepatic involvement in the lymphomatous process is uncommon and primary hepatic lymphomas are rare. The etiology is not yet known but it is thought that hepatitis B and C may be risk factors. The therapeutic approach is not yet fully defined.

Aims & Methods: The aim of this study was to evaluate the clinical manifestations and the prognostic factors of advanced hepatocellular carcinoma (HCC) in patients with Hepatitis B and Hepatitis C. All authors have declared no conflicts of interest.

Introduction: Inhibition of microRNA-21 (miR-21) prevents necrosis in the mouse pancreas. In turn, we recently showed that necroptosis contribute to hepatic necro-inflammation in the common bile duct ligation (BDL) mouse model.

Aims & Methods: We aimed to evaluate the role of miR-21 in mediating deleterious processes associated with cholestasis. The functional crosstalk between miR-21 and necroptosis was investigated in vitro. miR-21 expression was evaluated in the liver of primary biliary cholangitis (PBC) patients. C57BL/6 wild-type (WT) or miR-21-deficient (miR-21−/−) mice were subjected to BDL or sham surgeries, with biochemical, molecular and histological analysis of hepatic damage, fibrosis, necroptosis and bile acid metabolism, after either acute (3 days) or chronic (14 days) injury.

Results: Studies in miR-21−/− primary mouse hepatocytes established a functional link between miR-21 and necroptosis through cyclin dependent kinase 2 (CDK2AP1). miR-21 expression increased in the liver of PBC patients. C57BL/6 wild-type (WT) or miR-21-deficient (miR-21−/−) mice were subjected to BDL or sham surgeries, with biochemical, molecular and histological analysis of hepatic damage, fibrosis, necroptosis and bile acid metabolism, after either acute (3 days) or chronic (14 days) injury.

Conclusion: miR-21 ablation ameliorates liver damage and necroptosis in BDL mice; as such, inhibition of miR-21 should arise as a promising approach to treat cholestatic liver diseases. P9074 CHOLEDOCHOLITHIASIS ALWAYS NECESSARY IN EXTREMELY ELDERLY PATIENTS?

Gastroenterology, Ise Res Cross Hospital, Ise City/Japan

Contact E-mail Address: n-okuda@ise.jrc.or.jp

Introduction: Endoscopic sphincterotomy, endoscopic papillary balloon dilation, and endoscopic retrograde cholangiopancreatography (ERCP) are widely recognized as safe and effective treatments of cholelithiasis. However, endoscopic stone removal does have some complications. Although the life expectancy of elderly patients has increased dramatically worldwide, little information is available on the necessity of complete endoscopic stone removal in extremely elderly patients.

Aims & Methods: The aim of this study was to evaluate the safety and efficacy of complete endoscopic stone removal in extremely elderly patients. We retrospectively evaluated all extremely elderly patients (older than 90 years) who had undergone complete stone removal for cholelithiasis at Ise Red Cross Hospital between January 2012 and December 2016. Included patients were divided into complete stone removal and incomplete stone removal (failure to achieve complete stone removal and insertion of a plastic stent) groups. We compared the complication rate, overall survival (OS), and disease-specific survival (DSS) rate between the two groups.

Results: In total, 67 patients were included this study; 36 (54%) had complete stone removal and 31 (46%) had incomplete stone removal. The median age of the patients was 92 years (range 90-100 years), median follow-up period was 462 days (range 6-1449 days) and the male-to-female ratio was 15:52. Baseline characteristics (age, body mass index, performance status, and comorbidities), rate of complications (pervaporation, bleeding, hypoxemia, or decreased blood pressure during the endoscopic procedure), and total number of endoscopic procedures did not significantly differ between the two groups. The median number of stones was one (range 0–5) and two (range 1–5) (P = 0.013), while the median diameter of the largest stones was 9 mm (range 0–27) and 14 mm (range 5–32) (P = 0.001) in the complete and incomplete stone removal groups, respectively. During the follow-up period, OS was 33.5% and 41.9% and DSS was 5.56% and 3.22% in the complete and incomplete stone removal groups, respectively. Kaplan-Meier analysis found no significant difference in OS and DSS between the two groups (P = 0.187 and P = 0.581, respectively).

Conclusion: Patients in the incomplete stone removal group tended to have more numerous and larger stones. This single-centre retrospective study revealed no significant difference in OS and DSS between the two groups. Complete stone removal might not be always necessary in extremely elderly patients aged 90 years and older.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Bile Duct Injury (BDI) following laparoscopic cholecystectomy is a persisting problem. The rendezvous procedure (RV) provides a combined endoscopic and percutaneous approach in order to re-establish bile duct continuity in complex BDI.

Aims & Methods: The aim of this study is to assess short-term and long-term outcomes of the RV. All consecutive patients with BDI referred to our tertiary center were analyzed retrospectively. RV procedure was performed when endoscopic stenting or PTCD failed and when deemed feasible by a dedicated multidisciplinary team including a hepatopancreato-biliary surgeon, gastroenterologist and interventional radiologist. Classification of BDI, technical success of RV, procedure-related complications and outcomes were assessed.

Results: Among a total of 812 patients, RV was performed in 47 (5.8%) patients, of which 31 (66%) were diagnosed with complete transaction of the bile duct (type D;Strasberg type E injury). Primary success rate of RV was 94% (44/47 patients). Reasons for failure (N = 3) were inability to pass a stricture and inability to make contact between the two wires. In 26/47 patients (55%) RV was the final successful treatment. In 17/47 patients (36%) RV acted as a bridge to
surgery; although the RV was initially successful, late complications (stenosis, stent dysfunction) required elective hepaticojejunostomy (HJ). Procedure-related adverse events occurred in 10 patients (18%) with cholangitis being the most frequent complication (N=4.7%). No life-threatening adverse events and no 30-day mortality occurred.

Conclusion: In experienced hands, RV is safe with a final non-surgical success rate of 55%. When endoscopic stenting fails in patients with complex BDI, RV can be considered as a viable treatment option before surgical repair.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0739 TRANRECTAL GALLBLADDER PRESERVING 
CHOLECYSTOLITHOTOMY AND POLYECTOMY BY PURE NOTES
B. Liu
Gastroenterology, The First Affiliated Hospital of Zhengzhou University, 
Zhengzhou/China
Contact E-mail Address: 3217265358@qq.com
Introduction: Transcolonic and transrectal NOTES in human cases was greatly 
restricted by the fact of fecal contamination. We developed a detachable intra-
colonic balloon to help keep the colon sterile by blocking the colonic lumen. 
Although cholecystectomy is widely used for treating gallbladder polyps and 
gallstones, there is still a controversy about whether or not the gallbladder 
should be preserved. However, postcholecystectomy syndromes, such as bile 
duct injury and the correlation with colon cancer, remind us of the importance 
of gallbladder preservation.

Aims & Methods: Approved by the Independent Ethics Committee, we’ve com-
pleted 8 transrectal gallbladder preserving cholecystolithotomy (TRGCP) and 3 
transrectal gallbladder preserving polypectomy (TRGPP) and 2 combined cases 
by pure NOTES. Moreover, 1 case of TRGCP was done by hybrid NOTES. As 
the figures show, the balloon was placed in the transverse colon to block the 
colic lumen, and the distal colon cavity was disinfected with povidone-iodine 
solution. An incision was made on the anterior rectal wall 12–17cm from the 
anus. The endoscope was advanced into the peritoneal cavity with liver and 
gallbladder identified. The bile was aspirated before an incision on the gallblad-
ner wall was made. Stones and/or polyps were found inside of the gallbladder. 
Stone extractor and biopsy forceps were used to take out the stones. The 
polyps were coagulated and removed by electric biopsy forceps. The muscular layer 
and the adventitial layer were successively closed with endolips. Peritoneal cavity 
lavage was performed with sterile saline. The rectal incision was closed with 
endoclips and endoloops tightly. At the end of the procedure, the balloon was 
pulled out after being deflated.

Results: The mean operation time (from incision making till the last clipping) was 
180.5 min. (89–467 min.). 6 hours after anesthesia, the patients could drink water, 
and liquid diet was resumed 24 hours later. Postoperatively, 4 of the 14 patients 
felt mild abdominal distention which disappeared within 12 hours when they 
were able to get off the bed. For 1 patient with acute cholecystitis, a hybrid 
NOTES with laparoscopy was performed. Moreover, gallbladder drainage and 
peritoneal lavage were used, and the abdominal pain relieved soon. All 
the patients were discharged without any adverse events and all felt good during 
the follow-ups.

Conclusion: The usage of the detachable balloon can prevent the operative field 
from fecal contamination effectively. TRGCP and TRGPP by pure NOTES are 
suitable for both males and females. Transrectal route provides a novel alterna-
tive approach for the treatment of gallbladder polyps and gallstones. To our 
knowledge, this is the first human case series of transrectal gallbladder preserving 
cholecystolithotomy and polypectomy by pure NOTES. However, multcentered, 
prospective, controlled researches with more cases are needed in the future.

Disclosure of Interest: All authors have declared no conflicts of interest.
61.5 years old. There were 17 patients (38.6%) with intrahepatic cholangiocarcinoma, 9 patients (20.5%) with perihilar cholangiocarcinoma, 7 patients (15.9%) with extrahepatic cholangiocarcinoma and 11 patients (25.0%) with gallbladder cancer. All patients had stage IV disease and median number of prior anticancer treatments of patients was 2 (range 1–5). After an average of 1.5 months of treatment (range 0.5–10.0 months), three patients (6.8%) presented progressive disease as best overall response, 23 patients (52.3%) presented progression and 18 patients (40.9%) could not survive until response evaluation. Median progression free survival was 1.7 months (interquartile range (IQR) 0.8–2.3 months) and median overall survival from study enrollment was 2.5 months (IQR 1.4–4.9 months). During treatment, 25 patients (55.6%) could maintain tolerable general condition without increasing ECOG PS, and 35 patients (79.6%) could maintain or decrease the requirement for morphine as pain killer. During treatment, there were 12 cases (12/44, 27.3%) of severity grade 3 adverse events (AE) and no cases of grade 4 AE. Most common AE was ALT/AST elevation (11/44, 25%) followed by anemia (10/44, 22.7%). The major causes of the drop outs from study were due to disease progression or patient’s death (30 cases, 66.7%), and there were only five cases (11.5%) who dropped out due to adverse drug reactions or severe AE.

Conclusion: KML001 was safe and well tolerated in respects of adverse events. KML001 was also shown promising result in disease control and pain control. KML001 can be another palliative treatment option for patients with advanced biliary tract cancers who non-respond to gemcitabine based chemotherapy.

Disclosure of Interest: All authors have declared no conflicts of interests.
differentiating between (pre)malignant and benign polyps (p = 0.174 and p = 0.589 respectively).

Conclusion: Diagnostic accuracy of TAUS for diagnosis gallbladder polyps is moderate and decreases further when differentiating between polyp types. TAUS would regularly provide false positive results, leading to unnecessary surgery. There was no evidence that diagnostic test accuracy of EUS was better than TAUS. Further studies of high methodological quality are needed to determine diagnostic accuracy of EUS and TAUS for differentiating between polyp types.

This abstract is based on a pre-peer review draft of a Cochrane Review.

**P0743** DIAGNOSTIC VALUE OF CONTRAST-ENHANCED ULTRASONOGRAPHY IN HIGH MECHANICAL INDEX CONTRAST MODE FOR POLYPOID LESIONS OF THE GALLBLADDER

H. Miwa1, K. Numata1, A. Hirotsu1, K. Sanga1, Y. Gouda1, K. Irie1, T. Ishi2, T. Kaneko1, K. Sugimoto1, S. Maeda1

1Gastroenterological Center, Yokohama City University Medical Center, Yokohama/Japan

Contact E-mail Address: miwa@yokohama-cu.ac.jp

Introduction: In its early stages, gallbladder cancer is an asymptomatic disease, and is associated with a poor prognosis if found in an inoperable condition. Several investigators have reported the utility of contrast-enhanced ultrasonography (CEUS) in low mechanical index (MI) contrast mode using a microbubble contrast agent for gallbladder lesions. However, CEUS images with low MI setting are influenced by the echogenicity of background B-mode and cannot depict precise vessel images, in contrast with high MI contrast mode.

Aims & Methods: The aim of this study was to assess the diagnostic value of CEUS in high MI contrast mode for characterizing polypoid lesions of the gallbladder (PLG). Thirty-six patients with PLG, including 17 with gallbladder cancer and 19 with benign polyps, who underwent CEUS were enrolled. The institutional review board approved this study and informed consent was obtained. Perfluorobutane-based contrast agent and high MI contrast mode was used for CEUS. Two blinded readers retrospectively evaluated images obtained in B-mode and CEUS. Kappa values, which reflect inter-observer agreement. Subsequently, patients were stratified according to lesion size at the largest diameter, and the diagnostic accuracy for gallbladder cancer in B-mode and CEUS were assessed.

Results: Two patients with malignant PLG could not be evaluated in B-mode due to sludge. Kappa values for CEUS were graded as good or excellent, and were better than B-mode. Age and size of malignant PLGs were significantly larger than benign lesions. In B-mode, 80% (12/15) of malignant PLGs exhibited heterogeneity (p < 0.01). On CEUS, malignant PLGs exhibited sessile-shape (76% [13/17]), dilated vessels (71% [12/17]), irregular vessels (82% [14/17]), and heterogeneous enhancement (59% [10/17]) (p < 0.01). Except for heterogeneous enhancement, all features remained significantly different after stratification according to size of PLG between 11 mm and 20 mm on CEUS. The sensitivity, specificity, and accuracy for diagnosis of gallbladder cancer was 80% (12/15), 79% (13/19), and 73% (25/34) in B-mode, 94% (16/17), 89% (17/19), and 92% (33/36) on CEUS, and 88% (7/8), 91% (10/11), and 89% (17/19) on CEUS after stratification according to size, respectively.

Conclusion: CEUS in high mechanical index contrast mode was a useful modality for differentiating gallbladder cancer and benign PLGs.

**P0744** ASSOCIATION OF CIRCULATING ADIPONECTIN LEVELS AND TUMOR STAGE IN BILIARY TRACT CANCER

A. Saray, B. Gogov, N. Zubcevic, D. Prohic, A. Mehmendovici, A. Pahalovic

Department Of Gastroenterology And Hepatology, Clinical Center University of Sarajevo, Sarajevo/Bosnia And Herzegovina

Introduction: Multiple recent studies have indicated that some of adipose tissue-derived hormones may significantly influence the growth and proliferation of GI tumors including liver cancer (1, 2). However, the role of adipokines such as adiponectin and leptin in biliary tract cancer have not been well studied before. The aim of the study was to analyze plasma concentrations of adiponectin and leptin in cholangiocarcinoma (CC) patients and to compare these concentrations to clinicopathological parameters.

Aims & Methods: Baseline levels of adiponectin and leptin were determined in 38 consecutive patients with newly diagnosed cholangiocarcinoma and 38 healthy control subjects. The association between adiponectin and leptin and tumor stage was evaluated using nonparametric Spearman’s correlation test. Control subjects were matched to case patients by age, sex and BMI. Survival analysis used the Kaplan-Meier curve and the Cox proportional hazards model.

Results: Overall median adiponectin concentrations were lower in CC patients versus control subjects (5.1 vs 9.3 mg/mL, P = 0.001). In CC patients with T stage 2–4 (n = 22) median adiponectin concentrations were significantly lower than in CC patients with T stage 1 (n = 16) (3.8 vs 6.6 mg/mL, P = 0.001). The mean leptin levels were not significantly decreased in CC patients (P = 0.45). Adiponectin concentrations were inversely correlated with tumor T stage (r = –0.811, P = 0.01) of CC patients. Higher adiponectin levels at baseline were associated with increased overall survival in T stage 2–4 patients (Cox F test = 2.139, P < 0.05).

Conclusion: This study identified an association between adiponectin levels and tumor stage suggesting a potential role for adiponectin in progression of cholangiocarcinoma. Furthermore these results suggest, for the first time, that serum adiponectin levels might represent a prognostic indicator in patients with CC. Our results support the hypothesis linking adipose-tissue derived hormones levels to growth of obesity-associated cancers (3). Adipokines appear to play an important role in risk prediction and management of cholangiocarcinoma patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0745 PRETREATMENT BODY MASS INDEX AND WEIGHT CHANGE DURING PERIOPERATIVE CHEMOTHERAPY AFFECT SURVIVAL OUTCOME IN ADVANCED BILIARY TRACT CANCER PATIENTS

Seoul National University College Of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul/Korea, Republic of

Contact E-mail Address: schmeiche80@gmail.com

Introduction: Recent studies have been conducted to investigate the association between obesity and survival in cancer patients. Cancer has a significant influence on the nutrient status of patients and obesity can affect the pharmacokinetics of anti-cancer drugs. The impact of obesity on survival is known to vary in different cancers. Biliary tract cancer was less frequently analyzed and most of the studies were on the relationship between obesity and cancer incidence.

Aims & Methods: We performed this study to investigate the association between BMI and survival in advanced biliary tract cancer patients with chemotherapy. Between January 2005 and December 2015, two hundred and eighty-four patients who underwent chemotherapy for biliary tract cancer were retrospectively reviewed. The relationship between BMI (kg/m²) and overall survival (OS) was assessed. Based on World Health Organization BMI category and 2014 Clinical Practice Guidelines for Overweight and Obesity in Korea, BMI was classified as follows; underweight, <18.5 kg/m²; normal, 18.5-22.9 kg/m²; overweight, 23.49-24.9 kg/m²; obese, ≥25 kg/m².

Results: Median OS was 12.1 months for underweight patients, 10.5 months for normal patients, 16.1 months for overweight group, 13.6 months for obese patients, respectively. (p = 0.047) Univariate analysis showed that BMI, local status of disease, operation, radiotherapy and ECOG performance were significantly associated with better survival. Compared with normal patients, overweight patients (BMI 23-24.9 kg/m²) had a reduced risk of mortality in multivariate analysis (HR 0.491, CI 0.334-0.721; 95% p = 0.036). In the additional analysis for the effect of change in body weight and BMI to the overall survival, larger amount of change in body weight was associated with further decrease in overall survival.

Conclusion: Slightly overweight status and the maintenance of body weight during the initial period of chemotherapy is independent predictor of better overall survival in advanced biliary tract cancer patients with good performance status.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0746 THROUGH THE CATHETER BIOPSY METHOD FOR BILIARY CARCINOMA

T. Okuzono
Department Of Gastroenterology, Sendai Kousei hospital, Sendai/Japan

Contact E-mail Address: okuzonotoru@gmail.com

Introduction: To perform curative operation of biliary carcinoma, the pre-operative identification of exact proximal and distal margins is important. A biopsy forceps is conventionally inserted to common bile duct via duodenal ampulla by an antecedent guide wire. Cannulation of the bile duct with the biopsy forceps may sometimes be difficult in cases where no sphincterotomy is performed, placing the patient at risk of post-ERC pancreaticitis after multiple attempts to advance the forceps into the duct. Pancreato-biliary endoscopists have reported the biopsy methods.

Aims & Methods: The aim of this study was to assess the feasibility and safety of this new method. To assess the feasibility and safety of this new method, we conducted a retrospective review of biliary duct biopsies with this new method conducted in Sendai Kousei hospital from February 2015 to October 2016. All patients who had biliary stenosis were included. Patients' demographic data, technical success, adverse events and the diagnostic accuracy were evaluated.

Results: A total of 95 biopsy procedures were performed in 40 patients. The technical success rate was 95% (90/95). Post-ERC pancreaticitis occurred in 1 of 40 patients (2.5%, 1 grade 1 patient). There were no other adverse events like perforation or bleeding. The diagnostic yield of biopsy procedures was 100% (7 of 7 patients).

Conclusion: The new biopsy methods to biliary stricture were feasible and safe. It opens up exciting possibilities for endoscopic preoperative diagnosis of the biliary carcinoma.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Patients with perihilar cholangiocarcinoma (PHC) have few treatment options and a poor prognosis. Most staging models for patients with PHC have been developed for the minority of patients with potentially resectable disease and are not applicable to the vast majority of patients.

Aims & Methods: The aim of this study was to develop a prognostic score for all PHC patients using variables available at presentation. All consecutive patients with PHC (regardless of tumor stage and treatment) in two tertiary referral centers between 2002 and 2014 were identified. Baseline patient and tumor characteristics were collected and a retrospective outcome analysis was performed. In total, 331 patients underwent exploratory laparotomy with a median OS (95% confidence interval) of 20.7 (17.8-23.6) months. Adverse outcomes were found in 229 patients (69.2%): 145 patients (43.8%) had preoperative adverse outcomes of the exploratory surgery, 53 (16%) patients had postoperative adverse outcomes and 31 (9.4%) patients experienced both peri- and postoperative adverse outcomes. Median OS for patients with an adverse outcome was 13.1 months (11.3-15.0) compared to 50.9 months (39.6-62.2) in patients without adverse outcomes (p = 0.0049). CA 19.9 serum level (HR 1.22 (95% CI 1.07-1.38), tumor size (HR 1.33 (95% CI 1.14-1.56), WHO performance status 3–4 (HR 1.48 (95% CI 1.10–1.95), hepatitis involvement (hazard ratio (HR) 2.38, 95% CI 1.16–4.99, p = 0.0422), CA 19-9 above 1000 U/mL (HR 3.26, 95% CI 1.14–11.8, p = 0.0195), and tumor involvement of the hepatic artery on imaging (HR 2.07, 95% CI 1.01–4.33, p = 0.0492) were independent prognostic factors for an adverse outcome at exploratory laparotomy. A risk score based on these factors is defined in this study as the following. A risk score based on these factors identified patients with a substantial (49%), high (66%), and very high (87%) risk of adverse outcome.

Table 1: Calculation of prognostic score

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Score</th>
</tr>
</thead>
<tbody>
<tr>
<td>CA 19.9 (U/mL) ≥1000 U/mL</td>

Introduction: Patients with perihilar cholangiocarcinoma (PHC) have few treatment options and a poor prognosis. Most staging models for patients with PHC have been developed for the minority of patients with potentially resectable disease and are not applicable to the vast majority of patients.

Aims & Methods: The aim of this study was to develop a prognostic score for all PHC patients using variables available at presentation. All consecutive patients with PHC (regardless of tumor stage and treatment) in two tertiary referral centers between 2002 and 2014 were identified and included. Baseline patient and tumor characteristics were collected from medical records. Cox proportional hazards regression was used for multivariable analysis. Age, BMI, bilirubin, CA 19-9, and tumor size were modeled as continuous covariates.

Results: A total of 674 patients were included of whom 342 (50.8%) had unresectable disease at presentation and 176 (26.2%) underwent exploratory laparotomy. Multivariable analysis identified age (HR 1.41 (95% CI 1.23–1.63)), BMI (HR 1.11 (95% CI 1.05–1.17)), serum bilirubin level (HR 1.45 (95% CI 1.21–1.71)), CA 19-9 serum level (HR 1.22 (95% CI 1.07–1.38), tumor size (HR 1.33 (95% CI 1.14–1.56), WHO performance status 3–4 (HR 1.48 (95% CI 1.10–1.95), suspected distant metastases on imaging (HR 1.69 (95% CI 1.29–2.08), unilateral HA involvement (HR 1.28 (95% CI 1.01–1.57), and main/bilateral HA involve- ment: (HR 1.61 (95% CI 1.21–2.14) as independent prognostic parameters. Based on these factors, a prognostic score was created to predict survival for patients with PHC from the time of presentation. Discrimination using Kaplan-
Meier curves, and calibration curves revealed good predictive abilities. The risk score identified patients with a 1-year survival probability ranging from 15% to 73%.

**Conclusion:** We developed a prognostic score to predict overall survival for PHC patients using eight independent poor prognostic factors available at presentation. This score may help to inform patients and guide individualized treatment decision making.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0749 THE OUTCOMES OF ERCP FOR THE PALLIATION OF MALIGNANT JAUNDICE IN ENGLAND BETWEEN 2001 AND 2015**

P. Harvey, S. Baldwin, J. Myttor, F. Evion, P. Patel, N. Trudgil
1Gastroenterology, Sandwell and West Birmingham NHS Trust, Birmingham/United Kingdom
2Health Informatics, University Hospital Birmingham, Birmingham/United Kingdom

**Contact E-mail Address:** philipharvey@nhs.net

**Introduction:** Malignant biliary obstruction has a poor prognosis unless secondary to a resectable primary cancer. Recent data on PTC for the relief of malignant obstruction in a palliative setting demonstrated a high early mortality. We have therefore examined outcomes of ERCP in inoperable malignant obstruction.

**Aims & Methods:** The Hospital Episode Statistics (HES) database contains diagnostic and procedural data for all hospital attendances in England. HES is linked to the Office for National Statistics (ONS) to provide mortality data. All subjects from April 2001 to April 2015 in England with an ICD10 code for cancer 2 years prior to ERCP or in the following 6 months were examined. Subjects undergoing a curative surgical procedure were excluded. Associations between demographics, co-morbidities, unit ERCP volume and mortality were examined by logistic regression.

**Results:** 49055 subjects were included in the study of whom 48.7% were male, median age 74.5 years (range 19–104). Pancreatic cancer was the most common aetiology (63.5%). Followed by liver and intrahepatic bile duct malignancy (19.4%). Mortality was 4.16%, 10.9% and 19.4% for 7 day, in hospital and 30 day respectively. In multivariate analysis male gender (OR 1.14, (95% CI 1.08–1.20) p=0.001), increasing by age quintile 64–71 (1.34, (1.23–1.47) p<0.001), 72–78 (1.44–1.72) p<0.001, 78–83 (1.68–2.00) p<0.001), p=0.001, 530 (2.78, (2.55–3.03), p<0.001); most deprived quintile (1.22, (1.12–1.33), p=0.001); increasing co-morbidity score 1 to 5 (1.09, (1.02–1.16), p=0.012), 6 to 10 (1.12, (1.12–1.35), p<0.001) 11 to 15 (1.49, (1.33–1.66), p<0.001), 16 to 20 (1.71, (1.55–1.88), p<0.001); 21 to 25 (2.08, (1.69–2.55), p<0.001); advancing year of ERCP 2013/14 (0.78, (0.69–0.98), p=0.001), 2014/15 (0.85, (0.74–0.98) p=0.028); and previous renal failure (1.92, (1.77–2.09), p<0.001) were associated with increasing 30 day mortality. Asian ethnicity (0.82, (0.67–0.99), p=0.036). Cancer of extraplacental and unspecified parts of biliary tree (0.60, (0.55–0.65), p<0.001) and upper tertile of unit ERCP activity (>230) per annum (0.86, (0.80–0.93), p<0.001) were negatively associated with 30 day mortality.

**Conclusion:** Short-term mortality in subjects with malignant biliary obstruction following ERCP was high. A better prognosis was observed in; high-volume ERCP units, Asian ethnicity and extrahepatic primary cancers. Male gender, advancing age, increasing co-morbidity score, greater deprivation and previous renal failure predicted death at 30 days. 

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0750 EARLY DEVELOPMENT OF NONALCOHOLIC FATTY LIVER DISEASE IN GENETICALLY PREDISPOSED CHILDREN: WHETHER LIVER PATHOLOGY AND CARDIOMETABOLIC DISTURBANCES COINCIDE IN CARRIERS AND NON-CARRIERS OF THE RISK ALLELES.**

J. Plat1, J. van Dijk2, J. Vreugdenhil1
1Department Of Human Biology, School Of Nutrition And Translational Research In Metabolism (nutrim), Maastricht University, Maastricht/Netherlands
2Department Of Gastroenterology And Hepatology, University Hospital Maastricht, Maastricht/Netherlands

**Contact E-mail Address:** cpienar@gmail.com

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) is a common chronic liver disease and in particular a health threat in obese children. Single nucleotide polymorphisms in genes encoding PNPLA3 (rs738409) and TM6SF2 (rs58542926) contribute to the development of NAFLD. It is however unknown whether liver parameters and cardiometabolic disturbances coincide in carriers and non-carriers of these risk alleles in an at-risk obese pediatric population. Therefore, we assessed cardiometabolic derangements, genetic predisposition for NAFLD and liver transaminase levels in children with overweight and obesity.

**Aims & Methods:** One hundred and seventy-four children (49% boys) from the Centre for Overweight Adolescent and Children’s Healthcare (COACH) at the Maastricht University Medical Centre were genotyped for PNPLA3 C148M and TM6SF2 E167K. Anthropometric, cardiometabolic risk and liver-related parameters were determined.

**Results:** Anthropometric parameters did not differ significantly between carriers and non-carriers of the risk alleles. ALT and AST were significantly higher in PNPLA3 G allele carriers as compared to the C allele carriers (ALT; CC 21, (19.93–22.84); GG 26, 50 (19.34, 50); GG 27, 50 (21, 00, 40, 00); GG 30, 60 (26, 03, 60, 00) (p=0.004)). The odds ratio for having ALT levels above the cut-off values increased for every PNPLA3 G allele, with an OR of 2.51 (1.22;5.18; p=0.004) for the PNPLA3 CG genotype and 5.54 (1, 53;20, 02; p=0.009) for the GG genotype, compared to the CC genotype. Carriers of the PNPLA3 risk allele did not show a deteriorated metabolic profile compared to non-carriers. The TM6SF2 T allele carriers also showed a tendency increased transaminase levels, but a significantly healthier cardiometabolic profile compared to non-carriers. The metabolic syndrome was more prevalent in risk allele carriers. These results suggest that hepatic aberrations and metabolic disturbances apparently do not develop concordantly in this specific population. Furthermore, these children with a high liver risk may not be identified by measuring cardiometabolic parameters.

**P0751 TWO-DIMENSIONAL SHEAR WAVE ELASTOGRAPHY IN CHILDREN: WHAT IS THE REPRODUCIBILITY?**

J. Plat1, J. Vreugdenhil1, J. van Dijk2, A. Beelen1, S.A. Popescu2, I. Sporea2
1Pediatric Department, 2VICTOR BABES University of Medicine and Pharmacy, Timisoara/Romania

**Contact E-mail Address:** cpienar@gmail.com

**Introduction:** Pediatric chronic liver diseases are becoming a public health issue. Ultrasound based elastographic techniques have emerged as non-invasive methods of pediatric liver fibrosis assessment. The most recent are two dimensional elastographic (2D) techniques. While they are non-invasive and highly reproducible in children, there is still no consensus regarding the number of measurements to be performed for a high-quality evaluation.

**Aims & Methods:** We aimed to investigate the number of liver stiffness measurements (LSM) needed for a high-quality evaluation using this 2D SHE technique. We conducted a prospective study which included 73 children (age range: 3–17 years, mean age 11.73±3.55 years, 37% girls, mean body mass index (BMI) 23.12±7.38 kg/m2). We used the 2D-SWE.GE (Logiq E9, GE Healthcare, Chalfont St Giles - UK), with a C1-6-D probe. One examiner performed 10 LSM for each child. We randomly extracted 1 LSM, 2 LSM, 3 LSM and 5 LSM from all 10 and calculated their respective medians. We employed the Friedman test to compare the medians of 1, 2, 3, 5 and 10 LSMs. We used the interclass correlation coefficients (ICC) to assess the agreement between the medians of 1, 2, 3, 5 and 10 LSMs.

**Results:** Medians calculated from 1, 2, 3, 5 and 10 LSMs were similar (4.22±0.91 kPa vs 4.22±0.91 kPa, 4.23±1.03 vs 4.22±0.99 kPa vs 4.19±0.99 kPa, p=0.94). Furthermore, the agreement between medians calculated from 1, 2, 3, 5 and 10 LSMs was excellent (ICC =0.960, 95% confidence interval: 0.944-0.974).

**Conclusion:** We suggest obtaining 5 LSM for a high-quality evaluation using this 2D SHE technique.

**P0752 PERCUTANEOUS EMBOLIZATION OF VISCERAL ARTERY PSEUDO-AnEURYSMS - A TERTIARY CENTER EXPERIENCE**

R. Chavan1, J. Singh1, Z. Nabi, R. Kalapala1, D.N. Reddy3
1Gastroenterology, Asian Institute of gastroenterology, Hyderabad, Hyderabad/India

**Contact E-mail Address:** drradhikachavan@gmail.com

**Introduction:** Visceral artery pseudo-aneurysms are rare, but potentially fatal if rupture. Pseudoaneurysm usually occurs most frequently after pancreatitis. Angiembolization with conventional trans-catheter approach is the standard treatment. Direct percutaneous embolization has been commonly used for treatment of peripheral artery pseudoaneurysm when trans-catheter approach is not feasible. However, very limited data is available regarding its safety and efficacy in visceral artery pseudoaneurysm.
Results: 23 patients (18 male) with mean age of 34.47 ± 21.28 (7–72) years, underwent direct percutaneous embolization for visceral pseudoaneurysm. Most common aetiology for pseudoaneurysm was pancreatitis (16) followed by erosions obstructing view of feeding artery in 5 patients, and recurrence after previous embolization in 6 patients. Agents used for embolization—glue with lipiodol (21), coil (1) and coil with glue (1). Mean procedural time was 11.3 ± 2.11 (8–16) minutes and fluoroscopy exposure time was 2.4 ± 1.34 (1–6) minutes. Percutaneous embolization was successfully performed in all patients (technical success 100%). Mild adverse events included— local site pain in 19 (80%) patients. Moderate adverse event included— splenic infarct in 5 patients, all of which responded to conservative management. There were no major adverse events and no occurrence of distant embolization. At median follow up of 90 days (30–3186) there was no recurrence of pseudoaneurysm (clinical success 100%).

Conclusion: Percutaneous embolization is safe and effective for treatment of visceral artery pseudoaneurysm. Percutaneous technique may be considered as an alternative to trans-catheter embolization in cases of challenging anatomy, multiple collaterals and recurrence after previous embolization precluding trans-catheter embolization.

Introduction: Chronic (CP) and autoimmune pancreatitis (AIP) are characterized by intraductal inflammation and proliferation of ducts. Whether CP is proinflammatory to autoimmunity is still unclear. AIP is considered mostly a T-cell mediated disease; however, in induction of chronic pancreatitis macrophages play a pivotal role. Cyclic dependent kinase (cdk) inhibitors are critical regulators in inflammatory disease as they influence differentiation, activation and proliferation of immune cells, and apoptosis. In particular, p21 has been described as a mediator of inflammation and various autoimmune diseases by regulating T-cell activation and promoting macrophage development. We therefore examined the role of p21-mediated inflammation in AIP.

Aims & Methods: Human pancreas samples from CP and AIP patients were evaluated for p21 expression. To investigate the effects of p21 in pancreatitis, we intercrossed lymphotxin overexpressing mice (Tg(Ela1-LTa, b)) – a model to study CP and AIP – with p21 deficient (p21−/−) mice. Infiltrating cells were visualized by immunohistochemistry, supported by gene expression analysis in an early and a progressive phase. Circulating autoreactive and the presence of tertiary lymphoid organs (TLOs) were analysed to assess autoimmunity.

Results: p21 was upregulated in human CP patients but remained unchanged in AIP patients, p21 deficiency in LT mice (Tg(LTa, b)) prevented early pancreatic injury. LTp21−/− mice had normal serum amylase, reduced inflammatory gene expression and cell influx. In acinar cells diminished proliferation and aborted activation of non-canonical NF-kB pathway was observed. In contrast, 12 months old LT mice with and without p21 had similar inflammatory gene expression and T & B cell infiltration. Interestingly, LT and LTp21−/− mice had comparable tertiary lymphoid organs (TLOs), autoreactive antibodies and elevated IgG levels. However, acinar cell proliferation, acinar-to-ductal metaplasia and acinar non-canonical NF-kB pathway activation remained impaired in LTp21−/− pancreata.

Conclusion: Our findings indicate that p21 is crucial for pancreatitis in LT-driven pancreatic injury. p21 is involved in early acinar secretion of inflammatory mediators that attract innate immune cells. However, p21 is not essential for humoral immune response, accountable for autoimmunity and lack of p21 does not rescue AIP. Consequently, p21 interplays in the pathogenesis of pancreatitis and renders acinar cells less susceptible to proliferation and transdifferentiation. We therefore suggest that chronic and autoimmune pancreatitis follow different inflammatory processes.

Introduction: Various forms of pancreatitis (e.g. severe acute pancreatitis, auto-immune pancreatitis type 2) are characterized by an infiltration of neutrophil granulocytes. Yet, despite sharing the feature of granulocytic infiltration, these diseases take opposing natural courses of disease. A novel function of granulocytes, the formation of aggregated neutrophil extracellular traps (agNETs), has been described and called for a reevaluation of the specific role of neutrophils in pancreatitis. We were interested in the specific function of granulocytes in various models of pancreatic inflammation.

Aims & Methods: Experimental models of pancreatic inflammation were employed including caerulein-induced pancreatitis and a novel model of IL-17A-induced pancreatitis. The susceptibility of disease was characterized by immunohistochemistry, RNA expression and flow cytometric analyses.

Results: Transgenic systemic delivery of IL-17A alone can induce granulocytosis and neutrophil infiltration to the pancreas. Interestingly, neutrophils do not recruit into the pancreatic ducts with and forms aggregates in the ducal lumen. Our experimental models further indicate that peptidyl arginine deiminease 4 (PAD4) is critical for intraductal aggregate formation and that PAD4-deficiency abrogates disease progression. Mechanistically, we identify the pancreatic juice as a strong instigator of neutrophil extracellular matrix. Characteristic single components of pancreatic juice, such as baccarionate ions and calcium carbonate crystals, induce aggregated NET formation.

Conclusion: Granulocytes aim to contain an inflammatory focus and enter pancreatic ducts with potentially detrimental consequences to dependent areas of the organ.

Introduction: Mitochondrial dysfunction is a hallmark of several disease pathogenesis including acute pancreatitis (AP). Our results suggest that mitochondrial damage is crucial in bile acid induced inhibition of pancreatic ductal HCO3− secretion, however the details of mitochondrial function and dysfunction in pancreatic ductal epithelial cells (PDEC) is not known yet.

Aims & Methods: The aim of our study was to characterize the mitochondrial distribution and function in PDECs under physiological and pathophysiological conditions. Guine pig and Cyclophilin D WT and knock out (KO) mouse pancreatic ducts were used. Mitochondrial distribution was studied by electron microscopy (EM). Mitochondrial membrane potential (ΔΨm) was measured by confocal microscopy and pancreatic ductal HCO3− secretion by microfluorometry.

Results: EM measurements revealed that the mitochondrial density is significantly higher on the apical side of the guinea pig PDEC compared to the middle or the basal segment in HEPES solution. The apical mitochondrial density increased further in CO2/HCO3− buffered solution, or during the administration of 5 mM forskolin. This was also confirmed by the ΔΨm measurements as we detected increased TRMM fluorescence on the apical side of the PDEC during stimulation. The genetic KO of cyclophilin D significantly reduced the loss of ΔΨm and protected pancreatic ductal HCO3− secretion during the administration of 300 μM chenodeoxycholic acid.

Conclusion: Our results revealed that mitochondrial function has a central role in the function of PDEC presumably by providing ATP for fluid and ion secretion. On the other hand the opening of MPTP seems to be crucial in the bile acid induced toxicity offering a potential therapeutic target in AP.

Introduction: Infectious complications are main causes of mortality in severe acute pancreatitis. Most infections in AP are intestinal origin (2). The Nucleotide oligomerization domain 2 (NO2) is a NO-like receptor family member that senses and responds to bacterial wall peptides (3). Guenther et al. reported that p.R702W mutation was found to be associated with multiple organ failure and mortality in patients with AP (4). We aimed to investigate whether there is a correlation between NO2 variants and AP severity in this study.

Aims & Methods: Group 1 (n = 27) was healthy. Group 2 (n = 36) and Group 3 (n = 32) were composed of mild and severe pancreatitis patients according to the Atlanta 2012 classification (5). Four NO2 variants and sex interquartile (IL-6), Tumor Necrosis Factor-α (TNF-α) and lipopolysaccharide-binding protein (LBP) levels were studied.

Results: We detected p.R702W variant in 3 patients (3/32, 9.4%) in severe pancreatitis group, but this variant was not seen in the other two groups. 1007fs variant was found in 3, 3 and 1 patient in mild (3/36, 8.3%) and severe pancreatitis (3/32, 9.4%) groups, and in healthy group (1/27, 3.7%), respectively. There was no significant difference in the frequencies of NO2 variants between groups. Serum IL-6, TNF-α and LBP levels were significantly higher in the severe pancreatitis group than in the healthy group and mild pancreatitis group (all p < 0.001). However, there was no significant difference between these cytokine levels and NO2 variants.

Conclusion: Our results suggest that there may be a relationship between the presence of p.R702W variant and severe pancreatitis.}

Introduction: Acute pancreatitis (AP) has a wide clinical spectrum, ranging from mild cases with transient organ failure (TOF) to cases with multiple organ POF/TOF, with POF further categorized into multiple vs single POF, toOF, with POF further categorized into multiple vs single POF. There is no effective treatment for late (7–17 days) or early severe (≤7 days) AP. The aim of this study was to analyze which complications were independently associated to worse outcomes (time to oral refeeding, invasive treatment, ICU admission, hospital stay and mortality). Patients with AP were prospectively enrolled at 23 centers, 60% had biliary etiology, 17% necrotizing AP and 14% vascular complications. Associations between possible determinants and outcome variables were assessed through binary logistic regression analysis (with adjustment for sex, etiology, Charlson comorbidity score (including age) and recurrent AP in the model).

Results: Among 1753 patients, 1065 patients were included. Independent determinants of increased morbidity and mortality (vs category with lower risk) were: persistent organ failure (POF) vs transient organ failure (TOF), all local complications (especially combined periampullary and pancreatic necrosis) vs no local complications, infected necrosis vs sterile necrosis and multiple-organ POF vs single-organ POF. We found no independent effect for late (7–17 days) or early POF nor POF associated to infected necrosis vs sterile POF.

Conclusion: Results of this study suggest that any determinants of severity should be included in a future classification of severity of AP are 1) local complications, where necrosis should be further categorized into infected vs sterile and 2) POF/TOF, with POF further categorized into multiple vs single POF.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic ultrasound-guided transmural drainage (EUS-TD) has been shown to be a safe and effective minimally invasive treatment for walled-off necrosis (WON). However, in some cases, simple drainage is not sufficient to manage the symptoms of WON and step up approaches such as direct endoscopic necrocectomy (DEN) and surgical necrocectomy may be required. The associations between WON drainage and patient outcomes have been published in some small studies, but the relationship between oncological outcomes and step-up approaches remains unclear. We aimed to retrospectively correlate the clinical characteristics including morphology and extent of WON with oncological outcomes.

Aims & Methods: We performed a retrospective study of 489 patients with a first episode of acute pancreatitis from September 2012 to September 2015. We collected relevant information of disease course and follow up until June 2016. We retrospectively classified these patients according to etiology, explore the relevant characteristics of WON associated with step up approach, and performed univariate and multivariate regression of the mechanism of the acute renal injury following acute necrotizing pancreatitis.

Results: The mean size of WON was 126.63 ± 46.79 mm. WON-TD was technically successful in 48.87% (76/157) patients and 26.54% improved with EUS-TD alone while step-up approach was used in 19 patients. WON-TD was attempted step-up approach in 96 patients (38 males; mean age 60.79 ± 13.44) with symptomatic WON treated by an attempted EUS-TD initially were enrolled in this study. The relationship between the outcome of treatment and the clinical characteristics including morphology and extent of WON was evaluated.

Conclusion: The step up approach is safe and effective for the treatment of WON. Multi-locular, large size and extensive WON were important predictors for performing a step up approach. Gas bubbles sign within necrotic tissue after EUS-TD may help to perform necrocectomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Clinical data has indicated that severe acute pancreatitis is a serious inflammatory disease with a systemic inflammatory response and multiple organ dysfunction. Acute renal injury caused by acute pancreatitis is a common complication that is associated with a high rate of mortality. Although the pathogenesis of acute necroizing is not completely clear, the activation of inflammatory cytokines and coagulation are keys in the etiology.

Aims & Methods: We examined 155 patients with acute necrotizing pancreatitis. According to the international classification in 98 patients we diagnosed the moderate severe AP, and in 57 patients the severe AP. Disorders of kidney function were in 48 patients. We determined the creatinine level, indicators of hemostasis and inflammation.

Results: Analysis of the relationship of inflammation and hemostasis in patients with severe pancreatitis and renal dysfunction is accompanied by decreased of activated partial thrombin time (FV = 25.22, p < 0.0001), increased of thrombin time (FV = 19.428, p = 0.00004), fibrinogen concentration (FV = 6.046, p = 0.03588), D-dimers level (FV = 2.8456, p < 0.0001), and level of soluble fibrin-monomer complexes (FV = 34.015, p < 0.0001), lack of activity of anti- thrombin III (FV = 42.123, p = 0.0001), increased synthesis of C-reactive protein (FV = 15.591, p = 0.0002), excessive production of proinflammatory cytokines (FV = 1.997, p < 0.0001), IL-6 (FV = 21.076, p = 0.00002), and TNF-α (FV = 25.643, p < 0.0001). In acute pancreatitis patients with renal dysfunction was shown a direct correlation between severity of renal failure (SOFA score) and concentrations of IL-6 (R = 0.41484, p = 0.000584), CRP (R = 0.510742, p = 0.0002), D-dimers (R = 0.324169, p = 0.008456), soluble fibrin-monomer complexes (R = 0.290750, p = 0.017868), and duration of thrombin time (R = 0.29607, p = 0.018514).

Conclusion: The mechanism of the acute renal injury following acute necrotizing pancreatitis is complicated by the inflammatory cascades and hypercoagulable state is initiated this pathological process.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute Pancreatitis (AP) may be severe in up to 20% of patients with substantial morbidity and mortality, which is related to a generalized inflammatory response. In some patients, this severe inflammatory response is down-regulated; in others it escapes control. Our group has previously described a TH1 profile associated with poor prognosis in AP, and a TH2 profile associated with a mild or moderate condition.

Aims & Methods: Our aim was the development of an index for an early assessment of prognosis in AP. We analyzed 12 cytokines in 117 patients, upon
admission to hospital. A receiver operating characteristic (ROC) analysis was built at day 0 for the multiple discriminant analysis was performed, using the Wilks lambda test, to identify the variables that differ most between patients with mild AP and moderate/severe AP. A ratio calculated using the most discriminant cytokines was studied in relation to severity and mortality.

Results: ROC curves showed that TH1 cytokines IL6, IFN-γ and TNF-α can be measured for the prediction of severe AP, while TH2 cytokines IL4, IL13, GMI-CSF, for the prediction of a mild or moderate condition. A stepwise analysis showed that IL13 and IFN-γ were the biomarkers which contributed most to the discrimination between mild and moderate/severe AP (Wilks’ lambda = 0.855, p < 0.0001; Wilks’ lambda = 0.747, p < 0.001, respectively). We calculated the IL13:IFN-γ index. This ratio was significantly higher in patients with mild AP when compared between groups (p = 7.36 × 10-8). This difference was also observed between severe AP and the rest of the patients (p = 0.007). The ROC curve was also modified, increasing the area under the curve (AUC), the sensitivity and the specificity, in relation to AP severity. Calculating an IL13:IFN-γ ratio that could be of great interest in the assessment of prognosis in AP. A high value of the IL13:IFN-γ ratio at hospital admission is associated with a good prognosis of AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0763 CORRELATION BETWEEN POST-ERCP SERUM AMYLASE LEVELS AND CT FINDINGS IN ERCP-INDUCED PANCREATITIS: A PROSPECTIVE MULTICENTER OBSERVATIONAL STUDY

Introduction: According to the diagnostic criteria by Cotton et al. post-ERCP acute pancreatitis is defined as the persistence of serum amylase levels three times or higher than the upper limit of the standard for 18 hours. The accurate diagnosis of early pancreatic inflammation is strongly recommended, in order to prevent the progression to severe acute pancreatitis. We investigated the cutoff serum amylase level that suggested ERCP-induced pancreatitis in a prospective multicenter study.

Aims & Methods: In Japan, we performed a high-volume center study, 2078 patients examined by ERCP during April 2015 and May 2016 were prospectively followed. CT was performed in patients whose serum amylase level exceeded the institutional upper limit on the day after ERCP (after 12-20h) to investigate the presence of or absence of pancreatic necrosis. Two expert radiologists independently judged the images blinded and judged the presence or absence of pancreatitis based on the Balthazar grade. Patients with a preexisting high amylase level, clinically demonstrated infection or inflammation due to malignant lymphoma, or CT showed persistent upper abdominal pain for 4 h or longer. However, the criterion of acute pancreatitis was also modified, increasing the area under the curve (AUC), the sensitivity and the specificity, in relation to AP severity.

Results: Amylase levels increased on the following day in 402 (21.5%) of the 1868 patients included, and 340 patients examined by CT were included in the analysis. ERCP-induced pancreatitis was diagnosed based on imaging in 204 patients (10.9%). The cutoff amylase level for judging the presence or absence of pancreatitis on the following day was 2.73 times higher than the institutional upper limit (sensitivity: 73.3%; specificity: 90.0%; positive likelihood ratio: 3.48, negative likelihood ratio: 0.34) with an AUC of 0.80. The cutoff level after 2h was 2.73 times higher than the institutional upper limit (sensitivity: 45.6%; specificity: 79.7%; positive likelihood ratio: 2.24, negative likelihood ratio: 0.68) with an AUC of 0.63. Abdominal pain under 4h was noted in 36 of the 204 patients in the pancreatitis group, and 12 of 136 patients in the non-pancreatitis group with a sensitivity of 17.7%; specificity, 91.1%; positive likelihood ratio, 1.99; and negative likelihood ratio, 0.90. Abdominal pain that persisted longer than 4h occurred in 75 patients in the pancreatitis group and 12 in the non-pancreatitis group with a sensitivity of 36.7%; specificity, 91.1%; positive likelihood ratio, 4.12; and negative likelihood ratio, 0.69.

Conclusion: The appropriate cutoff serum amylase level for judging ERCP-induced pancreatitis on the day following ERCP is 2.73 times higher than the institutional upper limit. The diagnostic value of serum amylase levels 2h after ERCP persisting abdominal pain persisting for longer than 4h, then sensitivity was high but the specificity was low. Therefore, setting a cutoff serum amylase level on the day after ERCP is very useful to diagnose ERCP-induced pancreatitis.

Introduction: Post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) is a common and serious adverse event following ERCP, with a reported incidence of 9.7% in unselected patients [1]. Given huge economic and clinical burden, effective approaches for post-ERCP pancreatitis prophylaxis remains a major priority for research. Nonsteroidal anti-inflammatory drugs (NSAIDs) have also been shown the potential efficacy in prophylaxis PEP across high-risk patients, especially for diclofenac or indomethacin [3–5]. Recently, a prospective, double-blind, controlled trial conducted by Levenick [6] and colleagues in the USA showed that the reduction in PEP using indomethacin was not as significant as previously reported. In fact, even group cases of pancreatitis occurred in indomethacin group compared with placebo group. Subsequently, a high-quality meta-analysis also concluded that there is no prophylaxis for the prevention of PEP among average-risk patient[s] [7]. These findings raised the question that whether administration of rectal indomethacin should be recommended in average-risk patients.

Aims & Methods: We aimed to determine the effective benefit of rectal indomethacin in the prevention of post-ERCP pancreatitis in average-risk of patients. We systematically searched on EMBASE, Medline, Cochrane Central Register of Controlled Trials and CINAHL library before October 2016. Studies that evaluated rectal administration of indomethacin in the prevention of post-ERCP pancreatitis were included in the analysis. We adopted a random-effects model to calculate overall relative risk (RR) and 95% confidence interval (CI).

Results: We identified ten randomized clinical trials from initial search and finally included in the meta-analysis. Administration of rectal indomethacin significantly reduced the incidence of PEP in combined population (RR, 0.63; 95% CI, 0.50–0.77). There was no significant heterogeneity across included studies (I2 = 14.2%, P = 0.31). In subgroup analysis, rectal indomethacin was effective in both high-risk (RR, 0.49; 95% CI, 0.35–0.71) and average-risk (RR, 0.69; 95% CI, 0.55–0.86) patients and reduced the risk of mild and moderate to severe pancreatitis. The overall results remained unchanged and robust in sensitivity analysis. There was no evidence of significant publication bias among this meta-analysis.

Conclusion: Rectal administration of indomethacin is an effective approach to prevent the incidence of post-ERCP pancreatitis both in high-risk and average-risk population undergoing ERCP. Moreover, how much effective randomized controlled trials are needed to further investigate the optimal timing for administration of indomethacin.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute pancreatitis (AP) is one of the most common gastrointestinal diseases requiring hospitalization with an annual incidence of 13–50 cases per 100,000 persons. It is a potentially fatal disease with an overall mortality ranging from 2 to 8%. Both epidemiology and outcomes are variable according to the different countries. Furthermore, few studies have considered the impact of hospital units on AP outcomes.

Aims & Methods: To evaluate both the trend and outcomes of acute pancreatitis according to the admitting hospital units: Surgery, Internal/General Medicine, Gastrointestinal (GI) Unit, Intensive Care Unit (ICU). This is a retrospective
cohort study based on the anonymous computerized database of hospital discharges in Veneto Region (North-East of Italy). The principal diagnosis of AP according to the International Classification of Diseases 9th revision, Clinical Modification (ICD 9-CM, code 577.0) of the hospital discharges was selected. The period from January 2001 to December 2015 was analysed. Veneto population was considered as the reference population (in the period, it varied from 4,529,823 to 4,927,527 inhabitants, with 51% females). Hospitalization, Length of stay (LOS), in-hospital mortality, need for surgery (according to the DRG 191–194, 199–201 which identified bilio-pancreatic surgery) were reported according to hospital Units. Statistics: Chi squared for trend and Odds Ratio (OR) were applied.

Results: During the analysed period, 23,389 overall hospitalizations for AP, annual hospitalization of 32 patients/100,000 inhabitants and in-hospital mortality of 3.2% were observed. Characteristics of the patients were: mean age: 62.2 +/−19.3y, 54% Males (M); Female (F) mean age: 65y +/−19.3y, male age: 39.4+/−19.3y (p < 0.05). Hospitalizations was higher in males (M: 35.4, F: 28.4, OR 1.24 (95% CI: 1.20–1.27, p < 0.05) and it increased in a stepwise progression from youngest to oldest patients (from 4.4 to 151.2 p < 0.05). A similar trend was observed when considering in-hospital mortality (from 0.5 to 10.3%, p < 0.05). From 2001 to 2015, hospitalization (32.4 to 29.5, p = 0.04), in-hospital mortality (1.41 to 0.79, p < 0.05) and need for surgery (NFS: 5.6% to 3.0%, p < 0.05) trends decreased. Conversely, admission trends increased during the analysed period both in General Medicine (from 36 to 63, p < 0.05) and Gastrointestinal (GI) units (from 14 to 29, p < 0.05). The Overall in-hospital mortality was the lowest in GI Units with a NFS of 3.6% (see Table). In comparison to General Medicine Units, GI units were associated with a low in-hospital mortality (OR: 0.37, CI 95%: 0.28–0.49, p < 0.001) whereas ICU requirement was seen in significantly more patients in AP group (59; 37%) than in ACP (5; 11%) and RAP (0%; p < 0.001). 41 (26%) of AP, 2 (4%) of ACP, but none of patient with RAP needed ventilatory support (p < 0.001), while 13 (8%) of AP patients, 1 (2.2%) of ACP and none with RAP required dialysis (p < 0.05). Mortality in AP, ACP and RAP was 29 (18%), 2 (4.4%), 0 (0%) respectively (p < 0.05).

Conclusion: The present study showed that patients with more severe disease course as compared to both ACP, while those with RAP had the least severe course.

Contact Email Address: trond.engjom@helse-bergen.no

Introduction: The Scandinavian-Baltic Pancreas Club database collects data from patients with chronic pancreatitis (CP) in Nordic countries. Grading of structural changes is important in the description of a CP cohort.

Aims & Methods: We aimed to characterise structural changes of the pancreas in patients with CP. Subjects with definitive or probable CP according to the M-ANNHEIM diagnostic-criteria were included. Structural changes were graded according to the M-ANNHEIM-classification. A subgroup was also scored by the modified Cambridge score. Clinical data on disease-duration, nutrition, exocrine function, pain, alcohol/smoking habits and frequencies of malnutrition and diabetes were collected. A grouping of the M-ANNHEIM score (A: Normal = 0, B: Minimal change = 1 + 2 and C: Moderate/marked = 3 + 4) was performed for correlation to the clinical data.

Results: The database contains 932 patients (623 men). The M-ANNHEIM-score was present from 446 subjects and both imaging scores from 93 subjects. According to M-ANNHEIM subjects were graded as: 0: Normal (8.1%), 1: Equivocal (22.9%), 2: Mild (12.1%), 3: Moderate (17.9%) and 4: Marked (17.9%). According to M-ANNHEIM subjects were graded as 0: Normal (8.1%), 1: Equivocal (22.9%), 2: Mild (12.1%), 3: Moderate (17.9%) and 4: Marked (17.9%).

Conclusion: Subjects with marked structural changes had the highest lifetime smoke-doses. There was poor correlation of structural changes to the clinical features. The two imaging scores demonstrated acceptable correlation and agreement. Poor agreement in normal/minimal-change groups may reduce the value of the scores where they are most needed. The results are presented on behalf of the SBPC study group.

Contact Email Address: nelly.muller@aphp.fr

Introduction: SPINK1 is a gene coding for the inhibitor of the cationic trypsinogen. Heterozygous mutations prevalence is estimated at 2%. They are recognized as a risk factor for chronic pancreatitis. However few data are available regarding the natural history and the risk of complications in these patients.

Aims & Methods: A prospective monocentric study was carried out from 2000 to 2016 to describe the natural history of SPINK1 mutation related pancreatitis. All patients referred for idiopathic acute and/or chronic pancreatitis with a SPINK1 mutation, were included and followed annually. Epidemiological, genetic, clinical and morphological data were collected.

Results: We included 158 patients. Mutations of SPINK1 were: heterozygous (65%), homozygous (8%) NS4S, others (27%). Median age at first symptoms was 40 years (22-71). Diagnosis was 20 [2-73] and 29 years [3-76]. During follow-up (median length:7 years), clinical manifestations were pancreatic pain (73%), pseudo-cyst (1%), acute pancreatitis (77%), cholestasis (6%), exocrine pancreatic insufficiency (EPI) (33%), diabetes (15%) and pancreatic adenocarcinoma (n = 6.4%). Calciifications and ductal abnormalities were found in 56% and 62%. Endoscopic treatment and surgery were performed for 16% and 14% of the patients. Four patients died (including 3 due to pancreatic cancer). The risk of pancreatic cancer at 55, 60, 70 and 75 years was 9.4%, 14.7%, 28.9% and 46.7%. Risk factors of cancer were calcifications (p = 0.03) and EPI (p = 0.04).

Conclusion: SPINK1 mutations should be searched for in young patients with idiopathic pancreatitis. Risk of pancreatic cancer is probably underestimated.

Introduction: The Scandinavian-Baltic-Pancreatic-club database collects patients with chronic pancreatitis (CP) from Nordic countries. Description of exocrine pancreatic insufficiency (EPI) and consequences is important in characterization of CP cohorts.

Aims & Methods: Characterise EPI from CP in a Northern European cohort. Patients with definitive or probable CP (M-ANNHEIM diagnostic criteria) were included from nine centres. Demographic data, body-mass index (BMI), faecal elastase (FE), enzyme-doses and lab-parameters were collected. Values: Mean (SD) unless otherwise stated. EPI-classification grouped patients as follows: A: Normal; B-Mild: EPI not requiring enzymes, C-Proven: EPI requiring enzymes.

Clinical parameter (A) (B) (C) Proven (%)

Exocrine pancreatic function (%) 33 16 51

Faecal Elastase (µg/g) (mean (SD)) p < 0.001

368 (161) 128 (144) 51 (69)

Nutrition: BMI (kg/m²) (mean (SD)) p < 0.001

24.6(4.9) 23.7(4.3) 22.6(4.3)

Frequency BMI < 18.5 (%) p < 0.005

5 16

Vitamin D: Frequency <25µg/L (%)(I vs II) p < 0.005

7.4 23.7 17.6

Enzyme Treatment (lipase-units/day) (median [IQR range])

0-75000 [7500-15000]

Hemoglobin: (median [IQR range]) p < 0.05

11.8(2.7-3.0) 10.7(2.8)

Faecal Elastase and disease duration (years)**

<10: 143(175) > 10: 91(18)

*p < 0.001. 9% received <5000 lipase-units/day. 14 subjects having FE > 200 received enzymes, 48 subjects with FE < 100 received no enzymes.

**no age/sex differences in EPF

Conclusion: In our material frequency of EPI is higher than reported in the NAPS2 study (31%). Consequences of EPI were lower BMI, more frequent underweight, higher enzyme-doses and lower haemoglobin. Need for vitamin D supplements was highest in the group with mild EPI not receiving enzymes. Exocrine function was correlated with disease duration, but neither with age nor gender.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0774 FLUID AND HCO3− SECRETION AND CFTR ACTIVITY IS INHIBITED BY CIGARETTE SMOKE EXTRACT IN GUINEA PIG PANCREATIC DUCTAL CELLS

Introduction: Smoking represents an independent risk factor for the development of chronic pancreatitis (CP). It is well documented that secretion of pancreatic ductal alkaline fluid (which is regulated mostly by the anion exchanger and CIC) is diminished in CP.

Aims & Methods: In this study we would like to understand whether smoking has any effects on pancreatic ductal fluid and HCO3− secretion. Guinea pigs were exposed to cigarette smoke four times a day for 30 min for 6 weeks. The CFTR expression was analysed by immunohistochemistry. Pancreatic ducts were isolated from guinea pig pancreas. Cigarette smoke extract (CSE) was prepared by smoking of 15 cigarettes into 10 ml distilled water by a smoking machine. Intracellular Ca2+ concentration and pH were evaluated by microfluorometry. Flow secretion was measured by video microscopy. CFTR currents were detected by whole cell configuration of patch clamp technique.

Results: Cigarette smoking significantly diminished the expression of CFTR and the fluid and HCO3− secretion in guinea pig pancreas. CSE dose dependently decreased fluid and HCO3− secretion in guinea pig pancreatic ducts via inhibition of anion exchanger, Na+-H+ exchanger and Na+-HCO3− cotransporter and also forskolin-stimulated Cl− current of CFTR Cl− channel. CSE incubation altered the pattern of carbobach-induced Ca2+ signal in pancreatic ducts suggesting that some of the inhibitory effects may be regulated by calcium signalling.

Conclusion: Cigarette smoking and CSE inhibits pancreatic ductal fluid and HCO3− secretion and the activity of the CFTR which may play role in the smoke-induced pancreatic damage. This study was supported by OTKA, MTA, SZTA and UNKp.

Introduction: Rapid on-site cytologic evaluation (ROSE) for determining the suitability of a specimen often provides high efficacy of endoscopic ultrasound-guided fine needle aspiration (EUS-FNA). In our center, we propose an additional role of ROSE in histological diagnosis aimed at improving diagnostic accuracy.

Aims & Methods: From January 2009 and December 2015, 215 patients were evaluated who underwent both EUS-FNA for pancreatic solid lesions and surgery. Aims & Methods: From January 2009 and December 2015, 215 patients were evaluated who underwent both EUS-FNA for pancreatic solid lesions and surgery. We retrospectively compared the diagnostic performance of ROSE during EUS-FNA with the final diagnosis confirmed by surgically resected specimens. Diagnosis by ROSE using Diff-Quik® was carried out by both a cytopathologist and an endoscopist.

Results: The median of needle passes required for ROSE was 1 (range, 1–5). Final diagnoses for the 215 lesions were pancreatic ductal adenocarcinoma (PDAC; n = 102), pancreatic ductal endosomouscaroma (PDASC; n = 9), pancreatic neuroendocrine tumor (pNET; n = 30), solid pseudopapillary neoplasm (SPN; n = 9), metastatic tumors (n = 4), and acinar cell carcinoma (ACC; n = 1). Primary lesions for metastatic tumors in the pancreas were renal cell cancer (RCC; n = 2), small cell lung cancer (SCLC; n = 1), and colon cancer (n = 1). ROSE could not diagnose 14 cases. When adenocarcinoma (excluding mucinous) was suspected by ROSE, ROSE diagnosed 94.6% (159/168) of adenocarcinomas. When special type tumor (pNET, SPN, RCC, SCLC) was suspected by ROSE, ROSE diagnosed 96.4% (27/28) of special type tumor.

Conclusion: All adenocarcinomas suspected by ROSE were malignant tumors. When special type tumor (pNET, SPN, RCC, SCLC) was suspected by ROSE, Diagnostic accuracy of ROSE was 96.4%. Diagnostic accuracy using ROSE is high agreement in final histological diagnosis. It is suggested that ROSE may also be useful for diagnosis of special type tumor.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** Pancreatic ductal adenocarcinoma (PDAC) has one of the most dismal prognoses of all cancer types. Diagnostic techniques for early malignant lesions are limited, which shows an evident need to understand the pathomechanism leading to PDAC and find a suitable marker for early detection. Initial processes in PDAC development involve acinar to ductal metaplasia (ADM) with further neoplastic progression into four pancreatic intraepithelial neoplastic (PanINs) stages. After accumulation of mutations, these lesions will further evolve into PDAC. Gastrokine 1 & 2 (GKN1 & GKN2) are secreted proteins found only in the stomach where they are involved in gastric epithelial homeostasis. While current research focuses on the exploration of tumor-suppressive properties of GKN1 in gastric tumors, nothing is known about GKN function in other organs. A whole genome microarray of KrasG12D Ptf1aCre (KC) mice, a mouse model with predisposition to pancreatic cancer, revealed strikingly high gastrokine expression. We will further analyze the involvement of GKNs in the development and progression of PDAC and explore the possibility to use them as biomarkers.

**Aims & Methods:** GKN2 expression was confirmed by qPCR in human and mouse pancreas samples. The presence of GKN1 was verified by western blot and immunohistochemistry (IHC) in mouse pancreas. Mouse pancreatic juice and serum were analyzed by proteomic analysis. To investigate the role of GKNs in carcinogenesis in vivo, we established mouse models by intercrossing KC mice with Gkn1-/- and Gkn2-/- mice respectively. The capacity of acinar cells lacking Gkn1 and Gkn2 to transdifferentiate into ductal lesions in vitro was tested.

**Results:** GKNs were upregulated during early stages of pancreatic carcinogenesis in mouse and peri-tumoral human pancreas. GKNs were absent in healthy pancreas and tumor tissue. IHC showed specific GKN1 expression in premalignant PanIN lesions, while GKN2 positive cells were also localized in the stroma. ELISA and proteomic analysis in mice confirmed the secretion of GKNs into pancreatic juice. Preliminary results from the first timepoint of analysis showed accelerated tumor development in GKN1-/- and GKN2-/- mice. Wild type acinar cells transdifferentiated into ductal lesions only in the presence of TGFα. On the contrary, Gkn1-/- and Gkn2-/- acinar cells transdifferentiated spontaneously, and resulted in a higher number of ADMs.

**Conclusion:** We identified for the first time specific gastrokine expression in pre-neoplastic lesions in human and mouse pancreatic tissue. The secretion into pancreatic juice during carcinogenesis could make gastrokine a potential biomarker for the detection of early pancreatic premalignant lesions. With our mouse models we will provide in vivo evidence on the role of GKNs as potential tumor suppressors in the pancreas.

**Introduction:** Pancreatic cancer is one of the deadliest malignancies and there are no effective therapies for it. According to a search of The Cancer Genome Atlas (TCGA) and recent studies in Kirsten rat sarcoma (K-RAS) tumors, tumour protein (TP53), Cyclin-dependent kinase inhibitor (CDKN2A) and Cyclin-dependent kinase inhibitor (CDKN2B) are the most frequent genetic aberrations in human pancreatic cancer (91%, 63%, 53% and 34% of cases, respectively). Macropautophagy (Large-scale removal of cytoplasmic components by autophagy) has been implicated in some of human diseases, and it plays a complex role in pancreatic cancer.

**Aims & Methods:** We aimed to investigate autophagy response in a new humanized genetically-modified adult mouse model of pancreatic cancer. To induce pancreatic tumours, control mice expressing oncogenic K-RAS (K-RAS) and ShRNA-targeting tumour suppressors Egr3, Cdkn2a and Cdkn2b (liverinhibitors-KTCC) were injected into pancreas of 9-week old adult mice. Autophagy was detected by immunofluorescence staining for autophagocytic protein light chain-3 (LC3-L) and Lysosomal-associated membrane protein 1 (LAMP-1). Additionally, the expression of autophagic protein LC3, autophagy related protein 7 (ATG7), LAMP-1 and P62 were determined by western blot. In vitro, pancreatic duct epithelial cells of normal mice were primary isolated, LC3 was determined by immunofluorescence staining in the liverinhibitors-KTCC infected primary cells.

**Results:** Mice developed pancreatic cancer ten weeks after liverinhibitors-KTCC injection, both in macrography and histopathology analysed. The mRNA levels of autophagic genes Atg7 and Atg12 were up regulated. In addition, the LC3-L/LAMP-1 positive area was significantly increased. And co-localization of LC3-L and LAMP-1 was found in pancreatic tumour sections. Moreover, the increased protein levels of ATG7, LC3, LAMP-1 and decreased P62 protein was observed in the pancreatic tumour tissues. In vitro, the protein level of LC3 in the liverinhibitors-KTCC infected primary cells was increased by 6 times when compared with that in the control primary cells (P = 0.0104).

**Conclusion:** An adult mouse model of pancreatic cancer can be generated by altering Kras, Tp53, Cdkn2a and Cdkn2b genes. Besides, increased autophagy was measured during the development of pancreatic cancer. These findings provide considerable insight into the role of autophagy in pancreatic cancer and autophagy inhibition might be a potential target in treating pancreatic cancer.

**Introduction:** Hyperthermia as a positive additive to chemotherapy is described in multiple studies. Despite controversial results hyperthermic intraperitoneal chemotherapy (HIPEC) is a standard treatment option for some types of gastrointestinal cancer that invades peritoneum. However, the results of clinical data and basic research are uneven. Moreover, there is a lack of fundamental knowledge on additive cytotoxic effect of hyperthermia on cancer cells of different origin.

**Aims & Methods:** Our aim was to analyse gastrointestinal cancer cell response to various hyperthermia levels, accomplished by chemotherapy, in a manner of cell cytotoxicity, apoptosis and intracellular cisplatin concentration. Cancer cell lines of gastric (AGS), pancreatic (T4M4) and colorectal (Caco-2) origin were exposed to cisplatin and different temperature regimens (37°C to 45°C) either in isolated manner, or in combination. Cells were treated for one hour, mimicking HIPEC timing in clinical setting. The intracellular concentration of cisplatin was measured immediately after experiment by mass spectrometry. 48 hours later changes of cell viability and apoptosis rates depending on temperature in addition to cisplatin treatment were evaluated by MTT and Annexin7 AAD flow cytometry respectively.

**Results:** Response of AGS to hyperthermia was as implied. Viability of the cells was gradually decreasing by raising the temperature. CACO-2 cells had no significant response to temperature rise up to 42°C, but at 43°C viability dropped by 14% constantly remaining at higher temperatures. T4M4 cells acted in unpredictable manner, whereas decreasing viability by 30% in the interval between 37°C to 42°C and 20% increase at 43°C was observed. Following simultaneous exposure to hyperthermia and cisplatin we observed no additive temperature effects in interval between 37°C to 45°C. However, at particular temperature regimes, we observed temporary proliferation increase: AGS – at 42°C (33%); T4M4 – at 43°C (32%). Higher temperatures dramatically inhibited AGS – by 70%, T4M4 - by 76%. There was the linear pattern of slight decrease (up to 26% at 45°C) of viability in CACO-2 cells. Isobologram analysis of combined hyperthermia and cisplatin treatment revealed strong antagonism of hyperthermia and chemotherapy in all analyzed cell lines. Nevertheless, hyperthermia of 43°C in addition to cisplatin promoted apoptosis of AGS cells by 33%, CACO-2 by 26%, T4M4 by 19%. Moreover, application of hyperthermia (43°C) could contribute to increase of intracellular cisplatin concentration by 30%, 20% and 18% AGS, CACO-2 and T4M4 cells respectively.

**Conclusion:** Our results indicate that there is no linear contribution of hyperthermia to chemotherapy in all analyzed cell lines. Therefore, in clinical setting it should be applied individually, regarding cancer type. Moreover, particular temperature can worsen the treatment and increase cancer cell growth.

**Introduction:** Cachexia is a debilitating wasting disease associated with cancer. It is a complex syndrome that affects multiple organ systems, and causes significant morbidity and mortality. In the case of pancreatic cancer, cachexia is one of the most important causes of death. Cachexia is characterized by a complex interaction between the tumor and the host, leading to a state of unexplained weight loss, anorexia, muscle wasting, and a low-grade inflammatory response. The cause of cachexia is multifactorial, involving both tumor-derived and host factors. The exact mechanisms that underlie cachexia in pancreatic cancer are not fully understood, but it is thought to be related to the immune response and the production of cytokines and other inflammatory mediators. The aim of this study was to investigate the involvement of cachexia in the local spread of pancreatic ductal adenocarcinoma.
Introduction: Cachexia is a multifactorial syndrome, characterized by the loss of skeletal muscle mass which is not fully reversible by nutritional support. Activin play a dominant role in the development and progression of cachexia and also in tumor cell growth in pancreatic adenocarcinoma via non-SMAD (MAPK, PI3K/Akt) pathways. Cachexia might be a keypoint in pancreatic ductal adenocarcinoma (PDAC) progression and is involved in cachexia in a subset of pancreatic cancer. The goal is to assess the significance of ezrin protein expression in PDAC related to the clinical stage and survival.

Methods: Our goal was to assess the significance of activin protein expression in PDAC related to the clinical stage and survival. There were included patients with histological proven of adenocarcinoma (n = 115) and a median follow-up of 24 months (range 3–124). The plasma levels of activin were analyzed using western blot. The t test was used to determine the differences between the two groups, Kaplan-Meier curve and log-rank tests were used to determine the differences in survival curves of studied patients.

Results: Activin was overexpressed more frequently in PDAC compared to controls (p = 0.001), and has been closely related to advanced clinical stage (stage III-IV), tumor size, location and with the presence of metastasis (p < 0.05). Activin expression was higher in patients with type 2 diabetes (p = 0.04). No relationship between activin level and the patients age, sex or tumor size, was noted. Patients with activin high expression had a shorter survival time than PDAC patients with activin low expression (Log-rank = 4.35; p = 0.03).

Conclusion: Activin pathway is related to cachexia and the local spread of PDAC, metastasis, the presence of diabetes and survival.

Discussion: The aim of this study was to assess QoL during chemotherapy in patients with advanced pancreatic cancer. Twenty-one Japanese patients with unresectable advanced pancreatic cancer and performance status 0–1 were included in this study. All patients were treated with FFX or GnP as first-line chemotherapy. QoL was assessed using the European Organization for Research and Treatment for Cancer Quality of Life Core Questionnaire (EORTC QLQ-C30), and anxiety and depression were measured using the Hospital Anxiety and Depression Scale (HADS) at baseline and 2 weeks and every month after initiation of chemotherapy. Changes between score at baseline and median score after chemotherapy were compared using Wilcoxon signed-rank test. Continuous variables are presented as median (range).

Results: Thirteen male and 8 female patients were included, with a median age of 65 (59–72) years and BMI of 21.2 (16.0–26.2) kg/m². The chemotherapy regimens were FFX in 5 men and 2 women, modified-FFX in 4 men and 4 women, and GnP in 4 men and 2 women. Eight patients took opioids for pain, and 4 received celiac plexus neurolysis. Regarding global health status (GHS) and functional scales in QLQ-C30, baseline scores were: GHS: 50 (17–92%); physical: 87 (53–100%); role, 83 (33–100%); emotional: 67 (33–100%); cognitive: 83 (33–100%); and social: 67 (11–100%). After chemotherapy, role function scale was decreased significantly (p = 0.04), and nausea (p = 0.02) and diarrhea (p = 0.049) were more frequently observed, while global health status (p = 0.002). In analysis according to patients’ background, a lot of evaluation in patients with BMI < 21 kg/m² tended to be worse than in those with BMI ≥ 21 kg/m² after chemotherapy. Regarding HADS, in baseline, 5 patients reported depression, 7 borderline depression, 5 anxiety requiring intervention, and 5 anxiety requiring follow-up. There were no significant changes in HADS after chemotherapy.

Conclusion: In patients with advanced pancreatic cancer, GHS and mental status had already deteriorated at baseline. Although pain scale might be improved due to analgesic treatment, role function scale, nausea and diarrhea became worse during chemotherapy. In particular, QoL tended to deteriorate in lean patients. These results indicate that pain as well as QoL factors should always be considered to manage chemotherapy properly in patients with advanced pancreatic cancer.

treated by EUS-CPN. Clinical information was obtained retrospectively from the medical records and all patients reporting symptoms until the patient died or was lost to follow-up. Between November 2014 and March 2017, 70 patients with PC pain were enrolled. We performed EUS-CPN by injection of 5 ml of bupivacaine mixed with 15 ml of pure ethanol on the celiac plexus, and performed fine needle aspiration guided fine needle aspiration needle. Treatment response was assessed by self-reported pain relief and change in the daily dose requirement of morphine. Treatment response was defined as to decrease or stay of the same amount of morphine consumption after EUS-CPN, or achieve morphine dosage level within 4 weeks after EUS-CPN if morphine consumption temporarily elevated because of the delayed response of EUS-CPN. Pain evaluation was conducted at 1 week, 4 weeks, and 12 weeks after EUS-CPN and tumor disease progression. Repeat EUS-CPN was statistically significant and confidence intervals were two-sided; a p value at diagnosis or death. Survival probability was calculated with the Kaplan-Meier method. Jaundice was the leading presentation symptom in 74 (17%), weight loss in 164 (37.7%), pain in 105 (24%), new-onset diabetes in 43 (9.9%). Diagnosis was incidental in 24 cases (5.5%) or related with undetected complaints in other 24 (5.5%). The diagnostic delay was significantly shorter for patients with jaundice (mean 1.1 months) compared to those with pain (3.6), new-onset diabetes and cachexia (mean 3.6 months). PDAC independent risk factors for developing PDAC, such as smoking, obesity, alcohol intake, diabetes and PDAC family history, and diagnostic delay has not been explored specifically.

Aims & Methods: We aimed to investigate the association between presentation symptoms, diagnostic delay, risk factors for PDAC at stage at diagnosis and survival. This was a retrospective analysis of a single-centre cohort of prospectively evaluated PDAC patients with the above mentioned data recorded in a dedicated database. Fisher test for comparison of proportions for categorical variables and Student’s t-test for continuous variables were employed. Multiple logistic regression analysis was employed to investigate factors associated with metastatic stage at diagnosis or death. Survival probability was calculated with the Kaplan-Meier curve and Cox analysis was employed to calculate hazard ratios (HR). Tests of statistical significance and confidence intervals were two-sided; a p < 0.05 was considered to be statistically significant.

Results: In 434 PDAC patients the mean diagnostic delay was 4 months (95% CI 3.6–4.4). Jaundice was the leading presentation symptom in 74 (17%), weight loss in 164 (37.7%), pain in 105 (24%), new-onset diabetes in 43 (9.9%). Diagnosis was incidental in 24 cases (5.5%) or related with undetected complaints in other 24 (5.5%). The diagnostic delay was significantly shorter for patients with jaundice (mean 1.1 months) compared to those with pain (3.6), new-onset diabetes and cachexia (mean 3.6 months). PDAC independent risk factors for developing PDAC, such as smoking, obesity, alcohol intake, diabetes and PDAC family history, and diagnostic delay has not been explored specifically.

Introduction: Pancreatic cancer is a lethal disease and the fifth most common cause of cancer-related death in Korea. Pancreatic cancer patients show dismal prognosis with a 5-year survival rate less than 10%, because the majority of patients are diagnosed in advanced stage. Since the late 1980s, gemcitabine-based chemotherapy has been used as a mainstream of metastatic pancreatic cancer (mPC) treatment and various combination therapies (such as combination with capcitabine or erlotinib) had been attempted to improve the patients’ survival, so far. Recently, MPACT trial, a randomized phase III trial showed that combination of gemcitabine and nab-paclitaxel had statistically significant survival benefit compared with gemcitabine monotherapy. Based on the results of this trial, gemcitabine with nab-paclitaxel combination therapy is currently being used as a standard therapy for pancreatic cancer patients. However, only 2% of the MPACT trial study population was Asian, and other researches on Asian population group are also lacking. Therefore, we investigated treatment efficacy and safety of gemcitabine plus nab-paclitaxel combination therapy for mPC treatment in Korean population.

Aims & Methods: Total 66 metastatic pancreatic cancer patients treated with gemcitabine (1000mg/m2) and nab-paclitaxel (125 mg/m2) regimen (on day 1, 8, 15 of a 28-day cycle) as the first line chemotherapy from February 2016 were identified using the Severance Hospital Pancreatic Cancer Cohort Registry. Treatment efficacy (overall survival (OS), progression-free survival (PFS), objective response rate) and treatment-related adverse events (AE) of patients (occurrence rate, severity grade and dose-intensity) were analyzed.

Results: The median follow-up period was 7.4 months (range 1.5–14.9 months); during this period, 21 (31.8%) patients died. Median cumulative dose of gemcitabine and nab-paclitaxel were 13,000 mg/m2 and 1487.5 mg/m2. The median OS, PFS and objective response rate were 12.0 months (95% confidence interval [CI] 9.515–14.485), 7.8 months (95% CI 5.021–10.579) and 48.5%, respectively. The incidence of neurotoxicity was 54.5% and 12 (18.2%) patients experienced grade $\geq$ 3 neurotoxicity. 30 (45.5%) patients showed grade $\geq$ 3 gastrointestinal AE was observed in 11 (16.7%) patients and 28 (42.4%) patients experienced dermatologic AE such as alopecia and skin eruption. About 59% of patients experienced treatment delays due to adverse events. Dose reduction was performed in 39 (59.1%) patients and 14 patients experienced treatment cessation due to severe AE.

Conclusion: These results suggest that gemcitabine and nab-paclitaxel combination therapy is effective for metastatic pancreatic cancer treatment in East-Asian population group. Similar to previous studies, this combination therapy showed remarkable neurotoxicity and myelosuppression. Careful monitoring and proper management during chemotherapy is required.

Disclosure of Interest: All authors have declared no conflicts of interest.

hENT1-positive patients (MST: 25 versus 25, respectively). We suspect that genetic factors may play a role in this observed variability.

**Aims & Methods:** In the present study, we evaluated hENT1 and dihydroxyproline-dine dehydrogenase (DPD: enzyme involved in the degradation of teaglutin) expression in EUS-FNA samples for evaluating and predicting the clinical effect of ES-WF (n=4) or pain (n=5) following EUS-FNA sampling. Prior to ES-CRT administration. In total, 95 formalin-embedded PDAC samples were obtained. In the samples determined to have sufficient material remaining following cytological-histological diagnosis (n=76), hENT1 expression was evaluated via immunohistochemistry (IHC) examination and DPD expression was observed using ddPCR analysis of hENT1, a further assessment of DPD expression was carried out in those samples determined to have sufficient material remaining (n=58).

**Results:** By reusing the EUS-FNA specimens after diagnosis of PDAC, hENT1 and DPD expression could be sufficiently assessed in 79.2% (76/95) and 61.1% (58/95) of these cases, respectively. In those sufficient for hENT1 testing, 67.1% (51/76) were found to be positive. And in those sufficient for DPD testing, 27.6% (16/58) were found to be positive. MST was significantly longer in hENT1-positive patients (20.8 versus 5.4 months, P < 0.001). As for DPD, MST was significantly longer in DPD-negative patients (33 versus 14 positive, P < 0.001). In the multivariate model including pretreatment clinical factors (age, sex, tumor location, tumor size, UICC-T classification, hENT1 expression, and DPD expression) and the clinical response after GS-CRT (response of GS-CRT, reduction rate in serum CA19-9 level, and distant metastasis after GS-CRT), only hENT1 expression (HR = 3.51; 1.54-7.98, P = 0.003) and DPD expression (HR = 0.232; 0.108-0.496, p < 0.001) were found to be significant independent prognostic factors.

**Conclusion:** hENT1 and DPD expression observed in EUS-FNA samples can be useful clinical predictors in PDAC cases treated with GS-CRT.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Statins are widely prescribed both for primary and secondary prevention of coronary artery disease and for the treatment of dyslipidemia. Several studies evaluated the association between statin use and the onset of pancreatic cancer (PDAC) in order to evaluate a possible chemopreventive effect, with inconsistent results. Previous systematic reviews and meta-analysis evaluating researches published up to 2012 did not find any association to the risk, but the last few years of studies with interesting results have been published.

**Aims & Methods:** The aim of our study was to conduct a new systematic review and meta-analysis to clarify this association. A comprehensive literature search of PUBMED for articles published up to November 2016 and abstracts presented between 2012-2016 at the DDW and ASCO conventions was carried out. Eligible studies were case-control studies (CC), cohort studies (C) and randomized controlled trials (RCTs) assessing the effect of statin use on the risk of PDAC, compared with placebo or no treatment. Studies had to report Odds Ratio (OR), Relative Risk (RR), or Hazard Ratio (HR), estimates with 95% confidence interval (CI), or provide sufficient data for their calculation. Pooled adjusted ORs with corresponding 95% CIs were calculated using random effect model. Publication bias was assessed through Begg and Mazumdar test. Heterogeneity was assessed by means of the I² value.

**Results:** A total of 21 studies (12 CC, 6 C, 3 RCTs) contributed to the analysis. A total of 11833 PDAC patients and 2991084 controls were included. The pooled incidence of PDAC was 0.27% (3161/1167130) among statin users and 0.44% (8144/1835153) among the non-users. The overall pooled result for all studies evaluated a reduced risk of PDAC among statin users (OR 0.82; 95% CI 0.80–0.84; p = 0.0019), compared to non–statin users (a 28% protective effect). The protective effect was limited to case-control studies (OR 0.72; 95% CI 0.56-0.93) and not to cohort (OR 0.93; 95% CI 0.73–1.19) nor RCTs (OR 1.04; 95% CI 0.81–1.32). New publication bias was found.

**Conclusion:** This is the first meta-analysis showing that statins exert a protective effect on the incidence of PDAC. Further studies taking into account statin dose, duration and subgroups of patients are needed in order to clarify the association.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0791 AN IMPROVED DIGESTIVE POLYMERASE CHAIN REACTION PROTOCOL TO CAPTURE LOW-COPY KRAS MUTATIONS IN PLASMA CELL-FREE DNA BY RESOLVING "SUBSAMPLING" ISSUES**

**Introduction:** Genetic alterations responsible for the initiation of cancer may serve as immediate biomarkers for early diagnosis. Plasma levels of circulating cell-free DNA (cfDNA) have been shown to be higher than those in healthy individuals; however, the major technical challenge for the widespread implementation of cfDNA genotyping as a diagnostic tool is the insufficient sensitivity and specificity of detecting early-stage tumors that shed low amounts of cfDNA. Droplet Digital PCR (ddPCR) has rather high precision and sensitivity for absolute quantification (0.01%). However, due to very low target concentrations of cfDNA in plasma, there may be an intrinsic error due to “subsampling” (Ref. 1). This is caused by limited cfDNA yield and missing targets at very low abundance during compartmentalization in ddPCR-based liquid biopsy assays. Such issues potentially result in large variations or errors in quantification, even when using highly accurate platform. Using ddPCR technology for early cancer diagnosis and risk stratification is still challenging.
Aims & Methods: In this study, we aimed to overcome the subsampling issue and to establish a ddPCR-based framework for quantification of rare tumor cell-derived mutant alleles for non-invasive diagnosis of gastrointestinal cancer. To establish more reliable ddPCR protocol for quantification of low-frequency alleles within a limited cDNA pool, two-step multiplex ddPCR targeting eight relevant mutant KRAS variants was examined using a Bio-Rad QX200 droplet digital PCR platform. Plasma samples from patients with colorectal (n=10) and pancreatic cancer (n=9) were evaluated, and cDNA from healthy volunteers (n=30) was utilized to calculate reference intervals.

Results: Limited cDNA yields in patients with resectable colorectal and pancreatic cancers did not meet the requirement for efficient capture and quantification of mutant KRAS. The subsampling issues and tic cancers did not meet the requirement for efficient capture and quantification of rare mutant alleles by ddPCR. To overcome the subsampling issues and achieve better assay specificity, we attempted pre-amplification of plasma cDNA using primers flanking KRAS exon 2 as the first-step PCR. Eight pre-amplification cycles followed by a second-run ddPCR were sufficient to approximate 5000-10,000 target alleles/ng cDNA, resolving the subsampling issue; furthermore, the signal-to-noise ratio for rare mutant alleles against the massive background was presented by the wild-type allele was significantly enhanced. The cut-off limit of reference intervals for mutant KRAS was determined to be ~0.09% based on samples from healthy individuals.

Conclusion: The modification introduced in the ddPCR protocol facilitated the quantification of low-copy alleles carrying driver mutations, such as oncogenic KRAS, in localized and early-stage cancers using small blood volumes, thus offering a minimally invasive modality for timely diagnosis.

Introduction: Rapid on site evaluation for endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) of the pancreas provides immediate information regarding cellular adequacy, avoiding repeated procedures.

Aims & Methods: The aim of this study was to evaluate the impact of ROSE in EUS-FNA of solid pancreatic lesions. Retrospective study of consecutive EUS-FNA of solid pancreatic lesions, in a tertiary center, between 2012 and 2016. A total of 259 EUS-FNA were performed in patients with mean age of 63.4 (+/-12.8) years. The anatomical distribution of the lesions was: 56.4% in the head, 17% in the body, 10% in the uncinate process and 5.8% in the tail. The mean number of passes were 3.3 (+/-1.4) and the needle size was 25G in 60.8% and 22G in 23.8%. ROSE was performed in 34.7% of the punctures (23.6% along with the initial EUS-FNA), with a mean number of passes 3.4 (+/-1.9). The diagnostic yield of initial EUS-FNA without ROSE was 44.8% vs 83.6% when ROSE was performed (p < 0.001). When not conclusive, there was no significant differences in the diagnostic yield of the repeated EUS-FNA (with and without ROSE). Beyond ROSE in the first puncture, higher levels of Ca 19.9 (199 vs 10 ng/mL, p = 0.001), size of the lesion (36.1 vs 29.8 mm, p < 0.001), invasion of adjacent structures (64.6% vs 43%), and malignancy (73.2% vs 25.4%, p < 0.001) were associated with EUS-FNA diagnostic accuracy. In multivariate analysis, ROSE (p = 0.001) and the size of the lesion (p = 0.023) were independent predictors of adequate diagnostic samples. In this regard, ROSE improves the definitive diagnosis in solid pancreatic lesions (duodenal adenocarcinoma 54.7%), benign in 25.8% and indeterminate in 9.3%.

Conclusion: In agreement with the reported evidence, ROSE along EUS-FNA improved the diagnostic yield in solid pancreatic lesions and should be considered whenever possible in the first procedure, until an overall adequate diagnostic yield (>80%) is achieved.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Postoperative digestive fistula remain a challenging condition associated with a high morb-mortality, unsatisfactory healing rates and high refractoriness. The limitation of current approaches highlights the need for a better therapeutical strategy in terms of both long-lasting efficacy and safety. Mesenchymal stem cell (MSCs) are strongly involved in tissue injury repair. MSCs feature an immune-privileged status while displaying pro-angiogenic,

Tuesday, October 31, 2017 09:00-17:00
Endoscopy and Imaging II - Hall Tapp
and antifibrotic properties. Increasing evidences point out MSC action via subcellular extracellular vesicles (EVs). MSC EVs recapitulate the therapeutic properties of their cellular counterparts while offering remarkable advantages in terms of safety (no proliferation, no differentiation, no vascular occlusion following administration) and shelf life stability. Herein, we evaluated, in vivo and in vitro, the healing potential of MSC EVs delivered through a thermoresponsive gel (Pluronic F127) allowing the administration in a sol state through a catheter and gelation in situ at body temperature to retain EVs at fistula site. 

Aims & Methods: Seventeen esophageal fistulas were surgically created by placing two plastic stents during 30 days into the neck of 9 pigs and randomized into control group (n = 6) and treated groups (gel alone n = 6 and gel-EVs n = 5). In the gel-EVs group, Pluronic F127 gel contained allogeneic EVs collected from the swine adipose stem cell conditioned medium. Cellular-to-nuclei ratio demonstrated enlarged, while cancer cells were characterized by irregular size and autofluorescence imaging in gastric tissue. Under MPM, gastric dysplasia tissue were completely and radiologically evaluated of fistula healing was performed at day 30 and day 45, before histological assessment.

Results: All fistulas were successfully induced at day 30. At day 45, the control group featured open internal and external fistula orifices in all pigs. For this group, radiological evaluation showed open fistula tracts, which were confirmed by histology. In the gel group and gel-EVs groups, radiological examination showed a complete fistula closure in 67% (4/6) and 100% (5/5) of the animals, respectively. In the gel group, histological analysis confirmed a complete fistula for 3 from 6 cases while a partial closure was observed for 1 case from 6. In the gel-EVs group, histological complete fistula closure was reported for 4 from 5 cases while a partial closure was evidenced in 1 from 5 cases. In comparison with control group, treated fistulas showed a reduced inflammatory infiltrate and fibrosis and an enhanced angiogenesis, especially in the gel-EVs group.

Conclusion: This study provides the first evidence in the literature that MSC-EVs may represent a promising treatment effect in a pre-clinical animal model. EVs were characterized and fully administered via a thermoresponsive Pluronic F127 hydrogel, gelling in situ to enable EV retention in the fistula tract. Besides, the gel further provided a proangiogenic and an anti-inflammatory effect. The combined action of MSC EVs and the gel enhanced the healing associated with an anti-fibrotic effect in the esophageal fistula model. This investigation paves the way towards a future subcellular localized fistula therapy merging safety and efficacy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Compared with histopathology, real-time histology or virtual biopsy is important for clinical diagnosis, especially for endoscopic examination. Based on two photon fluorescence (TPEF), multiphoton microscopy (MPM) imaging were compared by the experienced pathologist. Cellular-to-nuclei ratio demonstrated enlarged, while cancer cells were characterized by irregular size and autofluorescence imaging in gastric tissue. Under MPM, gastric dysplasia tissue were completely and radiologically evaluated of fistula healing was performed at day 30 and day 45, before histological assessment.

Results: All fistulas were successfully induced at day 30. At day 45, the control group featured open internal and external fistula orifices in all pigs. For this group, radiological evaluation showed open fistula tracts, which were confirmed by histology. In the gel group and gel-EVs groups, radiological examination showed a complete fistula closure in 67% (4/6) and 100% (5/5) of the animals, respectively. In the gel group, histological analysis confirmed a complete fistula for 3 from 6 cases while a partial closure was observed for 1 case from 6. In the gel-EVs group, histological complete fistula closure was reported for 4 from 5 cases while a partial closure was evidenced in 1 from 5 cases. In comparison with control group, treated fistulas showed a reduced inflammatory infiltrate and fibrosis and an enhanced angiogenesis, especially in the gel-EVs group.

Conclusion: This study provides the first evidence in the literature that MSC-EVs may represent a promising treatment effect in a pre-clinical animal model. EVs were characterized and fully administered via a thermoresponsive Pluronic F127 hydrogel, gelling in situ to enable EV retention in the fistula tract. Besides, the gel further provided a proangiogenic and an anti-inflammatory effect. The combined action of MSC EVs and the gel enhanced the healing associated with an anti-fibrotic effect in the esophageal fistula model. This investigation paves the way towards a future subcellular localized fistula therapy merging safety and efficacy.

Introduction: Type 2 diabetes is associated with fatty liver disease which are highly prevalent, often overlapping metabolic disorders where upstream insulin resistance is thought to be a common pathogenic driver. Simultaneous treatment of both conditions has been reported with insulin sensitizing interventions including oral or intravenous glucose receptor agonists, TZDs), and bariatric surgery. Duodenal Mucosal Resurfacing (DMR) is a minimally invasive endoscopic procedure that has demonstrated glycemically efficacy in patients with T2D seemingly via an insulin sensitizing mechanism. We report data supporting 12-mo durability of improved metabolic indices in patients with T2D after a single DMR procedure in a single-arm, open-label, multicenter study.

Aims & Methods: In this endoscopic DMR procedure, the duodenal mucosa was treated with hydrothermal ablation using a patented balloon catheter. Efficacy was analyzed in a modified intent-to-treat cohort (mITT, patients who received ≥1 ablation) stratified into baseline alanine aminotransferase (ALT) level tertiles: lowest (ALT ≤ 20 U/L), middle (20 < ALT ≤ 35 U/L), and upper (ALT > 35 U/L). Change from baseline (ALT) was examined across tertiles. The primary end point was change from baseline ALT level at 12-mo post-DMR. Change from baseline ALT level at 12-mo post-DMR was 0.72%; respective body weight changes were −1.5(4.9)% (P = 0.003), −1.0(7.0)% (P = 0.003), −0.3(1.1)% (P = 0.003), and −0.3(1.1)% (P = 0.003). In the middle and lowest tertiles, 12-mo ALT reductions were −4(6)% and −2(3)% U/L.

Conclusion: A single DMR procedure in patients with T2D produced significant reductions in HbA1c up to 12 months in the total cohort. In the highest baseline ALT tertile group, ALT was significantly lower at 12 months compared to baseline at 12 months accompanied by significant lowering of glycemia up to 12 months. Further studies are planned to quantify the efficacy, safety and durability of the hepatic and glycemic effects associated with DMR.}

**P0798 REBAMIPIDE SOLUTION AS A NOVEL SUBMUCOSAL INJECTION PROMOTES HEALING SPEED AND QUALITY OF ESD-INDUCED ULCER BY SUPPRESSING FIBROSION**

1Development Of Minimally, Keio University, Tokyo/Japan
2Department Of Pathology, Keio University, Tokyo/Japan

Contact E-mail Address: aifujimoto@ak.keio.jp

Introduction: Peroral administration of rebamipide in additional to proton pump inhibitor (PPI) was reported to be effective to promote ulcer healing after endoscopic submucosal dissection (ESD). In this pilot study, we assessed the efficacy and safety of a novel rebamipide solution as a submucosal injection agent for ESD using in vivo porcine models.

Aims & Methods: The protocol was approved by the ethics review board of our animal experimental laboratory in advance (13055-0). ESDs of about 30 mm in diameter were performed at four sites in the stomachs of three pigs. An endoscope blinded to the test agents performed the ESDs with a 2 cm rebamipide solution at two sites (rebamipide group) and with base solution alone at the other two sites (control group). The safety and the treatment results of rebamipide group were assessed. The gastric ulcer stages were evaluated by endoscopy once weekly up to week 4 after the ESD to determine a healing score based on ulcer staging using the classification of Sakita and Miwa. A1 stage was defined as score 1. A2, H1, H2, S1, S2 were defined as healing score 2, 3, 4, 5, 6, respectively. The average scores of each week were compared in the rebamipide group and the control group, with a Wilcoxon test. One pig was sacrificed at 1 week after the ESD and the other two were sacrificed at 4 weeks, for pathological evaluation of ESD-induced ulceration and ulcer scarring by HE. The number of neutrophils and width of the fibrosis were measured from hematoxylin and eosin stained sections and from the HE stained sections under ×400 magnification and the average counts of the five fields. The width of the fibrosis was defined as the maximum diameter of the fibrotic tissue in the depth direction from the submucosa to the muscle layer at a site of ESD-induced ulceration or ulcer scarring.

Results: There were no adverse events related with the use of the rebamipide solution. The average healing score was significantly higher in the rebamipide group than in the control group (p=0.02). The healing score by endoscopy for evaluation of ulcer size and intra gastric fibrosis was significantly less extensive in the rebamipide group than in the control group at 4 weeks (p=0.02). In the evaluation of inflammation, the average number of neutrophils was significantly lower in the rebamipide group than in the control group at both 1 week and 4 weeks, but not to a significant extent.

Conclusion: The rebamipide solution appeared to be safe and effective as an injection material for promoting the healing of ESD-induced ulcers. It also seemed to smoothen the folds of the ulcer circumference after ESD by suppressing fibrosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0799 EFFECT OF ILAPRAZOLE ON THE HEALING OF ENDOSCOPIC SUBMUCOSAL DISSECTION-INDUCED GASTRIC ULCER: INTERIM ANALYSIS OF RANDOMIZED, MULTICENTER STUDY**

Introduction: The optimal treatment regimen or duration of endoscopic submucosal dissection (ESD)-induced gastric ulcer has not been established. The aim of this study was to assess the efficacy of novel PPI, ilaprazole for the treatment of ESD-induced gastric ulcer.

Aims & Methods: This was a prospective, open-label, randomized multicenter study. Between June 2015 and April 2017, a total of 1034 patients who underwent ESD for gastric neoplasm were randomly allocated with ilaprazole 20 mg or rabeprazole 20 mg daily for 8 weeks. The primary outcome was ulcer healing rate at 4 and 8 weeks.

Results: In the intention-to-treat analysis, the ulcer healing rate of each treatment group was not significantly different at 4 or 8 weeks (ilaprazole vs. pantoprazole; 96.7% vs. 96.4%, P=0.80 at 4 weeks, 99.7% vs. 99.0%, P=0.19 at 8 weeks). There was no independent predictive factors for a high ulcer healing rate in the multivariate analysis.

Conclusion: According to this interim analysis of trial, ilaprazole and rabeprazole showed no significant difference in the healing of artificial gastric ulcer. Most of the ulcers achieved complete healing within 4-8 weeks.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0800 THE EFFECT OF VONOPRAZAN FOR ENDOSCOPIC SUBMUCOSAL DISSECTION-INDUCED ULCERATION AND POSTOPERATIVE BLEEDING**

Department Of Gastroenterology, Nippon Medical School, Tokyo/Japan

Contact E-mail Address: gogogo.with.yyy@gmail.com

Introduction: ESD is the standard treatment for early gastric cancer and less invasive procedure compared with gastrectomy. Proton pump inhibitors (PPIs) have been widely used for the treatment of ESD-induced gastric ulcers. Many studies have reported that it is critical issues for ESD procedure to prevent postoperative bleeding. Vonoprazan, a potassium-competitive acid blocker (P-CAB), has a strong and continuous inhibition of gastric acid secretion, and is expected to improve effectively ESD-induced gastric ulcerations compared to the treatment with PPIs.

Aims & Methods: To determine whether vonoprazan can ameliorate more effectively ESD-induced gastric ulcerations and can reduce the incidence of postoperative bleeding than PPIs. We compared the healing rate of ulcerations and bleeding incidence in the patients treated with vonoprazan with those treated with PPI. 139 patients who underwent gastric ESD between January 2015 and December 2016 were enrolled in Nippon Medical School Hospital. 11 patients who were injected triamcinolone into mucosa preventing stricture of the prepylorus were excluded. 59 patients were treated with P-CAB for 4 weeks (P-CAB group) and 69 patients were treated with PPI (4 omeprazole, 22 esomprazole, 11 lanosoprazole or 32 rabeprazole) for 4 weeks (PPI group), and subsequently underwent ESD for gastric neoplasm. This study was to assess the efficacy of novel PPI, ilaprazole for the treatment of ESD-induced gastric ulcer.

Results: The incidence of postoperative bleeding was not significantly different between P-CAB group and PPI group. The incidence of delayed bleeding was not significantly different between P-CAB group and PPI group. There was no independent predictive factors for a high ulcer healing rate in the multivariate analysis.

Conclusion: Vonoprazan is superior to PPI in acid suppression, but there were no significant differences in ulcer healing and bleeding incidence between the two groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0801 EFFECT OF ANTIMICROBIAL THERAPY ON DELAYED BLEEDING AFTER GASTRIC ESD: A RETROSPECTIVE ANALYSIS IN 665 CASES**

Gastroenterology, Nippon Medical School Hospital, Bunkyo-ku, Tokyo/Japan

Introduction: The optimal treatment regimen or duration of endoscopic submucosal dissection (ESD)-induced gastric ulcer has not been established. The aim of this study was to assess the efficacy of novel PPI, ilaprazole for the treatment of ESD-induced gastric ulcer.

Aims & Methods: This was a prospective, open-label, randomized multicenter study. Between June 2015 and April 2017, a total of 1034 patients who underwent ESD for gastric neoplasm were randomly allocated with ilaprazole 20 mg or rabeprazole 20 mg daily for 8 weeks. The primary outcome was ulcer healing rate at 4 and 8 weeks.

Results: In the intention-to-treat analysis, the ulcer healing rate of each treatment group was not significantly different at 4 or 8 weeks (ilaprazole vs. pantoprazole; 96.7% vs. 96.4%, P=0.80 at 4 weeks, 99.7% vs. 99.0%, P=0.19 at 8 weeks). There was no independent predictive factors for a high ulcer healing rate in the multivariate analysis.

Conclusion: According to this interim analysis of trial, ilaprazole and rabeprazole showed no significant difference in the healing of artificial gastric ulcer. Most of the ulcers achieved complete healing within 4-8 weeks.

Disclosure of Interest: All authors have declared no conflicts of interest.

Immediate submucosal dissection (ESD) for superficial gastric neoplasms is gaining an acceptance as one of curative treatment options. However, delayed bleeding still exists as a major complication of ESD. On the other hands, the number of patients taking antithrombotic agents are increasing because of evidence of antithrombotic therapy for prevention of thrombotic events has been established and population aging advances, which is thought to be a serious problem related to increasing delayed bleeding after ESD.

Aims & Methods: To assess the influence of antithrombotic therapy on delayed bleeding rate during ESD, we retrospectively investigated the delayed bleeding rate after ESD among the continuation of antithrombotic agents, the cessation of antithrombotic agents and heparin bridge therapy. 735 lesions in 665 patients were treated with ESD from January 2006 to December 2016. We compared the delayed bleeding rate in 153 patients receiving antithrombotic therapy with 512 patients without that. Furthermore, we compared the delayed bleeding rate in the patients continuing antithrombotic therapy with that in the patients with the cessation of antithrombotic therapy or with heparin bridge therapy. The patients who were taking antithrombotic agents were treated with continuation aspirin or clopidogrel. The cessation period of antithrombotic therapy before ESD followed the guidelines for therapeutic endoscopy in antithrombotic agent—users from Japan Gastrointestinal Endoscopy Society. We defined delayed bleeding as a hematemesis, a melena, or a decrease of Hb > 2 g/dl.

Results: The delayed bleeding rate in the patients receiving antithrombotic therapy was 14.4% (22/153), which was significantly higher than that in the patients without antithrombotic therapy (5.7%: 29/512) (p = 0.0007). The median timing of delayed bleeding in patients receiving antithrombotic therapy and that in patients without antithrombotic therapy were 5.7 ± 4.6 days and 7.0 ± 6.8 days, respectively, without significant difference (p = 0.48). Of 153 patients taking antithrombotic therapy (13.1%: 13/122, continuation group and 39.5%: 45/114, antithrombotic agents but all of them were antiplatelet drugs) during ESD (continuation group), 38 discontinued antithrombotic therapy and resumed it after ESD (cessation group), and 30 switched to heparin therapy before ESD (heparin bridge group). One patient was excluded because of uncertain about the period of cessation. The delayed bleeding rate of continuation group, cessation group and heparin bridge group were 13.2% (5/38), 13.1% (11/84) and 20.0% (6/30), respectively, without significant difference (p = 0.63). The delayed bleeding rate of continuation group was not different compared to cessation group but heparin bridge group seemed to be high (20.0%), but there was no significant difference compared to that of total number of continuation and cessation group (13.1%: (16/122), p = 0.24). Deep vein thrombosis was observed in one patient in the cessation group.

Conclusion: Antithrombotic therapy increased the delayed bleeding rate. However, the delayed bleeding rate in the patients taking antithrombotic therapy during ESD was similar to that in the patients discontinuing antithrombotic therapy. Therefore, it is inappropriate that the patients with high risk of thrombosis continue antithrombotic therapy on gastric ESD, but the heparin bridge therapy requires a further examination.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0084 TRANSLANTATION OF AUTOLOGOUS ESOPHAGUS MUCOSA TO PREVENT STRICURE AFTER CIRCUMFERENTIAL ENDOSCOPIC SUBMUCOSAL DISSECTION OF EARLY SQUAMOUS CELL

L. Zhang1, F. Chaoqi2, Z. Xin1, X. Pux1, Z. Xin1, Y. Jin1, X. Xia, B. Jianying. Gastroenterology, Xinqiao Hospital, Third Military Medical University, Chongqing, Qing/China

Contact E-mail Address: 182235337@qq.com

Introduction: Esophageal submucosal dissection (ESD) to remove superficial esophageal neoplasms is gradually becoming the standard treatment for superficial esophageal cancer, but is associated with esophageal stenosis, particularly when ESD involves the entire circumference of the luminal. Many methods to prevent post-ESD stricture, such as repeated Endoscopic balloon dilatation (EBD), temporary stent insertion, and oral steroid and intralesional steroid injection, have been used in different institutions. In recent years, new techniques such as autologous oral mucosal sheets or extracellular matrix scaffold material have also been suggested to manage esophageal strictures. There are no standard guidelines to prevent stricture in a patient with circumferential mucosal defect after ESD. In this study, we aimed to assess the effectiveness and safety of endoscopic transplantation of autologous esophagus mucosa in preventing formation of strictures after ESD.

Aims & Methods: We performed a single-arm, single-institute study. Nine patients who underwent wholly circumferential ESD for superficially extended

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: LDA increased gastric bile acid contents, which delayed the ulcer healing and increased the bleeding after ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) permits en bloc resection for early GI lesions. The number of the patients taking anti-thrombotic agents including low-dose aspirin (LDA) has increased. The Japanese guidelines recommended endoscopic procedures without interruption of LDA therapy in patients at high risk of thrombotic events who use LDA alone. And, aspirin also is known to cause gastric mucosal damage though the exact mechanisms are still unclear.

Aims & Methods: In this study, we aimed to clarify whether LDA treatment and gastric bile acid contents synergistically affect on postoperative bleeding and healing rate of ulcer after gastric ESD procedure. A total 224 patients with gastric neoplasms were treated with ESD at Nippon Medical Hospital, between January 2013 and June 2016. To investigate whether anti-thrombotic agents affect the ESD procedure-induced ulceration and ESD postoperative bleeding rate, we compared ulceration reduction rate (one month after ESD), postoperative bleeding rate and gastric bile acid contents among the patients treated with low dose aspirin, other anti-thrombotic agents and non-anti-thrombotic agents.

On the day of ESD and one day after ESD, gastric juice was taken in endoscopy and total bile acids were measured spectrophotometrically after the enzyme treatment of gastric juice. Results: LDA increased gastric bile acid contents, which delayed the ulcer healing and increased the bleeding after ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

esophageal squamous cell carcinoma at the endoscopic center of Xinxiao Hospital, Third Military Medical University (Chongqing, China) from January 2015 to February 2017, were enrolled in this study. We collected specimens of autologous esophageal mucosal tissue from these patients. After undergone ESD, these mucosal specimens were the first to be fixed to the “ulcer surface” by hemoclips and then fixed by means of a covered metal mesh stent. The stent was removed on post-procedure day 7. All patients were monitored by endoscopy.

Results: In bloc ESD was safely achieved in all cases. The overall longitudinal diameter of resected specimens was 117.8 mm (range, 70 to 150 mm). Autologous esophageal mucosa was successfully transplanted to a “ulcer surface” using an endoscope. The number of mucosal patches ranged from 8 to 28. Complete re-epithelialization occurred within a median time of 8.6 days with a graft survival rate at 93.06%. Postprocedural stricture accompanied by dysphagia occurred in seven patients on post-procedure day 24.7 (range, 18–34 days). The median sessions of EBD and intralesional steroid injection was 3.3 (range 1–6). No other serious complications occurred in these patients, such as the overall bleeding and perforation. Eight patients were still alive during the mean follow-up period of 11.6 months (range, 2.5 to 21 months). One patient developed lung metastasis and died of the disease 15 months after ESD.

Conclusion: Transplantation of autologous esophageal mucosa appears to be a safe means of relieving the severity of esophageal stenoses following circumferential ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
2. Hochberger J, Koehler P, Wedi E, Gluer S, Rothstein RI, Niemann H, 2012; mosis (6%) and duodenal bulb (6%). esophagus (28%), gastric body (16%), antrum (11%), esophagus-jejunal anastomosis (10%), gastrocolic fistula (6%) and after endoscopic procedure (n = 10). Mean fistula size was 5.8 mm (range, 1.5–13.7 mm). The clinical success rate was 67.8% (n = 16). The median follow-up period of post-procedural fistulas or perforations was 11.6 months (range, 2.5 to 21 months). One patient developed lung metastasis and died of the disease 15 months after ESD.

Conclusion: ESD can be safely and effectively used in patients presenting with post-surgical fistulas or perforations and, when feasible, may be more advantageous and less costly than surgery. Further research is required to characterize the determinants of long-term success and risk factors for failure.

Disclosure of Interest: All authors have declared no conflicts of interest.

was reached in 290/301 (96%) procedures. A perforation occurred in 3/301 (1%) patients. CI 0.21–3.89]. Two perforations were closed with clips, all three patients received intravenous antibiotics and were admitted to hospital for 2, 3 and 9 days. Bleeding requiring intraprocedural hemostasis occurred during 15% of procedures. Significant post-procedural bleeding requiring intervention was observed in 5 cases (2%). Dysphagia requiring endoscopic dilation occurred in 7 patients (3%), after ER with a mean number of 4 ± 2.9 resected pieces. Mean total procedure time for ER using the new NBMB device was 33 ± 17.1 minutes.

Conclusion: The new NBMB device used in this study proved to be effective for resection of early neoplastic lesions in BE: successful ER was achieved in 96% of procedures. Perforations were seen in 1% and significant post-procedural bleeding in 2%, complications were effectively managed endoscopically.

P0807 COST–EFFECTIVE ANALYSIS COMPARING STANDARD BIOPSY VS. DIGITAL BIOPSY BY CONFOCAL ENDOMICROSCOPY
Gastroenterology, Instituto Ecuatoriano de Enfermedades Digestivas, Guayaquil, Ecuador

Contact E-mail Address: gengchong15scu@163.com

Introduction: Endoscopy has greatly influenced gastrointestinal diagnostics. However, most lesions can be suspected but not certainly diagnosed only on the basis of endoscopic findings and therefore, endoscopy is needed. On the other hand the reliability of detecting lesions histologically depends on the site, number, and size of biopsy (Bx) specimens with a 20–30% probability of sampling mistakes. Probe based Confocal Laser Endomicroscopy (p-CLE) allows endoscopic in-vivo mucosal cellular evaluation of the gastrointestinal (GI) tract with a high (90%) diagnostic accuracy. It allows to perform target Bx. Moreover, the NVP is >98%. There is no information in the literature regarding the economic impact of performing digital biopsies (DBx) by p-CLE.

Aims & Methods: The aim of this study is to perform a cost–effectiveness analysis comparing the diagnosis of upper GI tract pathologies using only standard Bx following the literature recommendations (LR) vs. the diagnosis with DBx using p-CLE. This was a retrospective study with prospective collection data of patients included from Jan 2014 to Nov 2016. The pathologies included for p-CLE evaluation are summarized in Table 1. The diagnosis costs using standard Bx was calculated following the literature recommendations (Table 2). The standard Bx costs included the histological process and physician honoraria per Bx (USD 50.00), and one biopsy forceps per patient (USD 38.00). The DBx costs by p-CLE included the probe, the processor and the physician honoraria (USD 500.00). Baseline characteristics, p-CLE indications, the diagnostic accuracy of p-CLE and costs were described.

Results: 78 patients were included, 51.2% were female. The mean age was 50.18 years old. p-CLE indications distribution was: esophagus 29 (37.2%), stomach 46 (59%) and duodenum 3 (3.8%) subgroups. Biopsies were performed in 71/78 patients. p-CLE indications distribution was: esophagus 29 (37.2%), stomach 46 (59%) and duodenum 3 (3.8%) subgroups. Biopsies were performed in 71/78 patients.

Bx: biopsies; LR: Literature Recommendations. a. For initial diagnosis. b. For follow-up. c. Cost includes histological process and physician honoraria per biopsy (USD 50.00). and the Bx forceps per patient (USD 38.00).

Conclusion: In our population, the digital biopsy by p-CLE proved to be more cost-effective; when ≥10 biopsies were indicated, like in cases of a Barrett’s Esophagus ≥4 cm, a Gastric Tumor, or in the context of two or more suspected pathologies (e.g.: esophageal and gastric disease).

P0808 GASTRIC PER-ORAL ENDOSCOPIC PYLOROTOMY (G-POEM) IN THE TREATMENT OF REFRATORY GASTROPARESIS: EXPERIENCE OF THE FIRST 9 CASES IN A MEXICO
Endoscopy, IMSS, Mexico city/Mexico

Contact E-mail Address: mondragonmd@yahoo.co.uk

Introduction: Gastroparesis is a syndrome characterized by a delayed gastric emptying absence of a mechanical obstruction. Reduction in QOL scores have been observed. Etiologies include: idiopathic, diabetic, post-surgical. Diagnosis is based on the combination of symptoms and a delayed gastric emptying scintigraphy(GES) of >10% after 240 min. Multiple treatments have been used: medical treatment results have been not promising, so new treatment options have been explored. G-POEM is a new endoscopic treatment which is based in the POEM treatment for achalasia patients and consist in a creation of a submucosal tunnel in order to perform an endoscopic pyloromyotomy. Initial results have been promising.

Aims & Methods: The aim of this study was to evaluate the safety and efficacy of G-POEM in a group of Mexican patients with refractory gastroparesis. This prospective study was carried out in a tertiary care center in Mexico city, between December 2016 and April 2017. We included patients with refractory gastroparesis defined as presence of symptoms such as: nausea, vomiting, early satiety with inability to finish a normal meal, bloating and upper gastrointestinal pain. These patients were on medical treatment and didn’t respond and have a positive gastroparesis cardinal symptom index (GCSI) score combined with a >10% of retention at 240 min in the GES study. Exclusion criteria were malignancy, peptic ulcer disease, normal GES and coagulation disorders. Procedure steps were following an POEM procedure, beginning 5cms below pyloric arch with an longitudinal incision, then submucosal tunnel creation, myotomy of the piloric arch up to the serosa and 2cms before this point and finally closure with clips. Follow-up included GCSI, endoscopy and GES at 3 months after procedure.

Conclusion: Characteristics, of procedure, and patients were documented. Student paired t-test was used for comparisons between groups and p < 0.05 was considered as statistically significant.

Results: There were 9 patients included in this initial study, the mean age was 42.4 ± 8.5years. 6 patients were female and 3 male. The most common etiology was postsurgical 4.9 (44.4%), followed by diabetic 3/9(33.3%) and idiopathic 2/9 (22.2%). The mean G-POEM time was 61.4 ± 7.8 min, and complications were self-limited and presented in only 4 patients. the GCSI score decreased 68% from the pre-procedure levels as well as the GES which decreased 67% compared with levels at 3 months after G-POEM (34.5 ± 5.1 vs. 13.1 ± 3.2 p = 0.003/ 20.74 ± 5.3 vs. 6.8 ± 1.78 p = 0.001 respectively). 7/9 (77.7%) normalized the GES(<10% at 240 min). Endoscopy at 3 months after procedure didn’t show any complication (Table 1).

Disclosure of Interest: All authors have declared no conflicts of interest.

P0809 ENDOSCOPIC MANAGEMENT OF FOREIGN BODIES IN THE UPPER GASTROINTESTINAL TRACT: A RETROSPECTIVE STUDY OF 1294 CASES
C. Geng, X. Li, X. Lei, C. Wang
Department Of Gastroenterology, West China Hospital of Sichuan University, Chengdu/China

Contact E-mail Address: gengchong15scu@163.com

Introduction: Foreign body (FB) ingestion including food bolus impaction is frequently encountered in clinical practice. Few studies with large sample size
towards endoscopic management of FBs had been reported. No direct evidence has demonstrated the relationship between duration of FB impaction and outcomes of endoscopic management. Moreover, it remained unclear whether endoscopic management of FBs under general anesthesia could improve endoscopic outcomes when compared with topical pharyngeal anesthesia.

Aims & Methods: The aim of the present retrospective study is to analyze our endoscopic outcome and explores the best timing and anesthesia methods of endoscopic intervention in population with FB ingestion. All consecutive patients suspected of FB ingestion were enrolled. The demographic, clinical and endoscopic data were collected and analyzed.

Results: Totally, 1294 cases were recruited in this retrospective research. The ages ranged from 7 months to 94 years, with a median age of 47.0 (31–63) years. The majority of patients (1191/1294 cases, 92.0%) presented with some symptoms after FB ingestion, in order of frequency dysphagia (415 cases, 32.1%), foreign body sensation (340 cases, 26.3%) and sore throat (267 cases, 20.1%). The duration of FB impaction ranged from 4 hours to more than 2 years with a median of 1.03 (0.63–3) days. Bony FBs, juubei pit, food bolus and dental prosthesis were the most frequent FBs in population. Anatomically, FBs were mostly impacted in the oesophagus (n = 1025, 86.9%), especially in the upper oesophagus (n = 782, 79.5%), followed by stomach (n = 95, 8.1%), duodenum (n = 36, 3.0%) and pharynx (n = 24, 2.0%). Nearly half of the patients (49.9%) developed FB-related complications, mainly including mucosal injuries (356 cases, 27.5%) and ulcers (210 cases, 16.2%). The most common underlying pathologies were oesophageal stricture (35 cases, 39.3%) and oesophageal cancer (11 cases, 15.5%). As the duration of FB impaction increased, positive finding and successful removal of FB by endoscopy significantly decreased (p < 0.001). Furthermore, complication rate significantly increased with time (p < 0.001). Age (OR = 1.15, 95% CI: 1.20–1.91, p < 0.001), type and location of FBs (OR = 4.51, 95% CI: 2.95–6.90, p < 0.001; OR = 2.26, 95% CI: 1.48–3.46, p < 0.001), anaesthesia methods (OR = 1.35, 95% CI: 1.05–1.75, p = 0.02) and duration of FB impaction (OR = 1.74, 95% CI: 1.50–2.0, p < 0.001) were verified as risk factors for development of FB-related complication by logistic regression analysis. General anaesthesia could not improve positive FB detection (p = 0.181) or success rate of endoscopic management of FBs (p = 0.135), as well as decrease the complication rate when compared with topical pharyngeal anaesthesia (p = 0.52). VS 47.5%, p = 0.033).

Conclusion: FB-related complication rate increased with time, endoscopic management under general anaesthesia could not improve therapeutic effects when compared with topical pharyngeal anaesthesia. Overall, Patients suspected of FB ingestion should receive endoscopic management as soon as possible.

5Anubisscope, Karl Storz, Germany
6Friedrich Loeffler Institute, Neustadt/Germany

Contact E-mail Address: toshiyuki.yoshio@jfcr.or.jp

Introduction: Recent advances in endoscopic resection (ER) provide us increasing chances for resecting esophageal squamous cell carcinoma (ESCC) with muscularis mucosae (MM) and SM1 invasion. As MM/SM1 invasive cancer is reported to have 8–20% of metastatic risks and is defined as relative indication for ER in guideline by Japan Esophageal Society. For these, we perform additional therapy such as chemo radiotherapy (CRT) or operation considering the risk of metastasis and patients’ condition.

Aims & Methods: To know the difference of metastatic risk and long time outcome, we retrospectively studied 121 cases of ESCC with pathological MM/SM1 invasion (MM/SM1:97/24) resected by ER from 2003 to 2013 in Cancer Institute Hospital. After pathological diagnosis of resected lesions, we performed additional therapy such as CRT, radiation therapy (RT) or operation, to the cases with lymphovascular invasion (LVI) or droplet infiltration (DI). Median observation period was 48 months.

Results: Enrolled cases included 112 males and 9 females and their median age was 66 (39–86). We resected ESCC by ESD in 71 cases and by EMR-C in 50 cases and their median size was 27 mm. Local recurrence was observed in 6 cases which were all after EMR (12%). As for local recurrence 5 cases were treated by re-EMR and 1 case by APC, resulted in no re-recurrence. Of 97 cases of MM, 15 cases (15.5%) had LVI, 10 cases (10.3%) had DI. We recommended additional therapy in 21 cases (21.6%). Additional therapy was performed in 15 cases (15.5%) (opc/RT/RT9/5/1). No case died of ESCC and 22 cases (22.7%) died of other diseases. Of 24 cases of SM1, 9 cases (37.5%) had LVI, 5 cases (20.8%) had DI. We recommended additional therapy in 12 cases (50.0%). Additional therapy was performed in 9 cases (37.5%) (opc/RT/RT:9/7/5). Three cases died of ESCC and 5 cases (20.8%) died of other diseases. Comparing both groups, tumor size and local recurrence rate were not different each other. The frequency of LVI was significantly higher in SM1 than in MM (p < 0.05) and the frequency of DI was higher in SM1, although not significant (p = 0.161). The metastatic recurrence was observed significantly frequent in SM1 than MM (16.7% vs 2.1%; p < 0.01). The 5-year overall survival (OS); disease specific survival (DSS);relapse free survival (RFS) were 81.7%/100%/94.1% for MM and 62.9%/87.9%/91.7% for SM1. OS and RFS were not different each other, however, CSS was superior in MM than in SM1 (p < 0.01).

Conclusion: ESCC with MM invasion was superior in metastatic recurrence and CSS than ESCC with SM1 invasion, although we treat MM/SM1 in the same way. Additional therapy should be considered more positively in cases of SM1 than in cases of MM, considering metastatic risk and patients’ conditions.

P0811 GASTRIC ESD IN AN ANIMAL SURVIVAL MODEL USING THE ANUBIS-SYSTEM

J. Bernhardt1, H. Steffen2, P. Koehler3, S. Schneider-Kortath4, K. Ludwig5
1Dept. Of Endoscopy, Klinikum Suedstadt Rostock, Rostock/Germany
2Dept. Of Surgery, Klinikum Suedstadt Rostock, Rostock/Germany
3Friedrich Loeffler Institute, Neustadt/Germany

Contact E-mail Address: joern.bernhardt@kliniksuedrostock.de

Introduction: ESD in generally is still under evaluation. The one-piece resection of lesions larger than 2 cm has many advantages against piece meal resection. One problem in ESD is to lift and prepare the specimen simultaneously. We used the ANUBIS-system for intragastric ESD.

Aims & Methods: The experimental study was conducted in a porcine model in general anesthesia. We started the study with 7 pigs in a survival model using the Anubisscope (Carl Storz, Germany). After insertion of the scope insufflations were done with the two arms of the scope using a grasper and a hook-needle. Also the grasper could use for coagulation. The specimen was removed with the scope after closing its valves.

Results: The procedure was successful in all animals with operation time ranging from 102 to 189 minutes with a learning curve. After weight gain in all cases, the animals were sacrificed after postoperative day 42 and the workup showed competent healing with a star-like scar.

Conclusion: The use of an operating platform like the Anubisscope has the advantage of flexible preparation in opposite position of the instruments in ESD. The disadvantages are the only two degrees of freedom of the flexible instruments and the rotation-like movements. Also, it is not possible to reach all regions of the stomach.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0812 USEFULNESS OF NARROW BAND IMAGING WITH MAGNIFYING ENDOSCOPY AS A SCREENING TEST FOR GASTRIC CANCER

T. Morinushi
Gastroenterology, Kameda Medical Center, Chiba/Japan

Contact E-mail Address: moristatu@yahoo.co.jp
**Introduction:** Narrow band imaging with magnifying endoscopy (NBI-ME) is used to diagnose gastric cancer; however, whether NBI-ME is useful as a screening test for gastric cancers has not yet been determined. Additionally, it is important to consider the impact on the atrophy of the background gastric mucosa in gastric cancer screening because the incidence of gastric cancer depends largely on the degree of atrophy noted in the background gastric mucosa.

**Aims & Methods:** We aimed to determine the usefulness of NBI-ME as a screening tool for gastric cancer. We retrospectively studied 3515 patients who had undergone screening upper gastrointestinal endoscopy between April 2013 and March 2014. We excluded patients with advanced gastric cancer and those who had undergone gastrectomy. Thus, we studied 1080 patients who received NBI-ME and 2435 patients who had undergone conventional endoscopy. We classified the degree of atrophy of the background gastric mucosa using the Kimura-Takemoto classification. Severe atrophy was noted in 1620 patients (Group S), and mild atrophy in 1895 patients (Group M). We evaluated the biopsy rate, the detection rate of gastric neoplasms, and the accuracy of biopsy using NBI-ME compared to conventional endoscopy.

**Results:** The biopsy rate of NBI-ME and conventional endoscopy in Group M was 5.4 and 7.7%, respectively, while in Group S it was 14.9 and 14.8%, respectively. The biopsy rate did not differ significantly between those who received NBI-ME and those who had undergone conventional endoscopy. The detection rate of gastric neoplasms using NBI-ME and conventional endoscopy in Group M was 0 and 0.2%, respectively, while in Group S it was noted to be 4.2 and 1.8%, respectively. Thus, the detection rate of NBI-ME was significantly higher than that of conventional endoscopy in Group S (p < 0.01). The accuracy of biopsy with NBI-ME and conventional endoscopy in Group M was 0 and 3.2%, respectively, but in Group S it was noted to be 36.4 and 14.1%, respectively. Thus, the biopsy rate of NBI-ME is significantly superior to conventional endoscopy in Group S (p < 0.01).

**Conclusion:** NBI-ME as a screening test for gastric cancer is useful for patients with severe atrophy of the background gastric mucosa because this technique has shown a higher detection rate of gastric neoplasms and better accuracy of biopsy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**
95% CI, 0.552–0.661). In the validation set, the model also showed good discrimination (area under the ROC curve 0.689; 95% confidence interval [CI], 0.630–0.748; P = 0.0002), and in-vivo biopsy (OR, 3.90; 95% confidence interval [CI], 1.48–9.09; P = 0.0029), anti-platelet agent (OR, 3.07; 95% CI, 1.44–6.05; P = 0.002), and en-bloc resection (OR, 3.83; 95% CI, 1.34–10.34; P = 0.0059) as significant risk factors (C-statistic = 0.687; 95% CI, 0.595–0.769). In the validation set, the model also showed good discrimination (C-statistic = 0.650; 95% CI, 0.583–0.717). Based on the scoring system of odds ratio, bleeding risk was 4.1% in the low risk set (score ≤ 4), 7.0% in the high risk set (score > 4, P = 0.003) (validation set).

Conclusion: Our study investigated a prediction scoring system of estimating the bleeding risk, including the patient, endoscopist factors. A risk score can be calculated before the procedure and the endoscopists can predict bleeding potency before the gastric ESD. Based on the scoring system, endoscopists may alter therapeutic plans such as prolongation of admission dates or medication schedules.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We prospectively evaluated whether blue light imaging with white light imaging (BLI-ME) could be as efficient for diagnosis of EGC as blue laser imaging with magnifying endoscopy (BLM-1E). 43 patients with 45 tumorous lesions including 28 well-differentiated adenocarcinomas, two moderately differentiated adenocarcinomas, six poorly differentiated, and five adenomas that were diagnosed by biopsy specimens were enrolled in this study between December 2016 and May 2017. The patients with EGC underwent LED-BLM-1E observation, following BLM-1E observation in the same day. At first, an endoscopist evaluated a demarcation line and micromorphology in the part of EGC using LED-BLM-1E according to vessel and surface classification system. Then, the same endoscopist evaluated adenocarcinoma in the same part of EGC using BLM-1E. All of the EGCs were immediately resected by ESD after the observation of two modalities. All of the EGCs could be evaluated one-to-one correspondence between the endoscopic image and pathological finding in detail. Primary end point was to analyze the diagnostic accuracy of BLM-1E for EGC. Secondary end point was to compared the diagnostic accuracy and between LED-BLM-1E and BLM-1E. Our study was approved by the Ethical Review Committee of Kyoto Prefectural University of Medicine, and performed in accordance with the World Medical Association’s Declaration of Helsinki. In addition, this study has been registered in the University Hospital Medical Information Network Clinical Trials Registry (UMIN-CTR: http://www.umin.ac.jp/ctr/ctr_000025575/).

Results: The clinicopathological features in the patients were as follows; mean age was 71.9 ± 5.74, gender (male:female) was 31:14, location(U:M:L) was 9:15:21, macroscopic type (elevated: flat: depressed) was 18:1:26, median tumor size was 19.6 ± 19.6 mm, and final pathological diagnosis (well-differentiated adenocarcinoma: moderately differentiated adenocarcinoma: poorly adenocarcinoma) was 37:1:7, respectively. Diagnostic accuracy of demarcation line of EGC using LED-BLM-1E and BLM-1E were 91.1% (41/45) and 91.1% (41/45), respectively. The rate of high confidence for diagnosis of a demarcation line of EGC using LED-BLM-1E and BLM-1E were 84.4% (38/45) and 91.1% (41/45), respectively. There was no significant difference of diagnostic accuracy between two modalities. The consensus rate in the demarcation line, microscopic pattern, and microsurface pattern of EGC between LED-BLM-1E and BLM-1E was 80.0% (41/45), 97.8% (44/45), and 97.8% (44/45), respectively.

Conclusion: LED-BLM-1E were demonstrated the high diagnostic performance for diagnosis of EGC demarcation, similar to BLM-1E.

P0818 RISK FACTORS OF COMPLICATION RELATED TO ENDOSCOPIC MANAGEMENT OF FOREIGN BODIES IN THE ESOPHAGUS: A PROSPECTIVE STUDY IN 595 CASES FROM MULTIPLE CENTERS IN CHINA

L. Wang, L. Wang
The Second Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou/China

Contact E-mail Address: wanglj76@hotmail.com

Introduction: Foreign bodies (FBs) ingestion is a common medical emergency accounting for 4% of all emergency endoscopies, secondary only to the GI bleeding. 70% – 75% of FBs are located in the esophagus. The need of endoscopic management reached up to 63 – 76%. According to the latest guidelines from ESGE, emergent endoscopy is recommended for the impaction of sharp-pointed objects within 24 hours. However, there were still different opinions on the endoscopic methods with different FBs.

Aim: The study was performed from October 2015 to August 2016 among 595 patients with clinical suspicion of foreign body ingestion from 18 general hospitals in China. The patient data including age, gender, clinical features, and data about endoscopic management including types and locations of foreign bodies, retrieval devices, outcomes and complications were collected and analyzed.

Results: 1) The most common types of foreign bodies were fish bones (34.0%), chicken bones (22.1%), fruit nuclei (11.7%) and food bolus (14.6%). The majority of them were sharp objects (2.5 cm, 74.0%), subsequently followed by middle objects (2.5 – 6.0 cm, 24.5%) and long objects (> 6 cm, 1.5%). Most objects were lodged in the proximal esophagus (75.9%), followed by the middle segment (9.2%) and distal segment (8.9%) of esophagus. 2) 96.3% of all cases had obvious clinical symptoms. Clinical symptoms occurred more often in the proximal segment of the esophagus (98.1%) than any other segments of the upper gastrointestinal tract (92.6%) (P < 0.001). 3) The successful removal rate through endoscopy was 94.5%. It was even higher with general anesthesia (99.3%) than without it (92.7%) (P < 0.01). 4) Complication rate was as high as 34.0%, which was increased with long retention time and sharp objects (P < 0.001). The rate was increased by 2.2 and 6.1 folds after impacted for over 12 hours as compared to 12 hours. Logistic regression analysis indicated that sharp objects had obviously more complications than non-sharp ones (OR 3.36, 95% CI: 1.97–5.74). In particular, the incidence of perforation was 5.6%, which was strongly related with long retention time and sharp objects (P < 0.03), but not with locations or lengths of the objects (P > 0.05).

Conclusion: General anesthesia could largely improve the retrieval rate through endoscopy. Foreign bodies, especially sharp ones, should be removed as soon as possible within 24 hours, to further decrease severe complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: LCI is a novel color enhancement feature available for LASEREO endoscopy systems (FUJIFILM CO., Tokyo, Japan), which can enhance the slight color difference on gastrointestinal mucosa. Recently we reported that color enhancement of the diffuse redness by LCI was useful for the diagnosis of H. pylori infection. Therefore, we expected that LCI facilitate the endoscopic recognition of early gastric cancer and gastric adenoma by enhancing its color difference between normal and atypic mucosa.

Aims & Methods: The aim of this study was to evaluate the usefulness of LCI for recognition of early gastric cancer and gastric adenoma compared to conventional white light imaging (WLI), WLI with Indigo Carmine contrast staining (IC) and Blue Laser Imaging-bright (BLI-brt) imaging. We retrospectively analyzed 39 lesions in 33 patients who had endoscopic submucosal dissection (ESD) at Meiji Memorial Hospital from June 2014 to May 2016. All lesions were scanned with four imaging mode, WLI, IC, BLI-brt and LCI (LASEREO with EG-L590ZW scope), and assigned a recognition score from 3 (excellent visibility) to 0 (poor visibility) by three endoscopists.

Results: The overall mean recognition score of LCI was significantly higher than that of WLI/IC/BLI-brt (2.18 ± 0.073 vs. 1.56 ± 0.808/1.86 ± 0.099/1.91 ± 0.073). For type 0-Ha lesions (18 lesions), the mean recognition score of LCI was significantly higher than WLI and BLI-brt (2.26 ± 0.12 vs. 1.83 ± 0.12/1.4 ± 0.097), whereas no significant difference was seen between LCI and IC. However, for type 0-IIa lesions (17 lesions), the mean recognition score of LCI was significantly higher than WLI/IC/BLI-brt (2.11 ± 0.11 vs. 1.33 ± 0.10/1.44 ± 0.13/1.73 ± 0.10). And the mean recognition score of BLI-brt was higher than that of IC, but no significant difference was seen between LCI and IC. Regarding WLI, IC, and BLI-brt, the mean recognition score of type 0-IIa lesions in each mode was significantly higher than that of type 0-Hb or 0-IIc lesions. However, regarding LCI, there was no significant difference in the mean recognition score between type 0-IIa lesions and type 0-Hb or 0-IIc lesions. These results indicated that the detection of type 0-Hb or 0-IIc lesion was difficult compared to 0-IIa in WLI, IC and BLI-brt mode. However, LCI mode enable us to detect these type 0-Hb or 0-IIc lesion as easily as type 0-IIa.
P0821 GASTROINTESTINAL STROMAL TUMORS SHOULD BE RESECTED EVEN IN A SMALL SIZE – A RETROSPECTIVE ANALYSIS IN 33 CASES

H. Kawakubo2, H. Takeuchi2, Y. Kitagawa2, N. Yahagi1

GISTs are considered to be quite low. Laparoscopic endoscopy may be a less invasive and effective treatment for GIST patients. We present a retrospective study of 33 consecutive patients aged 59 ± 13.7 years-old and 23.3 ± 8.4 mm, respectively. The procedure was successfully completed in all cases in a mean procedure duration of 206 ± 43 min. The patients were discharged without severe adverse events 7.3 ± 1.5 days after the procedure. The first endoscopy after the procedure was performed 5.8 months after discharge in 22 cases, which showed no residual food in the remnant stomach in all cases. Neither apparent impairment of food intake nor disease-related death occurred and a body weight loss was 0.9 ± 2.3 kg during the mean observational period of 16 months. GIST was histologically diagnosed in 20 cases. A risk of recurrence/metastasis in these tumors including ulcerated GISTs was classified into high (2), intermediate (1), low (12) and safety of POEM for achalasia in patients older than 70 years. A total of 33 patients were enrolled in this study, who had undergone POEM for achalasia in elderly patients older than 70 years with significant improvement in symptoms.

Conclusion: All authors have declared no conflicts of interest.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0823 POST-POEM ESOPHAGITIS – REAL REFUX ESOPHAGITIS OR JUST A HEALING PROCESS?

D. Erhartova1, J. Krajcová2, Z. Vacková1, Z. Rabeková1, P. Stíranda1, T. Huel1, J. Spicak1, J. Martinek1

1. Department Of Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: denisaerhartova@gmail.com

Introduction: POEM has become a standard treatment of achalasia based on its excellent efficacy and safety. However, unlike in laparoscopic myotomy, POEM is not accompanied by an antireflux procedure and thus the rates of both clinically relevant post-POEM reflux (measured by symptoms and/or 24 h pH monitoring) and post-POEM esophagitis are key questions of long-term POEM safety. Several studies have reported the rates of post-POEM reflux and post-POEM esophagitis being as high as 30–40%. The aim of this retrospective analysis was to analyze whether esophageal erosions, detected endoscopically early after POEM, represent real reflux esophagitis or rather signs of still ongoing healing process after POEM.

Aims & Methods: A single-center retrospective analysis of 192 patients who underwent POEM in our institution. Three months after POEM, 162 patients underwent both pH monitoring and endoscopy and treatment with PPIS was assessed. At 24–36 months, a control endoscopy was performed in 41 patients to screen for esophagitis. We reviewed all available video recordings of POEM procedures and subsequent control endoscopies to analyze whether the localization of erosions was limited to the site of submucosal tunneling (e.g. between 2–4 o’clock in patients after anterior POEM) or also outside this area (real reflux erasure). We also analyzed evolution of esophagitis in time and correlated it with pH monitoring and intake of PPIS.

Results: At 3 months, esophagitis was present in 64 out of 162 patients (39.6%). Of those, 21 (33%) were on PPIS by the time of endoscopy and 43 (67%) were not. Among 43 patients with esophagitis and available video recording, 29 (67.4%) had erosion(s) only on the site of submucosal tunnel and 14 (32.6%) had erosions also elsewhere. Among patients with erosion(s) only on site of the tunnel, 13 (44.8%) had normal acid exposure time (assessed by pH monitoring

5. Gutmann C, Iwunna J, Tsokos M., et al. Deaths by propofol abuse. Results of one week later and to investigate the superposition of negative feelings by that euphoric reaction pattern under propofol sedation, to evaluate the reminiscence effect of the intense relaxation many years ago was a major reason to abuse propofol and feigned an indication for endoscopy to receive propofol.[8, 9]. Survivors after propofol abuse reported that the abiding memory of the intense relaxation many years ago was a major reason to abuse propofol years thereafter.[10]. However, it is unknown how many patients develop a euphoric drug reaction after endoscopy.

Aims & Methods: The primary objectives were to define the frequency of a euphoric reaction pattern under propofol sedation, to evaluate the reminiscence on site of submucosal tunnel and early esophagitis may be lower than previously thought.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: Over 42 months, 30 ESDs for SMT lesions were performed. The mean age was 62 years with 19 male patients (63%). Mean lesion size was 18 mm. Twenty-five patients (83.3%) had completely resected lesions. Four patients (13%) had involvement of the MP which was identified during the resection, and one patient (3%) had MP injury which precluded complete resection. Three of five lesions of the incompletely ESD procedures were in the proximal body of the stomach, however only two lesions of the completely resected lesions were in the proximal body (P=0.004). Otherwise, there were no significant differences between the patients and lesions characteristics. The histology of the SMT lesions were 9 NET, 6 leiomyoma, 5 Granular cell tumours, 4 inflammatory fibroid polypos, 2 Glis, 2 dystrophic Lipoma, one myofibroblastic tumour and one Warthin’s like tumour. Nineteen patients had completed surveillance endoscopy (SE) without an endoscopic and histological recurrence (Median follow up 18 months). Six patients are pending SE. The four patients with deep MP involvement were referred for surgery.

Conclusion: ESD for selected UGI SMT is an effective treatment. Long-term endoscopic follow-up confirmed the absence of recurrence endoscopically and histologically. MP involvement cannot be reliably excluded by prior EUS. This technique should be considered for UGI SMT lesions without MP involvement in experienced centres.

Introduction: The incidence of oesophageal cancer has increased significantly over the past two decades. The majority of these cancers are incurable at diagnosis. Therefore, the management is aimed at maintaining quality of life by ensuring adequate nutrition and palliation of symptoms, mainly dysphagia. Self-expanding metallic stents (SEMS) have a well-recognised role in the palliative management of patients with oesophageal cancer. These stents are inserted endoscopically, under direct vision (EC) or with fluoroscopic assistance to endoscopy (FAE). There is little evidence to compare outcomes between these approaches.

Aims & Methods: The objective of this study was to compare the outcomes, using various performance indicators, in patients who underwent SEMS for palliation in oesophageal cancer via different approaches (EC or FAE) at the Royal Infirmary of Edinburgh (RIE). A retrospective observational study was conducted between May 2014 to April 2016; a total of 62 SEMS. The approach to stent insertion was subject to operator choice and availability of fluoroscopic assistance, and as such can be akin to a randomized study. We compared early and late complications associated with two techniques. Early complications included pain, vomiting, bleeding, perforation and tachydysrhythmia. Late complications included tumour growth, oesophageptisis, stent migration and stent failure. We also compared morbidity, the need for repeat procedures and the number of additional stents required following each approach.

Results: Forty-seven stents were inserted by EC and fifteen by FAE. The median age among the two groups were comparable at 75 and 69 years respectively. There was male predominance in both the groups (70% and 67%). Adenocarcinoma was the most common malignancy (56%), followed by squamous cell carcinoma (35%) among the study subjects. We observed a higher frequency of technical difficulties with EC placement (13%) to FAE (0%), however no malposition was observed in the EC group. Early complications were comparable in both groups, however chest pain (21%) was more frequently associated with the EC group. Late complications such as tumour overgrowth, oesophagitis, oesophageptisis and stent migration were comparable in both groups. Food bolus obstruction and dysphagia was more common in EC place-ment (28%) to FAE (0%) necessitating a higher number of endoscopic procedures. However, a relatively higher number of re-stent procedures where performed in the FAE group. Median survival was comparable in both the groups.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: A value of the combination of magnifying endoscopy of and image enhancement endoscopy (IEE) technology (e.g. NBI, BLI) is reported in a diagnosis for the early gastric neoplasm. That method is useful, but in order to master it is necessary to learn and familiarize complex classifications. Therefore, this diagnostic method is still more difficult for general endoscopists. Linked Color Imaging (LCI) was recently developed using a laser endoscopic system (Fujifilm CF-Q180Z). LCI acquires images by simultaneously using narrow-band short wavelength light and white light in an appropriate balance. This combination of light provides more information about the vasculature and architecture on the mucosal surface than that obtained with typical white-light imaging. When we use acetic acid indigocarmine mixture (AIM) with LCI mode, we reported that the magnifying images of early gastric cancer are very clear, three-dimensional and near to real histology. So, we examined the examined the utility of this method.

Aims & Methods: This was a prospective observational study performed at a single tertiary referral center. The subjects were 120 lesions of 115 patients with gastric neoplasm. We are indicated the endoscopic submucosal dissection (ESD), and were given preoperative endoscopy in our hospital from September 2014 to February 2017. Firstly we observed the lesions by magnifying endoscopy with the BLI mode and diagnosed using VS classification system. Secondly we observed the lesions by magnifying endoscopy with LCI + AIM method and diagnosed using VS classification system. Furthermore, we classified tumor differentiation into high differentiation, moderately differentiated, and poorly differentiated by its surface pattern. Finally, we classified the visualization ability of the surface fine structure in Clear, Visible, and Invisible and evaluated it. We believe that a magnifying endoscopy diagnosis of the gastric cancer is enabled by the pathology results, 92 lesions were gastric cancer and 28 lesions were gastric adenoma. The differentiation ability of a cancer and the non-cancer (adenoma) did not have the significant difference between the BLI mode and the LCI + AIM methods. Diagnosis of differentiation of gastric cancer was correct in 87 of 92 cases (94%). In the classification of visualization ability, 32 lesions were Clear, 44 lesions were Visible, 44 lesions were Invisible by BLI mode. On the other hand, 45 lesions were Clear, 64 lesions were Visible, 11 lesions were Invisible by LCI + AIM method. In the visualization ability of the surface fine structure, LCI + AIM method is significantly clearer than BLI mode (p < 0.001).

Conclusion: When we use AIM, indigocarmine accumulates in pits of the duct, and duct structures become clear by the acidic acid. By LCI mode, we can observe the vascular pattern of the lesion clearly. So by the combination of AIM and LCI, we can observe the endoscopic images closer to actual histological images. By this method, we can compare histopathology with an endoscopic image intuitively, so we believe that a magnifying endoscopy diagnosis of the gastric cancer is enabled even if we do not use various confusing classifications.

Finally, we classified the visualization ability of the surface fine structure in Clear, Visible, and Invisible and evaluated it. We believe that a magnifying endoscopy diagnosis of the gastric cancer is enabled even if we do not use various confusing classifications.

Aims & Methods: The aims of our study were to evaluate and compare the efficacy, safety, and clinical outcomes of gastric ESD in patients aged 85 years or older and in younger patients. The subjects were 705 patients who collectively presented with 876 gastric tumors (288 adenomas and 588 early gastric cancers). All patients underwent ESD at our hospital between June 2007 and December 2016. Patients were divided into two groups: elderly (aged ≥ 85 years, consisting of 59 patients with a collective 71 lesions) and non-elderly (Group B: aged < 85 years, consisting of 646 patients with a collective 805 lesions). We evaluated the clinical and pathological findings, resection rates, complications, and long-term outcomes, including the survival rate. The local and distant recurrence rates were analyzed in the cohort with curative resection and observationally managed with non-curative resection. The 3- and 5-year overall survival and tumor-specific survival rates were analyzed in the entire study cohort.

Results: The patients' mean ages were 87 (Group A) and 71 years (Group B), and the male-to-female ratios were 30/29 (Group A) and 646/805 (Group B). No significant differences were found in the mean tumor size for Group A (15 mm) and Group B (20 mm). Regarding histopathological findings, the prevalence rates of tubular adenoma were 28.3% (21/71; Group A) and 33.8% (267/805; Group B); intramucosal carcinomas, 52.1% (37/71; Group A) and 53.8% (433/805; Group B); shallow submucosal invasive carcinomas (< 500 μm), 70.0% (52/78; Group A) and 65.6% (528/805; Group B); and deep submucosal invasive carcinomas (> 500 μm), 11.3% (8/71; Group A) and 6.6% (53/805; Group B). Once again, the groups showed no significant differences. The en bloc resection rates were 97.1% (71/71; Group A) and 97.3% (782/805; Group B); histological complete resection rates were 94.4% (67/71; Group A) and 92.9% (748/805; Group B), and the curative resection rates were 78.6% (56/71; Group A) and 86.5% (695/805; Group B). Among the non-curative cases, 13 (86.6%) of the 15 patients in Group A (46.3%) of the 33 patients in Group B died, and disease-specific mortality rates in Groups A and B were 0% (0/71) and 0.5% (4/805; Group B). Regarding long-term outcomes, analysis of recurrence revealed the local and distant recurrence rates to be 0% for Group A and 0.9% (7/746; local) and 0.1% (1/746; distant) for Group B. Concerning survival analysis, the mean follow-up period in Group A and Group B was 839 and 1156 days, respectively. There were no significant differences observed in the survival rates. 6 (10.0%) of 59 patients in Group A and 54 (9.3%) of 646 patients in Group B died, and disease-specific mortality rates in Groups A and B were 0% (0/71) and 0.8% (5/646), respectively.

Conclusion: Gastric ESD in patients aged 85 years or older can be effectively and safely performed. According to the long-term outcomes, gastric ESD performed as a local resection (total biopsy) in elderly patients may be acceptable, even in non-curative cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO031 RESULTS FROM THE FIRST UK VIRTUAL COMPLEX POLYP MDM

A. Chattree, M. Rutter

Gastroenterology, University Hospital of North Tees, Stockton on Tees;United Kingdom

Contact E-mail Address: amitchattree@nhs.net

Introduction: Data from the UK Bowel Cancer Screening Programme (BCSP) has established that the assessment and management of large non pedunculated colonic polyps (LNPCPs) varies markedly, leading to variable and often suboptimal outcomes, especially for the most complex lesions. A multicentre complex polyp multidisciplinary team meeting was created within the North East of England BCSP with the aim of ensuring more robust decision making and management of complex LNPCPs.

Aims & Methods: A virtual multicentre MDM was conducted via audioteleconferencing within the North East of England between 2014-6 to discuss complex LNPCPs (LNPCPs with increased risk of malignancy or complexity associated with endotherapy, as defined in BSG/ACPGBI guidelines1). Non-discussed LNPCPs were not discussed. Patient data was distributed securely via NHSmail. Outcomes were assessed prospectively using key performance indicators (KPIs) from the BSG/ACPGBI guidelines.

Results: 61 complex LNPCP cases were managed via the MDM with 8 excluded from analysis (7: managed prior to MDM referral, 1: MDM advice not followed), 27 lesions were managed with primary endotherapy, 23 with primary surgery and 3 cases conservatively. Of the endoscopic cases, 2 required surgery due to failed endotherapy and was referred to a finding meeting. 12-month recurrence was 8.7% with no reported complications. The rate of surgical management using the BSG/ACPGBI KPI (including only surgically managed benign lesions or lesions subject to failed endotherapy) was 39.5%.

Disclosure of Interest: All authors have declared no conflicts of interest.
rate of complexLNPCPs with features suggestive of increased malignancy risk was 22% in the high-ADR group. Overall, mean ADR was 23.06% (SD 0.55) with a min-
imum of 5.0–1 cm and those bigger than 2 cm. Regarding shape, proportion of peduncu-
lated adenomas were noted in 46% of adenomas with 1–2 cm in size, but have lower proportions of pedunculated adenomas than those with a low ADR. In our study cohort no significant differ-
ences in flat shape or diminutive size was measurable.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Patients of endoscopists with high (≥20%) adenoma detection rate
(ADR) have less risk for interval cancer than those of those with an low ADR
(<20%). Lesion-related-factors, such as size, shape and histology influence
the probability of finding adenomas with high ADR during screening endo-
scopy. Aims & Methods: Our study aim is to investigate the differences of size, shape and
serrated histology of adenomas between low- and high-ADR group in our screen-
ing cohort. We analyzed 2534 screening colonoscopies performed by 268
deoacoscopists between 2007 and March 2017 within the austrian certificate of
screening colonoscopy. T-Test was used to assess differences.

Results: 39.1% of endoscopists were categorized in the ADR low- and 60.9% in the
high-ADR group. Overall, mean ADR was 23.06% (SD 0.55) with a mini-
mum of 0.39% and a maximum of 48.72%. In the low-ADR-group mean ADR
was 14.56% (SD 0.42) and 28.51% (SD 0.50) in the high-ADR group. Relating to
size, there was a significant difference (p = 0.029) in detection of adenomas of 1–
2 cm with a mean of 8.44% (SD 6.02) in low- vs. 10.22% (SD 6.44) of all adenomas
in high-ADR group but no differences between adenomas <0.5 cm, 0.5–1 cm and
those bigger than 2 cm. Regarding shape, proportion of peduncu-
lated adenomas in low-group ADR differ significantly higher p = 0.002, with a
mean of 19.36% (SD 14.60) vs. 17.04% (SD 9.55) but there were no differences
discrepancies between flat and sessile adenomas. With a mean proportion of 4.43% (SD 5.61)
vs. 6.64% (SD 5.97), the proportion of sessile sessile adenomas (SSA) differ
significantly between low-ADR vs. high-ADR group (p < 0.01). There was no significant
difference regarding traditional sessed adenomas (p = 0.800).

size ADR-Group Mean SD p-value
<0.5 cm ≥20% 34.04 6.02 p = 0.029
<0.5 cm <20% 23.59 15.46
≥20% 31.81 7.28
0.5–1 cm ≥20% 18.23 p = 0.980
<20% 20.58

Introduction: ESD is a complex procedure, mainly in non-Asian countries where the
learning process is not well established. Results may be improved in Western
Europe by performing ESD with a careful selection of lesions for ESD and avoiding those
with greater chance of technical difficulty. Factors predicting technically difficult ESD
when it is performed by non-Asian endoscopists should be clarified.

Aims & Methods: We aimed to identify the potential risk factors that are asso-
ciated with a higher technical difficulty during ESD in a Western European
setting where there are no available Asian experts. We prospectively recorded
consecutive ESD cases performed by members of the ESD Working Group of the
Spanish Society of Digestive Endoscopy. Demographic and clinical characteris-
tics of the patients, location and morphology of the lesions, and technical factors
were collected. We defined difficult ESD as those aborted procedures, time-con-
suming (duration >180 min.) or when changing the technique to piecemeal resec-
tion was needed to remove the tumor. Analyses were carried out using IBM SPSS
Software for Windows (IBM Corp., Armonk, NY, USA). Parametric continuous
variables are reported as the mean ± standard deviation (SD). A Kolmogorov-
Smirnov test was used to evaluate normal distribution. Categorical variables are
reported as either frequencies or percentages. Statistical differences between
the groups were analyzed using a chi-squared method for categorical data. The
meaningful variables with a p value <0.1 in the univariate analysis were included
in the logistic regression model. Multivariate analysis was performed using
binary logistic regression methods. Odds ratios (ORs) and 95% confidence inter-
vals (CI) were calculated to assess the strength of the influence of each individual
variable.

Results: We included 265 lesions in 265 patients [mean age ≤ SD: 69 ± 10; 150
males (56.6%)]. They were recruited in 15 Spanish University Hospitals between
January 2016 and March 2017. Location of the lesions were: esophagus (n = 7;
2.6%), cardiac (n = 5; 1.8%); stomach (n = 48; 18.1%); duodenal bulb (n = 1;
0.3%); colon (n = 144; 54.3%) and rectum (n = 60; 22.6%). Mean lesion size
was 8.46 ± 18.5 mm. Median duration of the procedure was 105 min. (8–375).
In 73 cases (27.5%) criteria for difficult ESD were fulfilled. Endoscopic resection
was aborted in 7 cases (2.6%). When endoscopic resection was achieved (n = 258;
97.3%) both situations, duration ≥3 h and a piecemeal resection, were noted in
21 (8.1%) patients. Duration ≥3 h in 25 cases (9.7%) and unsuccessful en blocc
Conclusion: The factors independently associated with technically difficult ESD (aborted procedures, time-consuming or finished with a piecemeal resection) were: lesion size >30 mm, poor manoeuvrability, recurrent lesions and intra-procedural bleeding. Except for the last one, the remaining factors can be identified during the first diagnostic endoscopy. Endoscopists who will start performing ESD should try to avoid these difficult procedures in the early part of their learning curves.

Introduction: We established the Laparoscopy Endoscopy Cooperative Surgery (LECS) procedure to overcome the limitation of colorectal endoscopic submucosal dissection (ESD). This procedure is a local full-thickness resection of the combined procedure of laparoscopy assisted colectomy (LAC) and ESD procedure. Also, it is the method that is epoch-making for minimal invasive treatment that kept an intestinal function.

Aims & Methods: The aim of this study was to investigate the feasibility and safety of LECS procedure applied with endoscopic submucosal dissection (ESD) technique obtained adequate surgical margin. We performed ESD on 1341 patients (male: female = 777:564; mean age, 66.1years). Among these cases, six cases had perforation (0.4%), and three of six cases required emergent surgery. We examined the cause of perforation and the limit of ESD from the view point of safety. We performed one-piece resection for 11 cases (male: female = 7:4; mean age, 63.5years) of colorectal tumors using LECS procedure. In the first, the indication of LECS is at high risk of the perforation by the treatment of ESD and EMR and is the lesion that safety cannot secure. In addition, the indication is the lesion which is curable by the local excision without lymph node dissection. Therefore, submucosal invasive (T1) cancer with the risk of lymph node metastasis does not become the indication for this full-thickness resection technique. From the above-mentioned basic concept, indications of the LECS procedure for colorectal tumors were thought to be as follows: 1) Intra-mucosal carcinoma (Tis) and adenoma with high-grade atypia involved appendix or diverticulum. We examined the clinicopathological outcomes of the above-mentioned 11 cases.

Results: Four of six cases that caused perforation in ESD were cases with fibrosis in the submucosal layer. Three cases of those were moderate to severe degree fibrosis cases, and a limit of ESD seemed to exist in these lesions from the viewpoint of safety and curability. We accomplished full-thickness resection successfully for 11 cases using LECS procedure as follows: 5 cases of Tis cancer, 4 cases of adenoma, 1 case of schwannoma, and 1 case of GIST. The results we judged as the indication of LECS procedure were as follows: three cases accompanied by severe degree fibrosis, 2 cases involved diverticulum, 3 cases involved appendix, 2 cases of submucosal tumor, and 1 case of poor endoscopic operability. These cases were considered a limitation of ESD due to the high risk of perforation. An operative time was an average of 195.8 minutes (127 to 332), and the perioperative bleeding was an average of 8.0 ml (3 to 20). We experienced no complications, and average post-operative hospital stay was 7.76(2 to 12) days. Histological examination of the resected specimens revealed negative lateral and deep margins. The postoperative follow-up was carried out first a half year later, and it was every one year subsequently. In the above-mentioned follow-up schedule, blood examination, colonoscopy, CT scan were performed for clinical evaluation. The residual/local recurrence case was absent for 31.6 months (range 10-60 months) for the mean follow-up period. Also, without complications such as postoperative anastomotic stricture or adhesive ileus, we followed favorable course.

Conclusion: We developed a LECS procedure to overcome the limit of ESD, and completed full-thickness one-piece resection of the tumors considered as high risk of perforation in the endoscopic treatment.

The interviews provided an in-depth understanding of patient experience of GI procedures. 6 over-arching and inter-linking themes emerged across all procedures. Anxiety, expectations, choice/control, communication/information, comfort and embarrassment/dignity. Relation of themes was seen e.g. if the procedure appointment was sooner than expected, patients were anxious about the potential outcome. Choice was important in terms of appointment, endoscopist and choice of pre-medication, however it was highly individualised. Communication prepared patients and managed expectations, with one patient describing poor endoscopist communication affecting the whole experience. Patients described embarrassment related to changing and waiting areas; sensitive nature of the test; exposure and physical reaction. Discomfort during the procedure was attributed to instrument and air insertion.

Conclusion: Despite heterogeneity between procedures consistent themes related to patient experience emerged. This work will be used to develop PREMs for gastrointestinal Endoscopy.

Introduction: Adequate bowel preparation is important to perform colonoscopy for accurate mucosa examination, lesion detection and treatment. Walking exercise is known to be effective for colon cleansing. However, it is difficult for patients with uncomfortable walking to improve the status of bowel cleansing.

Aims & Methods: Therefore, we prospectively evaluated the clinical feasibility of the abdominal vibration stimulation for bowel cleansing and clinical validity of the abdominal vibration stimulation for bowel cleansing.

Introduction: Patient experience is increasingly recognised as a key measure of quality of care. Ensuring positive experience is important to patients and fundamental in maximising participation in screening programmes and re-attendance for surveillance procedures. Current measures of patient experience of gastrointestinal (GI) endoscopy are clinician derived.(1) Patient Reported Experience Measures (PREMs) should be patient derived and incorporate pre-and post-procedure experience. We aimed to identify themes considered as important to patients undergoing GI procedures as a basis for developing PREMs.

Aims & Methods: We aimed to identify themes important to patients undergoing GI investigations, to enable questionnaire development. Patients who had undergone upper or lower GI investigations (gastroscopy, colonoscopy and CT pneumocolon) were invited to attend for a semi-structured interview. 32 interviewees were purposefully sampled to ensure diversity. Interviews were conducted by a research fellow trained in qualitative methods and were audio recorded and transcribed verbatim. Recruitment continued until saturation was achieved. Analysis used qualitative thematic methods focusing on anticipated and emergent themes, using constant comparison to ensure that all perspectives were included.

Results: 168 patients were approached. 32 interviews were completed (12 gastroscopy, 10 colonoscopy and 10 CT pneumocolon), with a male:female ratio of 18:14. The time interval from examination to procedure ranged from 5 to 44 days. Mean age was 63.1 years (SD 11.5).

Preparation. In this randomized, prospective, investigator-blind study and single center study, 141 inpatients for elective colonoscopy were randomized to two groups. PEG solution was used for bowel cleaning in all patients. The one is walking over 3000 steps and the other is having abdominal vibrator more than 30 minutes before colonoscopy. After examination we recorded procedure results, sedation information, patient's satisfaction and adequacy of bowel preparation by using the Boston Bowel Preparations Scale (BBPS).

**Results:** There were no significant differences between vibrator group (n = 75) and walking group (n = 66) in bowel preparation quality (Total BBPS 7.40 vs 7.23, p = 0.519), withdrawal time (30.40 vs 30.05 mins, p = 0.829), number of polyps (4.09 vs 3.17, p = 0.085), patient satisfaction (4.39 vs 4.12, p = 0.249) and number of diarrhea after taking PEG (11.49 vs 11.42, p = 0.903). Vibration group was superior than walking group in time of first defecation after taking PEG (112.89 vs 123.42 mins, p = 0.005) and cecal intubation time (6.23 vs 8.52 mins, p = 0.011).

**Conclusion:** Bowel preparation accompanied with abdominal vibration stimulation showed almost similar results to a walking group which was conventional methods for adequate bowel preparation. The patients with the condition which cause uncomfortable gait such as old age, CVA, Parkinsons, or joint disease, bowel preparation with abdominal vibrator is expected to help in proper bowel cleansing for therapeutic colonoscopy.

**P0839 COMPARATIVE STUDY OF ELECTRICAL AND RHEOLOGICAL PROPERTIES OF DIFFERENT SOLUTIONS TO PERFORM SUBMUCOSAL INJECTION**

**Aims & Methods:** To analyze the electrical (R) and rheological (temperature, viscosity, height and lasting of the cushing) properties of different submucosal solutions in an ex vivo model of porcine stomach. Tested solutions were: Saline (S), Gliceol (GC), Hyaluronic acid (HA), Distilled water (DW), Platelet-rich Plasma (PRP), Glucosated saline 10% (GS), Gelaspan (GP), TriBio (TB) and Ossa3, I. Marı´n1, J. Boix1, R. Bartolı´4

**Results:** The solutions that showed the best basal R were: PL, HA, GS, TB and PRP. At 60 minutes, the best R were: PRP, TB, PRP + TB, HA and GS. The best durability at 60 minutes was for TB, PRP, TB+PRP and PL that maintained the height at around 80% of its original in comparison to the other substances with were at around 60%. During the resection the solutions that underwent a lower temperature increase were: TB + PRP, PL, and TB.

**Conclusion:** Based on electrical and rheological properties, the best submucosal solutions to perform safer endoscopic resections are: TB + PRP, TB, PL and PRP.

**Disclosure of Interest:** V. Lorenzo-Zúñiga: Authorship of the patient All other authors have declared no conflicts of interest.

1. 2016 Commonwealth Fund International Health Policy Survey of Adults.
Conclusion:
The incidence of synchronous advanced neoplasia (AN) of rectal LSTs with a skirt was significantly lower compared with rectal LSTs without a skirt (46.8% vs 27.3% and 0.02) between LSTs with and without a skirt. In contrast, there was no significant difference with respect to the rectum (6.0% vs 6.6% and p = 0.41). The total number of AN in rectal LSTs with a skirt (n = 7; right colon: 2; left colon: 2 and rectum: 3) was significantly lower than in rectal LSTs without a skirt (n = 74; right colon: 35; left colon: 34 and rectum: 5). There were significant differences in the right colon (p = 0.03) and the left colon (p = 0.04), while there was no significant difference between these groups with respect to the rectum.

3Pathology Department, University Hospital Germans Trias, Badalona/Spain

Introduction: Endoscopic resection of large lesions leads to extensive mucosal defects and submucosal exposure, with a substantial risk of adverse events. The prevention of these complications is inefficient with current methods. Endoscopic shielding, as a simple and safe technique, has been proposed to improve mucosal restoration, and therefore, the incidence of these events. Previous reports have confirmed the efficacy of the placement of hydrogels based on platelet-rich plasma (PRP) (1) or hialuronic acid with other substances (TriBio) (2), but never the combination of both hydrogels, in the prevention of delayed complications after mucosal damage.

Aims & Methods: To assess the efficacy of endoscopic shielding with the combination of PRP and TriBio in a rat model of thermal injury. Thermal injury was obtained according to our rat model (3). Lesions were performed in male Sprague-Dawley rats (400–450 g) under general anesthesia. Animals were randomized to receive one of the following shields onto the lesions: PRP + TriBio, PRP and TriBio. Rats underwent endoscopic follow-up at 7 days and 2 weeks. Afterwards, animals were sacrificed and ulcers sites were macroscopically and histopathologically evaluated.

Results: Animals treated with PRP + TriBio obtained the best results in comparison with other hydrogels (PRP and TriBio). Mucosal healing rate (percentage of mucosal restoration) at 14 days was significantly higher with PRP + TriBio (100% vs 82% and 90%; p < 0.05). Histological study confirmed these data, showing total restoration of mucosal layer with PRP + TriBio

Conclusion: The use of a combination of two covering agents (TriBio and PRP) is the best approach to obtain mucosal healing in a rodent model of endoscopic thermal injury in colon.

Results: Intratumoral injection was feasible in all animals with no adverse events. Biopsies of the neoplastic tissue showed residual tumour necrosis in 3.50±0.35 for the 2D system. The score was significantly higher for the 3D system than for 2D endoscopy (p<0.001). When comparing the evaluations by the experts, non-experts, and medical students, the differences in the scores by the non-experts and medical students were noted to be higher (p<0.05). In contrast, the scores by the experts were also higher for the 3D system, but no statistical difference was observed (3.50±0.53 for 2D endoscopy and 3.87±0.35 for the 3D system, p=0.08). As a result, 10 out of 12 observers noted that the 3D system had better visibility than conventional 2D colonoscopy, and none of the observers noted deterioration in visibility with the 3D system.

Conclusion: The present findings suggest that the 3D imaging system improves the visibility of non-polypoid colorectal neoplasms and may be more effective for non-experts. Our findings would contribute to improvement in the detection of these neoplasms.

Disclosure of Interest: All authors have declared no conflicts of interest.

4Centre For Person-centered Care, Institute of Health and Care Sciences, University of Gothenburg, Gothenburg/Sweden

Contact E-mail Address: jessica.rylander@vgregion.se

Introduction: Pain is a subjective perception, which contributes to difficulties to provide adequate pain relief according to every patient’s needs. Colonoscopy is by many patients considered as a painful and strenuous procedure. Approximately 6 to 8 mm. Anti-VEGF in comparison with Anti-EGF obtained the best results (significantly reduction in size and cell necrosis). However, only alfibeprotide showed total acute tumoral necrosis. This subgroup reported severe, very severe or extremely severe pain. 90% of the patients were given analgesics and sedation during the investigation. For patients who reported, “severe, very severe or extremely severe pain” (n=111), pain was underestimated by physicians and nurses in 58% of all assessments. This was most commonly seen among the youngest patients, 18–29 years (n=9), where pain was underestimated in 25.5% among the group. There was also a difference according to gender: physicians underestimated pain in 60% of men who reported “moderate pain” (n=66) while the nurses underestimated pain in 27% among the same group of men. Women’s pain was overestimated by caregivers in 26% (n=188) of all cases with mild pain. Patients undergoing colonoscopy for the first time (n=331), and reporting “moderate pain”, were underestimated by physicians in 58% and by nurses in 25%. 58% of the patient reports that they were anxious before the procedure. This group reported more pain than the group without anxiety (p<0.001). Presence of anxiety and a high level of agreement between patients, caregivers and the patient’s pain report. The agreement between pain reports from patients and caregivers were poor to fair, with slight differences between nurses (Kappa=0.37; p<0.000) and physicians (Kappa=0.29; p<0.000) in total, congruent pain reports between patients and caregivers were seen in 36% of all assessments.

Conclusion: Agreement between caregivers’ and patients’ pain reports is far from perfect, and the agreement is influenced by several factors such as the profession of the caregiver, as well as patient factors including pain severity, anxiety, age, gender and previous experience of colonoscopy. The goal for the future should be to individualize the use of analgesics based on every patient’s needs, which seems to be of special importance in specific groups of patients.

P0844 A THREE-DIMENSIONAL IMAGING SYSTEM IMPROVES THE ENDOSCOPIC VISIBILITY OF NON-POLYPOID COLORECTAL NEOPLASMS

Department Of Gastroenterology, Graduate School of Medicine, Chiba University, Chiba City, Japan

Contact E-mail Address: matsumura919@yahoo.co.jp

Introduction: Three-dimensional (3D) imaging techniques have been developed in the medical field. Previous research reports that simulated 3D colonoscopy improves the detection of colonic lesions [1]. A novel 3D imaging system has been recently developed, which can create 3D virtual video images from conventional two-dimensional (2D) endoscopic images [2]. However, actual cases have not been studied.

Aims & Methods: This study aimed to investigate whether the 3D system can improve the visibility of colorectal neoplasms compared with conventional 2D endoscopy. We analyzed non-polypoid colorectal neoplasms and recorded their videos using conventional 2D endoscopy and the 3D system. The movies were evaluated by 8 endoscopists (4 experts and 4 non-experts) and 4 medical students. Each neoplasm was assigned a visibility score between 4 (excellent visibility) and 1 (poor visibility).

Results: The mean visibility scores were 3.35±0.58 for 2D endoscopy and 3.75±0.44 for the 3D system. The score was significantly higher for the 3D system than for 2D endoscopy (p<0.001). When comparing the evaluations by the experts, non-experts, and medical students, the differences in the scores by the non-experts and medical students were noted to be higher (p<0.05). In contrast, the scores by the experts were also higher for the 3D system, but no statistical difference was observed (3.50±0.53 for 2D endoscopy and 3.87±0.35 for the 3D system, p=0.08). As a result, 10 out of 12 observers noted that the 3D system had better visibility than conventional 2D colonoscopy, and none of the observers noted deterioration in visibility with the 3D system.

Conclusion: The present findings suggest that the 3D imaging system improves the visibility of non-polypoid colorectal neoplasms, and this is more effective for non-experts. Our findings would contribute to improvement in the detection of these neoplasms.

Contact E-mail Address: iacucem@yahoo.it

Introduction: The SCENIC consensus proposed recommendations for optimal detection and management of dysplasia during colonoscopic surveillance for IBD. Characterization of colonic lesions in IBD remains challenging even by using advanced endoscopic imaging modalities (high definition [HD], virtual chromoendoscopy [VCE] dye chromoendoscopy [DCE]). Aims & Methods: We aimed to develop a unified endoscopic classification of advanced imaging to predict histology of colonic lesions, and to validated by international experts (Frankfurt Advanced Chromoendoscopic Ibd LSions-FACILE Group). We developed an endoscopic classification of IBD lesions, based on morphology, colour, demarcation, surface pattern, vessel pattern, signs of inflammation (table). A library of 60 colonic lesions, including dysplasia, sessile serrated adenomas/polyps, invasive cancer and pseudopolyps collected at surveillance colonoscopy by using HD, DCE and VCE with i-scan or NBI were assessed. The diagnostic performance of the score was tested based on the final histopathology and the inter-observer variability of the eight examiners. The examiners have had to perform a pre-test (45 minutes) before analyzing the colonic lesions. Multivariate analysis with bootstrapping, of characteristics of the classification was performed to determine the strength of endoscopic predictors of dysplasia.

Results: Of the 60 IBD lesions, 33 (55%) were dysplasia, 6 (10%) cancer, 9 (15%) SSA/Ps and 12 (20%) pseudopolyps. Across the experienced international raters sensitivity, specificity, PPV, NPV and accuracy in predicting histology, were 72%, 91%, 46%, 72%, 77%. Individual rater accuracy ranged from 66% to 77%. Sensitivity, specificity, PPV, NPV, accuracy, for predictions made with high confidence were 72%, 90%, 97%, 46%, 76%, which were significantly more accurate compared with a low confidence of diagnosis (76% vs 65%; p<0.001). Univariate analysis showed that the non polypoid lesions, irregular and vessel architecture and signs of inflammation within the lesion were predictive of dysplasia. Subsequent multivariate analysis confirmed that of these endoscopic findings non polypoid lesion OR 11.6 (95% CI6.71–20.2), surface pattern

Introduction: Participants’ experience with a screening test can influence adherence, and therefore the efficacy of a screening programme. We compared the satisfaction with decision and willingness to repeat colorectal cancer screening with flexible sigmoidoscopy (FS) and faecal immunochemical test (FIT).

Aims & Methods: In a prospective, randomised trial 3257 individuals (50–74 years) were invited to either FS or FIT (1:1) of whom 1650 (52.6%) attended.

Disclosure of Interest: All authors have declared no conflicts of interest.

Surgical resection
with methylene blue 1% to characterize the surface, vascular pit pattern and the margins of the lesion. Each of the 7 patients had non polypoid colonic lesions, 4 were sessile (Paris Ia) and 3 flat (IIa/IIb). Four of them were amenable to endoscopic therapy and were successfully removed using endoscopic mucosal resection (EMR) en-block or piecemeal technique. Interestingly, one patient with multiple scattered ‘pseudopolyps’ had a 8 mm sessile pseudopolypoid lesion with a suspicious areas of SSA in the midst that was confirmed by real pCLE.

The endoscopic, endomicroscopic and histological findings of all the lesions were described in Table 1.

**Conclusion:** This case series highlights the first successful use of pCLE in combination with VCE and DCE to predict, characterise and treat colonic neoplasia in IBD. pCLE may be an additional tool to aid the endoscopist in therapeutic management by deciding endoscopic resectability versus colectomy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic submucosal dissection (ESD) is one of the most useful methods for treating early colorectal neoplasms and conventionally utilizes an IT, hook, or needle knife. However, because these devices are used without fixation to target, it confers a potential risk of complications due to unexpected incision. To reduce the risk of complications from ESD performed using a conventional knife, we used a scissors-type knife (SB Knife Jr: Akita Sumitomo Bakelite, Japan) that allows keeping an adequate dissection layer and preventing unexpected muscular layer injury. In the previous study, we reported that ESD performed using SB Knife Jr is a technically efficient and safe method for treating early colorectal neoplasms. However, the efficacy and safety of colorectal ESD using SB Knife Jr in elderly patients remain unclear.

**Aims & Methods:** The aims of our study were to evaluate the efficacy, safety, and clinical outcomes of colorectal ESD using SB Knife Jr in patients aged ≥75 years in comparison with those in younger patients. We evaluated 291 lesions in 271 patients (male-to-female ratio, 148:123; median age, 70 years) treated with ESD using SB Knife Jr between October 2010 to March 2017 at Kure Medical Center and Chugoku Cancer Center. The patients were divided into two groups, an elderly group (group A: age ≥75 years; 95 patients, 97 lesions) and a non-elderly group (group B: age <75 years; 176 patients, 194 lesions). We evaluated the en bloc resection rate, complete resection rate, curative resection rate, en bloc tumor size, procedural time, complications, and long-term outcomes, including survival rate. The 3-year overall survival and tumor-specific survival rates were analyzed in the entire study cohort, and the local and distant recurrence rates were analyzed in the cohort with curative resection and observationally managed with non-curative resection.

**Results:** The mean age was 80.0 years in group A and 64.3 years in group B. The male-to-female ratios were 45:50 and 103:73 in groups A and B, respectively. Regarding histopathological findings, the prevalence rates of tubular adenoma were 37.1% (36/97) and 36.1% (70/194); Tis, 30.2% (38/127) and 44.8% (67/194); T1a, 10.3% (10/97) and 10.3% (20/194); and T1b, 13.4% (15/97) and 8.8% (17/194) in groups A and B, respectively, showing no significant difference. The mean resected tumor size was 33.9 ± 16.6 mm in group A and 34.7 ± 15.2 mm in group B, and the median procedural time was 75.6 mm (range, 10-420 min) in group A and 75 min (range, 10-533 min) in group B, showing no significant difference. The en bloc resection rates were 96.9% (94/97) and 99.0% (192/194); the complete resection rates, 94.8% (92/97) and 94.8% (184/194); and the curative resection rates, 83.5% (81/97) and 88.1% (171/194) in groups A and B, respectively, showing no significant difference. Regarding complications, no perforation during the procedure occurred in any of the cases. The delayed bleeding rate was 1.0% (1/97) in group A and 2.6% (5/194) in group B. Delayed perforation and rectal bleeding occurred in one patient each in group A and were treated conservatively. Regarding long-term outcomes, the local recurrence rate was 1.0% (1/97) in group A and 0.5% (1/194) in group B, and no distant recurrence was observed in the recurrence analysis cohort. Regarding survival analysis (mean follow-up period; group A, 523 ± 469 days; group B, 628 ± 582 days), the 3-year overall and disease-specific survival rates were respectively 98.8% and 100% in group A, and 93.3% and 98.3% in group B. One patient (0.5%, 1/194) died of colorectal cancer (2.6%, 5/194) in group A, and one patient (1.1%, 1/95) died of other diseases in group A.

**Conclusion:** ESD performed with SB Knife Jr is a technically efficient and safe method associated with favorable long-term outcomes in cases of early colorectal neoplasms in elderly patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Sessile serrated polytys (SSA/Ps) are pre-malignant lesions that may lead to colorectal cancer in accelerated manner. These lesions are easily missed by endoscopists as these are difficult to detect in IBD patients. We aimed to assess the prevalence, detection rate and endoscopic findings of SSA/Ps in long standing IBD patients prospectively undergoing surveillance colonoscopy using dye (DCE) or virtual electronic chromoendoscopy (VCE) or high definition white light (HD-WLE) colonoscopy alone.

**Aims & Methods:** A total of 270 randomized patients (55% men; age range 20–77 years, median age 49 years) with long–standing IBD (median duration of the disease 14 years) undergoing surveillance colonoscopy were assessed by HD-WLE (n = 90), VCE (n = 90) or DCE (n = 90). Surveillance colonoscopy with High Definition (HD) alone, or with iSCAN VCE or DCE was performed. Endoscopic features were recorded in each group with regard to location, morphology (polyoid/non polyoid), size and mucosal pit pattern, and these were characterized using the Kudo modified classification system (Paris classification). The histology was reported by modified Vienna classification.

**Results:** Thirty -three SSA/Ps were detected in 20 (11UC; 9 CD; 11 female, age range 34–72 y, median age 61 years) patients out of the 270 patients with IBD (enrolled 12.2%). The endoscopic features of SSA/P lesions were: non-polypoid morphology (polypoid/non polypoid), size and mucosal pit pattern, and these were characterized using the Kudo modified classification system (Paris classification). The histology was reported by modified Vienna classification.

**Conclusions:** SSA/Ps are not an infrequent finding at surveillance colonoscopy in IBD. There are prevalent in the right colon location and these generally have Kudo pit pattern of I0. SSA/Ps can be recognized endoscopically by Kudo pit

Introduction: The histological characterization of colorectal polyps using FICE (Fujinon Intelligent Color Enhancement) technology presents high diagnostic accuracy. However, the excellent results in histological prediction are a reflection of the clinical practice by trained endoscopists, and their application remains to be confirmed outside this context.

Aims & Methods: To evaluate the in vivo histological prediction accuity of colorectal polyps using FICE technology in WLE (White light endoscopy) and using FICE technology, comparing both modalities. Prospective evaluation, using WLE and FICE, of colorectal polyps <10 mm in patients submitted to colonoscopy between 12/2016 and 02/2017 by four inexperienced endoscopists in FICE, except for a previous 20-minutes interactive session. Polyps were evaluated using the FICE classification (tubular or oval crypts (adenoma), round crypts or featureless appearance (hyperplastic polyps), indicating their confidence level (low <90% vs high >90%). Statistics: SPSS v23.

Results: 25 polyps were included, with a mean size of 4.5 mm, 14 adenomas, 10 hyperplastic and 1 serrated adenoma. From the global assessment of all polyps and observations, the use of the FICE classification for prediction of adenomato-suspicous lesions value of sensitivity, specificity, positive and negative predictive value identical to WLE (100%, 62.5%, 60% and 100%, respectively).

Overall, diagnostic acuity in histological prediction was identical in both modalities (76%). The individual acuity of the endoscopists ranged from 66% to 90% vs high >90%). Statistics: SPSS v23.

Conclusion: The use of FICE technology by inexperienced endoscopists in the histological prediction of colorectal polyps has no advantage over WLE, having both suboptimal accuracies. The lack of recourse to magnification may have contributed to these results.

P0853 POLYP DETECTION RATES IN COLONOSCOPIES PERFORMED UNDER GENERAL ANAESTHETIC COMPARED TO CONVENTIONAL SEDATION

Medicine, Epsom and St Helier University Hospitals, London/United Kingdom

Contact E-mail Address: ben.perren@doctors.org.uk

Introduction: Colonoscopies are performed under general anaesthesia (GA) for various reasons, but mainly due to previous procedures being poorly tolerated with normal sedation. During the procedure, the endoscopist must be aware of the patient’s comfort levels and reactions to endoscopic manoeuvres. Polyp detection can be influenced by the modality of colonoscopy: GA (64.7±14.2) and non-GA (65±14.2). There was a significant (p=0.005) difference in age between the GA (59.7±18.2) and non-GA (64.7±14.2). This may be associated with the higher prevalence of polyps detected in non-GA patients.

Conclusion: GA (64.7±14.2) and non-GA (65±14.2). There was a significant (p=0.005) difference in age between the GA (59.7±18.2) and non-GA (64.7±14.2). This may be associated with the higher prevalence of polyps detected in non-GA patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0854 PATIENT AND PHYSICIANS RELATED FACTORS ASSOCIATED WITH A HIGH ADENOMA DETECTION RATE IN ROUTINE COLONOSCOPY

2IGR, Villejuif/France
3Digestive Endoscopy Unit, Clinique de Bercy, Chartron-en-Pont/France

Contact E-mail Address: m.cavichi@wanadoo.fr

Introduction: Adenoma and polyp detection rates are correlated to the risk of interval colorectal cancer and is consequently considered as a quality benchmark of clinical practice. We propose to identify in our daily practice, all the endoscopists of our endoscopy unit.

Aims & Methods: 6027 colonoscopies were performed between 01/01/2016 and 31/12/2016 by 30 physicians. Regarding patients, the following data were prospectively collected: age, gender, indication for colonoscopy, preparation procedure, and quality of the preparation (assessed by the Boston Scale), number and size of polyps and polyp histopathology. Regarding physicians, age, gender, number of colonoscopies and mean withdrawal time (calculated from the normal colonoscopies) were studied. Neoplasia was defined as grade 4 or 5 of the Vienna classification: (4: non-invasive high grade neoplasia (high grade adenoma/dysplasia, non-invasive carcinoma and suspicion of invasive carcinoma; 5: invasive neoplasia (intramucosal carcinoma, submucosal carcinoma or beyond). Links between these data and polyp detection rate (PDR) were assessed by univariate and multivariate analysis (stepwise logistic regression).

Results: We enrolled 2719 Male patients (45.1%) and 3308 Female patients (54.9%). Among 6027 patients, 732 (12.1%) of patient <50 years-old and 330 (5.5%) of patient >50 years-old were excluded, respectively. There was no significant difference between groups regarding number of polyps. The median number of polyps per physician was 140 (range: 10–720). 2054 colonoscopies detected 3914 lesions or polyps: 2914 tubular/villous adenomas, 496 serrated adenomas, 242 hyperplastic polyps (hyperplastic polyps located in the rectum and sigmoid colon were not considered as at risk for cancer and were excluded), 212 other histology leading to a major surgery. The mean number of Polyps (MNLP) was 0.65 and a Polyp Detection Rate (PDR) of 14.2). There was a significant (p<0.05). In the multivariate analysis, the only factors associated with a high PDR were: familial history of polyp/cancer, screening or positive faecal immunochromatography test (FIT+) and quality of preparation. Regarding physician-dependent factors, a high PDR was significantly associated with patient-dependent factors: age, gender, a familial history of polyp/cancer, screening or positive faecal immunochromatography test (FIT+) and sex. In the univariate analysis, a high PDR was significantly associated with patient-dependent factors: age, gender, a familial history of polyp/cancer, screening or positive faecal immunochromatography test (FIT+) and sex.

Conclusion: In this large series of routine colonoscopies, we found medically-relevant polyps in more than one third of the patients, irrespectively of age and indications. In multivariate analysis, a high PDR was significantly associated with a high PDR: familial history of polyp/cancer, FIT+ and age of the patient. This may suggest that the gender and polyp has no longer a risk factor for polyps. In addition, even if there are still discrepancies regarding PDR among physicians, we founded a patient-dependent factor associated with a high PDR in the multivariate analysis.

Disclosed of Interest: All authors have declared no conflicts of interest.

P0855 EFFICIENCY OF COLONOSCOPY IN CASE OF POSITIVE FECAL IMMUNOCHEMICAL TEST: ONE-YEAR EXPERIENCE AND RESULTS ON 391 PATIENTS IN ROUTINE PRACTICE IN FRANCE

M. Cavichi1, G. Tharsi1, P. Burtin1, P. Cattan1, F. Venezia1, G. Tordjman1, A. Gillet1, J. Samama1, K. Nahon-Uzan1, D. KarSENT1
1Pôle Digestif/Paris Bercy, Clinique de Bercy, Chartron-en- Pont/France
2IGR, Villejuif/France

Contact E-mail Address: m.cavichi@wanadoo.fr

Introduction: Fecal immunochemical test (FIT+) has progressively replaced the gusac test for colorectal screening in average risk population in France since May 2015. With a high sensitivity and a good specificity, it is supposed to increase colorectal cancer risk detection. However, its efficiency has not been described in routine colonoscopy.

Aims & Methods: Among 6027 colonoscopies performed between 01/01/2016 and 31/12/2016 in our endoscopy unit, 391 were performed for a positive FIT (FIT+) due to a screening issue, an acute or chronic inflammatory bowel disease.
P0857 
TWO LIQUORS OF POLYETHYLENE GLYCOL (PEG) WITH 15 MG OF BISACODYL VERSUS 4 LIQUORS OF PEG FOR BOWEL PREPARATION TO COLONOSCOPY, PROSPECTIVE RANDOMIZED STUDY. PRELIMINARY RESULTS
Hepato-gastroenterology, CHU Med VI Oujda, Oujda/Morocco

Contact E-mail Address: mekamine@hotmail.com

Introduction: Adequate bowel preparation is one of the most important quality factors of colonoscopy. Several formulations of bowel preparation have been evaluated for the ability to have a clean colon and be well tolerated by patients. Currently, PEG 4L solution is the preferred method of bowel preparation to colonoscopy. This preparation has the disadvantage of being poorly tolerated by patients. Furthermore, recent studies have shown that a low-volume PEG solution used in combination with Bisacodyl for bowel cleansing is as effective and better tolerated as a large volume PEG (4L).

Aims & Methods: This study aims to assess the efficacy and tolerance of the new regimen of PEG plus Bisacodyl compared to the classical regimen (4L of PEG).

Materials and methods: A prospective comparative randomised study comparing the tolerance, acceptability, and efficacy of a protocol A based on 4L of PEG and a protocol B corresponding to 2L of PEG + 15mg of Bisacodyl. Using the Boston Bowel Preparation Scale (BBPS) by endoscopists who did not know bowel preparation type, to evaluate the quality of preparation.

Results: Sixty-six patients were included (35 in group A and 31 in group B), with a sex ratio = 1. The average age of patients was 52 ± 15 years [17-86 years] with a median of 51.5 years (range: 32-86). Patients in group B had found the preparation difficult or moderately difficult vs 3 in group B (p = NS) with mild to severe side effects 54% of group A and 29% of group B (p = 0.03) and A mean side effect of patient was 2.26 vs. 1.89 (p = NS). Nausea and vomiting were respectively 34% and 19% of patients in group A and 13% of patients in group B (p = NS). However, 5 patients in group A had sleep disorders vs only one case in group B. Four patients who received 4L of PEG had expressed their refusal to resume the same preparation if necessary while 2 patients in group B had refused. A score greater than or equal to 7 was recorded 67% vs 36%, respectively (p = 0.03). Among patients with a maximal score of 9 (99%), 4 patients in group B and no patient in group A. Seven patients refused to repeat the test even if indicated. This refusal was secondary to the preparation in 4 cases (2 cases of each group). Abdominal pain and post-endoscopic distension ( useStyles = "start_adv") were respectively (62.8% and 65.7% vs 52% and 22.5%) (p = 0.016 and p < 0.001).

Conclusion: Preliminary results from our study suggest that the low-volume 2 L PEG with bisacodyl does improve patient tolerability with a tendency to be better for Good bowel preparation as compared to the traditional 4 L PEG. We continue our study to have a more significant number of patients view these new protocols to further confirm our results.

Disclosure of Interest: All authors have declared no conflicts of interest.

Colonicoscopy on the Left, Right? I. Mocanu, A. Laranjo, S. Pires, N. Veloso, L. Gonçalves, R. Godinho, I. Medeiros
Gastroenterology, Hospital Espírito Santo de Évora, Évora/Portugal

Contact E-mail Address: irma.mocanu.24@gmail.com

Introduction: Contrast-enhanced colonoscopy is a new procedure to train, with high variability of time spent to reach the cecum, depending on endoscopist experience, patient characteristics and type of colonoscopy used. Recently, the ROLCOL study demonstrated an advantage in time and patient comfort during progression in right lateral position (RLP) when compared with traditional left lateral position (LLP).

Aims & Methods: To compare time to reach cecum, patient and endoscopist comfort (using a visual analogue scale (VAS) in colonoscopies with progression on RLP and LLP. Prospective study, between January and April 2017, of colonoscopies under conscious sedation, randomly assigned to RLP and LLP. Olympus 190 series and Fuji EC-530 W13 colonoscopes were used. Inclusion criteria: routine colonoscopies, patients ≥ 18 years of age, abdominal surgeries other than colonic, examinations done by residents in second and fifth year of training and specialists. Exclusion criteria: incomplete colonoscopies or prior history of colonic surgery.

Results: One hundred and eighty-eight colonoscopies (94 on each side) were included. There was no statistical difference in mean age (RLP: LLP = 61 vs. 64 years; p = 0.05), gender (49 Vs. 52 males; p = 0.05), body mass index (27.4 Vs. 26.4; p = 0.05), previous history of abdominal surgery (44 Vs. 34; p > 0.05), and 52% vs. 41% specialist (p = 0.05), sedation dosage (midazolam 1.04 Vs. 1.09 mg, petidine 25 Vs. 25 mg; p = 0.05) or colonoscopy preparation (BBPS 6 Vs. 6, p = 0.05). Globally, there was no difference in “time to cecum” between the two positions (612 Vs. 633 seconds; p > 0.05), nor the patients’ comfort (VAS 3.92 Vs. 3.94; p > 0.05). This did not change after exclusion of less experienced endoscopists colonoscopies (581 Vs. 579 seconds, VAS 3.71 Vs. 3.76; p > 0.05). Surgical and overweight patients did not benefit from any of the positions (time to cecum: 650 Vs. 702 and 570 Vs. 657; p > 0.05, comfort: 4.2 Vs. 4.12 and 3.83 Vs. 3.96; p > 0.05, respectively). However, endoscopists comfort was higher in LLP (4.62 Vs. 3.76; p < 0.05). Both groups required position change during progression or loop palpation by the nurse in equal percentage (54% Vs. 46%; p > 0.05) and 49.5% Vs. 50.5%; p > 0.05). Additionally, there was no difference in time to cecum, patients or endoscopists comfort between the colonoscopies performed with Fuji or Olympus colonoscopes.

Conclusion: In our experience, progression in right lateral position did not show additional advantage over standard LLP in time to reach the cecum or patients comfort. We did not find any difference in time to progression or comfort between Olympus and Fuji colonoscopes.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
Results: 1382 LSL in 1243 patients were analysed. 1155/1243 (92.9%) patients had a solitary LSL. The majority of patients with multiple LSL had two (77.3%) or three (15.9%) lesions. 889/1382 (64.3%) of LSL were G. G LSL were more likely to be solitary (87.0%) than NG LSL (77.5%, p < .001). G LSL were more commonly large (>40 mm in size) (49.3%) than NG LSL (26.0%, p < .001) and were more commonly found in the right colon (proximal to transverse colon) (54.2% versus 48.3%, p < .034). In 88 patients with multiple LSL the dominant LSL was G (49/88 [55.7%]). A dominant G LSL was associated with fewer other LSL than a dominant NG LSL, p = .029.

Table 1: The morphology of the dominant (largest) laterally spreading lesion (LSL) predicts the presence and number of synchronous LSL. Morphology of the dominant lesion did not predict the others would be of the same morphology (p = .697). The dominant LSL was large in 43.2% of cases. Size of the dominant LSL predicted size of the other LSL (p < .001). 58.6% of dominant LSL were located in the right colon. In 65.9% patients all LSL were in the same colonic segment; this was not predicted either by the location of the dominant LSL (p = .860) or its morphology (p = .228).

### Results

**Patient**
- Age, mean (standard deviation): 68.58 (10.12)
- Sex, female (%): 27 (79.4)
- Lesion
  - Size, median (IQR): 15 (14.5–20)
  - Location, proximal to transverse colon (%): 26 (63.4)
- Paris classification (%)
  - 0-IIa: 40 (97.6)
  - 0-IIb: 1 (2.4)
- Endoscopic evidence of dysplasia (%): 0 (0)
- Kudo, highest (%): 11 (27.3)
- Procedure
  - Duration, median minutes (IQR): 4.5 (1.4 to 6.3)
  - Pieces, median (IQR): 3 (3–5)
  - Protrusion within defect (%): 9 (22.0)
- Intra-procedural bleeding requiring intervention (%): 0 (0)
- Histopathology, serrated adenoma (%): 41 (100)
- Low grade cytological dysplasia (%): 3 (7.3)
- Outcomes
  - Clinically significant post endoscopic bleeding (%): 0 (0)
  - Delayed perforation (%): 0 (0)
  - Post procedural pain (%): 0 (0)
  - Admission to hospital for related complication within 2 weeks: 0 (0)
  - Follow up
    - Months to SC1, IQR: 6 (5–7)
    - Recurrence at SC1, (%), n = 8: 0 (0)
  - Histologic recurrence at SC1, (%), n = 5: 0 (0)

### Conclusion
There is potential for pCSP to become the standard of care for non-dysplastic large SSP. This may reduce the burden on patients and healthcare systems of removing SSP, particularly by avoidance of delayed bleeding.

P0061 THE PROSPECTIVE OBSERVATION STUDY FOR OVER 10MM COLORECTAL LESIONS ENDOSCOPICALLY RESECTED USING BIPOLAR SNARE

Gastroenterology And Endoscopy, National Cancer Center Hospital East, Kashiwa/Japan

Contact E-mail Address: hiroskn@east.ncc.go.jp

Introduction: Polyectomy of adenomas reduces death due to colorectal cancer; therefore, colonoscopy is the gold standard to detect and treat adenomatous lesions. Most adenomatous lesions are less than 20 mm in size. Therefore, these are not indication for endoscopic submucosal dissection (ESD). Currently, there are some reports about cold snare polypectomy (CSP). CSP is effective and easy to remove lesions of less than 5–10 mm in size. On the other hand, in over 10 mm lesions, many endoscopists would remove it by endoscopic mucosal resection (EMR) with monopolar snare. It is expected that the bipolar snare would decrease the incidence of perforation because of electric current flow peculiar to bipolar snare that does not flow through the wall of colon. So, by using bipolar snare, hot snare polypectomy (HSP) that can be easily resected in a short time may be safely performed for over 10 mm colorectal lesions. However, there is no report about them.

Aims & Methods: We aimed to clarify removal method, procedure time and complications for over 10 mm colorectal lesions endoscopically resected using bipolar snare. Consecutive patients with over 10 mm colorectal lesions endoscopically resected using bipolar snare in National Cancer Center Hospital East between September 2016 and March 2017 were enrolled in this study, prospectively. The removal method rate of these lesions, each procedure time, complete resection rate, bleeding rate and perforation rate, and pathological finding were assessed.

Results: A total 92 lesions in 67 patients were analyzed. 47 patients (70%) were male, and the median age was 67 years (range: 44–88). The median lesion size was 15 mm (range: 10–30). The macroscopic type was 33 (36%) polyoid lesions and 59 (64%) flat lesions. The location was 55 (60%) lesions in right colon, 31 (34%) left colon and 25 (28%) rectum.

---

**Table 1:** Baseline characteristics and outcomes of the 34 patients and 41 SSP that underwent piecemeal cold snare polypectomy (pCSP). IQR – interquartile range, SC1 - first surveillance colonoscopy.
in left colon and 6 (6%) in rectum. Pathological diagnosis was 22 (24%) hyperplastic polypl or SSA/P, 42 (46%) low grade dysplasia (LGD), 23 (26%) high grade dysplasia (HGD), and 11% submucosal invasive cancer. In the removal methods, HSP was 71 (77%) lesions and EMR was 21 (23%). The median procedure time of HSP and EMR was 37 seconds (range: 7–430) and 167 (range: 60–450) (p < 0.001). The median lesion size of was HSP and EMR was 12 mm (range: 10–30) and 20 (range: 10–26) (p < 0.001). The immediate bleeding of HSP and EMR occurred in 7 (10%) lesions and 6 (33%) (p = 0.009). The delayed bleeding of HSP and EMR occurred in 2 (3%) lesions and 0 (p = 0.437). Perforation was not occurred. No tumors were horizontal and vertical margin positive. In the pathological diagnosis, 86% of hyperplastic polypl or SSA/P, 86% of LGD, and 57% of HGD was resected by HSP, and submucosal invasive cancer was resected by EMR.

Conclusion: Of 10 mm colorectal lesions was resected by using bipolar snare, 77% were resected by HSP. The procedure time of HSP was significant shorter than EMR.

Disclosure of Interest: All authors have declared no conflicts of interest.

### P0862 THE SMSA POLYP SCORE RELIABLY PREDICTS ROBUST ENDPOINTS OF ENDOSCOPIC MUCOSAL RESECTION OF COLORECTAL LATERALLY SPREADING LESIONS

**Introduction:** The 'SMSA' polyp scoring system is a method of risk stratifying the difficulty of polypectomy based on expert consensus opinion. The score is simple, intuitive and has been developed in a large multicentre setting.

**Aims & Methods:** We aimed to determine the ability of the SMSA polyp score to predict robust endpoints after endoscopic mucosal resection (EMR) of colorectal laterally spreading lesions (LSL). The SMSA polyp score was applied to a prospectively collected multicentre database of LSL resected by EMR over eight years. This score describes the complexity of polyprectomy with respect to four major domains (table 2) and is subsequently divided into four levels. Standard inject and resect EMR procedures were performed with detailed patient, procedural and outcome data recorded prospectively over the study period including all features of the SMSA. In patients who had multiple lesions resected the largest lesion was resected for analysis. The primary endpoints were correlation of SMSA score with completion rate, adverse event rate and adenoma recurrence.

**Results:** 2035 lesions in 2035 patients (47.4% M, 45.2% right colon) underwent EMR. The majority of lesions were SMSA 4 (50.2%) with a median lesion size of 30 mm (range 20–160 mm). Failed single session EMR occurred in 97 (4.7%) and this was predicted by increasing SMSA (p < 0.001). Intra-procedural bleeding was significantly more common with increasing SMSA (SMSA 2, 19/229 (8.3%) versus SMSA 4 291/1158 (25.1%), p < 0.001). Clinically significant post EMR bleeding (CSPEB) was more common as SMSA increased with 4 (1.7%) in the SMSA 2 group and 90 (7.8%) in the SMSA 4 group, p < 0.001. Intra-procedural perforation and delayed perforation were no different between the groups. After EMR surgery at 2 weeks was more common in the SMSA 4 group (p < 0.001). Of those patients that underwent their first surveillance colonoscopy (SC1), endoscopic recurrence (EDR) was more common in the SMSA 4 group than the SMSA 2 group, 206 (23.7%) as compared to 9 (5.4%), p < 0.001. This was also the case for histologic recurrence (p < 0.001). The difference in EDR persisted to the second surveillance colonoscopy (SC2) with no recurrences in the SMSA 2 group and 90 (7.8%) in the SMSA 4 group, p = 0.001. The median lesion size of was HSP and EMR was 12 mm (range: 10–30) and 20 (range: 10–26) (p < 0.001). The immediate bleeding of HSP and EMR occurred in 7 (10%) lesions and 6 (33%) (p = 0.009). The delayed bleeding of HSP and EMR occurred in 2 (3%) lesions and 0 (p = 0.437). Perforation was not occurred. No tumors were horizontal and vertical margin positive. In the pathological diagnosis, 86% of hyperplastic polypl or SSA/P, 86% of LGD, and 57% of HGD was resected by HSP, and submucosal invasive cancer was resected by EMR.

**Conclusion:** SMSA is a simple readily applicable clinical score that identifies a subgroup of patients who are at increased risk of EMR related complications including CSPEB and recurrence. This information is useful for planning EMR lists with respect to time and resource allocation. Moreover SMSA could have a major impact on training, both in identifying appropriate training cases and providing an objective benchmark against which to assess the progress of trainees in EMR.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**PO863 USE OF ACETIC ACID FOR EVALUATING SESSILE SERRATED ADENOMA/POLYP: A PILOT STUDY**

S. Yamamoto, M. Shafazand

Gastroenterology, Sahlgrenska University Hospital O¨stra, Goteborg/Sweden

**Contact E-mail Address:** shu0515suke@gmail.com

**Introduction:** Sessile serrated adenoma/polyp (SSA/P) has been accumulated increasing attention since its risk for developing to cancer had been clarified. These polyps are difficult not only to detect but also to determine their precise margin after detection especially in right side colon. Such a difficulty leads high recurrence rate after endoscopic resection. Magnifying function and narrow band imaging (NBI) is reported to be useful for evaluation of SSA/P but it needs special equipment, extra time, and expertise. Easier, uncomplicated, and non time consuming method is desired. The use of acetic acid or acetic acid-indigo carmine mixture have been introduced into endoscopic diagnosis in Barrett’s esophagus, early gastric cancer, and colorectal early cancer. However, there have been no reports on using this agent as aid for the optimal diagnosis of the margin of SSA/P. If this rather cheap agent was helpful for realizing the precise margin of SSA/P, it could decrease insufficient removal of the polypl and recurrence after that.

**Aims & Methods:** The aim of this pilot study is to assess whether the acetic acid could facilitate the recognition of the margin of SSA/P. We used acetic acid as a mixture with indigo carmine and compared it to conventional evaluating methods; narrow band imaging (NBI) and indigo carmine. From December 2016 to February 2017, patients in whom SSA/P more than 10 mm were found in right side colon in daily practical colonoscopy by single endoscopist in our institute were included. We used the standard scope without magnifying function. First we observed lesions with conventional white light and NBI. Second, we recorded pictures with indigo carmine (IC) spray alone on it. Finally, we sprayed the mixture of acetic acid and indigo carmine mixture (AIC) directly through the endoscopic working channel without using catheter onto lesion. Using recorded pictures during these procedures, ability for recognizing the margin of polyps were thought to be as AIC better than IC, and
similarly 7.3 in 9 were better than NBI. Kappra value among participants was 4.8; moderate agreement (p = 0.0016). All polyps were removed endoscopically after evaluation. All lesions were histologically diagnosed as SSA/P without dysplasia.

Conclusion: Acetic acid was useful and promising to facilitate the endoscopic recognition of the precise margin of SSA/P in right side colon. Strength of this method is that it is very simple and needs no special equipment nor skill.

Introduction: Preoperative localization or tattooing is essential for minimally invasive surgery. Although preoperative endoscopic tattooing using India ink or indocyanine green is widely used, clinical evidence and safety profile supporting the use of these agents is lacking.

Aims & Methods: We assessed the efficacy and safety of preoperative endoscopic tattooing using autologous blood. A total of 80 patients who underwent endoscopic tattooing with autologous blood were included in this study. From February 2016, all patients who required localization of a target lesion before colorectal surgery underwent endoscopic tattooing using autologous blood at a single tertiary medical center, and the outcomes were collected prospectively. As a comparison, we retrospectively reviewed the medical records of a further 40 consecutive patients who underwent endoscopic tattooing using India ink before February 2016. The primary outcomes were the visibility of the tattooing in the peritoneal cavity and related adverse events.

Results: Endoscopic tattoos produced using India ink were visible in 38 (95%) patients, and tattoos created using autologous blood were visible in 36 (90%) patients. In the autologous blood group, the tattoo could not be identified in four patients due to excessive peritoneal fat, bleeding tendency, congenital anomaly, and tattoos inadequate depth. Eight (20%) patients in the India ink group and four patients (10%) in the autologous blood group experienced endoscopic tattooing-related adverse events.

Conclusion: Preoperative endoscopic tattooing using autologous blood is a feasible and safe modality for the preoperative localization of colorectal lesions.

Introduction: Lateral spreading tumors (LSTs) are defined as lesions > 10 mm with a low vertical axis and lateral extension. They are separated in 2 subclasses for each of them: granular LST (LST-G) with, or without large nodule; and non-granular LST (LST-NG), separated into flat lesions (Ha) and depressed lesions (Ha+Hc). Every subclass has been associated with a poor risk of cancer and submucosal invasion (T1sm)1, 2. Knowing this aspect could help for the decision of the resection technique (endoscopic mucosectomy EMR, endoscopic submucosal dissection ESD, or surgery). The aim of our study was to determine the rate of cancer (submucosal and mucosal adenocarcinoma) in a western series of LST treated by endoscopic resection, and to evaluate the ability of the endoscopist to predict the depth of cancer invasion.

Aims & Methods: The entire patients with a LST ≥ 20 mm treated between January 2012 and December 2016 in our single center were included. Endoscopic data were collected (size, location, LST classification, analysis of pit pattern, endoscopic suspicion of cancer). We also reported the resection technique, histological results, and the follow-up at 1 year.

Results: 377 LST were included in our study. The average age was 67.7 years old. The mean size of lesion was 40.6 mm. LST were located in the right colon, the rectum, the left colon and the transverse colon in 44.5%, 32.6%, 14.0% and 8.8%, respectively. The resection technique used was a monobloc EMR in 15.4%, piecemeal EMR (pEMR) in 42.9%, ESD in 27.3% and assisted ESD in 14.5%. ESD was associated with a significant lower risk of recurrence after 1 year (4% against 18.1%). Considering the LST classification, there were 27.0% LST-G without large nodule, 28.4% LST-G with large nodule, 35.5% flat LST-NG Ha, and 9.0% LST-NG with depression Ha+Hc. The overall rate of adenocarcinoma was 19.7%, and 9.0% with submucosal invasion. The rates of adenocarcinoma and the rates of submucosal invasion in every subtype of LST are reported in table 1. They were higher for LST-G with large nodule (34.5% and 15.9% respectively) and for LST-NG with depression (35.3% and 20.6%). Endoscopic predictors of submucosal cancer were invasive pit pattern (HR 33.0; p = 5.76e-07) and depression (HR = 11.86; p = 0.049).

Conclusion: Our western series confirm similar rates of submucosal adenocarcinoma according to the type of LST as compared to Asian series. LST-G with large nodule, and LST-NG with depression were associated with a higher risk of submucosal invasion and invasive pit pattern was the stronger predictor of malignancy. Endoscopic submucosal dissection should be systematically performed in these cases.

PO866 ETHNIC VARIATION OF COLONIC POLYPS: FINDINGS FROM AN INTERNATIONAL HOSPITAL FOR MEDICAL TOURISM IN THAILAND
S. Techapaisan1, V. Permpoon1, K. Pongpirul1
1Digestive Disease Center, Bumrungrad International Hospital, Bangkok/Thailand
2Department Of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore/United States of America/MD

Contact E-mail Address: kpongpi1@jh.edu

Introduction: Evidence on an international variation of pathological types and anatomical distribution of colonic polyps is beneficial for early detection and management but limited.

Aims & Methods: To characterize differences in colonoscopy findings by ethnicity, a random sample of patients aged at least 50 years without colonic symptoms or history of colorectal diseases who underwent colonoscopy were reviewed. Of 26,508 subjects, 2651 were randomly selected. Of 1300 subjects who met the inclusion criteria, abnormal findings were identified in 878 cases (67.54%), of which 452 cases had 940 polyps and 7 cancer lesions were found in 6 cases. Of 452 patients with polyps, half had only one polyp (53.76%) and were Asian (54.63%), followed by Caucasian (26.99%), Middle Eastern (15.71%), and other ethnic origins (2.65%) (Figure). Ethnicity-specific polyp prevalence were 36.26%, 38.05%, 27.24%, and 34.15%, respectively. Polyps of Caucasian subjects tended to be smaller (4.52 mm) and locate on the left side of the colon (65.3%) than that of other ethnicities (44.4%–60.53%). The majority of the polyps (84.04%) were small (< 5 mm) whereas 8.19% were large (> 10 mm); hyperplastic polyp, tubular adenoma (TA), and tubulovillous (TVA) adenoma were identified in 43.19%, 53.83%, and 2.34%, respectively. Premalignant (TA + TVA) polyps were found in 56.08%, 50.19%, and 64.23% of the polyps of Asian, Caucasian, and Middle Eastern patients, respectively. Premalignant lesions were found in 52.91% of small polyps.

Conclusion: The findings suggested that number, size, distribution, and pathological type of colonic polyps vary across ethnic groups. As more than half of small polyps were a tubular adenoma, we propose that polyps of all sizes should be removed when feasible.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Endoscopic submucosal dissection represents the standard of care for large superficial colo-rectal neoplasms in Japan. In Europe, only few studies reported on the results of ESD in the rectal location. Colonic ESD is more technically challenging because of the colonic loops, intestinal motility, the folded anatomy, problems caused by inconstant gravity, and submucosal fibrosis. Colonic ESD is also more risky because perforations are most often caused by colonic peristalsis (3). The goal of the current study was to report our experience in performing colonic ESD in two French centers during the perioperative period.

Aims & Methods: Retrospective bicentre study of all cases of colonic ESD performed between 01/2016 and 03/2017 for superficial pre-cancerous or cancerous neoplasms. Primary Endpoint was to evaluate the En bloc, R0, curative resection rate and extended curative resection rate (Curative resection + non-curative due to positive horizontal margins and without recurrent disease on endoscopic control). Secondary endpoints were to compare these results with results of rectal ESDs performed during the same period.

Results: 87 colonic ESD were performed in two French centers between 01/2015 and 03/2017 for superficial pre-cancerous or cancerous neoplasms. During the same period 93 rectal ESDs were performed for superficial pre-cancerous or cancerous neoplasms. Descriptive results: male 54 (61%), mean size of the specimen: 49 mm, mean duration of procedure 125.1 min, mean speed of ESD: 18.9 mm²/min, perforation rate: 9 (10.3%), post procedural bleeding rate: 2.3%, secondary surgery 13 (15.3%) (3 (23%) for a perforation; 10 (77%) for a failure or R0 resection: 77.5%, curative resection: 63.8%, extended curative resection: 87.4%. Secondary Endpoint: No statistically significant parameters have been found between rectal and colonic ESD (Table 1).

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Colonic ESD could be performed with similar results than rectal ESD in French expert teams with prior strong experience in rectal and upper digestive tract ESD. Colonic ESD is technically challenging because of the colonic loops, intestinal motility, the folded anatomy, problems caused by inconstant gravity, and submucosal fibrosis. Colonic ESD is also more risky because perforations are most often caused by colonic peristalsis (3). The goal of the current study was to report our experience in performing colonic ESD in two French centers during the perioperative period. calculated the SMSA score of difficulty and assessed the ability of SMSA to identify 5 future outcomes: 3-month recurrence, 1-year recurrence, global recurrence (endoscopy not effective after 2 or more treatments), delayed bleeding and perforation. We compared results with those obtained using a subjective classification of difficulty: easy or medium vs difficult. Comparisons were conducted using chi-square tests and complemented with logistic regression models.

Results: The SMSA scoring system classified 690 polyps (39%) as level 4 and 1098 (61%) as level 3, whereas the subjective classification system classified 399 (22%) as difficult and 1389 (78%) as easy or medium. The agreement between measures of difficulty was weak ($k = 0.22$% as difficult and 1389 (78%) as easy or medium). The agreement between measures of difficulty was weak ($k = 0.22$% as difficult and 1389 (78%) as easy or medium).

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Clinical significance of delayed bleeding is the most frequent adverse event following endoscopic colorectal mucosal resection. Observational and interventional studies on the efficacy of prophylactic closure (PC) following endoscopic mucosal resection (EMR) showed conflicting results.

Aims & Methods: The primary objective of this review is to evaluate the effectiveness in preventing bleeding and post-polyectomy syndrome (PPS) or perforation of PC of colonic mucosal defects following endoscopic resection. We performed a systematic review and meta-analysis of randomized controlled trials (RCTs) from MEDLINE. We included studies with humans submitted to colorectal endoscopic mucosal resection and in whom mucosal flat or sessile (Paris classification 0-I or Ia) lesions with an estimated size ≥10 mm were found and removed.

Results: 269 articles were initially screened: 5 were RCTs, 4 of them were pooled in the quantitative analysis. A total of 355 patients and 357 resected lesions (proximal colon: 220; distal: 337) were included. Endoscopic procedures: 459 loop polypectomies and 98 submucosal dissections. A total of 298 lesions were randomized to PC versus 259 to non-closure (NC). Number of events on PC group: delayed bleeding (n = 3), PPS and perforation (n = 61). Number of events on NC group: delayed bleeding (n = 13), PPS and perforation (n = 14). Prophylactic mucosal defect closure was effective in reducing delayed bleeding risk (OR 0.206, 95%CI 0.054–0.779; p = 0.020; I² = 0%; 2 RCT and 452 lesions included). There was a non-significant trend for PPS/perforation risk reduction after PC (OR 0.349, 95%CI 0.114–1.070, p = 0.066; I² = 0%; 2 RCT and 374 lesions included).

Conclusion: Prophylactic closure of mucosal defects after EMR of flat or sessile colorectal lesions ≥10 mm reduces risk of delayed bleeding. Further studies are needed to evaluate the effect on PPS/perforation prevention.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: ESD is feasible and efficient in very old patients. However, En bloc resection and R0 resection are less frequent than in younger patients probably due to more challenging lesions (more frequent cancer on the pathological analysis). ESD should be the treatment of choice for large rectal superficial neoplasms of the rectum in very old patients in view of its oncological efficiency and its safety in comparison to the surgical alternative.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0876 COLONOSCOPY SPLIT-DOSE PROTOCOL IMPLEMENTATION: A SINGLE-CENTRE EXPERIENCE
C. Palmela, C. Gomes, M.P. Costa Santos, M. Rocha, S. Pereira, D. Tavares, R. Ribeiro, A. O. Ferreira, E. Barjas, M. Bravo
Gastroenterology Department, Hospital Beato Angelico, Loures/Portugal

Contact E-mail Address: palmela.carolina@gmail.com

Introduction: Split-dose bowel preparation (SD) is more effective in bowel cleansing quality in patients from a district hospital. This was an exploratory observational study of patients who underwent total colonoscopy between Jan/2016-Mar/2017 with polyethylene glycol bowel preparation before and after SD protocol implementation. Bowel cleansing quality was assessed prospectively (using Boston Bowel Preparation Score) and compared between SD and PD groups. Tolerance was assessed using a patient questionnaire.

Results: A total of 344 patients were included, 53% were male, mean age of 61.8±13.6 years. Bowel preparation: 66% SD and 34% PD. Overall, 72% of colonoscopies occurred in morning shifts. Mean interval between finishing bowel preparation and colonoscopy was 4h50 (SD) and 8h09 (PD). Adequate bowel cleansing was found in 51% of patients (SD 83% vs. PD 79%; p = 0.34). There was an association between SD preparation and better overall cleansing quality in patients from a district hospital. There was a significant association between preparation and colonoscopy (Sh40 vs. 7h15; p = 0.010). Split-dose preparation was associated with a better cleansing in the right colon (2.17±1.69 vs. 2.03±0.65; p = 0.047) and a trend for better overall cleansing (6.70±1.87 vs. 6.32±1.90; p = 0.067). On morning shifts, there was a significant difference between PD and SD groups (p = 0.03). A trend for better overall cleansing was found in patients of age ≥70 years old. There was an association between SD preparation and better bowel cleansing in patients of age ≥70 years old (risk difference 0.42% 95%CI –0.03%–0.83%; p = 0.068). There was no difference between groups on bowel urgency (SD 2.6% vs. PD 1.7%; p = 0.718). SD preparation was associated with worse sleep quality (SD 25% vs. DA 7%; p = 0.004).

Conclusion: The implementation of a split-dose preparation bowel protocol in our hospital was associated with better bowel cleansing, especially on the right colon. Split-dose preparation was not associated with higher bowel urgency, although there was a worse sleep quality.

Introduction: Acute iatrogenic perforations are one of the recognized complications of both diagnostic and therapeutic gastrointestinal endoscopy. For decades, surgical treatment has been the standard of care, but endoscopic closure has become a more popular approach, due to feasibility and the reduction of the
burden of surgery, combined with the availability of various endoscopic closure devices.

Aims & Methods: To assess the technical and clinical success and safety of endoscopic closure, in total, and for each endoscopic device used. Also, to identify factors predicting success as a first line treatment, and failure of endoscopic treatment.

Medical literature (Cochrane library, EMBASE, MEDLINE) from 1996 till September 2016 was searched. A systematic review and meta-analysis were performed on studies reporting technical and clinical success of endoscopic closure of acute iatrogenic perforations, according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) guidelines.

Results: 764 studies were identified. 28 studies, in human, met our inclusion criteria and were analysed. A total of 474 endoscopic closures were observed: 74.5% (95% CI: 67.7%–82.8%). Technical success was 91.6% (n = 431/474, 95% CI: 84.5%–95.9%), and complication rate was 1.3% (n = 7/474, 95% CI: 0.3%–2.3%). Technical success for endoclips closure was 96.6% (95% CI: 94.2%–98.2%), and clinical success was 93% (95% CI: 87.1%–97.2%), and complication rate was 6.6% (95% CI: 5.4%–7.8%) for OTSC. For Ovesco (Over the scope clip device), technical success was 83.8% (95% CI: 63.9%–96.6%), clinical success was 77.9% (95% CI: 56.8%–93.3%), and complication rate was 4.1% (95% CI: 1.9%–6.9%). Technical success rate for Self-expanding metallic stent (SEMS) is 100% (95% CI: 71.5%–100%), clinical success is 91% (95% CI: 74.1%–108%), and complication rate of 9.1% (95% CI: 78%–112%). Only one study for endosuturing met our criteria, with technical and clinical success rate of 100%, and without any complication. Factors predicting failure of endoscopic treatment and need for early surgical intervention included large perforation size, leukocytosis, fever, severe abdominal pain, large amount of peritoneal free air, necrosis or soft inflammatory margins, unavourable anatomical site, stool contamination and failure of endoscopic closure.

Conclusion: Our study suggests that endoscopic closure is a suitable treatment option for acute iatrogenic gastrointestinal perforations. Several factors have been suggested as predictors of need for surgery as a first line treatment. The study is limited by the low methodological quality of most studies included, indicating the need for further research.

P0882 “O-RING SIGN” AS A NOVEL COLORECTAL FINDING WITH NARROW-BAND IMAGING FOR DETECTING DEPRESSED-TYPE COLORECTAL LESIONS

T. Fujii
Dept. Of Gastroenterology, TF Clinic Dept. of Gastroenterology, Tokyo/Japan

Contact E-mail Address: tfclinie@tkhiki.palala.or.jp

Introduction: In recent years, colorectal cancer (CRC) has become a focus of attention as likely representing “missed” or “rapidly-growing” lesions in colonoscopy screening for colorectal cancer (CRC). Currently, lesions thought responsible for CRC include sessile serrated adenomas/polyps or flat and depressed-type lesions occurring on the right side of the colon, and there is an increasing need for endoscopic modalities to prevent overlooking these lesions. Colorectal screening using narrow-band imaging (NBI) during colonoscopy withdrawal from the cecum, which was started at our clinic since November 2008, suggested that “O-ring sign” was superior to white-light imaging (WLI) colonoscopy in detecting flat and depressed-type lesions (1). With NBI, the depressed area of a lesion is recognized as “whitish” and the surrounding ring-like mucosa as “brownish”, which constitutes the “O-ring sign”.

Aims & Methods: We aimed to evaluate the incidence and characteristics of the “O-ring sign” in depressed-type colorectal lesions. A total of 227 endoscopically resected and histologically confirmed depressed lesions (IIa + Ic, 156, Ic, 71) were included for analysis. The colonoscopic images of these lesions were retrospectively examined for “O-ring sign” positivity and intensity (grade 0, negative; grade 1, mildly to moderately positive; and grade 2, highly positive). Of these, 16 were excluded as unvaluable and a total of 211 evaluable lesions were analyzed. Results: Of the 211 lesions (IIa + Ic, 141; IIc, 70) analyzed, 84 (IIa + Ic, 68; IIc, 24), 105 (IIa + Ic, 69; IIc, 36), and 22 (IIa + Ic, 12; IIc, 10) were found to be in grades 0, 1, and 2, respectively, with 60.2% of these shown to be “O-ring sign”- positive (127/211), with Ia + IIc and Ic accounting for 57.4% (91/141), and 65.7% (45/67), respectively, of these lesions. While an examination by tumor size and location revealed no clear tendency in “O-ring sign” positivity, an examination by grade revealed a higher “O-ring sign” positivity rate among those with high-grade dysplasia (84.6%, 11/13) than those with low-grade dysplasia (59.2%, 116/196).

Conclusion: NBI colonoscopy screening for the “O-ring sign” as an index appears to improve the detection of depressed-type colorectal lesions.

Contact E-mail Address: naohiko.akimoto07@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) has been acceptable as a minimally invasive therapy and providing en-bloc resection for early malignant and pre-malignant lesions of gastrointestinal cancer. Colorectal ESD has some difficulties such as a risk of perforation and its severity compare to gastric ESD. Hence, Colorectal ESD is more challenging than gastric ESD in endoscopic technique. In Japan, where has high incidence of gastric cancer, endoscopists

Conclusion: The overall performance of endoscopists significantly improved with on-the-job training, but did not meet the standards for the implementation of the "do not resect" strategy. However, the results may have been affected by the addition of an additional category (is) to the NICE classification.

could have many experiences of gastric endoscopy, which may be beneficial for the introduction of colorectal ESD. However, little is know about the learning curves of the young endoscopists who perform the colorectal ESD first.

Aims & Methods: We conducted multi-center retrospective observational study to elucidate the safety and learning curve of the trainee who perform the colorectal ESD procedure. Trainees were consecutively recruited. ESD was performed by three endoscopists in Nippon Medical School Hospital and Machida Ichio Hospital from 2010 to August 2016. The ESD devices were Flash knife BT (Fujifilm), Dual knife (Olympus), Hook knife (Olympus) or a combination of both used by operators. The endoscopist A and B, who had over 10,000 examinations of colonoscopy and experiences of gastric ESD (as expert group), and endoscopist C had about 1000 colonoscopy and stented colorectal ESD first (as trainee group). The completion rate of operation, which is defined as en-block resection rate without changing operator, operation time, speed (time/mm) and complications were analyzed in each endoscopist. Furthermore, we divided these procedures in three periods equally as early, middle and late.

Results: The mean age was 70 (range 26–91) years old, and genders were 158 males and 103 females. Tumor locations were proximal colon, distal colon and rectum in 143 (54.8%), 59 (22.6%), and 59 (22.6%), respectively. The histological types were well and moderately differentiated tubular adenocarcinoma, adenocarcinoma with colonic differentiation in 13 (5.2%), and neuroendocrine 2 (0.8%), respectively. There is no statistically significant difference in age, gender, tumor location, tumor size and histological type. The average operation time was 1 hour and 58 minutes (range 41–335 minutes). The completion rates of endoscopist A and B reached 100% in all three time periods and endoscopist C showed an increase: 41%, 67%, and 100% in the initial, middle, late period, respectively. In the operation time, there was a significant difference between endoscopists C (range 38.5, median 49.0) and (100 ± 60.8, median 85), B (62.9 ± 45.1, median 55.5) and C (P < 0.001). In addition, there was no difference in the operation speed of endoscopist C among each periods. The complications were perforation and delayed bleeding in 8 cases (3.9%) and 2 cases (0.8%). All cases recovered with medical and/or endoscopic treatment alone.

Conclusion: Trainee endoscopist may have a good learning curve in completion rate and increasing experience reflects in a remarkable success rate in colorectal ESD. Therefore it was determined that the training of colorectal ESD first was acceptable by the trainee endoscopist who had no experience of gastric ESD. Disclosure of Interest: All authors have declared no conflicts of interest.
received anesthesiologist-directed BPS, required bag-mask ventilation and the ERCP was aborted due to sedation effects. There was no mortality from any cause within 24 hours of ERCP. All patients were discharged from the advanced endoscopy suite without adverse events.

Conclusion: Endoscopist-directed BPS appears feasible, safe and efficacious for ASA I-III patients undergoing outpatient ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0877 DUODENOSCOPES AND LINEAR ECHOENDOSCOPES ARE NOT CONTAMINATED WITH BACTERIAL OR FUNGAL PATHOGENS NATIONWIDE PERSISTENT HIGH PREVALENCE IN THE NETHERLANDS

1Department of Gastroenterology & Hepatology, Erasmus MC University Medical Center, Rotterdam/Netherlands
2Medical Microbiology And Infectious Diseases, Erasmus MC University Medical Center, Rotterdam/Netherlands
3Staff Office Medical Devices, Erasmus MC University Medical Center, Rotterdam, the Netherlands, Rotterdam/Netherlands

Contact E-mail Address: a.rauwers@erasusmc.nl

Introduction: Recent studies describe multiple outbreaks of multi-drug resistant organisms caused by contaminated duodenoscopes, used for endoscopic retrograde cholangiopancreatography (ERCP) procedures. Contamination of duodenoscopes is attributed to their complex design, which includes a forceps elevator and elevator wire channel. Linear echoendoscopes (LEs), used for endoscopic ultrasound (EUS) procedures, have a similar design with an additional balloon channel. Previously, we found that contamination of duodenoscopes was widespread in the Netherlands. It is unclear if the increased awareness of contamination and associated outbreaks has improved reprocessing outcomes of duodenoscopes and linear echoendoscopes (DLEs).

Aims & Methods: This cross-sectional study was conducted to determine the prevalence of bacterial contamination of all reprocessed DLEs in The Netherlands. All 75 Dutch ERCP/EUS centres were invited to sample all DLEs using centrally distributed kits, according to uniform sampling methods explained in video instructions. Local staff sampled four to six sites per DLE depending on endoscope type, including swabs (protection cap, forceps elevator, flushes (biopsy, suction, air/water and forceps elevator channel) and brushes (biopsy, air/water and balloon channel). Samples were centrally cultured. Radiography of the Meglumine Diatrizoate was performed in each patient of SOBS group to evaluate the occurrence of duodenal biliary reflux. 74 patients who were treated at or two more ERCP with extrahepatic bile ducts stricture treated with ordinary plastic stents (OBS group) from last ten years were compared with SOBS group.

Results: (1) The mean age of SOBS and OBS were 68.8±15.6yrs and 60.4±14.7yrs (P = 0.002), respectively. (2) 35 (57.4%) and 34 (45.9%) patients were contaminate. (3) The first and second patency was 4.5 months and 5.6 months in OBS groups. All the patients in OBS group experienced at least three ERCP to exchange plastic stents. The mean first and second patency were 3.9 months in OBS patients with malignant biliary obstruction. Yet the mean patency was 5.1 and 6.5months in OBS patients with benign biliary obstruction. (4) The occlusion rates of SOBS and OBS group after 3, 4, 5, 6 months of first ERCP were 13.1% and 36.5%, 27.1% and 55.4%, 42.4% and 67.6%, 55.9% and 77.0%, respectively (P = 0.003, 0.001, 0.005, 0.15). Similar to our previous findings, in 47% of all Dutch ERCP/EUS centres at least one patient-ready DLE was AM20 or MGO contaminated. Thirty-two (15%) DLEs from 23 (37%) centres were contaminated. Thirty-two (15%) DLEs from 23 (37%) centres were contaminated with MGO, including Enterobacteriaceae, Pseudomonas aeruginosa and Candida albicans. The most common bacteria were identified in eight different duodenoscope manufacturers and in all nine duodenoscope types and three LE types. For both definitions, contamination was not detected in LE or DE-dependent (P-values < 0.72), nor type (P-values >0.14) or microbial surveillance dependent (P-values > 0.45).

Conclusion: Similar to our previous findings, in 47% of all Dutch ERCP/EUS centres at least one patient-ready DLE was AM20 or MGO contaminated. Of all DLEs, 15% was contaminated with digestive tract bacteria, indicating inadequacy of current reprocessing techniques. These results suggest that any additional awareness of contamination has had no lasting effect or that the current reprocessing technique is not suitable for current DLE designs. This highlights the need for new preventative measures to minimize the risk of interpatient microbial transmission by DLE.

P0888 TECHNICAL EVOLUTION OF A NEWLY-DEVELOPED DIGITAL CHOLANGIO/PANCREATO-SCOPY (SPYGLASS DS) FOR INTRAOPERATIVE EVALUATION OF PANCREATOBILIARY NEOPLASM

Gastroenterology, Sendai City Medical Center, Sendai,Japan

Contact E-mail Address: keiito@openhp.or.jp

Introduction: Although a newly digital cholangio/pancreato-scopy (SpyDS) has been reported to be useful for therapeutic purpose in patients with biliary diseases, clinical application for diagnostic purpose of pancreateobiliary neoplasm remains unclarified.

Aims & Methods: To evaluate the usefulness and safety of cholangio/pancreato-scopy using a SpyDS for preoperative evaluation of pancreaticobiliary neoplasm. Patients and methods: Between October 2015 and Feb 2017, consecutive 26 patients (19, cholangiocarcinoma; 7, IPMN) who underwent cholangio/pancreato-scopy using a SpyDS for preoperative evaluation were included in this study. Diagnostic accuracy of malignancy and tumor extent evaluation by cholangio/pancreato-scopy guided biopsy/cytology and adverse event after the procedure were retrospectively investigated.

Results: Of 19 patients with cholangiocarcinoma, success rate of SpyDS guided mapping biopsy was 83% (103/124 sites). Diagnostic accuracy of longitude
tumor extent using SpyDS plus mapping biopsy was 92%. One patient developed mild cholangitis after the procedure. As for IPMN, pancreatobiliary using a SpyDS could visualize intraductal papillary tumors in all patients, and SpyDS guided biopsy/cytology was successfully performed. Diagnostic accuracy of malignancy was 100% without any adverse event after the procedure.

**Conclusion:** Preoperative evaluation using a SpyDS plus histological evaluation for pancreaticobiliary neoplasm was found to be useful and safe. Further study is needed to establish evidence about the usefulness of this technique.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0889 ACUTE PANCREATITIS AND HYPERAMYLASAEMY DEVELOPMENT AFTER ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY – CHALLENGES AND PREVENTION

P. Petrov1, B. Petrov1, T. Vukova2

1University hospital “Sofiamed” - Sofia, Sofia/Bulgaria
2Excitable Structures, Institute of Biophysics and Biomedical Engineering - Bulgarian Academy of Sciences, Sofia/Bulgaria

**Contact E-mail Address:** dr.p.petrov@gmail.com

**Introduction:** Endoscopic retrograde cholangiopancreatography (ERCP) is one of the most technically complex procedures performed by gastroenterologists. After a significant increase in the indications for implementing ERCP, gastroenterologists began to pay greater attention to complications identification and prevention. Despite the widespread improvement of endoscopic techniques and increased experience of endoscopists, the rate of complications has not declined significantly.

**Aims & Methods:** To analyze the frequency of probable causes of asymptomatic hyperamylasaemy and acute pancreatitis after ERCP and their prevention. Two groups of patients were covered: a retrospective (340) and prospective (154) group. Patients had evidence of bile ducts impaired passibility of varying etiology. In these cases ERCP is the final stage in the diagnostic and therapeutic algorithm. All ERCPs were carried out by one expert endoscopist. Patients from the prospective group were administered intramuscularly with Diclofenac (75 mg) before and after the manipulation. The methods used in the study were: demographic data; history and physical examination; laboratory data; imaging methods; ERCP; clinical course and statistical methods for processing data received.

**Results:** The most common indication for ERCP in all patients was cholestasis constellation (88.1%). In a minority of patients ERCP was purely diagnostic (6.1%), while at 93.9% it was also therapeutic. Of all patients at 47 of cases (9.5%) hyperamylasaemy was observed, and at 12 or 2.4% - acute pancreatitis. The estimated true percentage for predicting lack of hyperamylasaemy with this predictive model is very good - 97%. Univarient logistic regression analysis identified the following risk factors for the development of acute pancreatitis: cannulation of the pancreatic duct and the presence of calculous cholecystitis when entering.

**Conclusion:** We detected a low incidence of asymptomatic hyperamylasaemy (9.5%) and acute pancreatitis (2.4%) in the group of patients which were subjected to ERCP. Clinical and laboratory parameters characterizing the patients who developed these complications, and risk factors for acute pancreatitis and asymptomatic hyperamylasaemy were determined. The effect of intramuscular Diclofenac administrated before and after ERCP has no effect.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Advanced endoscopy trainees (AETs) achieve ERCP competency at variable rates and specific case volumes do not ensure competence. However, training and credentialing guidelines continue to utilize an absolute procedure volume to determine competence. There are limited data on whether current training composition and volumes ensure ERCP competence in the US.

**Aims & Methods:** (i) To define ERCP learning curves, utilizing a centralized database, with a focus on cannulation rates using a large national sample of AET programs (AETPs). (ii) To critically examine the composition of current ERCP training in AETPs. ASGE-recognized AETPs were invited to participate and AETs were graded on every ERCP after completion of 25 hands-on ERCP exams. Grading was performed using our previously developed and validated tool [The EUS and ERCP Skills Assessment Tool (TEESAT)] which assesses technical and cognitive competence in a continuous fashion. Grading for each skill was done using a 4-point scoring system: 1-no assistance, 2-minimal verbal cues, 3-multiple verbal cues or hands-on assistance and 4-unable to complete. A comprehensive data collection and reporting system was built using REDCap, a web-based data collection software, and SAS to create learning curves using cumulative sum (CUSUM) analysis for overall and individual technical and cognitive components of ERCP. Individual results and comparison to peers were sent to AETs and trainers quarterly. Acceptable and unacceptable failure rates were set a priori. AETs with <20 evaluations were excluded and success was defined as a skill score of 1 or 2. Individual and combined graphs to assess change in cannulation success rates were constructed and the Cochran-Armitage trend test was used to assess improvement in success rates.

---
ERCP techniques are required. Papilla cannulation rates and strategies to increase AET exposure to advanced time provided to AETs. Selective native papilla deep cannulation needs to be native papilla cannulation which may, in part, be due to limited cannulation system. Using strict definitions, a minority of AETs achieved competency in curves using a novel web-based comprehensive data collection and reporting threshold numbers to determine competence. We report the feasibility of establishing curves and competence among AETs in ERCP validating the shift away from advanced cannulation techniques such as double-wire technique, placement of sphincterotomy in 1199 (53%) and 901 (40%) cases, respectively. The mean time allowed for cannulation was overall - 4.0 min (SD 4.3), native papilla - 5.7 min (SD 4.8), and AET failed cannulation cases - 6.2 min (SD 5). There was no change in the time allowed for native papilla cannulation during the 1-year period (p = 0.28). AETs were involved in a small proportion of cases requiring advanced cannulation techniques such as double-wire technique, placement of pancreatic duct stent and precut sphincterotomy (6%). Learning curves for individual endpoints, overall technical and cognitive aspects noted substantial variability. Majority of AETs achieved overall technical (60%) and cognitive (100%) competence at the end of training. While there was a statistically significant improvement in overall and native papilla cannulation rates (both p < 0.001), only 18% of AETs achieved competence for native papilla cannulation (Table 1).

Conclusion: The results of this study confirm the substantial variability in learning curves and competence among AETs in ERCP validating the shift away from threshold numbers to determine competence. We report the feasibility of establishing a centralized national database to report individualized ERCP learning curves using a novel web-based comprehensive data collection and reporting system. Using strict definitions, a minority of AETs achieved competency in native papilla cannulation which may, in part, be due to limited cannulation time provided to AETs. Selective native papilla deep cannulation needs to be a benchmark for assessing competence. Methods to improve native papilla cannulation rates and strategies to increase AET exposure to advanced ERCP techniques are required.

Results: Of the 62 programs invited, 20 AETPs participated and 20 AETs were included in the final analysis. At the end of training, median number of ERCPs performed/AET was 350 (15–500). Overall, 2649 ERCP exams were graded; the majority were ASGE biliary grade 1 (77%) and only 14% for pancreatic indication. Among biliary ERCP cases, AETs attempted native papilla cannulation and sphincterotomy in 1199 (53%) and 901 (40%) cases, respectively. The mean time allowed for cannulation was overall - 4.0 min (SD 4.3), native papilla - 5.7 min (SD 4.8), and AET failed cannulation cases - 6.2 min (SD 5). There was no change in the time allowed for native papilla cannulation during the 1-year period (p = 0.28). AETs were involved in a small proportion of cases requiring advanced cannulation techniques such as double-wire technique, placement of pancreatic duct stent and precut sphincterotomy (6%). Learning curves for individual endpoints, overall technical and cognitive aspects noted substantial variability. Majority of AETs achieved overall technical (60%) and cognitive (100%) competence at the end of training. While there was a statistically significant improvement in overall and native papilla cannulation rates (both p < 0.001), only 18% of AETs achieved competence for native papilla cannulation (Table 1).

Conclusion: The results of this study confirm the substantial variability in learning curves and competence among AETs in ERCP validating the shift away from threshold numbers to determine competence. We report the feasibility of establishing a centralized national database to report individualized ERCP learning curves using a novel web-based comprehensive data collection and reporting system. Using strict definitions, a minority of AETs achieved competency in native papilla cannulation which may, in part, be due to limited cannulation time provided to AETs. Selective native papilla deep cannulation needs to be an important benchmark for assessing competence. Methods to improve native papilla cannulation rates and strategies to increase AET exposure to advanced ERCP techniques are required.

Conclusion: or procedure-related variable significantly associated with the development of remaining 3 were mild. In the AHP group, 3 PEP were moderate and 4 were between both PEP incidences was not significant. Despite our study didn’t show between both groups. 3) Two patients (1.05%) developed aspiration pneumonia none were 94/21 in the F group and 59/16 in the non-F group. (Fisher’s test: p-value = 0.074). There were no significant differences of patient characteristics between both groups: the mean procedure times were 36.7 minutes in the F group and 30.3 minutes in the non-F group, respectively. The details of procedures for the major papilla (endoscopic sphincterotomy/endoscopic papillary balloon dilation/dilation others) were 40/13/5/56 in the F group and 25/5/3.4/41 in the non-F group. The distributions of endoscopic biliary drainage or stenting/none were 94/21 in the F group and 59/16 in the non-F group, (Fisher’s test: p-value = 0.85) There were no significant differences of procedure characteristics between both groups. 2) The mean procedure times were 36.7 minutes in the F group and 30.3 minutes in the non-F group, respectively.

P0984 \textbf{ERCP CYTOLOGY YIELD – DOES THE BRUSH MATTER?}

I. Mocama A, Laranjo S, Pires N, Veloso L, Gonçalves R, Godinho I, Medeiros

Gastroenterologia, Hospital Espirito Santo de Evora, Evora/Portugal

Contact E-mail Address: irina.mocama.24@gmail.com

Introduction: Extra-hepatic biliary tree strictures are caused by a variety of malignant and benign diseases. The brushing of such stenosis during ERCP is safe and easy to perform, however, it’s low sensitivity, ranging from 30% to 50%. Efforts to improve cytology yield include dilution of the stricture prior to brushing and multiple brush passages, both without significant success. In 2011, US Endoscopy introduced the Infinity® cytology brush - a 4Fr (4, 75 mm) device that combines soft and stiff bristles in order to improve acquisition of cytology samples.

Aims & Methods: We aimed to determine if a new-design brush can improve the diagnostic yield of biliary cytology. From February 2015 until December 2016, the new Infinity® brush was used in all cases of ERCP cytology. These were compared with historical controls, where a classical 8Fr biliary cytology brush was used. In both groups, at least two passages were made, with transfer to a thin prep solution, as per prior protocol. Follow-up data, namely clinical course, radiological data or other histological results were collected for a definitive diagnosis.

Results: Thirty-five new brush cases were compared with 52 historical controls. There was no significant difference between gender (57% Vs. 52% male; p > 0.05), age (mean 70 Vs. 74 years; p > 0.05), location of structure (common bile duct 77% Vs. 84%; p > 0.05), length of stricture (between 1–3 cm in 80% Vs. 84%; p > 0.05) or dilution prior to sampling (71% Vs. 84%; p > 0.05) between the two groups. Physicians’ impression of malignant stricture during ERCP was more frequent in new brush cases, with near statistical significance (91% Vs. 75%; p = 0.052). Sufficient sample size for cytological analysis was more frequently obtained in cases when compared to controls (86% Vs. 100%, p < 0.05). Definitive diagnosis were as follows (cases Vs. controls): pancreatic neoplasia 57% Vs. 48%, cholangiocarcinoma 25.7% Vs. 23%, ampulla 0 Vs. 1.9%, benign conditions 17.3% Vs. 21%, no definitive diagnosis 0 Vs. 6.1%. In malignant cases, there was no difference between sensitivities of the cases (31%) and controls (37%), either for pancreatic cancer (20% Vs. 24%; p > 0.05) nor cholangiocarcinoma (55.6% Vs. 50%; p > 0.05). Specificity, positive predictive value and negative predictive value of Infinity® brush and classical 8Fr brush were as follows: 100% Vs. 100%; 100% Vs. 100%, 23% Vs. 35.7%. One stricture with benign features on ERCP (3 cases Vs. 13 controls), 14 had negative cytology and 2 were inconclusive (both controls).

Conclusion: There were significantly more samples with adequate cellularity for cytological analysis with the new Infinity® brush, however, the global sensibility of the two standard devices. With both brushes, the yield is twice as better for cholangiocarcinoma than for pancreatic cancer. One disadvantage we noted with the Infinity® brush is the increased difficulty in passing very tight, fibrotic strictures, even after dilution, due to its width and rigidity. Further ways to improve results would be the routine production of a smear sample, cell block analysis or intra-duodenal biopsies. The future era of cholangioscopy could dramatically increase our ability to sample biliary strictures.

3. David Z., Martín G., Cecilia C., et al. Early precut is as efficient as pancreatic duct cannulation during therapeutic ERCP were identified from the ERCP database of 3 institutions in 5
48 (6.3%) in Single APA group, and 4 of 48 (8.3%) in Multiple APA group
Aims & Methods: When guidewire was placed in the pancreatic duct initially by
chance, the patients were randomized into early precut (Group A) or usual early precut sphincterotomy with pancreatic stent (Group B). In Group A, pancreatic duct cannulation within 5 times and attempted precut papillotomy with
our study group. In Group B, from the precut stent was inserted and
then precut with an incision over a pancreatic stent was done. Main outcome
measurements were frequency of successful CBD cannulation and post-proce-
dure related complications.
Results: From January 2015 to August 2016, the two groups were similar
with regard to patient demographics. A total of 50 patients were enrolled. 26 patients
were assigned to the Group A and 24 to the Group B. Successful CBD cannula-
tion was achieved in 23 of 26 (88.5%) patients in the Group A and 23 of
95.8%) patients in the Group B. The mean cannulation time was 16 minutes in the
Group B in 14.8 and minutes in the Group B. Post-procedure hyperamylasemia
was significantly higher in Group A. The overall incidence of post-procedure pancreatitis was 11.5% (3/26) in the Group A and 4.2% (1/24) in the Group B
(P < 0.001).
Conclusion: In patients with pancreatic duct cannulation initially by chance,
compare to early precut group, utmost early precut with pancreatic stent over
the guidelines can only facilitate biliary cannulation and the success rate but also promise low incidence of post-ERCP pancreatitis. In experienced hands,
 utmost early precut technique can dramatically reduce the risk of ampulla and risk of PEI compared with conventionally persistent cannulation attempts.
Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** In biliary access, repeated biliary cannulation attempts are a risk factor for post ERCP pancreatitis (PEP). Early precut is an effective technique for successful biliary cannulation and can significantly reduce the incidence of PEP. The aim of this study was prospectively to evaluate clinical efficacy the performance of utmost early precut with pancreatic stent in the patients in whom pancreatic duct cannulation was performed initially.

**Aims & Methods:** When guidewire was placed in the pancreatic duct initially by chance, the patients were randomized into early precut (Group A) or utmost early precut sphincterotomy with pancreatic stent (Group B). In Group A, pancreatic duct cannulation within 5 times and attempted precut papillotomy with our study group. In Group B, from the precut stent was inserted and then precut with an incision over a pancreatic stent was done. Main outcome measurements were frequency of successful CBD cannulation and post-procedure related complications.

**Results:** From January 2015 to August 2016, the two groups were similar with regard to patient demographics. A total of 50 patients were enrolled. 26 patients were assigned to the Group A and 24 to the Group B. Successful CBD cannulation was achieved in 23 of 26 (88.5%) patients in the Group A and 23 of 95.8%) patients in the Group B. The mean cannulation time was 16 minutes in the Group A and 14.8 in the Group B. Post-procedure hyperamylasemia was significantly higher in Group A. The overall incidence of post-procedure pancreatitis was 11.5% (3/26) in the Group A and 4.2% (1/24) in the Group B (P < 0.001).

**Conclusion:** In patients with pancreatic duct cannulation initially by chance, compare to early precut group, utmost early precut with pancreatic stent over the guidelines can only facilitate biliary cannulation and the success rate but also promise low incidence of post-ERCP pancreatitis. **Introduction:** In a recent, a digital version of single-operator cholangioscope (SpyGlass DS) and direct POC (DPOC) using a multibending ultrasound endoscope were introduced as improved forms of each POC, especially in image quality and technical difficulty, respectively.

**Aims & Methods:** In this study, we prospectively compared the procedure success rates of SpyGlass DS and DPOC according to the type of lesion. Both advanced image quality of SpyGlass DS and improved technical difficulty of DPOC by a multibending ultrasound endoscope showed comparable and high procedure success rates in patients with dilated BD. Future prospective studies focused on overall cost savings and long-term clinical outcomes are seems to be required for deciding adequate indications of each POC systems.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**

During this 12-months period we have performed 1102 ERCPs, in 458 of April 2017.

Aims & Methods: The cannulation of a virgin papilla is the most difficult and high-risk step in ERCP and it requires significant experience to maximize the success and to minimize poor outcomes. Cannulation rate is one of the accepted quality indicators of ERCP. It is mandatory to regularly assess quality indicators of endoscopic procedures to maintain and improve endoscopic service.

Aims & Methods: We prospectively collected data about cannulation details of all patients with virgin papillas and post-ERCP complications from April 2016 to April 2017.

Results: During this 12-months period we have performed 1102 ERCPs, in 458 of them we had virgin papilla. All ERCPs had therapeutic intentions and all of the patients were followed up. In 13 patients papillas were not successful due to duodenal stenosis (10) or postoperative situations (3/10). In two of them the indication was ceased (because the biliary obstruction resolved spontaneously), 11 patients got percutaneous transheaptic drainage (PTD). The primary cannulation success rate of accessible papillas was 88.5% (394/445) while the overall cannulation success was 96.6% (430/445). 56.1% of primary successful cannulations were achieved by conventional method, in 14.2% we used pancreatic guidewire assisted technique, in 20.1% we used early precut sphincterotomy, and in the rest cases we used combined techniques. In 51 primary unsuccessful cases we repeated ERCP attempt in 4 days on average and successfully cannulated 70.5% (36/51) of them at the second or third attempts. 27 of them were achieved by conventional method, 7 of them after extending the precut, one case with pancreatic guidewire technique, and we used profllactic pancreatic stent in one patient, as well. Out of the 15 patients with finally unsuccessful cannulation, we performed precut without deep cannulation in 10 cases. 7 of them resolved after precut, 2 of the 10 patients got PTD and one patient refused further investigation. In 4 patients out of the 15 unsuccessful cannulations the obstruction resolved without any further intervention and one patient got PTD. We had in sum 3.4% (15/445) post-ERCP pancreatitis, 7 of them were mild, and 8 moderate, we had no severe one. We observed endoscopic signs of biliary drainage in 63 of the 102 cases (61.8%) with some endoscopic techniques (inflation/coagulation/stenting), 7 of them (1.6%) required blood transfusion. Three patients suffered perforation during ERCP. One of them got biliary stent and was discharged uneventfully on the 8th day. We had 2 sphincterotomy related perforations, 1 had early surgery – he died on the 14th day, another patient had delayed surgery, he recovered.

Conclusion: Quality assessment of ERCP performance is essential. Our overall cannulation rate was acceptable. We used pancreatic guidewire assisted technique just after long phase of ERCP without deep cannulation in order to avoid long lasting traumatisation of the papilla. Our complications rate of post-ERCP pancreatitis was good while the post-sphincterotomy bleeding rate should be considered higher than in the literature, therefore we changed the technique of electrocautery.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0903** ENDOSCOPIC ULTRASOUND-BASED TRANSDUODENAL CHOLECYSTOTHOTOMY VIA DOUBLE-FLANGED FULLY COVERED METAL STENT WITH HOT STENT DELIVERY

S. Sun
Endoscopy Center, Shengjing Hospital of China Medical University, Shenyang/ China

Contact E-mail Address: sunsyucmu@aliyun.com

Introduction: Laparoscopic cholecystectomy (LC) has become the ‘gold standard’ for the treatment of symptomatic gallstones. However, before clinical implementation, instruments still need modification, and a more convenient treatment is still needed.

Aims & Methods: The aim of this study was to evaluate the transduodenal tractcholecystectomy technique in the treatment of gallbladder disease without choledocholithotomy in the patient with cholesterol gallstones and high surgical risks were enrolled between January 2015 and March 2017. Endoscopic ultrasound (EUS)-guided cholecystoduodenostomy by deploying a double-flanged fully covered metal stent with hot stent delivery was performed and endoscopic sphincterotomy (EST) was also performed during this procedure for those patients with accompanying common bile duct stones. One or two weeks later an forward-viewing endoscope was advanced into the gallbladder via the stent, and cholecystolithotomy or polypectomy was performed. After the stents were removed, a pigtail-type naco-cholecystic drainage catheter was inserted into the gallbladder over the guide wire and removed 2 days later. Four weeks later gallbladder was assessed by abdominal ultrasound.

Results: EUS-guided cholecystoduodenostomy with double flanged metal stent deployment was successfully performed in all of 26 patients (Male/Female, 11/15; mean age, 61 ± 16.19yrs). After the procedure, fistulas had formed in each of the patients and the stones of 7 patients expelled themselves completely. Endoscopic cholecystotomy (19) and polypectomy (2) were performed by using a single cautery under the small endoscope. The mean follow-up period was 11 months (range: 1–27months). Cholesterol gallstones recurrence were not detected in any patient during follow-up.

Conclusion: The EUS-guided placement of a novel metal stent with hot stent delivery is a safe and simple approach for performing an endoscopic cholecystoduodenostomy, which can subsequently allow procedures to be performed for treating biliary disease, including cholecystolithotomy.

Contact E-mail Address: helena.brinribeiro@gmail.com

Introduction: The second generation of quantitative ultrasound (EUS) elastography allows the quantitative analysis of tissue stiffness and can be a useful auxiliary tool in the differential diagnosis of pancreatic solid tumors (1)(2).

Aims & Methods: The aim of this study was to evaluate the accuracy of the quantitative EUS elastography in the differential diagnosis of pancreatic solid masses, discriminating malignant from benign masses, using strain ratio (SR) analysis. A prospective study was performed for 15 months and included 29 consecutive patients who underwent EUS for the evaluation of solid pancreatic masses. EUS elastography was performed by 2 operators, using a linear echoendoscope. The mean of 3 measures was considered as the SR final result for each lesion. EUS-fine-needle aspiration of the lesions was performed after SR assessment and the final diagnosis was based on the cytology or histology results.

Accuracy of the elastography was obtained by the analysis of ROC curves.

Results: Included 29 patients in a total of 30 lesions with conclusive histological/ cytologic diagnosis (8 inflammatory masses, 19 adenocarcinomas, 2 neuroendocrine tumors and 1 undifferentiated carcinoma). The mean SR value was significantly higher in the malignant tumors compared with the benign tumors (55.56 vs 23.93, p < 0.001). The sensitivity and specificity of SR for differentiation of pancreatic malignancy for a cut of 15.89 were, respectively, 95.45% and 87.5% (area under the curve of 0.89, 95% CI). The overall accuracy of the EUS elastography using the SR for the detection of pancreatic malignancy was 93%. Conclusion: Quantitative EUS elastography presents good accuracy in the differential diagnosis between malignant and benign pancreatic masses. It is a promising EUS technique in the diagnostic approach of solid pancreatic lesions, which may complement the study and characterization of the tumors, aiding in the diagnostic and follow-up of these patients.

Introduction: Significant heterogeneity in geographic distribution in the prevalence of mediastinal lymphadenopathies have been documented in CT studies. Awareness of the geographic prevalence and characteristics of lymphadenopathies will be relevant when performing endoscopic ultrasonography (EUS-TS) for non-malignant necrotic lesions. EUS-TS revealed higher rate of overall diagnostic accuracy comparing to ERCP-TS (82.8% vs. 60.2%, p = 0.001).

Results: From January 2011 to September 2016, we enrolled 125 patients and 32 patients were excluded due to the following reasons: loss of follow up in 8, EUS-TS of pancreatic duct in 23, and ERCP-TS from peripancreatic biopsy in 4. Among the enrolled patients (93 patients; 62 males, mean age 65.8 years), 86 (92.5%) had malignant tumor such as cholangiocarcinoma in 39, pancreatic cancer in 37, and other malignant tumors in 10 patients. And 7 (7.5%) patients had benign lesions. EUS-TS revealed higher short axis diameter (EUS-FNA) or biopsy (EUS-FNB) and ERCP-TS using brush cytology and/or forceps biopsy were performed. The diagnostic performances were compared between two techniques according to primary tumor sites.

Conclusion: In one of the largest series of patients, we showed that endoscopic ultrasonography has an overall high agreement and accuracy in the selection of gastric adenocarcinoma patients for neoadjuvant therapy, although they higher for proximal and intestinal lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0908 ACCURACY OF ENDOSCOPIC ULTRASOUND IN GASTRIC ADENOCARCINOMA PATIENT SELECTION FOR NEOADJUVANT THERAPY

J. M. Costa1, J. B. Soares1, B. Gonçalves2, S. Carvalho2, R. Gonçalves1

1Gastroenterology, Hospital de Braga, Braga/Portugal

2Pathology, Hospital de Braga, Braga/Portugal

Contact E-mail Address: julianamecosta87@gmail.com

Introduction: Recent studies documented the positive impact of neoadjuvant treatment for gastric adenocarcinoma T ≥2 and/or N +. Aims & Methods: We aimed to assess the accuracy of endoscopic ultrasound in the selection of patient with gastric adenocarcinoma for neoadjuvant therapy. A unicentric retrospective analysis of patients with the anatomopathological diagnosis of gastric adenocarcinoma between 2011 and 2016, who performed endoscopic ultrasound for staging and underwent surgery without prior neoadjuvant treatment. The concordance (kappa) and accuracy (S) and specificity (E) of the endoscopic ultrasound for T ≥2 and/or N + (criteria for neoadjuvant treatment) were assessed using the anatomopathological staging of the resected specimens.

Results: The final sample included 144 patients (64.6% male) with a median age of 68.5 ± 12.2 years. In most cases (80.6%), the neoplasia was distal (antrum, incisura angularis and body). The neoplasia was of the intestinal type, diffuse and mixed in 65.3%, 18.8% and 16% of the cases, respectively. After examination of the resected surgical specimen, 53.5% of patients had criteria for neoadjuvant treatment (T ≥ 2 and/or N +). The overall kappa, specificity and sensitivity of the endoscopic ultrasound for T ≥2 and/or N + were 0.720, p < 0.001), 85.2% (95% CI: 75.6–92.1%) and 87.3%, (95% CI: 76.5–94.4%), respectively. The overall kappa, specificity and sensitivity of the endoscopic ultrasound for T ≥2 and/or N + were higher in proximal lesions (cardia and JEG) (k = 0.924, S-94.4% and E-100%) compared with distal lesions (k = 0.671, S-82.5% and E-84.9%) and in intestinal type lesions (k = 0.765, S-84.9% and E-92.7%) compared with diffuse type lesions (k = 0.682, S-88.4% and E-80%) or mixed (k = 0.566, S-81.8% and E-75%).

Conclusion: In one of the largest series of patients, we showed that endoscopic ultrasonography has an overall high agreement and accuracy in the selection of gastric adenocarcinoma patients for neoadjuvant therapy, although they higher for proximal and intestinal lesions.

Introduction: Endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) for cystic fluid analysis for CEA and cytology had a change in the most accurate diagnostic method in these lesions. The role of repeated EUS-FNA for cystic fluid analysis in follow-up of PCNs is not clear.

Aims & Methods: To determine if patients with pancreatic cysts with a second repeated EUS-FNA for cystic fluid analysis for CEA and cytology had a change in cyst classification or on clinical decision. Retrospective analysis of a EUS database, with 284 patients who had EUS-FNA for pancreatic cyst evaluation from 2007–16, of which 35 had 2 EUS procedures, and of these, 22 had 2 consecutive EUS-FNA procedures.

**Introduction:** Despite advances in imaging techniques, differential diagnosis of pancreatic cysts still remains challenging. There has been an increasing interest in new pancreatic cyst biomarkers as a way to differentiate different cyst subtypes and avoid unnecessary surgery. Recently intracystic fluid glucose has been proposed as a promising marker. The aim of this prospective study was to verify this early finding.

**Aims & Methods:** We enrolled in the study all the patients who underwent Endoscopic Ultrasound (EUS) guided Fine Needle Aspiration of a pancreatic cyst at our Institution from October 2015 to February 2017. The cyst fluid was sent for cytology, mucin staining and determination of amylase, Carbohydrate Antigen 19-9 (CA 19-9), Carcinoembryonic Antigen (CEA) and glucose. When deemed necessary by the endoscopist, needle-based confocal laser endomicroscopy (nCLE) of the cyst wall and/or contrast-enhanced EUS was performed. A definitive diagnosis of the nature of the cyst was reached relying on surgery, cytology or mucin staining, a typical pattern of nCLE or by consensus (on EUS and nCLE features) by three expert endosonographers, blinded to cyst markers concentrations.

**Results:** Twenty-nine patients (13 males, median age 72 years, range: 30-83) entered the study. Nineteen (66%) pancreatic cysts were unilocular (74%), 10 (35%) were multilocular and the median largest diameter was 45 mm (range: 20-70 mm). Sixteen (55%) cysts were located in the pancreatic head, 10 (35%) in the body and 3 (10%) in the tail. CE-EUS was performed in 14 (48.3%) patients, nCLE was performed in 9 (30.7%) patients. Eighteen (62%) cysts were classified as mucinous (6 mucinous cystadenomas; 12 intraductal papillary mucinous neoplasm) and 11 (37.9%) as non-mucinous (6 serous cystadenomas; 5 pseudocysts). The final diagnosis was reached relying on surgery in 9 patients (31%), on cytology in 10 (34.4%), on nCLE in 8 (27.6%) and on consensus in 8 (27.6%). Mean glucose concentrations in mucinous cyst were significantly lower than in non-mucinous cysts (7.7 μg/dl vs 95.7 μg/dl, p < 0.0001). In the diagnosis of mucinous cysts, sensitivity of CA 19-9 (cutoff more than 5000 U/ml), CEA (cutoff more than 192 mg/ml) and glucose (cutoff less than 50 mg/dl) was respectively 22.2%, 66.7% and 94.4%. Specificity was respectively 72.7%, 100% and 100%. Accuracy was respectively 41.4%, 79.3% and 96.6%. Only two subjects in this cohort were affected by diabetes, this condition did not impact on intracystic glucose concentration.

**Conclusion:** Although limited by the small sample size, this study confirms the utility of intracystic glucose levels in differentiating mucinous from non-mucinous pancreatic cysts. This cheap, new marker outperformed CA 19-9 and CEA in sensitivity, specificity and accuracy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0911 UTILITIES OF LIQUID BASED CYTOLOGY IN EUS-FNA SAMPLES FOR THE PANCREATIC LESION:**

**Contact E-mail Address:** ishida_yaushake@kurume-u.ac.jp

**Introduction:** Liquid-based cytology (LBC) preparation method is one of the most advanced methods, which is widely used in gynecological and non-gynecological cytological samples, due to its ability to decrease screening time, insufficient sample rate, and air-drying artifacts compared to a conventional smear method. Additionally, immunocytochemistry (ICC) can be performed after LBC, which is used in gynecological and non-gynecological cytology samples, due to its ability to decrease screening time, insufficient sample rate, and air-drying artifacts compared to a conventional smear method. Additionally, immunocytochemistry (ICC) can be performed after LBC.

**Aims & Methods:** The aim of this study is to show the actual method of LBC and to evaluate the utility of LBC in EUS-FNA samples of the pancreatic lesions. 292 specimens obtained by EUS-FNA from patients with pancreatic disease were included in this study. Clinical information was prospectively recorded in 210 cases, acinar cell carcinoma in three cases, adenosquamous cell carcinoma in one case, invasive ductal carcinoma derived from IPMN in three cases, metastatic pancreatic tumor in eight cases, pancreatic neuroendocrine tumor (PNET) in 20 cases, solid pseudopapillary neoplasm in 11 cases, serous cyst (SCN) in five cases, mass-forming pancreatitis in four cases, and autoimmune pancreatitis (AIP) in 40 cases. Just after EUS-FNA, tissue sample in the FNA needle was flushed out into petri dish with saline. The sample was carefully examined to provide samples for biochemical and cytological examination. The liquid was formalin-fixed and processed for pathological evaluation. All residual liquid specimen in whole was immediately immersed in liquid-based fixation medium (CytoRichTMRed) at the bedside. The liquid was centrifuged and processed (a) LBC, (b) PCL with two protocols: group 1: Ciprofloxacin 200 mg iv, one-dose, immediately before FNA; and group 2: Ciprofloxacin 200 mg iv, one-dose, immediately before FNA plus three days of oral Ciprofloxacin 500 mg, bid. Retrospective statistical analysis of all the cases was performed to compare the results of the two protocol groups.

**Results:** Positive predictive values of cytology and histology are 99.1%(223/225) and 98.3%(201/205). Positive predictive values of cytology and histology are 18.7%(214/225) and 67.6%(152/225). 65.8% (48/73) of pathologically non-diagnosed cases could be diagnosed as malignancy owing to cytology. In 26 specimens where immunocytochemistry was needed, IHC was available in 23 of the 26 specimens (88.5%) and ICC was available in all specimens. In the three specimens, IHC was not available owing to pathological insufficiency. In 204 EUS-FNA samples obtained by EUS-FNA may be useful for reducing insufficient material rate and conducting ICC as well as in samples in other medical fields.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

prophylaxis is mandatory during EUS-FNA of PCLs, since it does not seem to have a protective effect. Moreover, the raise in antibiotic resistance and possible adverse effects related to their use should be balanced against the very low infectious complication rate of EUS-FNA. One limitation of our study is its retrospective nature, with a significant delay between the EUS-FNA and the time to inquiry, which could have biased the patients answers.

Introduction: The endoscopic ultrasound (EUS) has proven useful in the study and evaluation of the adrenal gland (AG) by endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA), in both the left and right glands.

Aims & Methods: To analyze the diagnostic performance, safety, on clinical management, predictors of malignancy and cyto-pathological correlation of the EUS-FNA with adrenal gland.

Results: A review of 205 EUS-FNA of adrenal gland in 200 patients (154 males). Average age: 65.3 (DE 9.6). Primary tumor: lung 69%, unknown 10%, other 20%. Adrenal gland left 191; adrenal gland right 14 (Main features: CT scan-proven adenopathy, high-uptake (82%), hypochogenic (88%) and suspected by endoscopist (69%)). Puncture technique most commonly used: cytological needle (75%), 22-G (64%), suction-syringe (66.3%), passes 2.17 (DE 1.38).

92% of samples allowed a cytological diagnosis, 60% malignant. Variables associated with malignancy: CT scan pathological morphology (OR: 2.99 IC 95% 1.41–6.44), heterogeneous pattern EUS (OR 2.99 IC 95% 1.13–3.97), morphological and extension of the EUS-FNA with adenocarcinoma. A size >5 mm (OR: 2.27 CI 95% 1.17 to 4.48). Pathological suspicion of the endoscopist was associated with a greater therapeutic change (OR: 4.48 CI 95% 2.38 to 8.62). No description of adverse events.

Conclusion: Adrenal gland by endoscopic ultrasound-guided fine-needle aspiration is a safe and high diagnostic yield method. The variables most associated with malignancy are the suspicious echo endoscopic images objectified by expert endoscopists, a heterogeneous pattern and variegated morphology. The results suggest the possibility of developing a predictive malignancy model pre-surgical.

P0915 RELIABILITY OF GISTs PRE-TREATMENT RISK ASSESSMENT CLASSIFICATION WITH EUS-FNB BY USING DESIGNED CORE NEEDLES

R. Grasas, P. Capone, F. Cereatti, E. Irlitano, VjeroK., M. Martinotti, G. Tansi, F. Buffoli
Gastroenterology, ASST Cremona, Cremona/Italy

Contact E-mail Address: robertograssas@yahoo.it

Introduction: The current classifications of non-metastatic GIST are based on post-operative pathologic criteria and are useful to estimate the potential risk of postoperative recurrence and determine the value of adjuvant Imatinib. The proposed pre-treatment classification currently recognized risk factors as tumor diameter, mitotic rate and site (gastric vs non-gastric). EUS-guided tissue samples remains mainstay for pathological diagnosis of GIST, but previous studies showed that EUS-FNA with standard 19 or 22 gauge needles does not reliably reflect GIST’s proliferation and size.

Aims & Methods: We aimed to investigate the EUS-FNB diagnostic yield for GIST and to evaluate whether EUS-FNB samples reflect prognostic criteria obtained from resected GISTs. A prospectively maintained database was retrospectively reviewed to identify consecutive patients with surgically resected subepithelial lesions who received a diagnosis of GIST at a previous EUS-FNB with a 19 or 22 gauge core-needle (EchoTip® ProCore™ Cook Medical). Size from EUS examination and mitotic/proliferative indexes obtained from EUS-FNB samples were compared with surgical specimens.

Results: Between November 2012 and December 2016 18 patients were studied (11 males, mean age 71.6 years, range 44–88 yo). The tumour site was the stomach in 15 out of 18 patients and the duodenum in 3 out of 18 patients. Agreement between EUS-FNB and surgical pathology was 100% with respect to the diagnosis of GIST (18/18). Proliferative indexes (Ki67/MIB1) were determined in 14/18 (77.7%) of all cases (as expected) in resected specimens. In our series Ki67/MIB1 were generally underestimated. We found only 2 patients with the required number of 50 HPFs for mitotic count examination. They showed a mitotic index <5/50 HPFs comparable to surgical specimen. No mitotic figures were seen in core biopsy specimen from any of the remaining 16 patients. In these patients the number of HPFs for mitotic count examination ranged from 1 to 22. In their corresponding surgical specimen we found mitoses in 16/16 patients, ranging from 1 to 5 per 50 consecutive HPFs. Tumour size of the surgical specimen exceeded (> 5 cm) the tumour size in 11 out of the 18 investigated cases (66.6%) and was equal (± 5 mm) in 6 cases (33.3%).

Conclusion: In our experience, EUS-guided tissue core biopsy have an extremely high diagnostic accuracy for GIST diagnosis, but underestimates the proliferation indexes and rarely allows for a reliable mitotic count. The main reason responsible for these results is the uneven distribution of the mitotic figures throughout the lesion, which may cause the biopsy to miss the most mitotically active areas. Furthermore, EUS examination generally underestimates the size of the lesions; this limit is fundamentally linked to the “bidimensional” evaluation of lesions obtained by ultrasound. In addition, the underestimation of the size is greater for large lesions because of the low depth of field evaluated by high frequencies used in EUS. Our data obtained with EUS-FNB are similar to previous studies with FNA and constitute a major limitation for developing a possible pre-treatment and biopsy-based risk classification of GIST. Alternative parameters (genotype profiling) must be validated on pre-surgical biopsy samples from GISTs for prognostication purposes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0916 TECHNICAL FEASIBILITY AND SAFETY OF ENDOSCOPIC ULTRASOUND (EUS)-GUIDED FIDUCIAL MARKER PLACEMENT USING A NOVEL SYSTEM WITH PRE-LOADED 22-GAUGE NEEDLES IN PANCREATIC CANCER PATIENTS

E.J. Shin1, S. Kim2, M. A. Kashash3, M.I. Canto4
1Gastroenterology And Hepatology, Johns Hopkins University School of Medicine, Baltimore/United States of America;MD
2Department Of Internal Medicine, Research Institute Of Clinical Medicine, Chonbuk National University Medical School, Jeonju/Korea, Republic of

Contact E-mail Address: eshinn3@jhmi.edu

Introduction: Pancreatic cancer (PC) remains a disease with overall poor prognosis, despite significant advances over the past decade. Stereotactic body radiation therapy (SBRT) is able to deliver higher biological effective dose to the tumor over a shorter period of time with reduced local toxicity compared to conventional external beam radiation therapy. EUS-guided fiducial placement has been shown to improve the accuracy and localization during SBRT.
Conventional EUS-guided fiducial placement requires back-loading each fiducial through the tip of the FNA needle. Thus, delivery of multiple fiducials can be cumbersome and time-consuming.

**Aims & Methods:** We aimed to evaluate the feasibility, safety, and performance characteristics of fiducial deployment in PC patients using a novel exchangeable FNA system with pre-loaded 22-gauge EUS fiducial needles. This was a single-center pilot study of 10 consecutive patients undergoing EUS-guided fiducial placement for SBRT. The fiducial delivery system contains a 22-gauge EUS fiducial needle insert through the exchangeable FNA system for total deployment of 4 markers in each patient. All patients underwent CT after fiducial placement as part of SBRT to evaluate successful deployment and compliance with the primary endpoint was procedure success, defined as deployment of at least 3 fiducials into the desired target area. Secondary endpoints were total procedure time, fiducial delivery time, and safety.

**Results:** Fiducial placement was attempted in 10 consecutive patients with PC (mean age 61.7 years, males 60%). The tumor was located in the head (n = 6), neck (n = 2), and the body (n = 2) of the pancreas. Mean size of the tumor was 2.7 cm (range 1.6–5.3). Procedure success was achieved in all 10 (100%) patients. All 10 patients successfully received fiducials. Mean total procedure time was 12.2 minutes (range 5–18). By comparison, using historic controls of the first 10 patients who underwent conventional EUS-guided fiducial placement, the mean total procedure time was 26 minutes (range 16–44, p < 0.002). Mean fiducial delivery time was 4.2 minutes (range 1–8). There were no immediate or delayed (7 days) complications.

**Conclusion:** EUS-guided fiducial placement with a novel exchangeable FNA system with pre-loaded 22-gauge EUS fiducial needle is quick, technically feasible and safe. This system may theoretically decrease the risk to the clinical staff by eliminating the need for back-loading fiducials through exposed needle tip and handling of potentially dirty needles. Given the potential safety and time advantages, further prospective studies are warranted for validation.

**Introduction:** Bubbles can impair the visualization of the small bowel (SB) mucosa during capsule endoscopy (CE). The aim of the study was to develop and to validate a computer algorithm, which would evaluate the abundance of bubbles in SB-CE. Two sets of 200 SB-CE normal still frames were extracted from 45 complete third-generation SB-CE videos. Two experienced SB-CE readers analyzed both sets of images twice, in a random order. Each still frame was categorized as "scarce in" or "abundant in bubbles (<10% or ≥10% of bubbles covering the frame, respectively). Reproducibility (κ coefficient), sensitivity (Se), specificity (Sp), Receiver Operating Characteristic (ROC) curve, and calculation times were measured for different algorithms (Grey-level of co-occurrence matrix [GLCM], fractal dimension, Hough transform, and Speeded-Up Robust Features [SURF]) using the experts’ reading as reference. Algorithms with highest reproducibility, Se and Sp were then selected for a validation step on the second set of frames. The criteria for validation were κ ≥ 0.81, Se ≥ 90%, Sp ≥ 85%, and a low calculation time.

**Results:** Both SURF and GLCM algorithms had high operating points (Se and Sp over 90%) and a perfect reproducibility (κ = 1). At the validation step, the GLCM detector strategy had the best diagnostic capabilities, with Se = 95.79%, Sp = 95.19%, and a mean calculation time of 0.037 s per frame. Table 1: Sensitivity (Se), specificity (Sp), negative predictive value (NPV), positive predictive value (PPV) and area under receiver operating characteristic curve (AUROC) of four algorithms for evaluation of bubble abundance in small bowel capsule endoscopy still frames (development step).

**Conclusion:** A GLCM detector strategy has high diagnostic performances to categorize "scarce in" or "abundant in bubbles" SB-CE frames. This algorithm is of interest for clinical use (i.e. quality in CE reporting) and for research (providing an objective comparison tool of different preparations, including anti-bubble agents).

**P0919 A NOVEL CAPSULE TECHNOLOGY PLATFORM FOR SPECIFIC LOCALIZED COLON DRUG DELIVERY:**

1) Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel
2) Rambam Health Care Campus, Haifa/Israel
3) Soroka Medical Center, Beer Sheva/Israel

**Abstract:** P0917

**Introduction:** Capsule endoscopy has been demonstrated to be a first-line tool for small bowel visualization. However, it has some limitations such as incomplete examinations - i.e: the capsule does not reach the cecum - leading to missing lesion diagnosis.

**Aims & Methods:** To evaluate those factors that can predict incomplete examinations, to identify those patients at risk for incomplete procedures and to define those approaches that may improve the efficiency of the examination reducing the time of the diagnostic process as well as the need to repeat procedures. A total of 1918 patients who underwent capsule enteroscopy at our center between 2008 and 2015 were retrospectively analyzed. We evaluated variables such as age, sex, anthropometric parameters, comorbidity, drugs, outpatient care, analytical parameters, indication of the test and transit times. Initially, a univariate analysis and then, a multivariate analysis using a logistic regression model were carried out.

**Results:** In the univariate analysis, the following variables showed a statistically significant association with the rate of incomplete examinations: age, gender, indication of procedure, outpatient care, history of abdominal surgery, heart disease, capsule ingestion posture, hemoglobin levels, renal failure and both gastric and small bowel transit times. These variables were included in the multivariate analysis: age was > 65 years (OR = 1.99, 95% CI: 1.34–2.95), gastric transit time > 41 minutes (OR = 2.60, 95% CI: 1.72–3.93) and small bowel transit time > 286 minutes (OR = 3.52 95% CI: 2.26–5.48) showed a statistically significant association with the risk of incomplete examination.

**Conclusion:** Incomplete capsule endoscopy is predictable. Patients older than 65 years and/or a gastric emptying time greater than 42 minutes are independent predictive factors for incomplete procedures. In these clinical scenarios, pharmacological preventive measures or endoscopic introduction should be taken into account to avoid incomplete examinations.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

The criteria for validation were κ ≥ 0.81, Se ≥ 90%, Sp ≥ 85%, and a low calculation time.

**Results:** Both SURF and GLCM algorithms had high operating points (Se and Sp over 90%) and a perfect reproducibility (κ = 1). At the validation step, the GLCM detector strategy had the best diagnostic capabilities, with Se = 95.79%, Sp = 95.19%, and a mean calculation time of 0.037 s per frame. Table 1: Sensitivity (Se), specificity (Sp), negative predictive value (NPV), positive predictive value (PPV) and area under receiver operating characteristic curve (AUROC) of four algorithms for evaluation of bubble abundance in small bowel capsule endoscopy still frames (development step).

**Conclusion:** A GLCM detector strategy has high diagnostic performances to categorize "scarce in" or "abundant in bubbles" SB-CE frames. This algorithm is of interest for clinical use (i.e. quality in CE reporting) and for research (providing an objective comparison tool of different preparations, including anti-bubble agents).

P0920 COLON CAPSULE ENDOSCOPY: HOW DOES PROCEDURE ACCURACY?

Introduction: A variety many of pharmaceuticals for the treatment of colon disease can be more effective and have less side effects if targeted for precise delivery in the colon. Over the years, many types of delivery vehicles have been developed with the aim of targeting the colon, such as PB-based delivery technologies, time dependent drug release mechanisms, pressure based mechanisms, flora sensitive mechanisms and others. These technologies have performed with variable degrees of success due to the wide distribution of motility and other physiological variability between patients. We describe a novel capsule technology which incorporates a diffused gas sensor that allows for an accurate sensing of colon entrance, as well as a 3D real time positioning system that allows for an accurate, programmable, localized, and in colon drug delivery system.

Aims & Methods: Data was collected from 14 patients that swallowed capsules in a multi-center clinical trial using an x-ray imaging capsule (GUT 2016). The patients were sent home to continue their normal life routine while the capsule naturally traveled in the gastrointestinal tract until excretion. (Subjects signed informed consent forms and the study was performed after local IRB approval). The capsules contained electronics and software that allowed for live communication between the capsule and a recording device that is placed directly on the patient’s back. This device tracks the position of the capsule and communicates with it, receiving diffused gas pressure from the capsule sensor and fusing this information with 3D position information from the capsule. The capsule system exhibited position accuracy of ±1 cm and the ability to detect movements in real time, as well as potential of ~1 ml of payload for drug containment.

Results: The average total transit time of the capsule was 43 hours (range: 15–68 hours). The average transit time to cecum was 13.8 hours, and the average time across the colon was 12.8 hours (range: 6–25). The position tracking and the RF communication between the capsule and the recorder showed >90% coverage in all cases, even in obese patients. No adverse events were reported. Figure 1 illustrates the recorder placement on the patient back. Figure 2 is a typical averaged capsule position trace in the colon.

Conclusion: A capsule with accurate position tracking, 2-way communication, and on line algorithms can determine colonic entrance and identify exact locations in the colon. A wide variety of drugs can accurately be delivered to their exact target in the colon. It enables for a more effective (high dose) and less toxic (no systemic delivery) therapy for IBD and cancer.

P0921 COLON CAPSULE ENDOSCOPY MAY REDUCE COLONOSCOPY MISS RATE – A MULTICENTER STUDY

Introduction: Colonoscopy miss rate is an area of intense focus, as it directly correlates with colorectal cancer incidence rate. Previous studies reported a colonoscopy miss rate of 2%–22%, depending on polyp size and histology [1]. Colon Capsule Endoscopy (CCE) is a visualization diagnostic modality of the colon mucosa, which has demonstrated high sensitivity for polyps and adenomas [2]. Determining the nature of polyps detected by CCE but missed by the imperfect gold standard (colonoscopy), may facilitate both optimization of CCE application (potential CCE additive value) and increase colonoscopy polyp detection.

Aims & Methods: Characterize polyps detected by CCE, which were missed by colonoscopy. 695 screening population participants, from 17 sites in the United States and Israel, underwent CCE procedure followed by a blinded colonoscopy. The overall colonoscopy adenoma detection rate in this study was very high – 39% [2]. Following the blinded colonoscopy, the patient's CCE report was assessed. Based on the findings in this report, the colonoscopy miss rate of 2% was estimated. Determining the nature of polyps detected by CCE but missed by the imperfect gold standard (colonoscopy), may facilitate both optimization of CCE application (potential CCE additive value) and increase colonoscopy polyp detection.

Aims & Methods: Characterize polyps detected by CCE, which were missed by colonoscopy. 695 screening population participants, from 17 sites in the United States and Israel, underwent CCE procedure followed by a blinded colonoscopy. The overall colonoscopy adenoma detection rate in this study was very high – 39% [2]. Following the blinded colonoscopy, the patient's CCE report was assessed. Based on the findings in this report, the colonoscopy miss rate of 2% was estimated. Determining the nature of polyps detected by CCE but missed by the imperfect gold standard (colonoscopy), may facilitate both optimization of CCE application (potential CCE additive value) and increase colonoscopy polyp detection.

Results: The 70 polyps missed by first colonoscopy and detected by second colonoscopy, 20 (29%) were 6 mm or larger (based on colonoscopy size estimation), 19 (27%) were either adenomatous or sessile serrated lesions and 16 (23%) were described as either flat or sessile-flat by colonoscopy performing physician. Stratification of polyps based on location:

<tr>
<td>P-value</td>
<td>0.007</td>
<td>1</td>
</tr>
</tbody>
</table>

Poor cases had significantly lower CCE sensitivity compared with fair, good and excellent cases, for 6 mm polyps (P-value = 0.007). When stratifying cases based on the current adequacy cutoff, sensitivity for 6mm polyps is similar in inadequate (“poor” + “fair”) cases compared to adequate (“good” + “excellent”) cases (70.1%, 78.5% respectively, P-value = 0.147).

References

Multivariate logistic regression revealed that after adjusting to polyp’s size, cecal and rectal segments were associated with increased chance of CCE additive value to colonoscopy (cecum vs. ascending or transverse colon: Adj.OR = 3.2 [95%CI: 1.3–7.6] and Adj.OR = 4.5 [95%CI: 1.4–14.6] respectively; rectum vs. ascending or transverse colon: Adj.OR = 2.6 [1.1–5.8] and Adj.OR = 3.6 [95%CI: 1.2–11.4] respectively). There were 59 patients (8.49% of study population), with at least one CCE additive value to colonoscopy event.

Conclusion: CCE has the ability to detect polyps missed by traditional colonoscopy, especially lesions in the cecum and rectum.

Introduction: Only small series (<10 patients) have described endoscopic management of postoperative pancreatic fistulas (POPF). The purpose of this retrospective study was to describe the indications, technique and results of endoscopic treatment of POPF.

Aims & Methods: From a prospective database of an endoscopic unit of a tertiary center, patients with POPF who underwent pancreatic endoscopic treatment during a retrograde endoscopic cholangiopancreatography (ERCP) were identified. From January 2010 and June 2016, POPF was classified according to the definition of the International Study Group of Pancreatic Fistula Working Group. The indications, the techniques and results of endoscopic drainage and the patients’ outcomes were registered.

Results: Among 6473 ERCP performed during the inclusion period, 31 patients had POPF treated endoscopically (14 men, 7 women, mean age 63±14.5 years). The male-to-female ratio was 2:1 in favor of the male gender. Pancreatic stents proved their efficiency in 98% cases, in only 3 patients deep cannulation being unsuccessful. On average, patients required 1, 15 ERCP procedures in order to obtain biliary access. ERCP indication for benign pathology was predominant (60%). The stents used were 5 Fr, 5 cm (102 patients) and 5 Fr, 3 cm (56 patients). Precut sphincterotomy was performed in 82 cases (37 before stent insertion and 45 after stent insertion). From all patients included, only 19 patients (12%) presented post procedure elevation of serum amylase 3 times higher than normal value associated with abdominal pain. Complications: Pancreatic stent insertion was efficient in all cases of pancreatic duct obstruction and with success in difficult situations. Regardless of their length, 5 Fr (3 cm, 5 cm) stents ensure the same success rate for cannulation and offers protection against post ERCP pancreatitis, as long as they are correctly inserted.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic ultrasonography (EUS)- guided biliary drainage (EUS-BD) is increasingly used in the treatment of malignant biliary obstruction after failed ERCP. However, Multi-step process for EUS-BD is closely related to adverse events.

Aims & Methods: The present study was designed to determine feasibility and effectiveness of stent placement using a thin delivery-system stent without dilatation step during EUS-BD. Three types of the new designed partially covered laser-cut metal stents (6-mm-wide and 60-mm-long) with 7Fr delivery catheter with hard tip (7Fr hard tip), 7.5Fr delivery catheter with soft tip (7Fr soft tip) were prepared respectively. A phantom model with a silicon plate was created. The plate was punctured with 19-G needle and a guidewire was passed the plate. The delivery system was advanced over the guidewire to pass the plate and the resistance force was measured. A biliary obstruction model was created by clipping the papilla in 10 pigs, EUS-BD (choledochoduodenostomy) using the thin delivery system stents was attempted following 19-G needle puncture without the use of dilation devices. The technical success and adverse events within 2 weeks after EUS-BD were analyzed for three types of stents.

Results: Among the three types of stents, 7Fr soft tip had the least resistance in the phantom model. In the animal model, the median common bile duct diameter was 6.81 mm (4.05–9.5 mm) and 29.3 minutes (16–47) respectively. In all pigs, EUS-BD using the three types of stents were technically successful. Dilation was unnecessary in 25% (1/4), 0% (0/2) and 100% (4/4) for the 7Fr hard tip, 7.5Fr hard tip and 7Fr soft tip, respectively. Even in the cases requiring dilation, stent placement was successful immediately after dilation only with a thin catheter (6.5Fr). Neither cholangiography nor balloon dilation was needed. There were no procedure-related complications occurring during and 2 week after EUS-BD. All stents remained in place without migration. At necropsy, fistulas were created between the bile duct and duodenum in all pigs and the growth of fibrous tissue was observed in the microscopic findings.

P0923 EFFICIENCY OF PANCREATIC STENTS IN DIFFICULT CANNULATION – A RETROSPECTIVE SINGLE - CENTER STUDY

Introduction: Difficult biliary cannulation is defined by the presence of one or more of the following: more than 5 contacts with the papilla while attempting to cannulate; more than 5 minutes spent attempting to cannulate following visualization of the papilla; more than one unintended, pancreatic duct cannulation or pancreatic duct stent insertion. In these situations, pancreatic stent insertion might prove to be very useful for prophylactic and tactical purposes.

Aims & Methods: We are proposing in this paper to present the experience of Clinical Emergency Hospital Bucharest regarding difficult biliary cannulation and the use of pancreatic stent insertion to be efficient in obtaining biliary access. This paper is a retrospective study of the patients who presented difficult cannulation and to whom pancreatic stents were inserted for prophylactic and tactical purpose. The purpose of this study was to describe the indications, technique and results of endoscopic management of pancreatic stents insertion.

Results: In the study included 158 patients with ERCP and difficult biliary cannulation, who required pancreatic stent insertion for prophylactic and tactical purpose. Patients’ mean age was 60 years, while the sex ratio was 2:1 in favor of the female gender. Pancreatic stents proved their efficiency in 98% cases, in only 3 patients deep cannulation being unsuccessful. On average, patients required 1, 15 ERCP procedures in order to obtain biliary access. ERCP indication for benign pathology was predominant (60%). The stents used were 5 Fr, 5 cm (102 patients) and 5 Fr, 3 cm (56 patients). Precut sphincterotomy was performed in 82 cases (37 before stent insertion and 45 after stent insertion). From all patients included, only 19 patients (12%) presented post procedure elevation of serum amylase 3 times higher than normal value associated with abdominal pain. Complications: Pancreatic stent insertion was efficient in all cases of pancreatic duct obstruction and with success in difficult situations. Regardless of their length, 5 Fr (3 cm, 5 cm) stents ensure the same success rate for cannulation and offers protection against post ERCP pancreatitis, as long as they are correctly inserted.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
Conclusion: Among the three types of stents, the 7Fr soft tip was suitable for ERCP in the phantom and animal models. This thin delivery system stent may be technically feasible and safety for EUS-BD and possibly reduce adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0925 TREATMENT WITH FULLY-COVERED METAL STENTS OF POST-SPHINCTEROTOMY EARLY AND LATE BLEEDING

G. Pambitta1, S. Pallotta2, A. D’Alessandro3, F. Iannuzzi2, E. Bareggi2, A. Ballerini1

1Digestive Endoscopy, ASST Fatebenefratelli-Sacco, Milan/Italy
2Digestive Endoscopy, Luigi Sacco Hospital, Milan/Italy
3Clinical Medicine And Surgery, University of Naples Federico II Clinical and Experimental Medicine, Naples/Italy

Contact E-mail Address: alex_balle@libero.it

Introduction: Post-endoscopic sphincterotomy bleeding is treated endoscopically with pharmacologic injection, electrosurgical coagulation, balloon tamponade or clipping, but severe cases may require angiographic or surgical approach. An alternative long-acting tamponade treatment with fully-covered metal stents (FCMS) has been advocated.

Aims & Methods: We report here on the use of FCMS in post-sphincterotomy early and late bleeding. Patients referred for in- and out-patient ERPC were informed of the potential off-label treatment with FCMS of post-sphincterotomy bleeding, and of treatment approval by the local ethical committee. We treated post-spincterotomy bleeding first with adrenaline and/or sclerosing agent injection. When this first line hemostasis failed, we placed short FCMS in the distal cholecodochus. Endoscopy was rescheduled after 1 month to remove the FCMS. During the early post-procedural period the patients were treated with blood transfusions if needed, and antiplatelet drugs as well as oral anticoagulants were avoided.

Results: 17 Patients (10M/7F), aged on an average 70 years (range 38–90) received 18 FCMS (10 mm × 40 mm, Boston Scientific) for failed hemostasis since tamponade was 100%. All patients had, with an average loss of 1 g/dl of Hb and 9 packed red cells units transfused. In our cases we had 1 outlier, a patient that had received needle-knife sphincterotomy without early bleeding but developed delayed bleeding with hypovolemic shock. He received a second ERCP and a FCMS after 3 days. After further 3 days the patient was in the intensive care unit because of persistent bleeding and we performed a third ERCP. The FCMS was in place, but we removed it, retreated the bleeding by injective therapy and placed a second FCMS, obtaining a stable hemostasis and receiving 8 red blood cells after 5 days. In the study the FCMS spontaneously migrated in 4/18 cases, one had been removed for incomplete bleeding control and substituted after 3 days, and 13 were easily removed as per protocol. In two cases FCMS were removed and a plastic double pigtail stent was placed in parallel for persistent choleodochal distal stenosis.

Conclusion: These cases represent a large collection of evidence showing that treating post-sphincterotomy early bleeding with FCMS is feasible, safe and effective. Late bleeding associated with needle-knife pre-cut was much harder to control and required endoscopic revision, intensive care unit support and re-stenting. Our results are consistent with and support previous research in the field.

P0926 EFFICACY OF SELF-EXPANDABLE METALLIC STENT PLACEMENT IN THE MANAGEMENT OF ANASTOMOTIC STRICURE AFTER ORTHOTOPIC LIVER TRANSPLANTATION

S. Jang, M. Parsi, R. Lopez, A. Bhatti, J. J. Vargo

Gastroenterology, Cleveland Clinic, Cleveland/United States of America/OH

Contact E-mail Address: jangs@ccf.org

Introduction: Anastomotic bile duct stricture (ABS) remains as one of the most common complications after orthotopic liver transplantation (OLT). Current standard of practice of endoscopic retrograde cholangiopancreatoscopy (ERCP) with insertion of multiple plastic stents (PS) often requires multiple procedures before achieving satisfactory stricture resolution. In recent years, studies utilizing covered self-expandable metallic stent (cSEMS) in refractory ABS management reported varying degree of success.

Aims & Methods: The aim of this study was to analyze efficacy of SEMS in resolution of anastomotic stricture in patients with orthotopic liver transplantation (OLT). Inclusion criteria: with or without to identify factor(s) influencing the likelihood of stricture resolution, the rate of adverse outcome(s) A retrospective cohort study was conducted using a registry of consecutive patients who underwent ERCP with biliary SEMS placement from January of 2010 to November of 2016 for the management of refractory ABS. Demographic variables including age, gender, and clinical variables including body mass index (BMI), number or prior ERCP with PS insertion, stent brand and dimensions and duration of SEMS insertion period were collected. The rates of stricture resolution, adverse outcomes including post ERCP pancreatitis, cholangitis and stent dysfunctions (occlusion, migration) were analyzed. This study was approved by the Institutional Review Board of the Cleveland Clinic.

Results: There were 47 OLT patients who underwent ERCP-cSEMS insertion for refractory ABS during the study period. Of 47 patients, 37 patients (78.9%) achieved stricture resolution after single SEMS treatment. Longer duration of SEMS insertion was the only variable associated with increasing probability of stricture resolution as there was 20% increase in odds of stricture resolution for every additional week SEMS was in place. Among those who achieved initial stricture resolution, 27 patients (57.4%) maintained bile duct patency throughout the follow up period. The most common adverse outcome was internal migration of cSEMS which occurred in 11 patients (23.4%). Post-ERCP pancreatitis was observed in 3 (6-4%) patients

Conclusion: The efficacy rate observed in resolving refractory ABS with cSEMS placement appears to be comparable to that of multiple ERCPs with PS placement method. Furthermore, durability of ABS resolution with cSEMS use further supports its potential long-term efficacy. Hence, cSEMS should be considered as a viable alternative, with no increase in risk of migration, and is associated with higher likelihood of ABS resolution. The high rate of internal migration observed with SEMS warrants further endeavor in stent design improvements.

P0927 "DISCONNECTED PANCREATIC DUCT" FOLLOWING EUS GUIDED DRAINAGE OF PANCREATIC FLUID COLLECTION - IS IT CLINICALLY RELEVANT? LONG-TERM FOLLOW UP FROM A LARGE VOLUME TERTIARY CARE CENTRE

Gastroenterology, Asian Institute of Gastroenterology, Hyderabad/India

Contact E-mail Address: drsundeeplakhtakia@gmail.com

Introduction: Disconnected pancreatic duct (DPD) can occur in patients after drainage of pancreatic fluid collections (PFC). Concerns have been raised about clinical relevance of DPDs.

Aims & Methods: To assess the frequency of DPD and its clinical significance after EUS guided drainage of PFC. Patients of acute or chronic pancreatitis with symptomatic PFC, who underwent Endoscopic Ultrasound (EUS) guided drainage between January 2011 to December 2016 were included, after an informed consent. Stents used for drainage procedure were either bi-flanged metal stents (BFMS) or double pigtail plastic stent. All these patients underwent MRCP between 4 to 8 weeks after drainage to evaluate pancreatic duct (PD) anatomy and confirm resolution of PFC. Subsequently, they had Endoscopic Retrograde Pancreatography (ERP) and, if required, stent removal. BFMS was removed in all patients. Plastic stents were retained indefinitely, if DPD was confirmed. All patients were systematically followed at 3–6 monthly intervals for any recurrence of PFC or new onset clinical event.

Results: A total of 407 patients (346 males, mean age 33.5 years, range 5-69 years) were followed up after EUS guided drainage for PFC. Of these 260 underwent BFMS and 147 underwent plastic stents placement. 319 patients had pancreato-gram (ERP and MRCP) after resolution of PFC. The pancreatic duct abnormalities observed were DPD in 197 (61.7%), PD leak in 36 (11.3%), PD stent in 20 (6.3%) patients. Normal PD was seen in 43 (13.5%) patients. Calcific pancreatitis was noted in 23 (7.2%). Among the patients with DPD, the location of PD ‘cut off’ was in head (32, 16.2%), genu (59, 29.8%), body (90, 45.6%) and tail (16, 8.1%). Overall, the follow-up after stent removal ranged from 3–72 months, with a median follow up of 12months. Pseudocyst recurred in 29 patients (8.5%) at a mean follow up of 3.5 months (range 1–30 months), which included PDSPS 27, PD stent 1, and CCP 1. 20/29 had pain (symptomatic) and 9 were asymptomatic. 15/20 underwent intervention (EUS drainage with plastic stent in 12, surgery in 3) and 5 resolved spontaneously.
P0928 FULLY COVERED SELF-EXPANDABLE METAL STENT IN THE MANAGEMENT OF DUODENAL RETROPERITONEAL PERFORATIONS DURING ERCP: A SINGLE CENTER EXPERIENCE

M. Pizzicannella1, G. Andrisani1, M. Martin0, R. Rea1, M. Pandolfi1, F.M. Di Matteo1
1Digestive Endoscopy Unit, Campus Bio Medico, Rome/Italy

Contact E-mail Address: f.dimatteo@unicampus.it

Introduction: ERCP-related perforation is rare (0.39%), but it is associated with a mortality rate of 7.8%. Duodenal retroperitoneal perforation (Type II) is the most frequent, among the ERCP-related perforations. The management of this complication has not been standardized yet: traditionally surgery was considered the only rescue therapy, but in the last years the majority of cases has been managed conservatively. The endoscopic treatment included biliary stent and/or nasobiliary drainage. In our institution, from 2010 we have been using fully covered self-expandable metallic stent (FCSEMS) with nasobiliary drainage always after resolution of the initial indication for ERCP. These stents have the advantage of covering the laceration and allowing free flow of bile into the duodenum instead of into the retroperitoneal space. The aim of this study was to evaluate in our cohort of patients, the benefits of FCSEMS in type II perforations.

Aims & Methods: We experienced six type II perforations associated with ERCP. We retrospectively evaluated the clinical findings, the length of hospital stay, the need for surgery and death.

Results: Of the 3250 ERCP procedures performed from March 2010 to November 2016, only six (0.18%) resulted in perforations (male/female, 2/4; median age: 69 years; age range: 54–80 years). ERCP procedures were performed with carbon dioxide insufflation. Five patients underwent ERCP for biliary stent placement and a sphencterotomy was performed and was immediately detected. Successful closure of persistent splencterotomy-related duodenal perforation using FCSEMS was obtained in all patients. One patient developed ERCP-related pancreatitis, successfully treated with medical therapy. Three FCSEMS were successfully removed after a median of 18 days, the remaining three fell out spontaneously. The median length of hospital stay was 8.5 days (range 4–20 days). There were no deaths or need for surgery.

Conclusion: The placement of FCSEMS is easy, safe and quick. In our cohort of patients, FCSEMS is the effective endoscopic approach for management of type II perforations recognized during ERCP.

Introduction: Refractory Esophageal Stenosis (RES) definition differs among studies. Unresolved benign esophageal stenosis even after 5 or more sessions of endoscopic dilation therapy in most studies. Until now, there have been no treatment showing the satisfactory results. Mitomycin C (MMC) inhibits DNA synthesis reduces fibroelastic collagen formation. Tried in RES in several studies. The meta-analysis about treatment of refractory gastrointestinal stenosis with MMC in total 24 studies. The most commonly reported site esophagus (79%). Only 9 recruited adult patients (n=38). Of these, 23 patients were RES.

P0931 THE CLINICAL Efficacy of Mitomycin-C injection therapy for refractory benign esophageal stenosis: a Preliminary study
S.G. Lim1, J. Kim1, K.M. Lee2
1Gastroenterology, Ajou University School of Medicine, Suwon/Korea, Republic of Korea
2Contact E-mail Address: mdlsk75@gmail.com

Conclusion: DS was achieved in 19 (95%), 12 (78%) and 21 (100%) of the patients at the first, second, and third follow-up visits respectively. The median duration of the treatment showing the satisfactory results. Mitomycin C (MMC) inhibits DNA synthesis reduces fibroelastic collagen formation. Tried in RES in several studies. The meta-analysis about treatment of refractory gastrointestinal stenosis with MMC in total 24 studies. The most commonly reported site esophagus (79%). Only 9 recruited adult patients (n=38). Of these, 23 patients were RES.
Conclusion: In our study, the mitomycin injection therapy was effective in patients who had retractable benign esophageal stenosis. The mitomycin injection therapy could be considered as an alternative for retractable benign esophageal stenosis. A large-scale prospective studies are required in future.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Anastomotic stenosis or dehiscence are serious complications of colorectal surgery. Colostomy or ileostomy and later redo anastomosis or Hartmann’s procedure are the mainstream of therapy, but edema and inflammation caused by neoplasm or perianastomotic abscess can predispose to recurrent dehiscence and stricture. Intraoperative mitomycin-C injection therapy has been used for the treatment of colorectal anastomotic failure, but it is not always effective.

Aims & Methods: We report the outcomes of the treatment of 132 colorectal anastomotic strictures with multiple reabsorbable stents. All patients, except two, had undergone at least one attempt with standard treatment, but it was unsuccessful.

Results: Most patients (99/132) were male (71.5%) and mean age was 73.5 years old (range: 32–95). The primary colorectal surgery was performed for rectal cancer (61.4%) and for diverticulosis (38.6%). The locations of anastomotic dehiscence were sigmoid colon (87.5%), descending colon (3.8%), and rectum (8.7%). The number of sessions of mitomycin-C injection therapy was one in 3 patients, two in 21 patients, three in 40, four in 37, five in 27, six in 9, and seven in 8 patients.

Conclusion: In our study, the treatment of colorectal anastomotic dehiscence and stenosis with multiple reabsorbable stents was successful in 76.1% of patients.
**P0934 EFFECTIVENESS OF REPEATED DILATIONS IN THE MANAGEMENT OF ESOPHAGEAL BENIGN STRICTURES**

**Introduction:** Refractory or recurrent esophageal benign strictures (REBS) are frequent, and defined as the impossibility to reach or maintain a diameter of 14 mm after 5 sessions of endoscopic dilation (ED). Because of a lack of guidelines, their management remains challenging, sometimes leading to surgical intervention.

**Aims & Methods:** The aim of this study was to define the efficacy of long-term and repeated ED in the management of REBS. This was a monocentric retrospective study involving patients managed in our tertiary center between January 2002 and April 2017 for REBS. All the endoscopic dilations were performed using Savary bougies or hydraulic balloons, depending on the operator’s choice. Demographical and clinical data were recorded for each patient. The endoscopic management was detailed with the number of procedures, the endoscopic device used, the diameter of dilation, and potential concomitant treatment (as self-expanding metal stent, steroid injection or incisional therapy). The primary endpoint was the efficacy of sustained and recurrent ED, defined as the absence of further dilation within 3 months of the last procedure or an interval between the 2 last ED greater than 3 months. A failure was considered in case of death, need for surgery, permanent enteral feeding tube or an interval between the last 2 procedures longer than 3 months. The secondary endpoints were to document the characteristics of dilation procedures and concomitant treatments, the decreasing of the number of dilations per trimester, and to elucidate potential predictive factors for success of ED.

**Results:** A total of 39 patients (23 men) with a mean age of 47.5 ± 20.7 years were included. The etiologies of strictures were anastomotic (46.1%), caustic (28.2%), peptic (10.3%) or other etiologies (radiation injuries, esophageal diverticulitis, severe viral esophagitis, 15.4%). A clinical success of repeated ED was achieved in 27 patients (69.2%). Twelve patients (30.8%) experienced failure, among them seven (17.9%) required frequent dilations, two (5.1%) underwent surgery, two (5.1%) maintained an enteral feeding tube, and one patient (2.6%) died consecutively to inhalation pneumonia. A mean of 9.8 ± 4 ED sessions were performed per patient, with a mean treatment duration of 22.6 ± 20.1 months. Regarding concomitant treatments, 16 patients (41%) had at least one fully-covered metallic stent placement, incisional therapy was performed in 11 patients (28.2%), and 3 patients (7.7%) received corticosteroid injections. The number of dilations per trimester gradually decreased over time. No significant predictive factor of success was found, such as etiology of stricture or the use of concomitant treatment, particularly. Nevertheless, an greater number of dilations during the first trimester could promote the success of the management (3.2 ± 2.2 dilations in the success group vs 2.2 ± 0.8 in failure group, p = 0.056).

**Conclusion:** Repeated and maintained endoscopic dilations are effective (70%) in the management of REBS, regardless of the etiology of stricture. A prolonged management up to 2 years, and the initial rhythm of endoscopic procedures may favor the final success. A systematic schedule for ED would improve the efficacy of this management.

**Introduction:** Endoscopic stenting with self-expandable metallic stents (SEMSs) is a widely accepted procedure for treating malignant colorectal obstruction. This procedure was covered by the National Health Insurance of Japan in January 2012, and the WallFlex colonic stent and Niti-S colonic stent can currently be used in Japan. In the previous study, we reported that the WallFlex colonic stent has more expanded force than the Niti-S colonic stent. On the other hand, the risk of stent-related perforation was lower when using the Niti-S stent due to its structure. Currently, we newly developed an SEMS (Niti-S structure, with 18-mm diameter with increased expanded force compared with the conventional type), which comprised the benefits of both WallFlex and Niti-S. In this study, we compared the efficacy and safety of the newly developed colonic stent with the conventional colonic stents.

**Aims & Methods:** This study aimed to compare the efficacy and safety of the newly developed colonic stent with the conventional colonic stents (the WallFlex colonic stent and the Niti-S colonic stent). Overall, 91 patients (96 lesions, male/female: 48/43, average age: 73.2 years) underwent endoscopic SEMS placement between November 2011 and March 2017 at Kure Medical Center and Chugoku Cancer Center. The WallFlex colonic stent was used in 36 patients (38 lesions: Group W), the Niti-S colonic stent in 51 patients (53 lesions: Group N), and the newly developed colonic stent in 5 patients (5 lesions: Group D). Stratified analysis of the clinical background, technical success rate, procedure time, clinical success rate, and complications was performed to compare Group W, Group N, and Group D.

**Results:** Endoscopic SEMS placement was attempted in 96 lesions as a bridge to surgery (BTS) in 52 lesions (54.2%) and as palliative therapy (PAL) in 44 lesions (46%). In Group W, SEMS was placed in 19 lesions (50%) as BTS and in 19 lesions (50%) as PAL; in Group N, SEMS was placed in 32 lesions (60%) as BTS and in 21 lesions (40%) as PAL; and in Group D, SEMS was placed in 1 lesion (20%) as BTS and in 4 lesions (80%) as PAL. The technical success rate was 100% in all groups. The overall clinical success rate was 93.7% (90/96): 89.5% (34/38) in Group W, 96.2% (51/53) in Group N, and 100% (5/5) in Group D. Complications within 7 days included abdominal pain (3/38, 8%).
