Introduction: Postoperative immunosuppression in transhiatal esophagectomy for patients with esophageal cancer is a common finding \cite{1}. In fact, both transhiatal and transthoracic esophagectomy induce severely depressed monocyte and T-lymphocyte cytokine production \cite{2}. Remarkably, lymphopenia is an independent predictive factor for long-term survival in patients with esophageal cancer \cite{3}.

Aims & Methods: The aim of this study was to assess the predictors of postoperative immune suppression in esophageal or esophago-gastric junction cancer. One hundred ninety three consecutive patients with esophageal or esophago-gastric junction cancer were enrolled in this retrospective study. White blood cells count, polymorph nucleate cells and lymphocytes counts were observed at preoperative time, post-operative day (POD) 1, 3 and 7. Post-operative complications were also recorded. Multiple regression models were fitted to the data to test the association between potential predictors and postoperative lymphopaenia and lymphopenia on POD1 as parameters of immune suppression.

Results: The lymphocytopenic count was 1, 240/ml (IQR: 0.895–1.700) on POD 1. The lymphocyte count on POD 1 was 0.670 mlq (IQR: 0.500–0.982), p < 0.001; on POD 3, it was 0.800 mlq (IQR: 0.580–1.070), p < 0.001; and on POD7, it was 0.825 mlq (IQR: 0.550–1.180), p < 0.001. In a model that also included the interval between the end of neoadjuvant therapy and the esophagectomy, the number of surgical accesses (laparotomy, thoracotomy and cervicotomy) and the number of nodal metastasis, only the final dose of radiotherapy resulted to be an independent predictor of postoperative lymphocyte count.

Conclusion: Patients with esophageal and esophago-gastric junction cancer present a significant post operative immunosuppression that lasts at least for the first postoperative week. The total amount of radiation received by the mediastinum is the only predictor of the postoperative and postoperative lymphocyte count.

Aims & Methods: The aim of this review was to determine the optimum choice and the neo-conduit following colorectal interposition after esophagectomy in adults. PubMed, MEDLINE and the Cochrane Library (January 1985 to January 2017) were systematically searched for studies which reported outcomes of colonic interposition after oesophagectomy in adults. The primary outcome measure was overall morbidity and secondary outcome measure was operative mortality.

Results: Twenty-seven studies, involving 1849 patients (median age 60 years, 1177 males, 697 malignant disease) who underwent colorectal interposition were analysed. The overall pooled morbidity rate of left vs. right colorectal conduit was 9.6% [95% CI (6.24–12.87), p < 0.0001] vs. 16.5% [95% CI (11.07–22.02), p < 0.0001] respectively. The overall pooled mortality rate of left vs. right colorectal conduit was 5.6% [95% CI (3.59–7.60), p = 0.0001] vs. 10.3% [95% CI (7.23–13.27), p < 0.0001] respectively. Retrosternal route placement was associated with the lowest overall pooled mortality of 9.2% [95% CI (6.48–11.99), p < 0.0001], and lowest overall pooled mortality of 4.8% [95% CI (3.74–5.89), p < 0.0001].

Conclusion: Left colon is the conduit of choice for colonic interposition after oesophagectomy in adults and the retrosternal route should be favoured.

Disclosure of Interest: All authors have declared no conflicts of interest.

Klebsiella pneumoniae carbapenemase-resistant (2.2%).

Introduction: The aim of this study was to critically explore whether suggestions that populations-at-risk for multi-antibiotic resistant Gram-negative and Gram-positive enteric rods, principally analyzed. Based on the positivity/negativity of preoperative surveillance cultures, patients were grouped by whether a dedicated lymphadenectomy was performed or not while those with missing information were excluded. Groups were compared for baseline characteristics. Positive lymphadenectomy was performed by univariate and multivariable adjusted logistic regression with adjustment for important patient- and tumor characteristics. Overall survival was assessed using Cox proportional hazard regression analyses before and after full bipartite pairwise propensity score matching.

Results: Of the 3879 patients included, 287 (7.4%) had T1a, 661 (17.0%) T1b, and 2931 (75.6%) T2 gallbladder cancer. Most patients were female (n = 2751, 70.9%), median age was 72 years (range 21–90). Among patients with T1a, T1b, and T2 disease, 102 (35.5%), 278 (42.1%), and 1526, (51.1%) underwent a dedicated lymphadenectomy, respectively. Over the study period, the rate of lymph node excision increased from 43% to 58% (p for trend = 0.005). The rates of positive lymph nodes were 11.8%, 16.2%, and 42.5% for T1a, T1b, and T2-stage, respectively. 5-year overall survival rate was 31.6% for patients without and 44.6% for patients with a dedicated lymphadenectomy and 58.6%, 43.9%, and 34.5% for T1a, T1b, and T2-stage, respectively. After multivariable adjustment, the odds of undergoing a lymphadenectomy increased with tumor stage compared to T1a disease (vs. T1b: OR: 1.37; CI: 1.01–1.86, vs. T2: OR: 1.95; CI: 1.48–2.57). Compared to their counterparts, patients who underwent lymphadenectomy for gallbladder cancer were more likely to have had an R0 resection status or radiation therapy, were diagnosed in later years, were younger, had a lower Charlson-Deyo-comorbidity score, were operated in high volume centers and traveled a longer distance to the treatment facility. In univariate analysis, no survival benefit of lymphadenectomy was found for T1a disease (HR 1.04, 95%CI 0.70–1.54) while lymphadenectomy improved overall survival in T1b (HR 0.72, 95%CI 0.58-0.90) and T2 stage (HR 0.59, 95%CI 0.53–0.65). Given significant bias of undergoing lymphadenectomy, full bipartite, pairwise propensity-score matching was performed. A trend towards overall survival benefit was also found for T1b disease (HR 0.49, 95%CI 0.39–0.69). Overall survival benefit remained for T1b (HR 0.68, 95%CI 0.51-0.91) and T2-stage (HR 0.63, 95%CI 0.55–0.71).

Conclusion: Our results support current consensus guidelines that T1b and T2 gallbladder cancer patients should undergo LA. However, based on the high rate of nodal positivity among patients with T1a disease and the trend towards overall survival improvement among T1a patients who underwent lymphadenectomy, we suggest to rethink this dogma and advocate to perform lymphadenectomy also in surgically fit elderly patients with T1a disease.

P0996 EFFECT OF TRICLOSAN-COATED SUTURE USE ON THE INCIDENCE OF SUPERFICIAL INCISIONAL SURGICAL SITE INFECTIONS AFTER GASTROENTEROLOGICAL SURGERY: A PROPENSITY SCORE MATCHING RETROSPECTIVE STUDY

K. Yamashita, S. Takeno, S. Hoshino, H. Shiwaku, S. Hasegawa Department Of Gastroenterological Surgery, Fukuoka University Faculty of Medicine, Fukuoka;Japan

Introduction: Surgical site infections (SSIs) after gastrointestinal surgery cause significant morbidity, prolong hospitalisation and increase health care costs. Thus, SSI prevention is critical. To prevent bacterial colonisation in suture material, which disables local mechanisms of wound decontamination, triclosan-coated sutures were developed. We retrospectively analysed the efficacy of triclosan-coated polydioxyanone sutures in abdominal fascia and skin closure using a propensity score matching analysis. We further analysed the surgery types for which these sutures are best suited.

Aims & Methods: The study protocol followed the principles of the Declaration of Helsinki and received ethical approval from the Ethics Committee of the Fukuoka University. Eligibility criteria included patients undergoing gastrointestinal surgery at Fukuoka University Hospital from January 2015 to July 2016. Data were conventionally analyzed for the control group from September 2012 to September 2013. In total, we included 1768 patients (control group, n = 640; study group, n = 1128) who underwent gastrointestinal surgery. Baseline differences and selection bias were adjusted using propensity score matching.

Results: Before matching, the SSI incidence differed significantly between the control and study groups for all gastrointestinal surgeries [12.4% (140/1128) vs. 5.5% (35/640); p = 0.0008] and hepato-biliary-pancreatic [16.4% (11/64) vs. 4.3% (6/136); p = 0.0049] surgeries. No significant difference was found between the groups for upper GI surgery, emergency surgery and others. Multivariable logistic regression analysis showed that triclosan-coated suture use for lower GI surgery was the independent factor affecting the SSI incidence (p = 0.017). The sutures demonstrated a significant efficacy in lower GI surgery.

Conclusion: Few studies have focused on the types of surgery best suited for triclosan-coated sutures. Our findings suggest that abdominal fascia and skin closure using these sutures reduces the SSI risk, particularly after lower GI surgery.

POLYURETHANE-FOAM AND FILM DRAINAGE
NEGATIVE PRESSURE THERAPY WITH OPEN-PORE

In recent years, laparoscopic proximal gastrectomy (LPG) has been actively performed in our institution to reduce invasiveness. However, proximal gastrectomy is sometimes followed by reflux. Until February 2015, we performed esophagogastrectomy with a circular stapler (CS) accompanied by fundoplication in LPG. After this period of 2015, to avoid the complication of ulceration, we have been using esophagogastrectomy with the double-flap technique (DFT) in LPG for gastric cancer.

Aims & Methods: We conducted this study to examine whether DFT can reduce the incidence of reflux and improve the outcome of postoperative hospital stay. Surgical factors, postoperative factors, and postoperative conditions were examined and compared between the DFT and CS groups.

Results: Twenty-three LPGs with DFT and 24 LPGs with CS were performed during the period. Compared with the CS group, the DFT group had a significantly longer surgical time (272.3 ± 55.5 vs. 241.1 ± 26.7 min; p < 0.01). Other surgical factors showed no statistically significant differences between the two groups. As for postoperative factors, although no significant differences in PPI intake, LA classification, and RGB classification were found, the DFT group showed a significantly lower score than the CS group (p < 0.01). Postoperative nausea and vomiting were observed in 9% of cases in the DFT group and in 19% of cases in the CS group.

Conclusion: Although LPG with DFT required a longer surgical time than LPG with CS, DFT is thought to be a safe reconstruction method in LPG. In addition to its safety, DFT can reduce postoperative reflux in patients who undergo LPG.

Introduction: Gastrointestinal (GI) leaks and perforations are difficult to manage and often mandate laparotomy and extensive surgical interventions for their repair. Endoscopic Negative Pressure Therapy (ENPT) has been developed to treat GI leaks and perforations such as leaks, fistulae and perforations. However, ENPT has only been utilized in the management of rectal and esophageal leakages.

By modifying the delivery catheter we were able to adapt ENPT to treat duodenal defects, that otherwise would have required surgery or more invasive methods to be employed.

Aims & Methods: Herein, we report ENPT using open-pore Polyurethane-foam and Film Drainage in a series of 10 patients with duodenal leakages. This is an open-label, retrospective, single-center study. Open-pore polyurethane-foam drainage (OPD) devices were constructed out of a piece (1.5 cm) of open-pore polyurethane-foam which was fixed surrounding the tip of a naso-gastric drainage tube. Small bore open-pore film drainage (OFD) device was constructed out of a piece (1.5 cm) of open-pore polyurethane-foam which was fixed surrounding the tip of a naso-gastric drainage tube. The open-film consists of two permeable membranes with a small interspace. Fluids are drained along the interspace and through the membranes. Diameter of small-bore OPD is 4–6 mm, depending on the diameter of the drainage tube. OPD is inserted transnasally. The foam is grasped with endoscopic forceps and guided to the duodenal lumen. After correct placement into the duodenal lumen for intraluminal ENPT, the tube is transferred out nasally, to become a naso-duodenal tube. Due to its smaller outer diameter OFD insertion is similar to placement of a naso-gastric or naso-intestinal feeding tube (i.e. through the nose). After nasal insertion into the esophagus OFD is grasped with a forceps and advanced into the stomach, and guided into the duodenal lumen for intraluminal ENPT. In case of a duodenal- cutaneous fistula the pull-through technique has been used for duodenal placement. In one case rendezvous technique was used for duodenal placement.

In case of a duodenal fistula, the pull-through technique was used for duodenal placement. In one case rendezvous technique was used. Ongoing follow-up of 10 patients treated with ENPT is ongoing.

Results: We treated 10 patients with ENPT because of a duodenal leakage. Reason of duodenal defects were: rupture of operative suture (n = 8),iatrogenic perforation due to intraoperative violation from system of a hemostasis. In case of a duodenal perforation, caused by a duodenal tube. Due to its smaller outer diameter OFD insertion is similar to placement of a naso-gastric or naso-intestinal feeding tube (i.e. through the nose). After nasal insertion into the esophagus OFD is grasped with a forceps and advanced into the stomach, and guided into the duodenal lumen for intraluminal ENPT. In case of a duodenal-cutaneous fistula the pull-through technique has been used for duodenal placement. In one case rendezvous technique was used for duodenal placement.

In case of a duodenal fistula, the pull-through technique was used for duodenal placement. In one case rendezvous technique was used. Ongoing follow-up of 10 patients treated with ENPT is ongoing.

Introduction: Laparoscopic cholecystectomy is the gold-standard for the treatment of gallbladder disease. Single-incision laparoscopic (SILS) cholecystectomy was introduced with the aim of reducing the invasiveness of classic laparoscopic surgery. Despite satisfactory cosmetic results of SILS cholecystectomy and its repute of a painless procedure, there are few published studies comparing early and long-term postoperative period of laparoscopic SILS cholecystectomy with laparoscopic four-port cholecystectomy.

Aims & Methods: The aim of this study is the comparative evaluation of SILS cholecystectomy and laparoscopic four-port cholecystectomy. Early and long-term postoperative period has been analyzed in 240 patients who underwent laparoscopic cholecystectomy including 120 cases of single-port technique and 120 cases of four-port technique. Both groups were compared in surgical time, pain syndrome severity (visual analog scale), need for analgesics, postoperative complications, hospital-stay, daily activity recovery and return to physical work, patients’ satisfaction of surgical results and their aesthetic effect.

Results: It was revealed that SILS cholecystectomy is associated with lower severity of postoperative pain, quick recovery of daily activity and return to physical work, high satisfaction of surgical result, and aesthetic effect compared with four-port cholecystectomy.

Conclusion: Further studies to standardize, evaluate the safety and benefits of SILS cholecystectomy are necessary.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic treatment of gastro-cutaneous and gastro-pulmonary leaks after bariatric surgery (BS). Surgical intervention may be indicated but is associated with high morbidity and mortality. The use of self-expanding esophageal metallic stents (SEMS) has become an effective alternative. Over the scope clips (OTSC) have also been used. Nevertheless some patients develop a refluxary fistulae after stent removal or other failed fistulous treatments. Cardiac Septal Defect Closure Device (CSDCD), used in interventional cardiology have been described to treat post-surgical digestive fistulae in non-bariatric cases. Aims & Methods: We aim to present the experience using CSDCD for gastric leaks. Methods: We present a case series of 42 patients with leaks secondary to gastric bypass (GBP) or sleeve gastrectomy (SG) from 4 centers were included. Data collected from november 2012 to January 2016 included sex, age, type of surgery, previous treatment, tract path, size of the leak opening and defect closure. Leaks were grouped according to the International Sleeve Gastrectomy Expert Panel Consensus in acute (post-operative days 1–7), early (1-6 weeks), late (after 6 weeks) and chronic (>12 weeks). Biliary catheters were adapted to introduce the CSDCD through the endoscopes working channels. Clinical success was defined as a complete closure of the tract path as assessed by contrast study after 2 months.

Results: 42 patients with leaks were included (31 SG, 11 GBP). Three acute leaks, 5 early, 2 late and 12 chronic. Prior failed therapies included: SEMS and enteral tube feeding (ETF), SEMS alone, SEMS and gastrosomy of excluded stomach, OTSC, ETF alone, jejunostomy and none (3 acute leaks had CSDCD as the primary treatment). Tract path was grouped as gastric-cutaneous (37), gastric-pleural (3) and gastric-bronchial (2). Median follow-up was 34, 8 weeks. All 3 patients with acute leak failed to close the defect. The CSDCD were removed within 7 days and SEMS were placed instead leading to defect closure. The 5 patients with early leaks had initial good response but within 30 days drainage recurred. The CSDCD were removed and replaced for a larger diameter device leading to permanent defect closure. Clinical success was achieved on 38 patients (90, 5%). In one patient with late leak the tract path was connected to an underlying cavity. Evolution was unsatisfactory and total gastrectomy accomplished.

Conclusion: CSDCD are effective to treat post bariatric surgery late and chronic leaks despite of the failed previous endoscopic treatment. Although early leaks finally healed it seems advisable to maintain conservative treatment and wait for the leak to become late or chronic before CSDCD placement. Acute leaks must be managed with a combination of SEMS, ETF, OTSC as first step. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Laparoscopic technique is the first choice for multiple surgical procedures today. Laparoscopic surgery differs from traditional open surgery in several aspects, for example two-dimensional view of a three-dimensional interior, higher demands on eye-hand coordination and lack of tactile feedback. Laparoscopic surgical skills can be substantially improved by simulator training. Learning via simulators are under constant development and it is important to understand the value of baseline characteristics and abilities to further optimize simulators and training curricula within surgical education. In this study, focus, will be the PC-gaming experience and visuospatial skill.

Aims & Methods: The aim of the study is to further analyse different factors to laparoscopic simulator training. 48 medical students completed three tasks in a laparoscopic virtual reality simulator, a validated Minimally Invasive Surgical Training (MIST, Mentice, Gothenburg, Sweden). Prior to the task, they performed a visuospatial test and answered questions regarding baseline characteristics (e.g. PC-gaming experience, age, gender, previous simulator experience). The data where analysed regarding different parts of the simulation (time, economy of movement, errors and total score).

Results: The group with high PC-gaming experience performed significantly better in total time (Mean difference = 32.17, p = 0.021) and economy of movement (M = 22.30, p = 0.035) compared to the low PC-gaming experience group (M = 38.40, p = 0.001). There were no differences between the groups in task number 3. A high visuospatial score correlated with a better total score (M = 71.68, p = 0.045) and total task score (M = 71.68, p = 0.045) between the groups. The group with both high PC-gaming experience and low visuospatial score performed worst in the simulator exercises.

Conclusion: PC-gaming experience and visuospatial skill have a positive impact on laparoscopic simulator performance. No remaining significant differences by either of the groups in task number 3. A high visuospatial score correlated with a better total score (M = 71.68, p = 0.045) and total task score (M = 71.68, p = 0.045) between the groups. The group with both low PC-gaming experience and high visuospatial score performed worst in the simulator exercises.

Introduction: Tuberculosis is a major cause of morbidity and mortality worldwide. Its incidence is continually increasing. Peritoneal localization is a particular entity, even less well known, because of its atypical and confusing symptomatology, which in most cases imposes a malignant condition.

Aims & Methods: We collected all patients hospitalized for peritoneal tuberculosis from the records of the gastroenterology unit of the National Institute of Gastroenterology, Tunisia between 2005 and 2015. The aim of this retrospective study was to study the epidemiology, clinical, pathological, diagnostic, therapeutic and evolutive specificities of peritoneal tuberculosis in its various presentations.

Results: The total number of patients was 65. It was 15 men (23.1%) and 50 women (76.9%). The sex ratio was 0.3. The mean age at diagnosis was 40 years (15–79 years). No personal history of tuberculosis has been found in our series. A personal history of tuberculosis was found in 3 patients (4.6%). The general signs of tuberculosis infection were frequently found (91%). The digestive functional symptoms that brought the patients to consult were: abdominal pain (87.7%), abdominal distension (87.7%), nausea (16.9%) and sub occlusive syndromes (4.6%). An abdominal mass was observed in only 4 patients (6.1%). Hepatomegaly and splenomegaly were noted in 2 cases for each. The intradural reaction was positive in only 24% of patients. The research of BK in the ascites fluid was systematically performed in all patients but returned negative in all cases. The quantiferon-TB Gold was performed in 3 patients only and returned negative. The mean level of CA 125 was 250.3 IU/ml. Confirmation of diagnosis was obtained on the histological analysis of peritoneal biopsy (17 patients) and on the surgical pieces. The main operative findings (in patients with coloescopy or exploratory laparotomy) were: Whist granulations (98%), adhesions (43.1%) and agglutinated loops (1.5%). The presence of tuberculous granuloma was observed in 22 patients (87%). The course of treatment was as follows: cure in 50 patients (80.6%), recurrence in 6 patients (9.6%), relapse in 2 patients and 3 patients were lost to follow-up. The mortality in our series was 0%.

Conclusion: Peritoneal tuberculosis raises diagnostic problems in the first place, because of its polymorphic and non-evocative clinical expression. Hence the value of carrying out radiological, endoscopic and histo-bacteriological investigations to confirm the diagnosis before the evolution towards serious or even fatal forms.

Introduction: Tuberculosis is the most common site of extra-pulmonary tuberculosis. No single test is adequate for diagnosis of abdominal tuberculosis. We collected all patients hospitalized for peritoneal tuberculosis in all patients. ABM remains an ongoing diagnostic dilemma requiring a high index of clinical suspicion.

Introduction: Inability to maintain a stable and beneficial microbiota is associated with chronic gut inflammation, which classically manifests as colitis but may more commonly exist as low-grade inflammation that promotes metabolic syndrome. Alterations in microbiota and associated inflammation can originate from dysfunction in host proteins that manage microbiota, such as the flagellin receptor TLR5, and/or be promoted by exogenous factors that disturb host-microbiota interactions, such as the detergent-like dietary emulsifiers carboxymethylcellulose (CMC) and polysorbate 80 [1, 2, 3]. That the complete absence of a microbiota (i.e. germ-free conditions) eliminates all evidence of inflammation in
TLR3-deficient and emulsifier-treated mice demonstrate that these models of gut dysbiosis and gut microbiota disruption on distribution and polarization of Th17-polarized cells are involved in pathogenesis of both diseases. Therefore, (CD4 T(+)IBD). Two major types of IBD are ulcerative colitis, limited to the colon and rectum and Crohn’s disease causing chronic intestinal inflammation, termed Inflammatory bowel disease (IBD). Disrupted regulation of LPMCs is implicated in pathology of a group of disorders, including gastrointestinal infections, autoimmune diseases such as inflammatory bowel disease (IBD), and various malignancies. In IBD, LPMCs function to eliminate invading pathogens from beneficial intestinal flora and swiftly remove them. The tissue may be considered as healthy in terms of IBD. We have employed an approach to these patients. Clinical activity seems more important to CD than UC patients in terms of disability. Crohn’s Disease (CD) or Ulcerative Colitis (UC) for at least 3 months and followed up at our outpatient clinic thereafter. Socio-demographic and clinical data were collected in a cross-sectional study. The Revised Life Orientation Test (LOT-R) and IBD-DI, respectively. The assessment of the patients included demographic predictors. Most (85.3%) was in clinical remission. The median IBD-DI-PT score was 17.9 ± 10.7, with no significant difference between DC and CU (p = 0.944). In univariate analysis, female gender, high level education, number of days off from work, articular manifestations, number of comorbidities, use of psychotropic drugs and pessimism (low LOT-R score) were significantly associated with higher disability (IBD-DI-PT score). In multivariate analysis, only female gender (β = 0.150), number of comorbidities (β = 0.186) and pessimism (β = 0.370) were significantly associated with higher disability. Clinical activity was assessed with higher disability index (IBD-DI-PT score). In multivariate analysis, only female gender (β = 0.150), number of comorbidities (β = 0.186) and pessimism (β = 0.370) were significantly associated with higher disability. Clinical activity was associated with higher disability only for CD patients (β = 0.321). Concomitantly, the ASF was maintained WT mice, loss of TLR5 did not result in low-grade intestinal inflammation nor metabolic syndrome in WT ASF animals. We are interested in the development of a robust method for isolation and characterization of LPMCs from human colonic mucosa, comparable with further extracellular vesicles (EVs). EVs released by immune cells and enteric bacteria have been identified as potential biomarkers of IBD and may serve as targets for therapeutic strategies.

References
significant increase was observed in patients undergoing treatment with corticosteroids. Regarding HLADR, statistical difference (p = 0.005) and CD62L (p = 0.001) in subpopulation of CD4+ T cells, a significant increase in the expression was observed in the group receiving biological therapy. Redirecting HLADR, statistical difference (p = 0.001) was observed between the groups. The markers CD38, CD62L and HLA-DR besides being classically markers of cellular activation, are also known as markers of diseases progression (Lovecchi et al., 2017). Some studies shows that CD+ T cells play a key role in the immune inflammatory response leading to CD but this cells are poorly characterized in the blood of the patients.

Aims & Methods: This study aimed to characterized CD4+ and CD8+ T cells in the blood of patients with CD. The study was performed in individuals with CD (n = 40) and healthy controls (n = 38). Blood of healthy donors and patients with CD was collected in clinical laboratory from Hospital Albert Einstein. CD4+ and CD8+ T cells was quantified by multiparametric flow cytometry. Dosage of calprotectin and ASCA was performed by commercial Elisa kit. The groups were compared for numerical measures using Student's t-tests, ANOVA, Mann-Whitney or Kruskal-Wallis, depending on the suitability of the data and the number of groups to be compared. The computational package used for the analyses was R 3.0.3 and GraphPad Prism 6.

Results: The highest prevalence in both group was female, aged between 19 and 66 years with a median of 37.5 years. Among clinical exams, 61% of cases presents the value greater than 200 in the dosage of Calprotectin, whereas in the control group the rate was only 18.4% (p = 0.015). Significantly higher percentage of patients with CD was collected in clinical laboratory from Hospital Albert Einstein. CD4+ and CD8+ T cells was quantified by multiparametric flow cytometry. Dosage of calprotectin and ASCA was performed by commercial Elisa kit. The groups were compared for numerical measures using Student's t-tests, ANOVA, Mann-Whitney or Kruskal-Wallis, depending on the suitability of the data and the number of groups to be compared. P0963 EOSINOPHILS-ASSOCIATED CYTOKINES AS INF Patrol inflammatory bowel disease biomarkers K. Neubah1, M. Matusiwick2, I. Bednarz-Misna2, S. Górska3, A. Gamian2, M. Krzyżewski-Korpacka2 1Gastroenterology And Hepatology, Wrocław Medical University, Wrocław, Poland 2Medical Biochemistry, Wrocław Medical University, Wrocław, Poland 3Laboratory Of Medical Microbiology, Ludwik Hirschfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wrocław, Poland Contact E-mail Address: kasianeu@gmail.com Introduction: Pathogenesis of inflammatory bowel disease (IBD) is multifactorial and establishing diagnosis requires a performance of series of variable tests. The alternative, non-invasive, markers of IBD are intensively searched for. Eosinophils are acidophilic multifunctional granulocytes that remain outside the mainstream research on IBD. However, they are a rich source of cytotoxic proteins, pro- and anti-inflammatory cytokines, chemokines and growth factors and are likely to contribute to both inflammatory and regenerative phases of the disease. Accordingly, peripheral eosinophils of IBD patients are primed and pre-activated. They display increased responsiveness, adhesiveness, migration, and degranulation and are characterized by up-regulated secretion of their mediators. Locally, increased number and activation of eosinophils have been repeatedly observed in areas of active inflammation. Despite the acknowledged contribution of eosinophils to the disease pathogenesis, available data on cytokines closely related to the development and activity of peripheral eosinophils in IBD patients are either scattered or non-existent. Aims & Methods: Aim of the study was assessment of the circulating eosinophil-associated cytokines and growth factors as differential markers and indicators of mucosal healing in inflammatory bowel diseases. The study population consisted of 277 individuals: 101 patients with Crohn’s disease (CD), 77 with ulcerative colitis, 16 with irritable bowel syndrome (IBS) and 83 healthy controls. The disease severity was assessed using the Crohn’s Disease Activity Index (CDAI) for CD and the Mayo Disease activity index (MDAI) for UC. Also, the Mayo endoscopic score was applied to evaluate the severity of bowel inflammation in UC patients. The concentrations of eosinophil-associated cytokines and growth factors: eotaxin, GM-CSF, IFNγ, IL4, IL5, IL8, IL10, IL13, RANTES and TNFα were measured simultaneously in the blood of a patient’s sera using LumineX xMAP® technology and referred to IBD activity and the levels of hscCRP. The suitability of eosinophil-associated cytokines and growth factors as differential markers and potential indicators of mucosal healing, individually and in multi-marker panels, was evaluated using ROC analysis. Results: As compared to IBS patients or healthy controls, patients with CD had significantly higher levels of II5, II8, IL12(p70), GM-CSF, and TNFα and patients with UC the levels of eotaxin, IL4, IL5, II8, IL12(p70), IL13, GM-CSF, and TNFα. As compared to CD patients, patients with UC had significantly higher levels of eotaxin, IL4, IL5, II5, and II1. In turn, the concentrations of II8 were significantly higher in CD than in UC. Except for IL13, all cytokines and hscCRP positively correlated with CDAI but only II12(p70) and hscCRP were significantly higher in patients with active than inactive CD. In UC, a positive correlation with MDAI was observed for hscCRP, GM-CSF, IL12(p70), and IFNγ and a negative one for IL8. The concentrations of hscCRP, GM-CSF, IFNγ, IL12(p70) and RANTES were higher in UC patients with active than inactive disease whereas those of II8 and TNFα were significantly lower. As differential individual markers, eotaxin displayed superior accuracy as an indicator of active UC (71%), followed by hscCRP as an indicator of active CD (66%). The combined assessment of eotaxin, hscCRP and IFNγ had slightly lower accuracy (72%) and allowing for a correct classification of 72% of patients. The concentrations of hscCRP, GM-CSF, IFNγ, and IL12(p70) were significantly and positively correlated with the degree of bowel inflammation, expressed as Mayo endoscopic score. Of these, a drop in GM-CSF had superior diagnostic accuracy (91%), followed by macroscopic score (91%), allowing for a correct classification of 87% of patients. IL5, IL8, IL12(p70), TNFα, and GM-CSF were significantly higher in both CD and UC than in IBS. Of these, IL8 had superior accuracy in differentiating IBS and IBD (91%), allowing for a correct classification of 93% of patients. Conclusion: Eosinophil-associated cytokines are elevated in IBD, more pronounced in UC and may support the differential diagnosis of IBD and aid in monitoring of mucosal healing. Disclosure of Interest: All authors have declared no conflicts of interest. P0964 MACROPHAGE IL10 SIGNALING IS REQUIRED FOR THE THERAPEUTIC EFFECT OF ANTI-TNF THERAPY IN INFAMYLITARY BOWEL DISEASE P. J. Koelink1, F. M. Bloemendaal1, L. Westera2, A. B. van ‘t Wout2, A. K. Gloumdemas3, B. Li4, T. L. Geiger5, M. E. Wildenberg6, G.R. Van Den Brink1 1AMC Amsterdam, Amsterdam, Netherlands 2Janssen Prevention Center, Janssen Pharmaceutical Companies of Johnson & Johnson, Leiden, Netherlands 3Department Of Pathology, St. Jude Children’s Research Hospital, Memphis, United States of America 4Tyrgut Institute, AMC Amsterdam, Amsterdam, Netherlands 5Dept. Of Gastroenterology, Academisch Medisch Centrum, Amsterdam, Netherlands 6Contact E-mail Address: p.j.koelink@amc.nl Introduction: Interleukin(IL)10 is an important anti-inflammatory cytokine for the maintenance of gut homeostasis. Defects in the IL10 signaling pathway in macrophages leads to deregulation of regulatory (M2) type macrophages and subsequent inflammatory bowel disease (IBD). IBD patients are frequently successfully treated with anti-TNFα therapy, although not all patients are responsive. Aims & Methods: We determined the effect of anti-TNFα therapy in both IL10 knock-out (KO) mice and in the CD4 + CD45Rb high T-cell transfer model of colitis. Macrophage populations were quantified using qPCR analysis for CD206 and F4/80 and flow cytometry for CD206. IL10 mRNA and protein levels were analysed with qPCR and ELISA. Results: Colitis in the IL10 KO mice was completely resistant to anti-TNFα therapy, in sharp contrast to the colitis in SCID or Rag1 KO mice upon transfer of wild-type or CD4 + CD45Rb high T-cells, which was significantly reduced by anti-TNFα therapy. Successful anti-TNFα therapy was accompanied by an increase of IL10 levels and an increase of regulatory (M2) type macrophages in the intestine. Blocking IL10 signaling, with an IL10 Receptor blocking antibody, diminished the therapeutic efficacy of anti-TNFα therapy. Anti-TNFα therapy was also blocking IL10 signaling in T-cells was not important for the therapeutic efficacy of anti-TNFα. In contrast, LysMcCre Il10 KO mice, defective in macrophage IL10 signaling, were unresponsive to anti-TNFα therapy upon receiving CD4 + CD45Rb high T-cells. In these mice there was also no increase of intestinal M2 macrophages. Conclusion: IL10 signaling in macrophages is pivotal for the therapeutic efficacy of anti-TNFα therapy in animal models for IBD. Defects in the IL10 pathway may also play a role in anti-TNFα non-responders which is subject of further investigation. Disclosure of Interest: All authors have declared no conflicts of interest. P0965 LONG-TERM CONSEQUENCES OF ANTI-TNF THERAPY: ROLE OF SCFAS AND INTESTINAL BARRIER INTEGRITY Y. Holota1, A. Bazan1, V. Stets1, N. Dziubenko1, T. Dovbychnyk1, T. Chernivska1, L. Zakordonets1, T. Serhiychuk1, I. Kaji1, G. Tolstanova1 1Bogomolets National Medical University, Kyiv/Ukraine 2Shevchenko National University of Kyiv, Kyiv/Ukraine 3Bogomolets National Medical University, Kyiv/Ukraine 4UCLA School Of Medicine/Cure, West LA V A Medical Center, Los Angeles 5United States of America Contact E-mail Address: julialagota@gmail.com Introduction: Epidemiological studies revealed that antibiotics exposure increases the risk of inflammatory bowel diseases (IBD) development (Hviid, 2011, Shaw, 2011, Krommon, 2012). However, mechanisms of this association are not fully understood. Recent studies revealed sustained alterations in gut microbiota after antibiotic treatment (Rashid, 2015, Dethlefsen, 2011), the full consequences of antibiotic treatment (Rashid, 2015, Dethlefsen, 2011), the full consequences of antibiotic treatment in both IL10 − /− and IL10 + /+ IL10 KO mice and in the CD4 + CD45Rb high T-cell transfer model of colitis. Macrophage populations were quantified using qPCR analysis for CD206 and F4/80 and flow cytometry for CD206. IL10 mRNA and protein levels were analysed with qPCR and ELISA. Results: Colitis in the IL10 KO mice was completely resistant to anti-TNFα therapy, in sharp contrast to the colitis in SCID or Rag1 KO mice upon transfer of wild-type or CD4 + CD45Rb high T-cells, which was significantly reduced by anti-TNFα therapy. Successful anti-TNFα therapy was accompanied by an increase of IL10 levels and an increase of regulatory (M2) type macrophages in the intestine. Blocking IL10 signaling, with an IL10 Receptor blocking antibody, diminished the therapeutic efficacy of anti-TNFα therapy. **Introduction:** According to our previous report, the imbalance of Treg/Th17 cells in the host is related with the reduction of CD45RA FoxP3high activated Treg (FrII) cells, which has the real function of immunosuppression, and with the elevation of CD45RA FoxP3low Th17 (FrIII) cells, which provide FoxP3low IL17a+ T cell activity, and make them resistant to immunosuppressive capacity. Activation of Toll-like receptors, especially TLR2, leads to elevation of FrIII, which show FoxP3low IL17a+ T cell activity. The levels of Treg cells were elevated in PBMC and LPC of group B compared with group A (4.215 fold, 0.104 P<0.05). But the level of CD3+ CD8+ T cells was decreased in spleen, PBMC, MLN and LPC compared with group B (0.533 fold, 0.100 P<0.05). The level of CD3+ CD8+ FoxP3low IL17a+ cells were decreased in spleen, PBMC, MLN and LPC compared with group B (5.967 fold, 0.158 P<0.05, 4.896 fold, 0.232 P<0.05 respectively). The level of CD3+ CD62L+FoxP3+ IL17a+ cells were decreased in spleen, PBMC, MLN and LPC with group B (0.533 fold, 0.100 P<0.05, 1.238 fold, 0.158 P<0.05, 2.523 fold, 0.044 P<0.05, 2.390 fold, 0.028 P<0.05 respectively). But the level of CD3+ CD62L+FoxP3+ IL17a+ cells were decreased in spleen, PBMC, MLN and LPC with group B (0.533 fold, 0.100 P<0.05, 1.238 fold, 0.158 P<0.05, 2.523 fold, 0.044 P<0.05, 2.390 fold, 0.028 P<0.05 respectively). (4) The levels of Th17 cells were elevated in PBMC and LPC of group B compared with group A (1.333 fold, 0.05). (5) The levels of Th17 cells were elevated in PBMC and LPC of group B compared with group A (1.333 fold, 0.05). (6) The levels of Th17 cells were elevated in PBMC and LPC of group B compared with group A (1.333 fold, 0.05). (7) The levels of Th17 cells were elevated in PBMC and LPC of group B compared with group A (1.333 fold, 0.05). (8) The levels of Th17 cells were elevated in PBMC and LPC of group B compared with group A (1.333 fold, 0.05).

**Conclusion:** Blocking TLR2, TLR2Nab could improve the level of FrII cells in PBMC, MLN and LPC, but reduce the levels of FrII and FoxP3+IL17a+ cells in DSS induced UC mice. Furthermore, TLR2Nab could alleviate the DAI index as well as the inflammation of CD45RA FoxP3low IL17a+ cells.

**FIRST ANALYSIS FROM UK IBD TWIN BIOBANK; 16S RNA GENE SEQUENCING IDENTIFIES REDUCED DIVERSITY IN ACTIVE IBD AND TAXA ASSOCIATED WITH ACTIVE DISEASE. PHENOTYPE TO LEVEL OF SPECIES**

H. Gordon1, M. Harbord1, J. Marchesi2, W. Blad1, T. R. Orchard3, J. M. LCDonald4, 1Gastroenterology, Chelsea and Westminster Hospital, London/United Kingdom; 2Imperial College London, London/United Kingdom; 3Gastroenterology, Imperial Healthcare NHS Trust, London/United Kingdom; 4Contact E-mail Address: marcus.harbord@chelsewht.nhs.uk

**Introduction:** Previous studies have shown that the gut microbiota plays an important role in IBD, however this role is not a confirmed fact and what bacteria are responsible for the disease. 16s gene profiling studies generate large amounts of information, however they can be confounded by genetic and environmental factors. Twin studies are instrumental in controlling for some of these variabilities, and in this study we investigated the microbiota of twin pairs discordant for Crohn’s disease (CD) and Ulcerative colitis (UC) using 16s RNA gene sequencing, with the aim of identifying taxa associated with disease.

**Aims & Methods:** Participants were recruited via the UK IBD Twin Registry. Stool samples were collected and frozen using standard methods. Participants who had received antibiotics within 3 months were excluded. Harvey-Bradshaw Index and Simple Clinical Colitis Activity Index were recorded. Full medical history was available from the UK IBD Twin Registry. Samples underwent 16s RNA gene sequencing using the Illumina MiSeq platform with our data analysis pipeline. PERMANOVA was used to evaluate associations with clinical metadata, which included matching of twin pairs for analysis, and STAMP was used to identify taxonomic differences between groups.

**Results:** 20 twin pairs discordant for CD (5MZ:15DZ mean age 52 years) and 17 discordant for UC (6MZ:11DZ mean age 59.7 years) were recruited. 7 subjects with CD had active disease as did 4 with UC. Gut microbiota from active CD patients had lower bacterial diversity compared to remission patients and healthy twins (Shannon diversity index, p < 0.01 healthy vs active UC, p < 0.05 active vs remission CD, 1-way ANOVA post-hoc = Tukey). Active UC patients also had lower bacterial diversity compared to remission UC patients and healthy twins (Shannon diversity index, p < 0.01 healthy vs active UC, p < 0.05 active vs remission UC) We found that active CD patients had a higher proportion of *Clostridium hylemonae* and *Lactobacillus delbrueckii* compared to healthy twins, and a lower proportion of *Faecalibacterium prausnitzii* compared to healthy twins (p < 0.05). We found that active UC patients had a lower proportion of *Attilispor spp* compared to their healthy twins and UC patients in remission (p < 0.05).

**Conclusion:** This study confirms previous findings showing decreased diversity in IBD patients and changes in some bacterial taxa, however our study is the first to show decreases in *Attilispor spp* in active UC. **Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** imke.atreya@uk-erlangen.de

**Introduction:** Chronic and acute inflammation is often associated with an upregulation of extracellular UTP and ATP nucleotides, which are able to interact with various cell types via purinergic G protein-coupled P2 receptors. Interestingly, former studies already described an increased expression of the ATP/UTP receptor subtype P2Y2 (P2Y2R) in the colonic tissue of IBD patients [1]. However, it remained unknown in how far immune cells of IBD patients are characterized by an increased expression of the nucleotide receptor P2Y2, which impacts relevantly on pro-inflammatory cascades.

**Aims & Methods:** P2Y2R mRNA and protein expression were evaluated in primary human CD4+ T cells from the blood of IBD patients or healthy donors was analyzed via qPCR or western blot, respectively. Furthermore, primary human CD4+ T cells were stimulated in the presence of UTP or the selective P2Y2R agonist 2-thio-UTP and activated in the presence of UTP or the selective P2Y2R agonist 2-thio-UTP and activated in the presence of UTP or the selective P2Y2R agonist 2-thio-UTP and activated in the presence of UTP or the selective P2Y2R agonist 2-thio-UTP and activated in the presence of UTP or the selective P2Y2R agonist 2-thio-UTP and activated in the presence of UTP or the selective P2Y2R agonist 2-thio-UTP and activated in the presence of UTP or the selective P2Y2R agonist 2-thio-UTP and activated in the presence of UTP or the selective P2Y2R agonist 2-thio-UTP and activated in the presence of UTP or the selective P2Y2R agonist 2-thio-UTP and activated in the presence of UTP or the selective P2Y2R agonist 2-thio-UTP and activated in the presence of UTP or the selective P2Y2R agonist 2-thio-UTP and activated in the presence of UTP or the selective P2Y2R agonist 2-thi-
M. Hausmann1, C. De Valliere1, M. R. Spalinger1, P. Spielmann2, R.H. Wenger2,

human CD4 T cells from IBD patients could be characterized by a significantly increased P2Y2R expression compared to healthy controls, while the expression levels of the P2Y4 receptor subtype turned out to be comparable between both groups. Further subdividing the group of included IBD patients into Crohn’s disease and ulcerative colitis patients, we could not observe a significant difference in the P2Y2R levels between both disease entities. Interestingly, the increased P2Y2R expression in the lymphocyte compartment of IBD patients seemed to be limited to CD4 T cells, as CD6 T cells of those patients even showed decreased P2Y2R levels. Regarding potential regulators of P2Y2R expression in the context of IBD, our data identified IL-6 and TGF-beta as mediators of increased P2Y2R expression in human CD4 T cells. Interestingly, high extracellular UTP levels resulted in a decreased expression of the TGF-beta1 receptor on CD4 T cells, implicating a potential negative feedback loop in which P2Y2R signaling might inhibit TGF-beta1 induced P2Y2R expression over time. The impact of P2Y2R on the pro-inflammatory capacity of human lymphocytes, our data indicate that the selective P2Y2R agonist 2-Thio-UTP is able mediate NFkB as well as STAT3 activation and to induce secretion of the pro-inflammatory cytokines IL-6 and IL-17 in stimulated human lymphocytes. Conclusion: The observed increased expression of P2Y2R in CD4 T cells of IBD patients together with the demonstrated pro-inflammatory effects of P2Y2R signaling in human T cells markedly strengthen the role of P2Y2R as a promising molecular target in IBD.

Introduction: Environmental hypoxia has been increasingly recognized as an important environmental factor associated with Inflammatory Bowel Disease (IBD). Hypoxia allows the stabilization of hypoxia inducible factor (HIF) complexes and has been linked to the activation of autophagy. HIF 1α is induced in the inflamed mucosa from IBD patients and mouse models of colitis, but its role in intestinal inflammation is still controversial since both, positive and negative effects have been reported. Aims & Methods: We aim to elucidate the effects of HIF1α stabilization in autophagy and the development of intestinal inflammation in a murine model of colitis. Female C57BL/6J mice between 8–10 weeks of age were exposed to 25% DSS in drinking water for 7 days, and received 8 mg of the hydroxylase inhibitor dimethylxaloylglycerol (DMOG) intraperitoneally every second day. Mice were killed at day 9, mucosal damage was assessed by colonoscopy and mucosal endo-scopic score of colitis severity (MEICS) was calculated. H&E staining was performed to visualize the histological damage. Expression of TNF, IL-6, IL-1β and Nlrp3 was analyzed by qPCR and protein expression of p-NFκB, NFκB, p-akt, mTOR, LC3, NfκB, p62, LCM was assessed by Western Blot. HT-29 cells were subjected to normoxia (21% O2) or hypoxia (0.2% O2) for 24h in the presence or absence of 40µM chloroquine. Cells were stained with DAPI and LysoTracker Yellow-HCK-123 to monitor lysosomal accumulation. Chromatin immunoprecipitation (ChIP) analysis was performed using an antibody against HIF1α and PCR was performed using the promoter-specific primers for the p62 promoter binding of HIF1α. Results: DMOG administration induced a significant lower reduction of body weight in DSS-treated mice compared to DSS-treated mice administered with vehicle. Furthermore, mice administered with DMOG presented less reduction in the colon length, a significant reduction in the MEICS and histological scores showing intact crypts in large areas without extensive infiltration or thickening of the mucosa. The mRNA expression of the pro-inflammatory factors TNF, IL-6, IL-1β and Nlrp3 was significantly reduced in mice treated with DMOG compared to vehicle-treated mice. At a protein level, DMOG administration reduced p-NFκB and NLRP3 expression. DMOG-treated mice also showed activation of autophagy, as evidenced by a decrease in p-mTOR and p62 expression and increase of LC3II. In vitro, hypoxia induced a significant accumulation of lysosomal proteins, a reduction of p-mTOR. The late-stage autophagy inhibitor chloroquine reverted this effect indicating that was autophagy-mediated. Finally, ChIP analysis revealed that hypoxia induced the binding of HIF1α to the promoter of p62. Conclusion: Our results indicate that DMOG-mediated HIF1α stabilization ameliorates DSS-induced colitis, activates autophagy and significantly reduces inflammatory gene expression and signaling. In cultured intestinal epithelial cells hypoxia triggers lysosomal formation and HIF1α binds to the promoter of p62, thereby promoting autophagy.

Introduction: There are several medical treatment options for inflammatory bowel disease (IBD), but all have drawback due to their significant adverse effects. Many new drugs are being developed for more safe and effective treatment. Apocynin is a chemical 4-hydroxy-3-methoxycinnamatephene which is an inhibitor of NADPH oxidase and has showed promising effect in various chronic inflammatory diseases such as asthma and atherosclerosis. Due to its anti-inflammatory effect and safety profile, apocynin can be a new candidate for the treatment of IBD.

Aims & Methods: In this study, we aimed to investigate effect of apocynin on colonic inflammation and the action mechanism using chemically-induced colitis mouse model. We used dextran sulfate sodium (DSS)-induced colitis model. 8 weeks male BALB/c mice were divided into four groups (each n=6): control, DSS only, DSS with apocynin, and DSS with sulfasalazine. Water (control and DSS group), apocynin (400 mg/kg) and sulfasalazine (150 mg/kg) were administered by oral route using sonde during 7 days. For western blot analysis, colon was lysed and protein was extracted. The following antibodies were used; iNOS (BD Biosciences), COX2, Nrf2 (Santa Cruz Biotechnology Inc), MCP-1, TNF-α, p-Nfr2, HO-1 (Abcam), and β-actin (Sigma).

Results: Protective effect of apocynin was evident by weight change and colon length. Histologic analysis also showed improved erosion and decreased neutrophilic infiltration in apocynin group compared to DSS group. In colon tissue, several pro-inflammatory enzymes and cytokines were decreased by apocynin. Apocynin also activated anti-inflammatory pathway by inducing activation of Nrf2 and production of heme oxygenase-1 (HO-1).

Conclusion: Apocynin, a NADPH-oxidase inhibitor, showed significant anti-inflammatory effect in DSS induced colitis model. Considering its good safety profile, this molecule can be a new candidate for the treatment of IBD.

Introduction: Fecal metabolic profiling has been shown to distinguish Inflammatory Bowel Disease (IBD) from healthy controls (HC), specifically with depletion of gut-associated short chained fatty acids (SCFA) as the predominant feature separating these groups (1). Previous and current studies have used proton nuclear magnetic resonance (1H NMR) spectroscopy or mass spectrometry (MS) to measure faecal metabolites and their concentration in IBD patients to different treatments. Both techniques require a significant amount of sample pre-processing. Rapid Evaporative Ionization Mass Spectrometry (REIMS) is a relatively new technology which applies a laser to a biological sample, and the resulting vapour, containing gas phase ions of metabolites and structural lipids, is analysed by a mass spectrometer (2). Unprocessed faecal samples can be rapidly assessed using this technique to obtain lipidomic spectral profiles (2). To our knowledge this is the first study that has used REIMS to investigate whether IBD patients can be distinguished from healthy controls using faecal samples. Aims & Methods: Unprocessed faecal samples from 109 IBD patients and 46 healthy controls were analysed using Rapid Evaporative Ionization Mass Spectrometry. Clinical and dietary data were collected, and patients with significant other co-morbidities were excluded. Partial least squares discriminative analysis (PLSDA) was performed to examine whether there were differences in the metabolic data between patients with Inflammatory Bowel Disease and healthy controls. Further samples were then carried out including examining whether ulcerative colitis could be distinguished from Crohn’s disease.
P0972 THE PATHOGENIC MECHANISM OF ARYL HYDROCARBON RECEPTOR MEDIATED ABNORMAL DIFFERENTIATION OF INTESTINAL ILC3/ILC1 IN CROHN’S DISEASE

X. Zhao, H. Zhang
Department Of Gastroenterology, Jiangsu Province Hospital and Nanjing Medical University, Nanjing/China

Contact E-mail Address: zhaoxq1718@c163.com

Introduction: The abnormal differentiation of intestinal innate lymphoid cells ILC3 and ILC1 exist in autoimmune disease. ILC3 decreased and ILC1 increased in Crohn’s disease (CD) patients, suggesting that CD patients have abnormal intestinal ILC3/ILC1 alteration.

Aims & Methods: The present study investigated the aberrant colonic mucosal ILC3/ILC1 in active CD patients and 2, 4, 6-trinitrobenzene sulfonic acid (TNBS)-induced colitis mice. The expressions of aryl hydrocarbon receptor (AhR) in colon of active and quiescent CD patients were detected by western blot and immunofluorescence. The ILC3/ILC1 were investigated in CD patients and 2, 4, 6-trinitrobenzene sulfonic acid (TNBS)-induced colitis mice (AhR-/-, AhR+/-).

Results: Compared to quiescent CD patients, the expression of aryl hydrocarbon receptor (AhR) in the intestinal tissue in active CD patients was decreased. Meanwhile, the number of ILC3 in active CD patients and AhR knockout mice was decreased while ILC1 increased. The intestinal inflammation in AhR knockout mice given TNBS was more severe than wild-type mice.

Conclusion: These findings suggest that AhR may mediate abnormal differentiation of ILC3/ILC1, and the production of inflammatory cytokines, finally, promotes the pathogenesis of CD.

P0973 PREVALENCE AND GENETIC DIFFERENCES IN ADHESION-RELATED GENES AMONG COMMENSAL AND ADHERENT-INVASIVE E. COLI STRAINS

C. Camprubi-Font, A. Seguí-Roig, N. Maeso-Sánchez, M. López-Siles, M. Martínez-Medina

Introduction: Long polar fimbrae (LpfA), Filh amino acid variants and ChiA chitinase have been related with adherent-invasive E. coli (AIEC) pathogenesis. Controversial results have been found regarding the prevalence of LpfA in AIEC vs non-AIEC (1, 2). Some Filh amino acid variants were reported to be specific for AIEC (3) whereas other variants were associated with phylotype B2. The origin of the strains (4). Differences in the ChiA sequence were reported between LF82 and K-12 strains but this gene has not been studied in other AIEC yet (5).

Aims & Methods: The prevalence of LpfA and the distribution of filh and chiA variants in the collection of AIEC and non-AIEC from different disease origins. Crohn’s disease (CD), ulcerative colitis (UC) and colorectal cancer (CRC) were studied with the purpose to determine if these genes could be used as molecular markers for AIEC identification and disease diagnosis. In a collection of 77 AIEC and 29 non-AIEC isolated from CD, UC, CRC patients and controls, lpfA gene was PCR-amplified to assess its presence and filh and chiA genes were sequenced to identify point mutations. For comparison of filh and ChiA protein sequences, UPGMA phylogenetic tree and allele identification was performed using MEGA5. The genetic differences were annotated using as reference the K-12 strain. Then, they were analysed statistically according to AIEC pathotype, filh and chiA variant, and disease origin by the χ2 test and non-parametric tests were used to evaluate amino acid variability regarding the adhesion and invasion indices.

Results: Low gene frequency for lpfA414 and lpfA154 was reported (11.7% and 16.7% respectively). LpfA154 was only found in strains from A (22%) and B1 phylgroup (86%) and no relation with AIEC phenotype or disease was observed. Two main clusters of Filh were obtained by phylogenetic analysis, classifying the strains according to the presence of S78N mutation. N70S and S78N variants were characteristic from strains of B2 and D phylgroups as none of the A or B1 strains presented it. Despite statistical significance was not reached, the strains with N70S, S78N, V163A, R166H mutations showed the highest adhesiveness. Regarding ChiA, two main clusters defined by the presence of an insertion in 312-314 residues were observed. None of the five previously mutations found in LF82 strain were associated with AIEC strains whereas the V415A variant was found specifically in AIEC (20%) (p = 0.049). Of note, among the strains harbouring the 312-314 insertion, a subcluster that shared identical amino acid sequence included the LF82 strain and the 44% of AIEC strains but only the 10% of the non-AIEC (p = 0.019). No differences were observed between Filh, ChiA variants and origin of isolation was observed.

Conclusion: In contrast with other studies, no relation of lpfA presence nor in Filh mutations with AIEC pathotype or disease was observed. Nonetheless, a variant in ChiA sequence more frequently found in AIEC isolates was reported, being an interesting signature sequence for the detection of at least a subgroup of AIEC strains. Further confirmation in a wider strain collection would be required.

levels. Data were further processed in QIIME employing MaAsLin and LEfSe tools for analysis of the output data.

Results: Microbial profiles in both PSC and UC were characterized by low bacterial diversity and significant change in global microbial composition. Rothia, Enterococcus, Streptococcus, Veillonella, and three other genera were markedly overrepresented in PSC regardless of concomitant IBD. Rothia, Veillonella and Streptococcus were tracked to the species level to identify Rothia mucilaginosa, Streptococcus infantis, S. adhaerens, and S. equi along with Veillonella parvula and V. dispar. PSC was further characterized by decreased abundance of Adhistructus,icornis and Prevotella corpori. Decrease in genus Phascolarctobacterium was linked to presence of colonic inflammation regardless of IBD phenotype. Akkermansia muciniphila, Butyrivibrio rumenii and Clostridium columbiam were decreased in UC along with genera Roseburia. Unclassified Actinomycetes species were markedly increased in overlap syndrome of autoimmune hepatitis (AIH) and PSC. Low levels of serum albumin were significantly correlated with enrichment of order Actinomycetales.

Conclusion: Microbial features were independent of concomitant IBD and could serve as potential biomarkers for IBD.

Contact E-mail Address: simon.keely@newcastle.edu.au

Introduction: The characteristic inflammation associated with IBD contributes to repeated cycles of epithelial wounding and repair in the intestine. The epithelium functions as a selective barrier, critical for mucosal protection. During intestinal inflammation, damage to the vasculature leads to reduced oxygen availability (hypoxia) at the mucosa. Epithelial wound healing processes occur in this hypoxic environment and are critical to restore barrier integrity and gut homeostasis. A key factor in the co-ordination of mucosal wound healing is the transcription factor HIF-1. HIF-1 mediates an array of protective mechanisms to cell survival and repair. Previous work has shown that pharmacological stabilisation of HIF-1α by prolyl hydroxylase inhibitors (PDHI) is protective in murine models of colitis. Importantly, our work has identified HIF-1-mediated induction of integrin-β1 at the mucosa as critical to this process.

Aims & Methods: We aimed to examine the functional role and post-translational activity of epithelial α-integrin subunits dimerizing with integrin-β1 to promote HIF-1-mediated wound healing by PDHI. Cell migration and inhibition scratch assays were performed on T84 monolayers (~1% O2 and/or PDHI (AKB-4924), wound closure was monitored over 24 hours. Monolayers were stained by immunofluorescence for cytoskeletal components. Key integrin subunits were linked to expression of the cytoskeletal organization therefore PHD3 compounds may enhance wound closure through integrin-β1-mediated organization of the cytoskeleton.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0977 EFFECTS OF TIME ON URINARY METABOLIC PROFILE DURING MUCOSAL HEALING IN INFLAMMATORY BOWEL DISEASE
1Gastroenterology, Imperial College Healthcare NHS Trust, London/United Kingdom
2Division Of Digestive Diseases, Department Of Surgery And Cancer, Imperial College London, London/United Kingdom
3Division Of Computational And Systems Medicine, Department Of Surgery And Cancer, Imperial College London, London/United Kingdom

Contact E-mail Address: l.hicks@imperial.ac.uk

Introduction: Metabolic profiling (metabonomics) has been proposed as a novel clinical tool in IBD to predict development of complex disease, or for longitudinal non-invasive monitoring of activity and/or response to drug treatment. Urinary metabonomics can distinguish IBD from healthy controls (1) but no studies to date have assessed the stability of these discriminatory profiles over time in IBD. The metabolic signature of IBD may not be unique and may change over periods of 3 years (2) but signals are influenced by multiple external factors including medication and surgery, so how these changes in IBD is unknown. The aim of this study was to compare baseline urinary metabolic profiles of IBD patients with a repeated sample several years later to assess similarity, and also to test if any clinical outcomes could be retrospectively predicted from the baseline sample.

Aims & Methods: Two urine samples from 39 IBD patients (22 Crohn’s disease (CD) and 17 ulcerative colitis (UC)) were collected - one at baseline and one several years later (range 7–9 yrs). These were analysed by 1H NMR spectroscopy. Disease progression was defined as initiation of immunosuppression or biologic therapy, progression of disease, and mucosal healing status. Principal components analysis was used to visualise the variance between the two time-points within the cohort. Orthogonal partial least squares discriminant analysis (OPLS-DA) was used to establish if the metabolic signatures could be used to predict adverse clinical outcomes in the patients studied.

Results: 57% of CD patients and 17% of UC patients had clinical progression at follow-up sampling. PCA showed clustering of sample pairs from the baseline and several years later in most individuals, suggesting intra-individual similarity across time. OPLS-DA showed no statistical models could be built to predict combined poor outcome based on the initial urinary metabolic profile (p = 0.26). However, the small subgroup who went on to require surgical intervention could be separated from the cohort in a model (Q2 = 0.015; p = 0.03) constructed on their baseline profiles.

Conclusion: The metabolic profile of IBD in an individual appears relatively stable over a significant time period despite a variety of clinical outcomes and interventions. Variations in longitudinal measurements appear to be subtle, and therefore replication of this technique for disease monitoring or prediction of principal outcomes may prove difficult. These results may suggest that metabolic profiling could be exploited to predict a higher risk of requiring future surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0978 BACTERIAL TRANSLOCATION CONTINUES IN ULCERATIVE COLITIS DESPITE MUCOSAL HEALING AND CURED CLINICAL REMISSION
A. Steel
Gastroenterology, Royal Liverpool & Broadgreen University Hospital, Liverpool/ United Kingdom

Contact E-mail Address: alan.steel@rlht.nhs.uk

Introduction: Mucosal healing is considered to be the hallmark of successful therapy in Ulcerative Colitis, and has become increasingly used as a target of therapeutic interventions. Loss of mucosal integrity and associated bacterial translocation of bacterial components across the mucosal epithelial barrier occurs in Ulcerative Colitis and persistance of a structural mucosal defect is a characteristic of chronic inflammatory bowel disease. Mucosal healing can be defined by clinical, microscopic and histological means but no clear definition of the required extent of mucosal healing exists, nor is there agreement on how functional mucosal healing is defined.

Aims & Methods: To define the extent and associations of mucosal healing in patients with Ulcerative Colitis, and the relationship with bacterial translocation and clinical remission. Patients with established diagnosis of Ulcerative Colitis undergoing endoscopic evaluation were recruited to the study (Ethics: South West London REC2 10/H0706/26). Clinical history and long-term follow-up data were recorded. Blood and mucosal samples were processed as mononuclear cells. Healthy controls recruited from cohort undergoing routine lower gastrointestinal investigations without positive findings. Flow cytometry characterisation of cells by cell surface CD45RO, CD27, CD14, CD48 and CD161 and cytokine expression after stimulation with bacterial enterotoxin B stimulation by IL-1, IL-17a, IL-22, TNF, IL-17F and IFNγ. Immunohistochemistry to define tight junction apical epithelial expression (Claudin 1, Claudin 4 and Occludin) and lipopolysaccharide within the lamina propria. Peripheral blood markers of bacterial translocation: bacterial DNA (16sDNA), lipopolysaccharide Binding protein (LBP), soluble CD14 and plasma lipopolysaccharide. Statistical analysis by Mann Whitney or Kruskall Wallis analysis with Dunn’s post test correction, or by Spearman rho correlation.
**Results:** 28 patients with Ulcerative Colitis, duration of disease 4 months to 31 years, aged 22 Healthy and 22 Colitis were recruited for the study. Half of the patients had active disease as assessed by Ulcerative Colitis Severity Score. Disease severity positively correlated with frequency of mucosal TH17 (CD4+HLA-17+) and IL-17f. Breaches in tight junction protein expression were greatly increased: Claudin 1 (p = 0.016) and occludin (p = 0.03). The serum marker of bacterial translocation, lipopolysaccharide binding protein (LBP) was elevated in UC compared to controls (p = 0.0078) and was positively correlated with breaches of Claudin 1 and Occludin. We found that fibrosis (r = 0.018) and increased colonic biopsies for the presence of lipopolysaccharide in the lamina propria demonstrated positive findings in healthy controls, supported by data from 16s rDNA analysis of blood from healthy controls. In the Ulcerative Colitis cohort in clinical remission the absence of lipopolysaccharide in the lamina propria was associated with elevated levels of LBP and increased breaches of Occludin (p = 0.0022).

**Conclusion:** Breaches of tight junction proteins in the colon of patients with stable clinical remission can be detected and are associated with perturbations of mucosal immunological function and markers of bacterial translocation. These findings require further study, specifically to examine the role of mucosal immune tolerance to lipopolysaccharide and other bacterial cell products that may be present in the healed mucosa of ulcerative colitis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0979 EFFECT OF FIBER AND FAT CONSUMPTION ON DISEASE ACTIVITY AND QUALITY OF LIFE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE**

I. Petkianaki, I. Mouzas, I. Koutroubakis
School Of Medicine, University of Crete, Heraklion/Greece

**Contact E-mail Address:** medp2011775@med.uoc.gr

**Introduction:** Diet may influence intestinal inflammation via various pathways but the evidence regarding the role of fiber or fat intake in patients with inflammatory bowel disease (IBD) is controversial.

**Aims & Methods:** The aim of this study was to investigate the association between dietary fiber or total fat intake and disease activity or quality of life in Greek IBD patients. We prospectively collected food frequency questionnaires (FFQ) from consecutive IBD patients at outpatient visits. The European Prospective Investigation into Cancer and Nutrition (EPIC) Study FFQ for Greek population with the MAFF photographic food atlas were used in order to collect information for dietary habits of IBD patients. Moreover, disease activity was measured using the disease activity index (SCCAI) for ulcerative colitis (UC) and the Harvey-Bradshaw index (HBI) for Crohn’s disease (CD)) as well as quality of life using the short inflammatory bowel disease questionnaire (SIBDQ) were evaluated. Patients’ demographic, clinical characteristics, nutritional status, laboratory data (C reactive protein (CRP), haemoglobin, erythrocyte sedimentation rate (ESR), platelets and albumin) and treatment data were recorded and analysed for all participants.

**Results:** A total of 141 consecutive IBD patients (53 UC, 88 CD, mean age 47.2±16.1 years, 84 males 57 females, BMI 26.7±5.3) were included. Patients’ mean daily fiber intake was 21.8 g (IQR 13.8-34.6) and mean daily total fat was 16.1 g (IQR 12.1-23.7) with 43.5% percent energy from fat. Regarding disease activity 34 (24.1%) patients had active disease with HBI or SCCAI score ≥5 whereas 45 (31.9%) patients had clinical remission can be detected and are associated with perturbations of mucosal immunological function and markers of bacterial translocation. These findings require further study, specifically to examine the role of mucosal immune tolerance to lipopolysaccharide and other bacterial cell products that may be present in the healed mucosa of ulcerative colitis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0980 PROGRESSION IN CROHN’S DISEASE BEHAVIOUR IN A PROSPECTIVE EUROPEAN POPULATION-BASED INCEPTION COHORT – THE ECCO-EPICOM COHORT**

**Introduction:** Crohn’s disease (CD) is a progressive disease that over time can lead to the development of complications such as strictures or internal penetrating disease that will ultimately lead to surgery. Only few population-based studies from the biological era and widespread use of immunomodulators have investigated the change in disease behaviour and subsequent risk of surgery in CD.

**Aims & Methods:** The EpiCom-cohort is a population-based cohort of unselected patients with inflammatory bowel disease diagnosed in 2010 in Eastern and Western European centres. Patients were followed prospectively for five years and clinical data were captured throughout the follow-up period. Disease behaviour was defined according the Montreal classification as B1: non-stricturing, non-penetrating, B2: stricturing; B3: penetrating based on endoscopy, cross-sectional imaging or surgery. The risk of surgical resection was analysed by Cox regression analyses using the proportional hazard assumption including multiple covariates (age, gender, disease location, diagnostic delay, smoking status, change in behaviour, geographic region and treatment with biologics within 6 months from diagnosis).

**Results:** A total of 488 incident CD patients were included in the study, of which 347 (71%) had B1. A total of 141 (29%) patients had complicated CD at diagnosis. After 5 years’ follow-up, this number increased to 190 (39%) (Table 1). Of patients diagnosed with B1, 35 (10%) progressed to B2 while 14 (4%) progressed to B3 after a median of 21 months (range: 0-62). The proportion of B1 patients changing behaviour was highest during the 1st year of disease (5%) but stable during the remaining follow-up period (approx. 2%/year). Colonic location (L2 region) was associated with progression of behaviour from B1 to B2/B3 (HR: 0.3 CI95%: 0.1-0.8), extra-intestinal manifestations at diagnosis (HR: 0.2 CI95%: 0.1-0.8), and the need for early biologics (HR: 2.5 CI95%: 1.2-5.1) were associated with progression in behaviour. During follow-up, a total of 107 patients had a resection. Of patients with B1 as initial behaviour a total of 37 (11%) patients had a resection. A change in behaviour from B1 to B3 (HR 6.8 CI95%: 3.0-15.6) and early biologics (HR 0.5 CI95%: 0.2-0.5) was
associated with the risk for resection. No difference in the results was found between Eastern and Western European patients.

### Conclusion

In this European population-based inception cohort of unselected CD patients 14% of patients with B1 progressed to B2 or B3 after five years of follow-up. The risk of surgery was increased in patients with B1 who progressed to B2/B3. No clinical predictors for progression in behaviour including smoking and treatment with biological therapy could be identified.

**Title:** CHANGES IN GUT MICROBIOTA COMPOSITION CORRELATE WITH SHORT TERM CHANGES IN FACIAL CALPROTECTIN AND CRP IN PATIENTS WITH CROHN'S DISEASE

**Authors:** D. Chan1, D. Kumar2, M. Mendall2

1. Department of Gastroenterology and Colorectal Surgery, St. George's Hospital, London/United Kingdom
2. Department of Gastroenterology, Croydon University Hospital, Croydon/United Kingdom

**Contact E-mail Address:** derekchan65@hotmail.com

**Introduction:** Faecal microbiota are believed to play an important role in the pathogenesis of Crohn's disease (CD). It is not known for certain whether gut microbiota composition (GMC) changes in response to inflammation or whether inflammation in the gut wall is a response to changes in GMC. Dynamic changes in bowel wall inflammation and short term changes in GMC have not previously been studied, but would give a clue as to the aetiological importance of GMC.

**Aims & Methods:** We aimed to assess the correlation between short changes in GMC and a faecal marker of gut inflammation faecal calprotectin (FC) and CRP, a marker of systemic inflammation.

We conducted a blinded sham controlled cross-over study of 32 subjects assigned to IgG4 guided exclusion diets. Each subject was randomised to one month of true or sham diet followed by a one month washout period followed by a further month of the other diet. Changes in other species and phyla were calculated. Kendall Tau correlation with change in FC and CRP with relative abundance of bacteria groups were calculated. Kendall Tau correlation was used to assess correlation between change in FC and CRP to change in relative abundance of various bacteria. We found significant negative correlation with change in FC and CRP with *Bifidobacterium* genus and change in FC with *Roseburia* genus. There were poor correlation and inconsistent changes in other species and firmicutes and bacteroidetes and Shannon diversity.

### Results

26 people fully completed the study. For each participant this provided as a species.

<table>
<thead>
<tr>
<th>Species</th>
<th>Kendall Tau</th>
<th>p value</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>Roseburia</em></td>
<td>0.295</td>
<td>0.126</td>
</tr>
<tr>
<td><em>Bifidobacterium</em></td>
<td>0.158</td>
<td>0.315</td>
</tr>
<tr>
<td><em>Shannon Diversity</em></td>
<td>0.320</td>
<td>0.027</td>
</tr>
</tbody>
</table>

### Conclusion

Bifidobacterium relative abundance correlate closely with short term changes in FC suggesting a possible causal association. Other genera and species had poor and inconsistent correlations with short term changes in FC suggesting that they may not be causally related to short term changes in gut inflammatory activity.

5. Department of Medicine, University of Rome "Sapienza", Rome, Italy

**Contact E-mail Address:** biancone@med.uniroma2.it

**Introduction:** Risk factors for colorectal cancer (CRC) in Inflammatory Bowel Disease (IBD) are still debated (1).

**Aims & Methods:** In a prospective multicenter, nested case-control IG-BBD study at 4 years, we aimed to assess the frequency and risk factors for incident CRC in IBD. The role of IBD phenotype vs thiopurines (IS) and/or anti-TNFs use as risk factors for CRC was also evaluated. From Jan. 2012 to March 2017, all incident cases of CRC in IBD pts referring to 16 IG-BBD Units were recorded. Each IBD pt with CRC (IBD-CRC) was matched with 2 IBD pts with no cancer (IBD-C) for IBD type (Crohn’s Disease, CD vs Ulcerative Colitis, UC), gender, age (<5 yrs). Cases of CRC derive from a larger cohort of IBD pts referring to the same Units, with incidence of any cancer separately reported at 4 years (follow up at 3 yrs reported for cancer overall) (2). Statistical analysis: data expressed as median (range), Wilcoxon test, Chi-squared test, Fisher exact test; multivariate logistic regression analysis.

**Results:** Incident cases of CRC occurred in 66 IBD pts: 41 UC (UC-CRC), 25 CD (CD-CRC). IBD-C group therefore included 198 pts (66 UC-CRC, 132 CD-C). UC group included 123 pts (41 UC-CRC, 82 UC-C) and CD group included 75 CD pts (25 CD-CRC, 50 CD-C). The frequency of incident CRC was higher in the tested UC versus CD population (62.1% vs 37.9%;p = 0.009). Gender was equally distributed in IBD groups (UC 44.3% vs CD 44.8%); UC vs CD: p = 0.1). The median age was comparable between IBD-C and IBD-C (UC-CRC vs UC-C 62 [37–86] vs 59 [35–86]; CD-CRC vs CD-C: 52 [23–76] vs 55 [22–76]; p = 1). UC duration was longer in pts with vs without CRC (20 [0–37] vs 10 [0–35]; p = 0.005). Conversely, CD duration was comparable between pts with vs without CRC (20 [1–47] vs 13 [0–35];< 10 yrs:24% vs 15 [30%];≥10 yrs:19 [76%] vs 75 [70%]; p = 0.58). IBD activity.

### Abstract

**P0981**

**Title:** CHANGES IN GUT MICROBIOTA COMPOSITION CORRELATE WITH SHORT TERM CHANGES IN FACIAL CALPROTECTIN AND CRP IN PATIENTS WITH CROHN'S DISEASE

**Authors:** D. Chan1, D. Kumar2, M. Mendall2

1. Department of Gastroenterology and Colorectal Surgery, St. George's Hospital, London/United Kingdom
2. Department of Gastroenterology, Croydon University Hospital, Croydon/United Kingdom

**Contact E-mail Address:** derekchan65@hotmail.com

**Introduction:** Faecal microbiota are believed to play an important role in the pathogenesis of Crohn's disease (CD). It is not known for certain whether gut microbiota composition (GMC) changes in response to inflammation or whether inflammation in the gut wall is a response to changes in GMC. Dynamic changes in bowel wall inflammation and short term changes in GMC have not previously been studied, but would give a clue as to the aetiological importance of GMC.

**Aims & Methods:** We aimed to assess the correlation between short changes in GMC and a faecal marker of gut inflammation faecal calprotectin (FC) and CRP, a marker of systemic inflammation.

We conducted a blinded sham controlled cross-over study of 32 subjects assigned to IgG4 guided exclusion diets. Each subject was randomised to one month of true or sham diet followed by a one month washout period followed by a further cross-over trial diet. stool and blood samples were obtained at time 0, 1 month (completion of first trial diet), 2 months (completion of washout) and 3 months (end of cross-over trial diet). Taxonomic profiling was performed using 16s RNA next generation sequencing. Copy counts were made for firmicutes and bacteroidetes as a phylum, Roseburia and Bifidobacterium as a genus and Faecalibacterium prausnitzii as a species. Shannon diversity was calculated.

**Results:** 26 people fully completed the study. For each participant this provided six timepoints for comparison: timepoint 1–2, 2–3, 3–4, 1–3, 1–4 and 2–4. The relative abundance of bacteria groups were calculated. Kendall Tau correlation coefficient was used to assess correlation between change in FC and CRP to change in relative abundance of various bacteria. We found significant negative correlation with change in FC and CRP with *Bifidobacterium* genus and change in FC with *Roseburia* genus. There were poor correlation and inconsistent changes in other species and firmicutes and bacteroidetes and Shannon diversity.

**Conclusion:** Bifidobacterium relative abundance correlate closely with short term changes in FC suggesting a possible causal association. Other genera and species had poor and inconsistent correlations with short term changes in FC suggesting that they may not be causally related to short term changes in gut inflammatory activity.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
pts with CRC were younger at diagnosis of IBD than their IBD-C (UC-CRC: a median of 54 yrs [15–76] vs 46 [20–73]; P = 0.04; CD-CRC: a median of 27 yrs [6–67] vs 37 [10–67]; < 0.01; UC-CRC vs CD-CRC: a median of 27 yrs [33%] vs 40 yrs [29%] vs 55 [67%]; P = 0.04). CD-CRC vs UC-CRC: the frequency of CRC was comparable between UC pts using or not IS and/or anti-TNFs (CRC-UC vs CRC-UC: IS monotherapy 6 [15%] vs 17 [21%]; Anti-TNFs monotherapy: no CRC; Combination: 5 [12%] vs 6 [7%]; no IS/no anti-TNFs: 11 [27%] vs 23 [28%]; p = 0.04). There were also observed no significant differences between CD pts treated or not with IS and/or anti-TNFs (CRC-CD vs CRC-UC: IS monotherapy: 4 [16%] vs 9 [18%]; Anti-TNFs monotherapy:2 [8%] vs 3 [6%]; Combination:10 [40%] vs 23 [46%]; no IS/no anti-TNFs: 16 [64%] vs 35 [70%]; p = 0.04). CD pts with CRC showed a higher frequency of pattern B1 (B1 vs B2 vs B3: 14 [56%] vs 3 [12%] vs 8 [28%]; p = 0.019). Risk factors for CRC considered in multivariate analysis included: age (<40 yrs vs 40 yrs), IBD duration (<10 yrs vs ≥10 yrs), smoking habits (Yes/No/Y), IS/no anti-TNFs (Y/N), IBD-related surgery, UC extent (rectal vs distal; subtotal vs distal), CD pattern (B3 vs B1, B2 vs B1), perianal CD. In UC, the only significant risk factor was UC duration (OR [95% CI]: OR 3.33 [1.44–9.11], as the other risk factors were not significant: OR 0.94 [0.36–2.98],1.28 [0.48–3.06]0.96 [0.36–3.06],1.78 [0.60–4.66].1.36 [0.66–2.89]0.38 [0.08–1.23], respectively).

Conclusion: In a prospective, multicenter, nested-case control IG-IBD study, incident cases of CRC were more frequent in UC than in CD. In our cohort, UC duration and perianal CD, but not immunomodulators use, were identified as significant risk factors for CRC.

Introduction: The human gut microbiome is made up predominately of four major bacterial phyla, Firmicutes, Bacteroidetes, Proteobacteria and Actinobacteria. Changes or imbalance of these phyla is termed dysbiosis. Systemically, in inflammatory bowel disease (IBD), key changes have been identified such as a reduction in beneficial bacterial species including Faecalibacterium prausnitzii and increases in more pathogenic species including members of the Enterobacteriaceae. Currently it is not understood if dysbiosis is the cause of, or the effect of, intestinal inflammation. It is difficult to chronologically assess the microbiota changes prior to developing IBD as currently we are unable to predict those individuals who will develop the disease. The pouch is a potential model to study pathogenesis of inflammation as 40% of those that develop pouchitis do so within 12 months. The relative short time from pouch formation to inflammation allows the longitudinal study of the microbiota which gives insight into potential microbial patterns occurring both in disease and non-diseased states. Interestingly, inflammation within the pouch is rarely seen in patients who have this operation for Familial Adenomatous Polyposis (FAP), thus raising the possibility that pouchitis shares a similar pathogenesis to the inflammation that is seen in ulcerative colitis.

Aims & Methods: 1. To understand changes in pouch microbota over time. 2. To understand pouch microbiota that is associated with pouch inflammation A computer assisted search of the on-line bibliographic databases MEDLINE and EMBASE was carried between 1966 and February 2016. Randomised controlled trials, cohort studies and observational studies were included. Inclusion criteria: Studies which reported microbiota analysis on either faecal samples or tissue from the ileo-pouch anal anastomosis. Studies that provided information on specific bacterial taxa. Exclusion criteria: Studies which did not report on patterns of individual bacterial taxon differences in the pouch. Studies on the microbiota of Colon’s disease or UC in isolation without any data on pouch patients. Studies with less than ten patients.

Results: The search strategy found 844. There were a total of 27 papers included in the analysis. Microbiota in pouchitis: Bacteroidetes, Enterococcaceae, Lachnospiraceae, Ruminococcaceae, Streptococci, Alcaligenaceae and Bifidobacterium were reduced in patients with pouchitis. Whereas Enterobacteriaceae, including E. coli Fusobacterium and Clostridia were increased in patients with pouchitis. One study highlighted bacteria that were exclusively found in pouchitis which included Lepotrixos, Pseudoodoromonas, Desulfosporosinus, Microctis, Methylobacter. Chronic pouchitis was associated with a significant increase in Staphylococcus aureus and it has been suggested that this may be a responsible pathogen for chronic pouchitis. Furthermore, Enterococcus, F. prausnitzii, Lachnospiraceae and Inserta Sedix MV and have been shown to be significantly reduced in chronic pouchitis patients. These differences were largely due to a decrease in sequences from members of the genera Ruminococcus, Dorea, Clostridium, and Eubacterium.

Conclusion: The microbiota undoubtedly plays an important role in both the inflamed and the healthy pouch. However, a direct causal relationship has not yet been established between individual microbiota changes and inflammation. There are many studies that highlight changes in bacterial composition, but studies are limited by heterogeneity of and in particular, analysis techniques and sampling strategies. Studies used a variety of methods to define microbial diversity which can be broadly split into culture vs culture-independent approaches. Culture-based studies are likely to have a bias towards culturing more aerobically friendly microbes than exist in a true pouch environment, thus over-representing aerobic bacteria whilst possibly under-representing anaerobic bacteria. The use of 16 S rRNA analysis methods will negate this effect and represents the future in accurately determining the microbiota.

P0987 OUTCOME OF ENDOCYTICALLY ALLELY REJECTED DYSPLASIC LESIONS IN ULCERATIVE COLITIS

Gastroenterologie, CHU Bab El Oued, Algiers/Algeria

Contact E-mail Address: houraisaoula@yahoo.fr

Introduction: For a long time, dysplastic lesions in ulcerative colitis are only treated by surgery. Recent guidelines recommend the complete endoscopic resec-
tion of dysplastic lesions in ulcerative colitis. dysplasia was detected after a mean follow up of 30.16 months (range: 7.56- 62.5). Neoplasic lesions were found in 5 patients (11.1%). Only one case of local abscess, resection of the sigmoid detected in a women that have had a high-grade dysplasia resected in the sigmoid; in 3 patients new dysplasic lesions localized in other segments of the colon than those initially resected. In one patient a serrated rectal adenoma was found in the same place where was resected a serrated adenoma, reflecting an incomplete resection.

Conclusion: Our results confirm that a complete endoscopic resection may be sufficient in dysplastic lesions occurred in ulcerative colitis. Nevertheless a closer follow-up is necessary because these patients may develop neoplastic lesions.

Introduction: Cytomegalovirus (CMV) infection has been associated to resistance to several immunomodulatory therapies in Ulcerative Colitis (UC) patients. The impact of CMV infection in UC patients treated with Vedolizumab is unknown.

Aims & Methods: We performed a retrospective case-control study of all patients with IBD treated by Vedolizumab from June 2014 to August 2016 by our gastroenterologist in our IBD center. All eligible patients had presented latent CMV infection with presence of IgG against CMV and undetectable CMV DNA load determined by real time PCR (qPCR) in colonic biopsies before treatment. During the follow-

load disease were considered as control group. After antiviral treatment, the CMV DNA load was found undetectable for all 6 patients. Treatment change was more frequent in the CMV disease group (HR = 3.15 [1.02-9.7], p = 0.03507) with only 16.7% patients who continued Vedolizumab treatment versus 65.4% in the control group (p = 0.062). Colectomy was also more frequent in the CMV group (33.3% versus 7.7% p = 0.064). By multivariate analysis, the only factor associated with the occurrence of CMV disease was a fecal calprotectin less than 260 mg/g stools at the beginning of the vedolizumab treatment. A previous CMV colonic infection also was more frequent but not statistically significant.

There was no association between CMV infection and Vedolizumab levels in the sera.

Conclusion: The occurrence of CMV disease, documented with high CMV DNA load on colonic biopsy samples, in UC treated with Vedolizumab is responsible for a negative impact on the natural evolution of UC, with more therapeutic failure and surgical treatment, even after an efficient antiviral treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0989 F-CALPROTECTIN USE IN INFLAMMATORY BOWEL DISEASE IS CHARACTERISED BY IMPROVED DIAGNOSTIC ACCURACY, LESS PATIENTS SUBJECT TO UNNECESSARY DIAGNOSTIC TESTING AND REDUCED COSTS, COMPARED WITH CONVENTIONAL SEROLOGICAL MARKERS AND COLONOSCOPY. THE SPANISH SCENARIO

Introduction: Gastrointestinal disorders may exhibit overlapping symptoms making diagnosis difficult in the primary and specialty care settings. Inflammatory bowel disease (IBD), with a prevalence of <0.5% in the general population[1], is characterized by chronic inflammation of the gastrointestinal tract, non-specific elevation of conventional inflammatory markers such as ESR and CRP and may present with extra-intestinal manifestations. Irritable bowel syndrome (IBS), in contrast, is a functional disorder without gastrointestinal inflammation and with an estimated prevalence of 10-20% [2]. Endoscopy is the gold standard for detecting and quantifying IBD vs. IBS, but due to the low prevalence of IBD, is negative in the majority of cases. Furthermore, it is invasive, expensive, and uncomfortable for the patient and not without risks. Moreover, inadequate bowel preparation prior to colonoscopy is known to
increase the burden of disease from both the clinical and the economic perspec-
tive; shorter intervals between repeated procedures, higher missed rates, patient 
inconvenience, and increased risk of complications are reported in the scientific 
literature. F-Calprotectin (FC) is a fecal marker of intestinal inflammation; IBD 
patients exhibit FC levels significantly higher than the general population; IBS 
patients, have FC levels that are lower than healthy controls, but significantly lower than 
IBD patients [3]. Therefore, FC can be used as a pre-endoscopic test to differ-
entiate between IBD and IBS. The present study aims at evaluating the cost-
effectiveness of FC compared to the combined usage of CRP and ESR, and the 
gold standard to distinguish IBD from IBS in Spain.

Aims & Methods: An 18-week Markov model was developed for each diagnostic 
strategy, simulating 1000 patients present to a primary care physician with 
non-specific gastrointestinal symptoms. In the model, 1.6% of the colonoscopies 
brought about complications [4], which may result in Emergency Room visits 
and surgery. Inadequate colon preparation (23%)[5] and consequent repeated 
colonoscopies (30.3%)[6] were also included in the calculations. Outcomes 
include cost savings, cost per correct IBD diagnosed, and colonoscopy reduc-
tion. Uncertainty was addressed with sensitivity analysis.

Results: FC is cost-effective when compared to CRP + ESR, and to colonoscopy 
(Table 1): It results in more correctly IBD diagnoses at a lower price. It reduces 
the number of unnecessary endoscopies, increasing the number of correctly diag-
nosed IBD (N = 63) and IBS (N = 26) patients.

</tbody>
</table>

Conclusion: Results show that the usage of FC as pre-endoscopic diagnostic tool 
is associated with fewer colonoscopies and correctly identifies more disease while 
decreasing the costs compared to the alternatives. Consequently, FC demonstrates 
superior value both from patient and payer perspective, while simultaneously 
increasing diagnostic efficacy.

Introduction: The increased use of immunomodulators and biological agents for 
the treatment of patients with inflammatory bowel disease (IBD) is associated 
with a key safety concern considering potential serious infection. Healthcare 
workers are at an increased risk for acquiring such infections due to close daily 
and close interactions with infected patients and asymptomatic carriers of 
pathogens.

Aims & Methods: We performed a retrospective observational study, collecting 
data from the Group of Etudes Thérapeutiques des Affections Inflammatoires du 
tube Digestif (GETAD) from January 2015 to June 2016, on all 482 consecutive 
patients with IBD (68.5% with rohn’s disease, 28.4% with ulcerative colitis and 
3.1% with IBD undetermined) who worked as healthcare workers (27.2% of phy-
sicians, 33.0% of nurses; 13.1% of nurses’ aides and 26.7% of other healthcare 
worker personnel working in interaction with in-hospital patients), in 17 tertiary 
centers in France and Belgium. We selected a control group of patients with IBD who 
were not working as healthcare personnel from the monocentric MICISTA database. 
Controls were matched on age (±2.5 years), sex, IBD type and date of IBD 
diagnosis (±2.5 years). Serious infection was defined as (1) Clostridium difficile 
faction (2) community-acquired pneumonia (3) Mycobacterium tuberculosis infection 
(4) any community-acquired infection that required hospitalization. Serious 
infection-free survival was studied with Kaplan-Meier method, log-
rank test and Cox regression model. In each patient, the duration of IBD was 
divided into semesters which were independently analyzed regarding the occur-
rence of serious infection too take into account the influence of various 
treatments.

Results: 482 patients (126 male; median age: 24.0 [IQR 19.9–32.1] years) were 
included in the present study. The median follow-up period was 9.3 [4.6–16.2] 
years. A total of 74 serious infection was recorded in healthcare workers includ-
ing 14 Clostridium difficile infection, 19 EBV or CMV-related serious viral infec-
tion, 8 tuberculosis infection including 4 tuberculosis and 4 tuberculous primo-
infection, 8 community-acquired pneumonia and 25 miscellaneous serious infec-
tion. The probabilities of serious infection-free survival were 1.0% at 0.6%, 1.1% 
and 14.1% at 1, 5, 10 and 15 years. No difference was found between healthcare 
workers and control patients regarding the occurrence of serious infection in 
time-dependent analysis and in independent semester analysis. However, a 
increased risk of tuberculosis infection was found in healthcare workers (0.07 
infections for 100 patient-years vs. 0.009, p = 0.02). In multivariate analysis, 
serious infection was decreased in patients with Crohn’s disease (OR = 0.63, 
IC95%[0.43–0.91], p = 0.01) and increased in patients treated with corticoster-
oids (OR = 3.05, IC95%[2.06–4.52], p < 0.001), immunosuppressant (OR = 1.98, 
IC95%[1.38–2.84], p < 0.001) and anti-TNF agents (OR = 2.93, IC95%[2.02– 
4.27], p < 0.001).

Conclusion: Although there is an increased risk potential pathogens in 
healthcare workers, this is not associated with a higher risk of serious infection 
as compared with controls with the exception of tuberculosis infection. 
Prospective studies are needed to confirm that the level of occupational exposure 
to potential pathogens should not be taken into account when discussing the 
interaction of immunomodulator or biological agents with the exception of the 
risk of tuberculosis infection.

Conclusion: In our cohort the frequency of HS varied between 13.4% and 41.7% defined by non-invasive methods. We found that the presence of metabolic syndrome and obesity were more frequent in patients with HS. Regarding factors related to IBD, patients with previous history of surgery were more frequently diagnosed with HS.

P0991 CORRELATION BETWEEN INFLAMMATORY BIOMARKERS AND ENDOSCOPIC SCORES IN ULCERATIVE COLITIS: WHEN SEVERITY MAKES THE DIFFERENCE?

C. Arieira1, F. Dias De Castro1, M.J. Moreira2, J. Cotter2
1Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães, Guimarães/Portugal
2Pt Government Associate Laboratory

Contact E-mail Address: catia_arianeira@hotmail.com

Introduction: Several endoscopic scores have been used to assess the severity of inflammatory activity in Ulcerative Colitis (UC), however, few consider the extension of the disease. Scores such as the Dublin Score (DS) and the Modified Mayo Endoscopic Score (MMES) combine the severity of inflammation with the extent of the disease.

Aims & Methods: We aimed to calculate the correlation between the endoscopic scores -Mayo Endoscopic Score (MES), DUBLIN, MMES and the biomarkers of inflammation - erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) over time and to compare the ability of these scores to predict Calprotectin >100 μg/L. This was a retrospective study, including patients with diagnosis of left or extensive UC who underwent colonoscopy between 2015 and 2016. The biomarkers were obtained with a maximum interval of one week in relation to colonoscopy and without introduction of new therapy. The Spearman test calculated the correlation between scores and biomarkers. ROC curves (AUC) were obtained for each score to predict Calprotectin >100 μg/L.

Results: 60 patients were included, 46.7% female patients with mean age 45.3 ± 12.8 years with median values of ESR 4.4 ± 12.8 mm, CRP 5.12 ± 6.00 mg/l and Calprotectin 354 ± 430 μg/g. The correlation between Calprotectin and MES was rs = 0.623 p < 0.001, for DS rs = 0.548 p < 0.001 and for MMES rs = 0.588 p < 0.001. Regarding CRP, a correlation with the MES was rs = 0.415 p = 0.001, and with the MMES rs = 0.404 p < 0.001 but no correlation was found with the DS. There was no significant correlation between ESR and endoscopic scores. To predict values of Calprotectin >100 μg/L the AUC for the MES was 0.848, for the DS 0.801 and for the MMES 0.815, and there was no statistically significant difference between the curves.

Conclusion: Although there is a good correlation between endoscopic scores and Calprotectin, the correlation between scores that take into account the extension were not superior to Mayo Endoscopic Score.

P0992 IBD - IS IT A RISK FACTOR FOR THE DIAGNOSIS OF HEPATIC STEATOSIS?

C. Arieira1, S. Monteiro2, S. Xavier2, F. Dias De Castro1, J. Magalhães1, M.J. Moreira2, J. Cotter2
1Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães, Guimarães/Portugal
2Pt Government Associate Laboratory

Contact E-mail Address: catia_arianeira@hotmail.com

Introduction: Although is not yet established, recent studies suggest an increase prevalence of hepatic steatosis (HS) in patients with inflammatory bowel disease (IBD). Factors such as chronic inflammation, previous surgeries, drug-induced hepatotoxicity, malnutrition and intestinal dysbiosis seem to be involved in the pathogenesis of this disease.

Aims & Methods: We aimed to assess the frequency of HS in IBD patients quantified by CAP (controlled attenuation parameter) and by clinical-analytical methods: Hepatic Steatosis Index (HSI) and Fatty Liver Index (FLI). A secondary aim is to investigate risk factors associated with HS in IBD patients. This was a cross-sectional study that included consecutive patients that were observed in our department between January and March 2017. Patients with known liver disease or alcohol habits were excluded. HS was defined as HSI > 5.18, and FLI (31.5 ± 24.3) among patients passed Metabolic Criteria. We found that patients with CAP ≥ 248 were more frequently obese (27.4% vs 0% p < 0.001), males (54.8% vs 36% p = 0.029) and presented more frequently metabolic syndrome (25% vs 4.6% p < 0.001). Regarding the IBD factors, patients with HS had a higher frequency of previous surgeries (30.0% vs16.1% p = 0.035). There were no differences between hospitalization, duration of the disease, use of corticosteroids or other IBD treatments.

Results: 149 patients included with mean age 40.7 ± 13 years, 83 female (55.7%), 59.7% with Crohn’s disease (CD). 62 patients (41.7%) had CAP ≥ 248.20 (13.4%) FLI > 60 and 40 (26.8%) HSI > 36. There were no differences in the mean CAP value (244.4 ± 54.2), HSI (33.3 ± 18.5), and FLI (31.5 ± 23.5) among patients with and without Hepatic Steatosis. We aimed to compare the AUC of the scores to predict HS. There was no statistically significant difference between the scores.

Conclusion: Rates of vitamin D deficiency, and osteoporosis were similar among patients on anti-TNF medications to those on no biologics. TNF group patients were diagnosed with osteoporosis at an earlier age compared to NB group. Patients on anti-TNFs also had statistically lower Z-scores at the spine. Prospective studies are necessary to further determine the role of anti-TNF medications in osteoporosis.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Infliximab (IFX) trough levels (ITLs) have emerged as a promising tool for the management of inflammatory bowel disease (IBD) patients and they correlate with clinical response and endoscopic remission. However, its use in clinical practice is still under debate, particularly in clinically stable patients.

Aims & Methods: 1) to describe real-life ITLs in clinically stable IBD patients; 2) to characterize factors associated with infratherapeutic ITLs; and 3) to evaluate the impact of ITLs availability by comparing the CCD with TLGD. The decisions between experts were also compared. Both comparisons were calculated by the concordance coefficient (C.C.D) was taken regarding clinical data and CRP. ITLs were measured just before the IFX infusion and were considered as infratherapeutic if <2 μg/ml. Once ITLs were known, 3 experts took a hypothetical decision on treatment based on the same clinical and biological data plus ITLs (ITL-guided decision –TLGD).

Results: A total of 224 IFX infusions from 74 patients (76% Crohn’s disease) were analyzed. Median (IQR) disease and IFX therapy duration was 10 years (5-18) and 23 months (7-61), respectively; 87% received concomitant immunosuppressant therapy; 70% were on standard dosing, whereas 10% were scheduled every 4-6 weeks and 5% every 12 weeks. 60% of patients with clinical and biological remission. Median (IQR) ITL values were 3.1 mg/ml (1.5-6.1). Median (IQR) ITLs were 1.79 μg/ml (0.5-3.74), with 52% of patients having infratherapeutic ITLs. In the multivariate analysis, the only risk factor for infratherapeutic ITLs was the presence of biological activity. Concordance between CCD and TLGD was poor (κ = 0.10 [95%CI:0.01-0.20] vs. κ = 0.11 [95%CI:0.01-0.21]) for experts A/B/C, respectively. This “disagreement” is due to a higher proportion of dose-escalations according to the TLGD as compared to the CCD. Among the 203 infusions in which no action was taken according to the CCD, 93 (40%), 48 (20%) and 65 (30%) would have been dose-escalated according to the TLGD for experts A, B and C, respectively.

Conclusion: Our results highlight the impact of the inflammatory burden on ITLs and their therapeutic range in patients clinically stable. Both the clinical and economical impact of ITL-assisted decision-making in IBD patients should be evaluated in prospective cohorts.

Disclosure of Interest: E. Domenich: Fees for advisory, lectures and research grants from MSD, Takada, AbbVie, Pfizer. All other authors have declared no conflicts of interest.

P0996 WHAT SITUATIONS PRODUCE PSYCHOLOGICAL MALAISE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE? PERCEPTIONS FROM PHYSICIANS AND PATIENTS. THE ENMENTE PROJECT

Contact E-mail Address: manubarreiro@hotmail.com

Introduction: Inflammatory Bowel Disease (IBD) patients live situations that may trigger negative feelings and psychological malaise. ENMENTE Project globally aims to improve identification and early management of psychological impact in IBD patients followed in Spanish hospital gastroenterology clinics. The aim of the study was to describe possible differences among perceptions from physicians and patients about the clinical situations triggering anxiety in IBD patients. Aims & Methods: During April 2016 two surveys were available on-line, one for IBD patients, in the ACCU Spain website (Confederation of IBD Spanish Patients’ Associations) and another one for physicians members of GITECCU (Spanish Group for IBD treatment). Both invited their members to participate by email and the patients’ survey was announced in social networks. The scientific committee (3 gastroenterologists, 2 psychologists, 1 nurse and 1 patient) decided which potentially stressful clinical situations were considered. Physicians and patients rated these situations on a scale from 1 to 10 as potential triggers of anxiety for the patient. A Mann-Whitney test was used to compare perceptions from patients and physicians taking 151 valid questionnaires from physicians and a randomized sample of 151 IBD patients’ questionnaires.

Results: The survey was completed by 912 patients (mean age 39 ±10 years, 67% women) and 170 patients (mean age 44 ±10 years, 58% women). Having an ostomy, fecal incontinence in public or surgery are important triggers according to both physicians and patients (table). Patients, however, experience anxiety from a possible new flare or from being fatigued, whereas physicians are more concerned about anxiety due to telling about a new IBD diagnosis and about pregnancy in IBD patients (table).

Conclusion: The main anxiety triggers in patients were having an ostomy, fecal incontinence in public, a surgery, a new flare and the feeling of fatigue. These last
two situations were scored higher by patients than by physicians. Teaching the patient to manage a new condition and treatment of fatigue are aspects that would help to reduce the anxiety feeling and should be taken into account in clinical practice Acknowledgements. P0997 EVALUATION OF LISA-TRACKER IMMUNOASSAY INFLIXIMAB AND ANTI-INFLIXIMAB FOR THE THERAPEUTIC DRUG MONITORING OF SB2 A. Berger1, A. Haccourt1, J. Salameh2, X. Roblin3, S. Paul4, 1Laboratoire D’Immunologie Cic1408, CHU Saint-Etienne, Saint-Etienne/France 2Biogen France, Nanterre/France 3University of St. Etienne Dept. de Gastroenterologie, Saint-Etienne/France 4Immunology, Hôpital Nord, Saint-Etienne/France Contact E-mail Address: stephane.paul@chu-st-etienne.fr

Introduction: Flixabts, an infliximab biosimilar referencing Remicade®, was developed by Samsung Bioepis, the joint venture between Samsung BioLogics and Biogen. SB2 received approval in EU for all approved indications of the reference infliximab. Many decision algorithms based on the measure of Infliximab (IFX) trough levels and antibodies to infliximab (ATI) have been increasingly used to optimize infliximab in Crohn’s disease and ulcerative colitis. The aim of our study was to appreciate if the biosimilar SB2 could be efficiently monitored using the Lisa-Tracker infliximab and anti-infliximab immunoassays developed by Therdag (France).

Aims & Methods: During this evaluation, standard curves of Infliximab and two different batches of SB2 were compared and then accuracy of the Lisa-Tracker IFX kit in detecting the spiked concentration of SB2 was measured using the Lisa-Tracker assay. Levels of infliximab (from 5 spiked samples with known amount of SB2 and 10 clinical samples from patients treated with infliximab) were calculated according to each of the 3 standard curves (infliximab, SB2 batch1 and SB2 batch2). All samples and standards were tested in duplicate. Recovery rate be ≥ 95% and the slope must be comprised between 0.9 and 1.1. Intra-run and inter-run precision were also measured with spiked samples of different known SB2 (from 2 to 12 μg/mL) amounts. Capacity of polyclonal antibodies directed against infliximab to block the detection of SB2 using the Lisa-Tracker infliximab assay and the capacity of SB2 to block the detection of anti-infliximab antibodies using the Lisa-Tracker anti-infliximab assay were tested.

Results: We demonstrated the perfect equivalence of infliximab standard curve to the SB2 standard curve and that the Lisa-Tracker assay is suitable for the quantification of SB2 in human serum samples (R² = 0.99; the levels of infliximab of the 20 samples were calculated according to the 3 standard curves infliximab, SB2 batch 1 and SB2 batch 2 with CV ranged from 2.1 to 12.6%). Quantification of SB2 was not disturbed by serum matrix and 95% of recovery were comprised between 82% and 113%. High intra-run and inter-run precision were obtained with the Lisa-Tracker infliximab assay for the quantification of SB2 (CV ranging from 3.3 to 17.9%). Finally, the capacity of polyclonal antibodies to infliximab to block the detection of SB2 and the capacity of SB2 to block the detection of anti-infliximab antibodies using the Lisa-Tracker anti-infliximab assay were tested.

Conclusion: In conclusion, Lisa-Tracker Infliximab and anti-infliximab assays are suitable for the monitoring of patients treated with SB2. Acknowledgements: Biogen provided the SB2 drug for this study. Biogen reviewed the manuscript and provided feedback to the authors.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0998 THE MEASURE OF TROUGH LEVELS OF INFLIXIMAB IS LINKED TO THERAPEUTIC RESPONSE IN IBD PATIENTS X. Robin1, A. Berger2, G. Boscotchi1, B. Faurie1, S. Nuncy3, S. Paul4, 1Gastroenterologie and Hepatology, VU University Medical Center, Amsterdam/Netherlands 2Department Of Pediatric Gastroenterology, VU University Medical Center, Amsterdam/Netherlands Contact E-mail Address: xavier.robin@chu-saint-etienne.fr

Introduction: If the association between trough levels of infliximab (TLI) and clinical remission or mucosal healing is demonstrated, we don’t really know the cause and effect between TLI and target value to obtain this association. So, the aim of our study was to evaluate the causality or the association between TLI and clinical remission.

Aims & Methods: We prospectively included all IBD patients treated in our IBD unit and in clinical remission (CDAI < 150 for Crohn’s Disease (CD) or partial Mayo score < 3 for ulcerative colitis (UC) with biomarker normalization (fecal calprotectin < 200 μg/g stools) or in deep remission (clinical remission with fecal calprotectin <50 μg/g stools). We analyzed median of TLI and fecal calprotectin at the inclusion (M0) and 6 months before eligibility (M-6). We excluded patients with deep remission at M-6.

Results: 111 patients were included (60 CD, sex ratio M/F: 0.8, 51 patients in deep remission at M0). All 111 patients were in clinical remission at M-6. Median fecal calprotectin at M-6 were similar in the two groups of patients (210μg/g in the group of patients who achieved deep remission at M0 vs 220μg/g in the group of patients who achieved only biomarker remission respectively; p=0.01). A ROC curve analysis was not able to isolate a cut-off value associated to deep remission achievement. (AUROC = 0.61). Next, we analyzed separately median of TLI and fecal calprotectin 6 months before eligibility (M-6) of patients in deep remission at M0 (51 patients). The median TLI was significantly lower at M-6 than at M0 (41 μg/mL vs 5.9 μg/mL respectively; p=0.03). Conversely, median fecal calprotectin was significantly higher at M-6 in comparison with M0 (190 vs 35 μg/mL); p=0.01). A negative and weak significant correlation between fecal calprotectin and TLI was observed (Spearman’s rank correlation coefficient (q) = -0.25; p = 0.045).

Conclusion: Although TLI may increase with decreased drug clearance due to deep remission, we show for the first time that the residual rate is the causal element for achieving clinical remission.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The prevalence of Clostridium difficile infection (CDI) in patients suffering from inflammatory bowel disease (IBD) has increased rapidly over the past several decades. However, the exact global epidemiology remains unclear because of insufficient data from developing countries.

Aims & Methods: The goal of our study is to examine the incidence of CDI in patients of our prospective, observational study evaluating IBD patients in a referral center was performed to evaluate the incidence of Clostridium difficile. Diagnosis was confirmed with stool toxin analysis. Demographic information, diagnosis, anatomic location, IBD therapy, antibiotic exposure, hospitalizations and outcomes were recorded. For a period of 3 years 202 IBD patients were studied, 105 of which have UC and 97 - Chron’s disease (CD). We used the Clostridium difficile Glutamat Dehydrogenase + Toxin A + B based on the principle of quantitative immunochromatographic assay for the determination of Clostridium difficile Glutamat Dehydrogenase, Toxin A and Toxin B in stool samples.

Results: The results show that all patients with a positive CDI test have a clinical picture, which resembles a relapse of the disease (p < 0.05). There's a tendency towards growth in the incidence of IBD patients who are CDI positive. Their number in 2016 is significantly higher than that in 2014. In 2014 it was ~5.90% with CD and 12.30% with UC, whereas in 2016 - 12.20% with CD and 27.80% with UC (p < 0.05). The results show that the incidence of CDI patients with UC is significantly higher than in patients with CD, respectively 18.1% to 9.30% (p < 0.05). There is a strong correlation between CDI incidence in patients with IBD and the severity of their disease. Patients positive for CDI have a much more severe course of the disease, UC (46.40%) and CD (24.20%) (p < 0.05).

Conclusion: There is an increase in incidence of CDI, and patients with UC are more affected by it. The results of our study are confirmed by other authors as well. A significant part of patients with CDI have a severe disease that needs extra prospective researches to determine the incidence and influence of the infection amongst patients with IBD, who receive different therapy regimes and also to understand how the CDI affects the evolution of the disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1001 DEVELOPMENT OF A NEW SCORE PREDICTIVE OF SUSTAINED CLINICAL REMISSION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE UNDER INFLIXIMAB- AZATHIOPRINE COMBINATION THERAPY
B. Sivard1, N. Willer1, J. Phelp1, E. Del Tedesco1, S. Paul1, X. Robin1
1Hepato-gastroenterology, university hospital of Saint-Etienne, Saint-Priest en Jarez; France

Introduction: There is no blood test predictive of sustained clinical remission in patients with Crohn’s Disease (CD) or Ulcerative colitis (UC) under Infliximab (IFX) - azathioprine (AZA) combination therapy.

Aims & Methods: All patients with CD or UC, consecutively treated by the combination of IFX-AZA between August 2015 and March 2017, were included in this monocentric study. Clinical, biological (blood cells count, liver function enzymes, C-reactive protein (PCR)) were retrospectively collected at baseline, at week 14 (W14) and at 6 months (W24) from the start of combination therapy.

Trough level of IFX (TLI) at W14 was also recorded. Sustained clinical remission was defined as clinical remission for 6 months with no need of AZA dose modification, nor therapeutic switch or need for surgery. A pre-
dictive score before combination therapy was developed basing on receiver operating characteristic (ROC) curves and logistic regression analyses.

Results: Of 71 patients enrolled (median age: 36.3 yrs; women: 52.5%; CD: 61.3%; current tobacco: 28.7%), 58 (81.7%) experienced sustained clinical remis-
sion. The clinical biological score was calculated at baseline by adding attributed points for these variables as follows: alkaline phosphatase <55U/L (11 pts), albumin <3.5 (1 pt), mean corpuscular volume <87 fl (4 pts), white blood cell count <9.3 x 109/L (4.5 pts), neutrophils <5.0 x 109/L (4 pts), body mass index >22 kg/m2 (3 pts), platelets count <330 x 109/L (3 pts), PCR >3.7 mg/L (3 pts) and C-reactive protein >10 mg/L (2 pts). A total score >17 was predictive of sustained clinical remission with good performance (Area under the curve (AUC: 90.1% [95%CI: 81.8%–98.5%]; sensitivity (Se): 81.3%, speci-
ficity (Sp): 90.9%; Positive predictive value (PPV): 97.7%; Negative predictive value (NPV): 58.9%), especially in UC patients (AUC: 98.2% [95%CI: 93.9%–100%]; Se: 90.5%, Sp and PPV: 100%: NPV: 66.7%). Corresponding outcomes for CD were also satisfying (AUC: 83.9% [95%CI: 70%–97.8%]; Se: 79%, Sp: 85.7%, PPV: 36%; NPV: 42.9%). In contrast, performance of TLI at W14 (>2.87 ug/mL) for the prediction of sustained clinical remission were mod-
erately interesting (AUC: 60.9% [95%CI: 58.7%–83.1%]; Se: 79.3%; Sp: 61.3%; PPV: 90.2%; NPV: 40%). These results were not significantly different between patients who had received an AZA monotherapy before combination ther-
rapy compared to those who did not.

Conclusion: This new score is a promising tool for the prediction at baseline of sustained clinical remission in inflammatory bowel disease patients who start combination therapy. It may help to identify easily patient benefiting from optimal optimi-
ization of IFX rather than early switch treatment in this setting. However, a prospective validation is needed before recommending its use in clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

Known Inflammatory Bowel Disease

Results: 2155 medical GI outpatient colonoscopies performed over 12 months were identified. 242 met inclusion criteria for the study. Median age of the patient cohort was 34 years (range 16-45), with 141 (58%) females. The cohort was stratified according to indications; Group A; 132 (55%) patients with diarrhoea predominant symptoms, and Group B; 110 (45%) patients with constipation/ abdominal pain and bloating. Coloscopy was normal in 104 (79%) of Group A and 102 (93%) of Group B (p = 0.002), 36 (15%) Colonoscopies were abnormal; 7 patients had active ileitis, 22 had colonic inflammation (12 IBD, 2 lymphocytic colitis, 8 non-specific inflammation), and 7 had ileocolonic inflammation (all diagnosed with IBD). 28 of (36%) patients with mucosal inflammation confirmed on histology had diarrhea (p = 0.0001). FC was available in 36 patients, and CRP in 171 patients. In Group A the negative predictive value, positive predictive value and specificity of CRP/FC were 88%, 43% and
As surgical resection is not curative in Crohn’s disease (CD), post-operative recurrence (POR) remains a crucial issue. The POCER trial (1) has demonstrated that postoperative enterography including diffusion-weighted sequences with apparent diffusion coefficient (ADC) parameter was significantly different: ADC (2.05 vs 2.20; \(p = 0.11\)). Faecal calprotectin values were significantly higher in patients with endoscopic POR, while none of the following MRI parameters was significantly different: ADC (\(p = 0.25\)) and MRI score (\(p = 0.17\)) were not significantly higher in patients with endoscopic POR (\(p = 0.262\)). In the first tertile, the quantitative score was significantly better in the PEG group (7.4 vs 10.4; \(p = 0.038\)) and related contrast enhancement (RCE) (75% vs 132%, \(p = 0.01\)) were higher in patients with endoscopic POR (\(p = 0.262\)). In contrast, MaRIA (5.0 vs 7.3; \(p = 0.15\)) and MRI scores (\(p = 0.17\)) were not significantly higher in patients with endoscopic POR (\(p = 0.262\)). In the PEG group, the mean duration of small bowel transit time was comparable between the three groups (198 min (PEG), 245 min (LD), 226 min (Water) (\(p = 0.102\)). The endoscopic activity of the disease was comparable between the three groups (\(p = 0.358\)). The cecal intubation rate was significantly lower in the PEG group 66% versus 91% (LD) and 94% (Water) (\(p = 0.04\)). No capsule impaction was observed. The mean quantitative cleanliness score for the whole small bowel was not significantly better for the PEG group (5.7) compared to the other modalities LD (6.3) and Water (6.5) (\(p = 0.262\)). In the first tertile, the quantitative score was significantly better in the PEG group (7.9) compared to the PEG group (6.8) (\(p = 0.043\)). The preparation by water was considered qualitatively better compared to the other two modalities (\(p = 0.04\)).

Conclusion: This is the first study evaluating the relevance of PEG preparation in a large population of adult patients with CD. Our study has demonstrated that there is no benefit in using PEG for the preparation of the small bowel before the capsule in patients with CD. Quantitatively, the two simplified preparation methods were more efficient than the preparation with PEG and qualitatively, the preparation using Link was characterized by better light imaging (WLI) and LCI. The Commission international de l'éclairage (CIE) LAB color differences (ΔC) were calculated among WLI and LCI in each ROI. After ROI was observed by colonoscopy, the biopsy specimen was taken in each ROI. Inflammatory cell infiltration, erosion, crypt abscesses, and goblet cell depletion were assessed, indicating that the higher ΔC mean easier color difference for recognition.

Results: The mean age of patients who were enrolled in the present study was 41.6 ± 17.7 years. The sex ratio (men/women) was 4:6. The type of extent of UC (ulcerative colitis/proctitis/left-sided) and the presence of ileal resection (yes/no) was recorded. The correlation between CIELAB color differences and histology. The mean ΔC of ROI without inflammatory cell infiltration was significantly higher than that of ROI with inflammatory cell infiltration (15.9 ± 4.9 vs. 12.3 ± 6.7, p = 0.046). The mean ΔC was not affected by histological findings of erosions, crypt abscesses, goblet cell depletion, crypt atrophy, crypt distortion, and basal plasmacytosis. LCI distinguished colon mucosal white color compared to WLI with use of three-dimensional color space, indicating the remission-colon mucosa of UC with no inflammatory cell infiltration in ROI was easily detected by LCI. The correlation between CIELAB color differences and Mayo endoscopic subscore. Low Mayo endoscopic subscore tended to be inversely proportional to high ΔC (ΔC: 23.7 ± 5.9 vs. 11.8 ± 5.1, 13.0 ± 9.0, but not significant in the present evaluation. The colon mucosa with the low Mayo endoscopic subscores were relatively easily detected by LCI compared to WLI.

Conclusion: The present pilot trial indicated that the inactive UC mucosa could be noninvasively be detected as the white area by the LCI mode compared to WLI, suggesting that LCI might be a novel approach for evaluating the disease activity.

P1008 FAECAL AMINO ACID PROFILES AS NOVEL NON-INVASIVE BIOMARKERS FOR THE DETECTION OF PAEDIATRIC INFLAMMATORY BOWEL DISEASE: A METABOLOMICS APPROACH
S. Bosch1, N. Van Gaal1, R. Zuurberg1, E. Struijs2, A. Bakkali2, K.h.n. De Boer1, T.G. J. De Meij1

Contact E-mail Address: s.bosch1@vumc.nl
Introduction: Inflammatory bowel disease (IBD) is primarily assessed by endoscopy, which is a costly and invasive procedure with serious risk of complication, underlining the need for novel non-invasive diagnostic biomarkers. In previous studies, plasma amino acid analysis has revealed significant differences between IBD subjects and controls. This 'aminostring' has not yet been studied in faecal samples of IBD patients. The aim of this explorative study was to compare faecal amino acid composition between paediatric de novo IBD patients and healthy controls, and between the phenotypes ulcerative colitis (UC) and Crohn’s disease (CD).

Aims & Methods: In this cross-sectional case-control study, paediatric treatment naïve IBD patients from a tertiary centre were included, before bowel cleansing and colonoscopy. Control patients were recruited from schools in the province North Holland, the Netherlands. All participants collected a faecal sample on which amino acid analysis was performed by means of high performance liquid chromatography (HPLC, Biochrom 30). To correct for the influence of faecal consistency, the samples were freeze dried for 24 hours before the analysis was performed. To prevent artifacts by peak overlap of different amino acids, outcomes of 5 nmol/mg or lower were excluded from further analysis.

Results: Faecal samples from 15 subjects (5 healthy, 5 UC, 5 CD) were analysed. Median age was 14 (8-17) years. Subjects and controls were matched on age and sex. A total of 42 different amino acids were analysed, of which 30 were excluded due to quantities of ≤5 nmol/mg. In particular, alanine, glycine, phenylalanine, leucine, isoleucine, valine and lysine differed between IBD patients and healthy controls with ratios up to 5:1 (table 1). In addition, UC and CD patients differed remarkably based on levels of glycine, phenylalanine and serine with ratios up to 4:1 (table 1).

*All levels are displayed in nmol/mg

Conclusion: This was the first pilot study to assess the potential of the faecal aminostring as non-invasive biomarker for disease activity of paediatric IBD. We observed remarkable differences in faecal amino acid composition between IBD patients and healthy controls, and between the IBD phenotypes. Whether these differences reflect decreased absorption or increased loss by inflamed intestines needs to be elucidated. Currently, we are awaiting the results of a larger proof-of-concept study on these faecal amino acid profiles.

Introduction: Measurement of infliximab trough levels (IFX-TLs) and antibodies to infliximab (ATIs) has been suggested as an important parameter for the optimization of IBD treatment of patients with inflammatory bowel disease (IBD).

Aims & Methods: We aimed to cross-sectionally investigate the correlation between IFX-TLs or ATIs and clinical, biochemical as well as endoscopic activity in Greek IBD patients. Consecutive IBD patients on maintenance treatment with IFX, were included. IFX-TLs and ATIs were measured using ELISA (Eagle Diagnostics, Richmond, VA, USA). IFX trough samples drawn before infusion. At the same time point of treatment using short IFX questionnaire (SIBDQ) and clinical disease activity score using Harvey-Bradshaw Index (HBI) for Crohn’s disease (CD) or simple colitis activity index (SCAI) for ulcerative colitis (UC) were assessed. Moreover, biomarkers (thromboglobulin, ESR, CRP, platelets, albumin) were measured and latest colonoscopies (within 6 months) were reviewed and evaluated for presence or not of mucosal healing.

Results: A total of 74 patients receiving IBD maintenance therapy [55 CD, 19 UC] were included, males mean age 42.3 years, 45 on combination therapy with immunomodulators (IMMs), 10 under intensified dose (either 10 mg/kg bw or 5 mg/kg/4–6w) were studied. Median time since IFX initiation was 26 (13–71) months and median value of serum IFX-TL was 4.33 μg/ml (0.03–3.07). Seven out 74 (9.5%) were positive for ATIs (>10 IU/ml). Patients on combination treatment had significantly higher IFX-TLs (6.98 μg/ml, 0.34–3.07) compared to those on IFX alone (1.85 μg/ml, 0.09–25.8) (p <0.01). Patients with positive ATIs had median IFX-TLs 0.99 μg/ml (0.09–4.0) statistically lower compared to those without (4.01 μg/ml, 0.03–3.69) (p<0.005). The correlations of IFX-TLs and ATIs with clinical, biochemical and endoscopic indices of disease activity in IBD patients are presented in Table 1. No other significant correlations between IFX-TL or ATIs with other disease characteristics were observed. In the logistic regression analysis only IFX-TLs (OR 0.86, 95% CI 0.76–0.97 p =0.017) and duration of IFX treatment (OR 0.97, 95% CI 0.95–0.99 p =0.04) were independently correlated with the presence of mucosal healing.

Table 1: Correlations of infliximab trough levels and antibodies to infliximab with clinical, biochemical and endoscopic indices of disease activity in patients with inflammatory bowel disease

<table>

P1010 COMPARATIVE INVESTIGATION OF ENTEROBIOTA BUSH IN ULCERATIVE COLITIS PATIENTS, AND THEIR CONSANGUINEOUS, AND NON-CONSANGUINEOUS RELATIVES
K. Fukuda
St Luke’s International Hospital, Tokyo/Japan
Contact E-mail Address: fukukatsu@luke.ac.jp

Introduction: In recent years, the gut microbiota has been recognized as a relevant fingerprint to predict the development of inflammatory bowel disease (IBD) like ulcerative colitis (UC). Accordingly, inter-individual variation in the gut microbiota may reflect inter-individual variation in the risk of developing IBD or other diseases. Further recently, the Next-Generation Sequencing (NGS) has been validated for determining bacterial species in faecal samples. Essentially, NGS is a molecular biology sequencing technique for the precise identification and assessment of bacterial species.

Aims & Methods: With the major focus of our study being to establish a relevant biomarker of disease activity in UC patients based on the intestinal microbiota, 82 UC patients together with 61 healthy relatives as controls were included for investigations. One hundred and twenty-five patients had active UC (group I) and 57 had quiescent UC; 29 with mild inflammation in the large intestine (group II), and 28 without inflammation (group III). The patients’ relatives were consanguineous (group IV, n = 33), and non-consanguineous (group V, n = 28). The subjects’ age ranged from 15 to 69 years. Faecal bacteria between groups I to V were compared by the t-test. The Discriminant analysis in all five groups was done for each Phylum, Class, Order, Family, Genus and Species. The Canonical Discriminant Function Coefficient (DF) for each bacterial community was calculated. The quantity of each bacteria was multiplied by the Df value, and the sum was termed the Discriminant Score (Ds). Next, we tried to analyze the quantity and the diversity of the bacteria which had significant difference.

Results: We obtained 1011 varieties of bacteria as Phyla, Class, Order, Family, Genera and Species. Any individual bacterial quantity with 0 value >95% of group I and group V, the mean of the individual quantity of bacteria >0.05% cases (684) were excluded. The t-statistics was done on 363 bacteria between groups I to V. Significant difference was calculated in 18 Species, 10 Genera, and 4 Families. The Discriminant analysis was done on these 18 Species from all groups. The Ds value showed an increasing tendency in this order: group I < group II < group III < group IV < group V. Significant difference was calculated for group I vs group II, vs group III, vs group IV, and vs group V (P < 0.05). Likewise, Group V vs group I, vs group II, vs group III (P < 0.05), indicating a relevant association between gut microbial species and the development of UC. In bacteria having significant difference, especially Bacteroidaceae Family and Bacteroides Genus were numerous clearly, and both were higher in group I, active UC. It’s odd that the diversity of Bacteroides Genus was higher in Group V, non-consanguineous relatives, but the quantity of Bacteroides Genus was higher in group I. And Bacteroides fragilis was increased in group I, and the others of Bacteroides were increased in group V, it depends on the amount of Bacteroides fragilis. In active UC, the amount of Bacteroides fragilis was increased, but the diversity of Bacteroides Genus was decreased. It’s very interesting, and the balance can be key point between Bacteroides fragilis and the diversity of Bacteroides in UC activity. And about Genus Anaerococcus, Finegoldia and Peptotrichilus, about Species Anaerococcus vaginalis, Finegoldia magna and Peptotrichilus gorbachi were increased in group I significantly. All these bacteria belong to Peptotrichilaceae Family.

Conclusion: In this study, we compared 363 bacteria between active UC patient to control, significant difference was calculated in 18 Species, 10 Genera, and 4 Families. To our knowledge, this is the first report on so many bacteria being related to UC activity. Additionally, the Ds related to UC, or otherwise absence of UC in the five groups. Potentially, Ds might be a clinically relevant biomarker of disease activity in UC. This is the first application of the Ds to the study of microbiota in UC patients, consanguineous and non-consanguineous relatives by using NGS. Moreover we could obtain a lot of interesting results about the quantity and the diversity of the bacteria, especially Bacteroides and Peptotrichilaceae. Clinical trial No: UMIN000017103

Langhorst J, Boone J, Lauche R, Ruefer A, Dobos GJ. Fecal Lactoferrin, Calprotectin, PMN-Elastase, CRP, EDN, PME and White Blood Cell Count as an Indicator for Musculoskeletal Healing and Clinical Course of Disease in Patients with Mild to Moderate Ulcerative Colitis: Post Hoc Analysis of a Prospective Clinical Trial. JOURNAL OF CROHNS AND COLITIS 2016; Feb 13
Introduction: At present, drug response to infliximab is monitored by trough levels of antibody levels. With fluently, another pathway of drug degradation has been hypothesized since MMP3 and MMP9 were found to be able to cleave IgG, like infliximab, in both animal and human experimental studies (1).

Aims & Methods: We collected serum samples in 102 patients (27 Crohn’s Disease and 75 Ulcerative Colitis) treated with stable doses of infliximab for at least 6 months ($t_0$) and 6 months thereafter ($t_1$). In each patient TL, ATI values and MMP3 levels were assessed at $t_0$ and $t_1$ by ELISA. In addition, MMP3 levels were also measured in 28 healthy subjects as controls. Clinical (HBI or Mayo score) and biochemical (CRP, fecal calprotectin) markers were assessed to define disease remission/activity. TL activity were considered therapeutic if $>3.8$ mcg/ml, ATI were considered positive if $>10$ mcg/ml. Data are presented as mean ± Standard Error Mean (SEM). Comparison among groups was performed by non-parametric tests.

Results: MMP3 levels were similar at $t_0$ and $t_1$ in patients which maintained therapeutic TL (14.5 ± 1.7 pg/ml and 15.0 ± 1.6 pg/ml, respectively) and in healthy controls (13.1 ± 3.0 pg/ml). Patient with low TL but ATI positive had significantly higher MMP3 levels compared to the group with low TL and ATI positive (33.2 ± 3.0 and 20.0 ± 2.7 respectively, p=0.0003), showing another pathway of drug degradation. 21 patients lost response between $t_0$ and $t_1$: 15 out of 21 patients demonstrated high levels of MMP3 (22.0 ± 2.1 pg/ml) already at $t_0$; in addition, 17 of these 21 patients were in clinical remission at $t_0$, while at $t_1$ all patients had disease activity.

Conclusion: Serum MMP3 levels are useful in predicting loss of response to anti-TNFa in patients with low TL but without ATI. High MMP3 levels predict with 90.5% accuracy loss of response over the next 6 months.

Introduction: More than one third of inflammatory bowel disease patients (IBD) possess genetic mutations, with the common, clearly the more incapacitating and which more alter the quality of life of IBD patients. These patients could benefit from a multidisciplinary approach for quicker diagnosis and for optimizing treatments.

Aims & Methods: The aim of the study was to evaluate the impact of a multidisciplinary approach carried out by both a rheumatologist and a gastroenterologist in the management of these patients. Therapeutic changes after the consultation were also evaluated. From April 2014 to April 2015, all IBD patients reporting arthritic pain to the IBD-dedicated gastroenterologist were referred to an experienced rheumatologist. The day of the consultation a multidisciplinary committee with a rheumatologist and a gastroenterologist evaluated and discussed in all patients their possible diagnosis and potential changes in their treatment. Assessment was made according to current guidelines and data recorded in a common database regarding the reasons why patients were remitted from IBD, their rheumatologic diagnosis and all changes implemented in their treatments. Results are shown in percentages.

Results: 112 consecutive IBD patients were remitted from the IBD Unit and analyzed by the committee. Mean age 38 years (ranging from 18 to 73). Most patients were women (67%), 19% were smokers and 23% former smokers. 51% of them had Crohn’s disease and 49% ulcerative colitis. The main causes for derivation from IBD were a suspicion of inflammatory arthropathies in 43% and of arthromyalgias in 40%. The more frequent diagnosis after the rheumatology consultation and the committee meeting were inflammatory arthropathies associated with IBD in 41% (51.5% presented axial arthropathies and 48.5% presented peripheral arthropathies) and fibromyalgia in 15%. Regarding treatment changes, after the multidisciplinary committee with a rheumatologist and a gastroenterologist, changes were made in 28% of patients. Of those, 35% of patients methotrexate was added in patients with biologic treatment (in some of them patients were in monotherapy, but in others the drug was introduced for replacing thiopturines). In 24% of patients sulfasalazine was introduced instead of mesalamine. In the other patients either other biologies like golimumab associated with IBD in 41% (51.5% presented axial arthropathies and 48.5% presented peripheral arthropathies) and fibromyalgia in 15%.

Conclusion: Multidisciplinary consultation combining inflammatory bowel disease and rheumatology allows both an earlier detection of inflammatory arthropathies associated with IBD and earlier changes in treatment, thereby helping to optimize the hospital resources. Fibromyalgia is common among IBD patients, though it is important that it is detected it should not be confused with other non-inflammatory conditions.

Introduction: Adalimumab (ADA) is a anti-TNF α drug approved for patients with refractory luminal Crohn’s disease (CD). Recently, mucosal healing (MH) emerged as a major therapeutic goal in inflammatory bowel disease. Few data are available on ADA trough levels (TL), anti-ADA antibodies (AAA) during long term follow-up of CD patients, and their potential association with MH and disease outcome.

Aims & Methods: The aim of our prospective study was to evaluate a possible association between achievement of MH, ADA TL, and AAA in CD patients. Moreover, we assessed the clinical usefulness of a possible correlation between clinical outcome and MH. We prospectively enrolled moderate to severe CD patients who were primary responders to ADA treatment. Blood samples were withdrawn at standardized time points during treatment (0-, 2-, 6-week and every 8 weeks thereafter), before ADA administration. ADA TL were measured using an homogenous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States). Disease activity was assessed by means of Harvey-Bradshaw Index (HBI, definition revised by HBI < 5). As to endoscopic activity, we defined MH in case...
of a value of Crohn’s Disease Endoscopic Index of Severity below 8, so far we included only complete MH and 31% had at least a minimal residual endoscopic activity. Endoscopic evaluation was performed within two weeks of blood sampling, and at least after 6 months of ADA treatment.

Results: In our prospective study we enrolled 22 CD patients primary responders to ADA therapy (13 males; median age 34 years; range 23–67 years) who had a median treatment duration of 52 weeks (range 24–121 weeks). ADA TL were significantly higher (P = 0.0002) in patients who achieved MH (12.1 mcg/mL, range 6.8–17.2 mcg/mL) as compared to patients without MH (4.50 mcg/mL, range 1.9–9.9 mcg/mL). Receiver Operating Characteristic curve identified an ADA TL cut-off of 6.43 mcg/mL as the threshold with the highest accuracy for identification of patients who achieve MH (AUROC 0.934, specificity 100%, sensitivity 81.8%, PPV 84.6, PNV 100). Moreover, achievement of MH was associated with absence of AAA (P = 0.012). Lastly, HBI was significantly lower (P = 0.0002) in patients with MH (4, range 3–8) than in patients without (11, range 4–17).

Conclusion: In our cohort of CD patients, we observed a clear association between MH, disease development, and clinical response. In this context, particularly, elevation of 6.43 mcg/mL has been identified as the best cut-off to obtain endoscopic remission or at least a minimal residual endoscopic activity. Moreover, we observed that CD patients on ADA therapy who achieved MH had a lower disease clinical activity. Thus, we support the use of therapeutic ADA monitoring for the management of CD patients in order to obtain clinical and endoscopic remission of the disease.

Introduction: Crohn’s disease (CD) management targets mucosal healing on ileocolonoscopy as a treatment goal.

Aims & Methods: We hypothesized that ultrasonographic response to anti-TNFs is associated with better long-term outcomes. Patients with CD treated with anti-TNFs who had a serial small intestine contrast ultrasonography (SICUS) between January 2011 and April 2017 were identified. Disease site (based on bowel wall thickness), extent of lesions, and presence of complications (stenosis, poststenotic dilation, abscess, or fistulas) were evaluated using SICUS. Inclusion required pre-therapy SICUS with follow-up SICUS after 12 months, or 2 SICUS ≥ 12 months apart while on maintenance therapy. At second SICUS, complete responders had improved lesions, and partial responders had new lesions, and partial responders had other scenarios. CD-related outcomes of corticosteroid need, hospitalization, and surgery were assessed at one year from the second SICUS.

Results: Seventy-nine CD patients treated with anti-TNFs (37% with Infliximab, 63% with Adalimumab) were identified. Most patients had ileal disease (67%) and strictureting phenotype (52%). Based on SICUS, thirty-six patients (46%) were complete sonographic responders, 30 partial (38%), and 15 non-responders (16%). Complete and partial responders at SICUS had a reduced risk for surgery in comparison with non responders [p = 0.003 (OR:34.6, CI:1.7–700), p = 0.003 (OR:12, CI:0.6–2.40)]. Complete responders at SICUS had a higher reduction of hospitalizations in comparison with non responders [p = 0.04 (OR:4.2, CI:1–17)]. Complete and partial responders at SICUS had a reduced risk for need for rescue corticosteroids in comparison with non responders [p = 0.005 (OR:7.8, CI:1.9–32.4), p = 0.002 (OR:5.2, CI:1.7–13.3)].

Conclusion: Ultrasonographic response to medical therapy is associated with significant reductions in long-term risk of surgery, hospitalizations and steroid usage among CD patients. These findings suggest the significance of response assessed by ultrasonography as a treatment target.

Introduction: Inflammatory bowel disease (IBD) is characterized by recurrent flare-ups leading to hospitalisations, surgery, and eventually disease progression. The exact role of psychosocial factors as triggers remains controversial and current literature focuses on the global presence of psychosocial symptoms preceding a flare instead of distinguishing pre-existing factors. Presently, we aim to explore the impact of newly developed symptoms of anxiety, depression, fatigue, psychological stress, and life events on IBD flares.

Aims & Methods: IBD patients were recruited from the MyIBDcoach study cohort (de Jong et al., Lancet 2017, in Press). MyIBDcoach is a telemedicine tool to monitor IBD patients at home. During the 12-month study period, participants reported on disease activity and psychosocial parameters (including psychological stress, anxiety, depression, fatigue, and life events) through MyIBDcoach every 1–3 months. Flares were defined as clinical disease activity in combination with one of the following: faecal calprotectin > 250 μg/g, disease activity on endoscopy or other imaging techniques, or dose escalation or initiation of new drug to induce remission. For all psychosocial parameters, a binary variable was created to indicate whether symptoms were newly developed or pre-existing with reference to the previous measurement, thereby correcting for invariability. A generalized estimating equation model was used to separately determine which psychosocial parameters were associated with flares in the three preceding months, correcting for immortal time bias after a flare and adjusting for gender, disease phenotype, smoking status and disease duration.

Results: In total, 2748 measurements from 381 IBD patients were included. Fifty-four (13%) were classified as a flare after clinical remission was achieved. Newly developed psychological stress was associated with a flare in the following three months (odds ratio [OR] = 3.01; 95% CI = 1.48, 6.12). Newly reported symptoms of depression (OR = 1.29; 95% CI = 0.53, 3.14), anxiety (OR = 1.06; 95% CI = 0.46, 2.34), fatigue (OR = 1.07; 95% CI = 0.39, 2.93), or the occurrence of a life event (OR = 2.07; 95% CI = 0.94, 4.55) were not significantly associated, although the latter did occur more frequently before flares. Conclusion: Newly developed psychological stress is associated with disease flares in IBD patients. Therefore, continuous monitoring could be a novel method for interventions such as mindfulness and coaching might be interesting to prevent flares and eventually improve disease course.

Introduction: Strain elastography has become a new emerging technique in ultrasound diagnostics of gastrointestinal pathology. Currently there is few published data on the use of elastography for making the diagnosis and following the course of inflammatory bowel diseases.

Aims & Methods: Objective. To assess the accuracy of strain elastography concerning stricture detection in Crohn’s disease (CD). Methods. 24 patients (13 with (<13%) flare after clinical remission was achieved. From 18 to 43y were included into the study, of 1 them having a colonic stricture, 1 patient having a stricture of ileal-transverse anastomosis and 22 patients having a stricture in the small intestine. Surgical treatment was carried out in 22 patients, in each case histopathological examination of the removed segments of the intestine was conducted. We performed transcutaneous ultrasound examination of the bowel using 7.5 MHz linear and 3.5 MHz convex probes with power Doppler mode and colonolescence in all 24 patients. Strain elastography was used during each US-examination to differentiate inflammatory and fibrotic strictures.

Results: Ultrasonographic examination invariably showed local narrowing of the intestinal lumen in stricture sites. Inflammatory stricture length was 29 mm (21.1–55.5), (median 2.5th - 97.5th percentile) with intestinal wall thickening of 6 mm (4.23-9.00) and the presence of ulcers. The lesion length in fibrotic strictures was 30 mm (20-60), wall thickness −6 mm (4.18-8.27), ulcers were visualized either. In 22.7% of cases we observed the signs of partial bowel obstruction. Strain ratio (SR) values for inflammatory strictures were 1.53 (0.43–3.71), for fibrotic strictures – 4.19 (1.57–6.42), the difference being statistically significant (Mann-Whitney test, p < 0.05). According to morphologic studies inflammatory strictures were characterized by transmural inflammatory infiltration. In fibrotic strictures we found fibrosis in submucosal layer with loci of muscularis propria involvement. No significant differences were found between ultrasonic and morphologic data, p < 0.05.
PI019 THE INFLAMMATORY BOWEL DISEASE DISABILITY INDEX INFLAMMATORY BOWEL DISEASE: RELATIONSHIP WITH DISEASE CHARACTERISTICS AND QUALITY OF LIFE IN A COHORT OF SICILIAN PATIENTS

Introduction: IBDs are disabling conditions that negatively affect physical, psychological, familial and social dimensions of life. The concept of quantifying disability has been introduced for the goal of evaluating the impact of many other chronic diseases. Thus, specific tools have been used to assess the impact of disease and its treatment options on relevant end-points such as health-related quality of life (HRQoL), measured by the IBD-Questionnaire (IBD-Q). Recently, the IBD-Disability Index (IBD-DI) has been developed to evaluate the entire spectrum of limitations in functioning in patients with IBD. This index is inspired to the International Classification of Functioning, Disability and Health (ICF). The aim of the present study was to assess the relationship between the IBD-DI, clinical characteristics and HRQoL in a cohort of Sicilian patients with ulcerative colitis (UC) and Crohn’s disease (CD) followed up in a referral center.

Aims & Methods: IBD-Q and IBD-DI questionnaires were administered to consecutive UC and CD adults outpatients from July 2016 to April 2017. The IBD-DI consists of 28 items that evaluate the 4 domains of body functions, activities and participation, body structures and environmental factors. IBD-Q consists of 32 questions grouped into 4 dimensions: bowel, systemic, social, emotional. Scores range from 1 (poorest QoL) to 7 (best QoL) with higher scores indicating better QoL. Disease activity was assessed by partial Mayo score for UC and by Harvey-Brandshaw Index for CD. The mean differences of DI score in relation to dichotomic clinical variables were performed by Student’s t test. By linear regression analysis we assessed also the relationship between DI and IBD-Q. Data were analyzed with SPSS and statistical significance of p values was defined if p < 0.05.

Results: Data from UC and CD patients were analysed separately. 100 UC patients (59% males, median age 49 years) were enrolled; 17% were smokers. 83% had inactive or mild disease, 17% moderate disease. None of the recruited patients had severe disease. Concomitant medications at the time of the interview were conventional therapy (5-aminosalicylic acid, oral steroids) in 72 patients (72%) or immunosuppressive therapy (immunosuppressant or anti-TNF-a) in 28 patients (28%). The mean IBD-DI score was 23.15±17.492; 62% of patients had low DI ≤25 (62/100) while 7% had high DI >50. No correlations were found between IBD-DI and gender, disease duration, disease extension (Montreal Classification) and immunosuppressive therapy. IBD-DI was related to clinical disease activity (p=0.001) and extraintestinal manifestations (p=0.005).

By linear regression analysis, IBD-DI was significantly associated with IBD-Q (R²=0.63, p<0.001). Interestingly, 5% (n=5) of patients with inactive or mild disease had severe disability (≥50) and 5% (n=5) with active disease had low disability (<25). 54 CD patients (59%, males, median age 41 years) were enrolled; 22% were smokers. 94% had mild disease, 17% severe disease. Concomitant medications at the time of the interview were conventional therapy (5-aminosalicylic acid, oral steroids) in 22 patients (40%) or immunosuppressive therapy (immunosuppressant or anti-TNF-a) in 2 patients (60%). The mean IBD-DI score was 20.17±16.24; 72% of patients had low DI ≤25 (39/54) while only 2 patients had high DI >50. No correlations were found between IBD-DI and disease characteristic (gender, disease duration, disease extension, extraintestinal manifestations). By linear regression analysis, IBD-DI was significantly associated with IBD-Q (R²=0.604, p<0.001).

Conclusion: Our preliminary results show that the IBD-DI is significantly related to HR-QoL both in UC and CD. In UC IBD-DI is also related to disease activity and presence of extraintestinal manifestations. However, most of our patients were in clinical remission. A larger sample with different grades of disease activity could provide a more accurate evaluation of the reliability of this tool in measuring functional status and disability in IBD. IBD-DI could become a major endpoint in RCTs targeting the course of IBD.

Aims & Methods: We conducted a prospective observational study at our tertiary care centre with the aim of assessing and correlating UC disease activity by clinical criteria, endoscopy, histology, serum and fecal biomarkers and PET-CT. 60 eligible patients of UC were enrolled into 3 groups (26 remission, 24 moderate and 10 severe activity) as per Mayo score and $^{18}F$ FDG PET-CT was performed within 72 hours of endoscopy. ESR, CRP and fecal calprotectin levels were determined for all patients.

Results: Of 60 enrolled patients, 10% patients had proctitis, 43.3% had left-sided colitis and 46.7% had extensive colitis. ESR, CRP, fecal calprotectin levels and rectal PET activity were significantly higher in patients with moderate and severe disease activity as compared to those in remission. Rectal PET activity showed a significant correlation with the Mayo score ($r=0.465$, $p<0.001$), endoscopic sub-score ($r=0.526$, $p<0.001$), histological score ($r=0.496$, $p<0.001$), and fecal calprotectin levels ($r=0.279$, $p=0.031$). Extent evaluation by PET-CT and colonoscopy also showed a significant correlation ($r=0.582$, $p<0.001$) with each other. We found that CRP at a cut-off level of $<12$mg/L had a sensitivity of 70.59% and specificity of 92.3%, and fecal calprotectin at a cut-off $<143$µg/g had a sensitivity of 82.35% and specificity of 88.46% to predict remission. Besides, PET-CT identified sacroilitis in 5, mesenteric stranding in 4, and adenocarcinoma in 1 patient.

Conclusion: PET-CT is a reliable non-invasive tool for assessing disease activity in UC with good correlation with the Mayo score, endoscopic score, histology and fecal calprotectin. It is an accurate measure to determine disease extent, and a good predictor of remission. Thus, with a better patient compliance, it holds promise in replacing colonoscopy where it is refused or difficult to perform.

**P1024 EMERGING ROLE OF IL-33/ST2 LEVELS IN PREDICTING MISSIONAL RESPONSE TO ANTI-TNF THERAPY IN UCLEAR COLITIS**

L.R. Lopetuso1, V. Petiot1, C. Graziani2, T. T. Pizzaro2, F. Scalaferri1, A. Gasbarrini1

**Contact E-mail Address:** lopetusoloris@libero.it

**Introduction:** Tumor necrosis factor (TNF) inhibitors (anti-TNF) are considered to be the first-line therapy for inflammatory bowel disease (IBD). The role of IL-33 and its receptor ST2 in modulating the IL-33/ST2 axis in inflammatory conditions is under investigation. The aim of our study was to explore the potential role of the IL-33/ST2 axis in the mucosal healing process mediated by anti-TNF therapy in UC.

**Aims & Methods:** The induction period was associated with remission in inflammatory conditions.

**Contact E-mail Address:** leonorps@gmail.com

**Conclusion:** IFX-TL (> 24 µg/mL) was associated with remission at week 22 (ROC 0.83; S: 61.5%; Sp: 81.3%) and at week 54 (ROC 0.79; S: 60%; E: 80%). On week 14, IFX-TL > 11 µg/mL was associated with remission at week 22 (ROC 0.80; S: 41.7%; Sp: 93.8%) and at week 54 (ROC 0.70; S: 44.4%; Sp: 86.7%). **Disclosure of Interest:** All authors have declared no conflicts of interest.

Conclusion: Upon analysis of 57,861 infliximab and adalimumab patient samples from 2012–2016, 43% exhibited anti-drug antibodies. We found that low-titer antibodies do not appear to impact drug levels. Our findings are consistent with American Gastroenterological Association Critical Care Pathways for Crohn’s Disease. Ulcerative Colitis and Crohn’s Disease. Comprehensive antibody scenarios were managed very differently (increase drug/consider immunomodulator vs. switch drug within class). High resolution antibody assays may be helpful in dosing TNF inhibitors and in other treatment and management decisions.

Introduction: Biomarkers of inﬂammatory bowel disease activity have been researched for decades but objective markers of disease severity that support clinical decision-making is still needed. Well-established markers include serum C-reactive protein and fecal calprotectin, but their use as a standalone surrogate for disease activity has been controversial. We hypothesize that novel objective markers of tissue inﬂammation are best identiﬁed at the site of disease with a tissue-level assessment of disease activity.

Aims & Methods: Biopsy samples were obtained from participants in the UNITI trials of ustekinumab in moderate-to-severe Crohn’s disease. The UNITI induction trials included two cohorts, patients who failed ≥1 TNF antagonists (UNITI-1) or patients who failed conventional therapies (UNITI-2). Pairs of adjacent biopsies were taken from the rectum, splenic ﬂexure, and ileum. One biopsy from each pair was assessed by Global Histology Disease Activity Score (GHAS) while the other was submitted to microarray analysis. Partial least squares regression and random forest were used to identify biomarkers associated with histological severity in the UNITI-1 cohort. Robustness of the resulting models was assessed using cross-validation within the training set and multiple external validation sets (deﬁned within the UNITI-1 and UNITI-2 cohorts).

Results: In UNITI-1, a single multivariate model comprising 16 genes was identiﬁed that predicted histological activity in rectum or splenic ﬂexure biopsies. This model was characterized by R² = 0.78 for the training set, and R² = 0.59, 0.54, and 0.32 on external validation sets also from UNITI-1. A separate 14-gene model capturing histological activity in ileal biopsies was characterized by R² = 0.5 for the training set and R² = 0.45 in the external validation set. In general, both models contained genes related to tissue degradation, barrier function, and immune regulation, including CXCL11 (I-TAC). Both models retained performance in external validation datasets from UNITI-2 but exhibited lower performance. De novo models generated from UNITI-2 also exhibited lower performance. Indeed, weighted gene co-expression network analysis indicated weaker associations between gene expression and histology scores for UNITI-2 compared to UNITI-1 subjects.

Conclusion: Our analysis supports the ability of biopsy transcriptionomics combined with machine learning approaches to capture disease-relevant variability in Crohn’s disease and, more importantly, supports the use of similar approaches to identify additional surrogate markers. Interestingly, this approach was more successful in the TNF antagonist failure cohort compared to the conventional therapy failure cohort. We hypothesize that this is related to increased strength of the transcriptional signal in the TNF antagonist failure cohort. We identiﬁed speciﬁc genes that could be used together as surrogates for histologic measurement, which may not be susceptible to the subjectivity inherent in GHAS scoring. Finally, the speciﬁc genes identiﬁed by our analysis provide insight into the molecular processes driving histological disease activity in Crohn’s disease.

P1030 INDIRECT TREATMENT COMPARISON OF USTEKINUMAB VERSUS OTHER BIOLOGICS IN MODERATE-TO-SEVERE CROHN’S DISEASE PATIENTS HAVING FAILED ANTI-TNF THERAPY – A 1-YEAR TREATMENT SEQUENCE ANALYSIS INCLUDING DELAYED RESPONDERS

Introduction: Indirect evidence is needed to inform the clinical efficacy of ustekinumab in Crohn’s disease (CD). Indirect treatment comparisons in CD are challenged by withdrawal trial designs limiting placebo arm attractivity. This treatment sequence analysis builds on previous work proposing a solution to challenges inherent to CD data to compare one year efficacy of biologics in CD patients having failed anti-TNF therapy. Analyses accounted for delayed responders (induction non-responders attaining response after additional doses) to generate more comprehensive estimates of biologics’ relative efficacies.

Aims & Methods: A systematic literature review identiﬁed randomized controlled trials in CD patients having failed anti-TNF therapy for induction and maintenance of ustekinumab (UST), adalimumab (ADA), or vedolizumab (VDZ). Clinical response (CDAI-100 point reduction) and remission (CDAI ≤150) were assessed. The probability of achieving response after induction was multiplied by the conditional probability of maintaining response/achieving remission at one year. Separate calculations were conducted for early and delayed responders. Their respective treatment sequence rates were summed to obtain overall response and remission rates. Placebo rates were imputed using data from patients induced and maintained on placebo from the IM-UNITI study, adjusted for responder and remitter induction rates. Bayesian analyses generated relative effect estimates that were compared to the primary direct evidence presented in the previous manuscript. A sensitivity analysis was conducted to investigate the impact of the induction response rate on the results.

Abstract: P1028. Table 1: Characteristics and outcomes among patients newly started on vedolizumab stratified by IBD type and history of immunosuppressive therapy

Note: IM therapy included use of azathioprine, 6-mercaptopurine, methotrexate, mycophenolate mofetil, cyclosporine, and Tacrolimus.
odds ratios (OR), credible intervals (CrI), and posterior distribution probabilities for superior of UST.

**Results:** Accounting for delayed responders, the absolute proportions of patients having maintained response and being in remission at one year were 30% of patients receiving UST every 8 weeks, 19% of those receiving VDZ every 4 weeks, and 5% of patients receiving ADA every other week or weekly. Results on a one-year treatment sequence analysis, probabilities for UST to be better than VDZ for achieving and maintaining response and remission were 99% (OR[CrI]:1.94[0.79;3.48]) and 98% (OR[CrI]:1.32[1.00;2.38]), respectively. UST had higher likelihoods of remission than ADA given weekly (OR[CrI]:1.36[0.72;2.58]) or every other week (85%, OR[CrI]:1.41[0.74;2.68]).

**Conclusion:** This approach deals with methodological issues inherent to CD trial data. In CD patients having failed anti-TNF therapy, ustekinumab had higher likelihood of response or remission than adalimumab and vedolizumab over a one-year treatment sequence. Additional induction doses and continued maintenance therapy with ustekinumab have demonstrated benefits in delayed responders compared to other biologics. Previous research is limited to indirect treatment comparisons in early responders only. Including delayed responders provides a more accurate picture of CD patients' response to biologics and better informs clinical practice.

**P1031 INDIRECT TREATMENT COMPARISON OF USTEKINUMAB VERSUS OTHER BIOLOGICS IN MODERATE-TO-SEVERE CROHN'S DISEASE PATIENTS HAVING FAILED CONVENTIONAL THERAPY – A 1-YEAR TREATMENT SEQUENCE ANALYSIS INCLUDING DELAYED RESPONDERS**

L. Mesana, M. Pacou, D. Naessens, S. Sloan, A. Gauthier

**Aims & Methods:** Clinical response (CDAI-100 point reduction) and remission (CDAI ≤150) for achieving and maintaining response and remission were assessed. The probability of achieving response after induction was multiplied by the conditional probability of maintaining response/achieving remission at one year. Separate calculations were conducted for early and delayed responders. Their respective treatment sequence rates were then summed to obtain overall response and remission proportions. Placebo rates were imputed using data from patients induced and maintained on placebo from the IM-UNITI study and adjusted for responder and remitter induction rates. Bayesian analyses generated relative odds ratios (OR), credible intervals (CrI), and posterior distribution probabilities for superiority of ustekinumab.

**Results:** When accounting for delayed responders, the absolute proportions of patients having maintained response and being in remission at one year were of 50% in patients receiving UST, 39% in those receiving VDZ, and 33 or 36% in patients receiving ADA every other week or weekly, respectively. Based on a one-year treatment sequence analysis, probabilities for UST to be better than VDZ for achieving and maintaining response and remission were 84% (OR[CrI]:1.39[0.73;2.62]) and 69% (OR[CrI]:1.19[0.59;2.38]), respectively. UST had higher likelihoods of remission than ADA given weekly (75%, OR[CrI]:1.33[0.83;2.02]) or every other week (82%, OR[CrI]:1.47[0.64;3.33]).

**Conclusion:** This approach deals with methodological issues inherent to CD trial data. In CD patients having failed conventional therapy, higher likelihoods of response or remission were observed for ustekinumab versus adalimumab and vedolizumab over a one-year treatment sequence. Additional induction doses and continued maintenance therapy with ustekinumab in delayed responders have demonstrated benefits compared to other biologics. Previous research is limited to indirect treatment comparisons in early responders only. Including delayed responders provides a more accurate picture of CD patients' response to biologics and better informs clinical practice.

**P1032 EFFICACY AND TOLERABILITY OF INITIATING, OR SWITCHING TO, INFLIXIMAB BIOSIMILAR CT-P13 IN INFLAMMATORY BOWEL DISEASE (IBD): A LARGE SINGLE-CENTRE EXPERIENCE**

R.P. Ratnakamaran, N. To, D. Gracie, C. Selinger, T. Clark, N. Carey, G. Dowson, K. Leigh, B. Lourner, A.C. Ford, P. J. Hamlin

**Introduction:** Anti-TNF therapies have revolutionised the management of IBD. Recently, the infliximab (IFX) biosimilar (CT-P13) received market authorisation for IBD allowing cost benefits with switches to CT-P13 with annual savings estimated at £5400 per patient (70 kg patient receiving 5 mg/kg every 8 weeks). We present our experience of switching patients from the original IFX to CT-P13 for new and existing patients.

**Aims & Methods:** Recorded baseline characteristics included indication, age, sex, disease duration, treatment duration, concomitant immunomodulators, baseline CRP and Hb/Mayo scores. Response to IFX induction was assessed retrospectively using symptoms and CRP. Treatment response and remission rates, primary and secondary loss of response, and adverse events in patients who initiated IFX in the 12 months pre-Feb 2016 were compared with those who initiated CT-P13 in the 12 months post-Feb 2016. Sustained response was measured before switch and at 3, 6, and 12 months post.

**Results:** 53 patients commenced IFX in the 12 months pre-Feb 2016 (26 Crohn's Disease (CD), 13 fistulating CD, 3 UC, and 10 Crohn's Disease/UC). Baseline characteristics did differ, with a greater proportion of UC patients in the CT-P13 cohort (51% vs 24.5% (p = 0.003)). This group had a higher mean CRP (20.2 v 10.6 (p = 0.008)) although a lower median Mayo score (5 v 11 (p = 0.007)). There was no difference in response (12(23%) v 15 (21.74%) (p = 0.905)), remission (14(26%) v 29(42%) (p = 0.074)), primary non-response (8(15%) v 45.8% (p = 0.087)), secondary loss of response (12(23%) v 15(21.74%) (p = 0.905)), or adverse events (6(11%) v 6(11%) (p = 0.629)) in those who initiated original IFX compared with CT-P13. Following switch, patients who initiated IFX in the 12 months post-Feb 2016, 19 patients were still on original IFX on 12 months post-switch. There was no difference in the response (21%) in v 24.5% (p = 0.797), remission (94.7% v 115(58.1%) (p = 0.367)), secondary loss of response (84% v 74.6% (p = 0.087)), primary non-response (0% v 0% (p = 0.971)), and adverse events (0% v 0% (p = 1)). Between the original IFX and CT-P13 respectively. Drug and antibody levels were available pre-switch to CT-P13 for 134 patients. Therapeutic drug levels with no significant antibodies were associated with clinical remission 12 months post-switch compared with undetectable drug levels with significant antibodies (60.6/7%) v 0% (p = 0.0008). Loss of response or discontinuation of therapy at 12 months post-switch was significantly lower in those with therapeutic drug levels and no significant drug antibodies compared with patients low/undetectable drug levels and significant antibodies (18/20%) v 7(100%) (p < 0.0001) and 67(6%) v 6(86%) (p < 0.0001) respectively.

**Conclusion:** There was no significant difference in response and remission rates, primary and secondary loss of response, or adverse events between originator IFX and CT-P13 during the first 12 months after switching. The presence of low/undetectable drug levels and significant antibodies pre-switch was associated with loss of response and discontinuation of treatment. Switching to CT-P13 in 191 patients in our unit lead to >£1million in savings.

HP eradication therapy does not exacerbate disease activity of IBD.

We then aimed to clarify the safety and efficacy of HP eradication in patients with IBD.

Aims & Methods:

This was a multicenter, retrospective cohort study in 26 institutions.

Patients who eradicated HP by proton pump inhibitor and amoxicillin-

based triple therapy after the diagnosis of IBD (ulcerative colitis (UC) or Crohn’s disease (CD)) from March 2005 to July 2015 were enrolled. Two IBD patients without a history of gender, age at diagnosis, severity, and observation

period were matched with each HP-eradicated patient were enrolled in the same institution. Disease activity of IBD at baseline, 2 and 6 months after observation (eradication) was investigated. Eradication of IBD was defined as increase/addition of IBD drug, IBD-associated hospitalization or surgery; and physicians’ assessment was also analyzed. Factors associated with exacerbation of IBD were assessed by univariate and multivariate logistic regression analyses.

Results:

A total of 429 IBD (378 UC and 51 CD) patients, including 144 patients who eradicated HP (eradication group) and 285 control patients (non-eradication group), were enrolled. IBD exacerbation rates in 2 and 6 months of observation were 16.2% (12/74) and 11.8% (17/144) in eradication group, which showed no significant differences compared with those of 4.9% (14/285) and 7.7% (22/285) in non-eradication group. Physicians’ assessment showed similar results in terms of disease exacerbation, but in 2 months of observation no patient was improved in eradication group whereas 3.2% (9/285) of patients was improved in non-eradication group (P = 0.019). Multivariate analysis revealed that the independent factor of IBD exacerbation after HP eradication was active disease at base-

line (OR 5.3 (95% CI: 1.5–16.9), P = 0.011). HP was eradicated in 82.9% (102/ 123) of patients using clarithromycin as first-line treatment and 90.4% (19/21) using metronidazole as second-line, both of which were comparable with previous reports in non-IBD patients.

Conclusion: HP eradication therapy does not exacerbate disease activity of IBD without affecting eradication rate but may improve disease activity, suggesting that careful observation is necessary after eradication, especially for patients with active disease.

P1034 EVALUATION OF PHARMACOKINETIC PROFILES OF SB2 AS A BIOSIMILAR OF REFERENCE INFILXIMAB

D. Shin, J.W. Kang, S. Park, Y. Lee, S. Lee

Samsung Bioepis Co., Ltd., Incheon/Korea. Republic of

Contact E-mail Address: sr0427.lee@samsung.com

Introduction: Based on the totality of evidence with similar analytical, pharmacokinetic (PK) and clinical results, SB2 was approved by European Medicines Agency and U.S. Food and Drug Administration as a biosimilar of the reference infliximab (INF) for all indications for which INF has been approved. Here we report the PK profiles of SB2 compared to that of INF in two animal models, healthy subjects and patients with rheumatoid arthritis (RA).

Aims & Methods: The pre-clinical PK profiles were evaluated in single and repeated dose studies (1, 3, and 10 mg/kg of SB2, European Union sourced INF [EU-INF] or United States sourced INF [US-INF]) in two animal models (Sprague Dawley [BD] rat and transgenic Tg197 mouse). The clinical Phase I study for PK was conducted in healthy subjects and patients with rheumatoid arthritis. The clinical Phase I study was conducted in healthy subjects and patients with rheumatoid arthritis and pre-clinical and clinical studies.

Results: In pre-clinical studies, all PK profiles from animal studies showed no significant differences in Cmax and AUC0–C6h between SB2, EU-INF and US-INF.

In healthy subjects, the 90% CIs for the primary PK parameters were within the pre-defined equivalence margin of 0.8 to 1.25 between SB2 and reference products (SB2 vs. EU-INF and SB2 vs. US-INF). In RA patients, the mean trough level was comparable between SB2 (ranging from 1.915 to 17.965 μg/mL) and EU-INF (ranging from 2.224 to 16.954 μg/mL) from week 2 to week 30. The PK profiles were also comparable between SB2 and INF when analysed by the presence of ADA in both Phase I and Phase III clinical studies.

Conclusion: Similar PK profiles of SB2 and reference products were confirmed in both Phase I and Phase III studies. The previously demonstrated analytical similarity and the data presented here indicate that similar PK are expected in all indications approved for SB2.

P1036 INFLIXIMAB DOSE BANDING SHORTEST LENGTH OF STAY OF INFLAMMATORY BOWEL DISEASE PATIENTS
J. Ollivier1, F. Pouillon2, A. Berrouneau3, S. Djabarouti1, F. Xuereb1, F. Zerbib2, D. Laharie1, D. Breuil1
1Pharmacy, CHU de Bordeaux, Pessac/France
2Gastroenterology, CHU de Bordeaux, Pessac/France

Contact E-mail Address: julien.ollivier@chu-bordeaux.fr

Introduction: According to infliximab (IFX) license in inflammatory bowel diseases (IBD), infusion doses are based on patient weight. In daily practice, treatment is prepared by pharmacist after clinical patient assessment, leading to an increased duration of hospital stay and consequently costs. A pharmacokinetic study (1) has shown that a weight-based dose (WBD) strategy does not reduce interindividual variability of IFX trough levels when compared to fixed doses. According to these findings, our hospital implemented dose banding (DB) of IFX infusions, defined by doses rounded up or down according to one of eight pre-determined standard doses with a maximum theoretical deviation of ±5%, that allowed to prepare infusions at the pharmacy before patient admission.

Aims & Methods: The aim of the study was to compare hospitalisation length of stay (LOS) between IFX DB as compared to those treated with IFX WBD. From February to March 2017, we conducted a prospective, case-control study in our unit, including all IBD patients admitted for an IFX infusion. Patients who should receive an IFX dose between 250 and 800 mg were included in the DB group (treatment pre-prepared at the pharmacy, sent to the hospital unit before patient admission and administered just after the clinical validation). Patients who should receive an IFX dose below 250 mg or above 800 mg were included in the WBD group (treatment prepared after clinical validation including weight, and then sent to the hospital unit). Patients were analysed only when precise length of stay could be obtained and measured in minutes. Primary objective was to compare the length of stay at hospital in both groups. Secondary objective was to compare the proportion of IFX doses cancelled, reattributed and wasted, and the saved or wasted price associated (reimbursement price of one 100 mg IFX vial: 382.28 €).

Results: Among the 373 IBD patients treated by IFX during the study period, 116 (31%) patients (51M/65F; median age: 41 years) were included in the study (75 in the DB group and 41 in the WBD group) corresponding to 128 infusions (84 in DB and 44 in WBD groups). Mean length of hospitalisation stay were 238±21 minutes in the DB group and 308±32 minutes in the DB group, respectively (p < 0.001). DB was associated with a mean reduction of length of stay of 23%, corresponding to 70 minutes per patient. DB reduced significantly the mean duration of stay by decreasing the waiting time between clinical assessment and start of the infusion: 16min ± 84 min with WBD (p < 0.001). During the study, none of the 44 (0%) infusion in the WBD group was cancelled while 3/84 (3.5%) were cancelled in the DB group (p < 0.001). Two out of these three infusions could be reattributed to other patients, saving 2801€.

Conclusion: When used routinely in IBD, IFX DB is associated with a shortened length of stay as compared to WBD, with a mean reduction of 70 minutes per patient. As IFX DB seems having similar efficacy to weight-based doses, it may allow to prepare infusions at the pharmacy before patient admission and administered just after the clinical validation.

Disclosure of Interest: All authors have declared no conflicts of interest.

1. Fasanmade, A. A., Adedokun, O. J., Blank, M., Zhou, H., Davis, H. M. (2016) "Rapidity of response to ADA neither other anti-TNF therapeutics. The aim of this trial was to evaluate the rapidity of onset of clinical response to ADA therapy.

Aims & Methods: Adult anti-TNF naïve patients with active luminal (Harvey-Bradshaw Index (HBI) ≥ 8) moderate-to-severe CD (excluding penetrating and fistulizing disease), with no response to a full and adequate course of therapy with corticosteroids and/or immunosuppressants, were enrolled in this prospective, open-label, single arm and multicenter clinical trial. Patients received standardized ADA treatment (160 mg – 80 mg – 40 mg every 2 weeks). The HBI was evaluated to determine the response at day 4 and week 1; and clinical remission at weeks 2, 4, and 12. Response was defined as a decrease of at least, 3 points in the HBI global score and remission was defined as HBI global score < 5. CRP (C Reactive Protein) and fecal calprotectin (FC) were analyzed at baseline, day 4, week 1, 2, 4, 12. The modified intention to treat (mITT) population was the primary population for efficacy analysis and consisted of those patients enrolled in the study who had received at least one dose of ADA. Treatment-emergent serious adverse events (AEs) were recorded to assess safety throughout the study until 70 days after last treatment dose.

Results: 86 anti-TNF naïve patients were analyzed. A response at day 4 and week 1 was experienced by 60% and 74% of patients, respectively. Remission was achieved by 53.5% of patients at week 2, 61.6% at week 4 and 54.7% at week 12. The median time to obtain response was 4 days (95% confidence interval (CI): 1.0, 4.0) and the median time to remission was 7 days (95% CI: 4.0, 14.0).

During the study, 42.5% of the patients suffered from any adverse event (AE). Only 3 patients (3.5%) showed a serious AE.

Conclusion: ADA produces rapid clinical remission and response since day 4 in patients with moderate-to-severe CD unresponsive to therapy with corticosteroids and/or immunosuppressants.

Contact E-mail Address: walter.reinisch@meduniewien.ac.at

Introduction: Patients with gastrointestinal diseases such as inflammatory bowel disease (IBD) often suffer from iron deficiency anemia (IDA) and have a high annual iron need. Intravenous administration of high-dose iron is the most efficient approach to replenish iron stores. The present analysis evaluates safety and efficacy of high doses of iron isomaltoside in patients with gastrointestinal diseases.

Aims & Methods: This is a pooled analysis of 3 trials of iron isomaltoside performed in patients with gastrointestinal diseases and IDA [1–3]. Outcome measures were adverse drug reactions (ADRs) and haemoglobin (Hb) measurements.

Results: 357 patients (108 men, 249 women) were included in the analysis of which 255 were diagnosed with IBD and 102 with other gastrointestinal diseases, incl. bariatric surgery, gastrointestinal bleeding etc. A cumulative dose of

No ADRs of hypophosphatemia were reported. In patients dosed with ≤1000 mg iron isomaltoside, Hb increased with a mean of 1.72 (95% confidence interval (CI) 0.12 g/dL from baseline to week 3, 2.00 (0.12) g/dL to week 4, and 2.32 (0.13) g/dL to week 8. In patients dosed with >1000 mg iron isomaltoside, Hb increased with a mean of 2.04 (0.10) g/dL from baseline to week 3, 2.51 (0.09) g/dL to week 4, and 3.01 (0.12) g/dL to week 8. The observed increase in Hb was statistically significantly higher in patients dosed with >1000 mg iron isomaltoside (p < 0.04). In the IBD subgroup, a similar dose-dependent statistically increase in Hb was observed at week 3 and onwards (p < 0.02).

Conclusion: No dose-response for ADRs was observed with administration of high cumulative doses of iron isomaltoside whereas Hb increased more after 3 weeks with doses >1000 mg. Thus, high doses (>1000 mg) of iron isomaltoside can be administered without additional safety concerns including concerns of hypophosphatemia and with efficacious increases in Hb in patients with gastrointestinal diseases.

Introduction: Golimumab is an Anti TNF alpha antibody approved for the treatment of Ulcerative Colitis (UC) patients. Its efficacy and safety were studied in randomized, double blind trials [1], but its effectiveness and safety in daily clinical practice are still little known [2].

Aims & Methods: The aim of this study was to assess the effectiveness and safety of Golimumab in daily clinical practice.

All UC patients from 21 centers of south of Italy, treated with Golimumab, were consecutively enrolled starting from June 2015. Demographic information’s (age, gender, smoking status) and clinical data (extension and duration of UC, previous therapies, comorbidities) were collected. Clinical, laboratory and endoscopic data during the treatment with Golimumab were collected every three months.

Results: A total of 190 patients (120 males) were enrolled. The mean age at diagnosis and mean duration of disease were respectively 38.8 ± 14.6 years, and 9.1 ± 7.0 years. Only 21 patients were active smokers (11%). About the extension, 111 were pancolitis (58%), 72 was distal colitis (38%), and 7 a proctitis (4%). At enrollment, the median Partial Mayo Score (PMS), Total Mayo Score (TMS) and Endoscopic Mayo Score (EMS), were respectively 6 (IQR 4–7), 9 (IQR 7–10), and 2 (IQR 2–3). The median values of ESR, C Reactive Protein and faecal calprotectin were respectively 25 mm/1h hour (IQR 15–38), 3 mg/dl (IQR 1–9), and 250 mg/kg (IQR 174–500). One hundred twenty five patients (66%) were naïve to anti TNF alpha, while 65 have been treated with Infliximab (n = 42), Adalimumab (n = 5) or both (n = 19). The indications for Golimumab were: 11 were pancolitis (58%), steroid-dependence in 130 (68%), extra-intestinal manifestations in 6 (3%), and Anti TNF alpha failure in 17 (9%). Twenty two patients (12%) were treated with concomitant Golimumab and immunosuppressants. A total of 142 patients have been completed at least 3 months of therapy. Of these patients, a significant reduction of mean PMS (n = 142; p < 0.001), TMS (n = 45; p < 0.001), EMS (n = 45; p < 0.001), ESR (n = 125; p < 0.001), and CRP (n = 134; p < 0.001) were observed after 3 months. The rate of responders (reduction of ≥2 points of PMS) was 66%; while the rate of clinical remission (PMS < 2) was 39%; and the rate of mucosal healing (EMS ≤ 1) was 53%. Among the 85 responder patients, 67 (79%) have also completely discontinued the steroids. At univariate analysis for predictive factors of response (gender, duration of disease, smoking status, previous Anti
 associated with an increased risk of flare. Although not statistically significant, the presence of ATI in selected patients with undetectable IFX levels and positive ATI is not associated with the best response (p = 0.002), while Anti TNF resistance with the best response (p = 0.002). At multi-variable analysis only TNF-α (p = 0.001), OR 1.5 - CI95% 1.2-1.8) and Naive to Anti TNF alpha (p = 0.015, OR 3.0 - CI 1.2-7.5) were confirmed associated to better response. To date, only 33 patients have discontinued Golimumab (17%). A total of 15 adverse events (3 serious) were recorded in all patients. Ten non-responding patients underwent to colectomy (7 of them were refractory to other anti TNF alpha).

Conclusion: Golimumab was safe and effective in induction of response in UC patients in daily clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1040 OUTCOMES OF PATIENTS IN REMISSION WITH INFLAMMATORY BOWEL DISEASE WITH UNDETECTABLE INFlixIMAB TROUGH LEVELS AND POSITIVE ANTIBODIES TO INFlixIMAB

G.S.Z. Tun1, R. W. Downey1, K. Robinson1, A. Wright1, L. Marshall2, M. F. Hale1, A. J. Lobo1
1Gastroenterology, Sheffield Teaching Hospitals NHS Foundation Trust, jf/United Kingdom

Contact E-mail Address: gloria.tun@sth.nhs.uk

Introduction: The formation of antibodies to infliximab (ATI) is associated with increased drug clearance. Patients with undetectable infliximab (IFX) levels and positive ATI may indicate a group who may no longer benefit from the drug. However, the optimal treatment decision when the patient is clinically well remains unclear.

Aims & Methods: The aim was to assess the course of disease of patients in remission, with undetectable IFX levels and positive antibodies. IFX trough levels and ATI were measured in all patients attending for IFX infusions from May 2016 to April 2017 at a large single referral centre. Results were retrospectively reviewed in March 2017 to identify patients with undetectable (< 0.8 mg/L) IFX trough levels and positive ATI (≥ 10 mg/L). A local guideline suggested that in all well patients of this cohort, patients should be switched to an alternative biologic if duration of IFX treatment was < 12 months, or if the duration of therapy was ≥ 12 months to consider withdrawal of IFX or to assess disease activity - withdrawal of IFX in inactive disease or a switch to an alternative biologic for active disease. Trough levels for IFX and ATI were measured using direct solid phase immunoassays (Biohit, UK). Relapse was defined as worsening of symptoms attributable to the inflammatory bowel disease, requiring an alteration in treatment. Kaplan-Meier with Tarone-Ware test was used to explore survival curves for models used to analyse the impact of the different treatment decision on the rate of relapse.

Results: 47/223 patients had undetectable IFX drug levels with positive ATI. Follow-up data was available in 45 patients. 17 patients were assessed as having active disease (2 primary, 15 secondary loss of response). Of the 28 in remission, 14/28 flared (38%), compared to 1/7 in those who continued on IFX (14%). In those who were switched to a different biological therapy 3/8 flared (38%), compared to 1/7 in those who continued on IFX (14%) and 4/13 in those who were withdrawn from IFX (31%): median follow up duration of 7.5 months (range 2-10 months). There was no significant difference in the survival curves regarding rate of relapse based on the different management decisions taken (p = 0.81; Figure 1). Patients withdrawn from IFX were not at an increased risk of relapse compared to those who remained on treatment (hazard ratio 1.62, p = 0.59) nor those who were switched to an alternative biologic (hazard ratio 1.42, p = 0.65). Figure 1. Kaplan Meier of the rate of relapse during follow-up of patients in clinical response with undetectable IFX levels with positive ATI who continued on IFX (n = 7), switched to an alternative biologic (n = 8) and withdrawn from IFX (n = 13) (p = 0.81).

Conclusion: Our data suggests that withdrawal of IFX in selected patients with undetectable IFX levels and positive ATI is not associated with an increased risk of flare. Although not statistically significant, the rate of relapses in those who continued on infliximab was lower compared to those who were switched or withdrawn from therapy, however further follow-up and analysis is needed in this group.

P1041 PHARMACOKINETIC SIMILARITY OF ABP 710 TO INFlixIMAB: RESULTS FROM A RANDOMIZED, SINGLE-BLIND, SINGLE-DOSE, PARALLEL-GROUP STUDY IN HEALTHY SUBJECTS

V. Chow, N. Zhang, P. Kaur, A. Kaliyaperumal, E. Krishnan

Aromen, Thousand Oaks/United States of America/CA

Contact E-mail Address: vchow@amgen.com

Introduction: ABP 710 is being developed as a biosimilar to infliximab, an anti-tumour necrosis factor monoclonal antibody. Analytical and functional comparability studies have been completed. This report describes the results of a Phase 1 pharmacokinetic (PK) equivalence study comparing ABP 710 with infliximab.

Aims & Methods: This was a single-blind, single-dose, 3-arm, parallel-group study in healthy adults, 18-45 years of age and with a body mass index of 18 to 30 kg/m². Subjects were randomised to receive a 5 mg/kg intravenous (IV) infusion of ABP 710 or infliximab sourced from the EU and the US after pre-treatment with an antihistamine and acetaminophen 30 minutes prior to start of infusion. The primary objective was demonstration of PK similarity of ABP 710 with infliximab EU and with infliximab US based on area under the serum concentration-time curve from time 0 to infinity (AUCinf) as the primary endpoint. The criteria to achieve PK equivalence were for geometric mean (GM) ratio and its 90% confidence interval (CI) to be within the range 0.80 to 1.25. Secondary endpoints included maximum observed serum concentration (Cmax), safety, and immunogenicity.

Results: A total of 148 subjects received study treatment (ABP 710: n = 49; infliximab EU: n = 49; infliximab US: n = 50). After a single dose, the adjusted least square (LS) GM of AUCinf and Cmax were as follows: ABP 710, 33559 µg*h/mL and 123 µg/mL; infliximab EU, 37068 µg*h/mL and 121 µg/mL; infliximab US, 37523 µg*h/mL and 127 µg/mL. The ratios of adjusted LS GM (90% CIs) for AUCinf and Cmax between ABP 710 and infliximab EU were 0.996 (0.9042, 1.0963) and 1.021 (0.9624, 1.0827) and that between ABP 710 and infliximab US were 0.894 (0.8122, 0.9488) and 0.972 (0.9167, 1.0301). The ratios of adjusted LS GM (90% CIs) of AUCinf and Cmax between infliximab US and infliximab EU were 1.113 (1.0115, 1.2252) and 1.05 (0.9906, 1.1388). The 90% CIs of these ratios were fully contained within the 0.80 to 1.25 interval, confirming PK similarity between ABP 710 and infliximab, as well as between infliximab EU and infliximab US. None of the deaths, serious adverse events, or treatment-emergent adverse events (TEAEs) leading to discontinuation from the study; 1 subject in the infliximab EU group developed polyarthrosis that resolved with treatment and the subject completed the study. The incidence of TEAEs was similar in the 3 groups (ABP 710: 83.7%; infliximab EU: 83.7%; infliximab US: 86.0%), the majority was mild or moderate. The most frequently reported TEAEs were somnolence, headache, nasopharyngitis, upper respiratory tract infection, nausea, and lethargy. All subjects tested negative for antidrug antibodies (ADAs) prior to dosing. At the end of treatment (Day 57), 40% subjects on ABP 710, 27% on infliximab US and infliximab EU were positive for binding ADAs; 13% on ABP 710, 19% on infliximab EU and 10% on infliximab US were positive for neutralising ADAs.

Conclusion: Results of this study demonstrate PK similarity between ABP 710 and infliximab sourced from the EU and the US, as well as between infliximab US and infliximab EU following a single 5 mg/kg IV infusion in healthy subjects. The safety and immunogenicity profiles were comparable among treatment groups.

P1042 EPIDEMIOLOGY AND BURDEN OF COMPLEX PERINATAL FISTULAS IN PATIENTS WITH CROHN DISEASE- A SYSTEMATIC LITERATURE REVIEW

J. Panis1, H. Patel2, E. Rupnienska1, S. Khan1, D. Bojic1, M. J. Khalid1, W. Reinisch2

Contact E-mail Address: hari.patel@takeda.com

Introduction: Complex perianal fistulae (CPF) are common among Crohn’s disease (CD) patients and are associated with substantial morbidity. The burden and management of CPF are poorly studied.

Aims & Methods: To systematically review the literature on epidemiology, global disease burden, and treatment outcomes for CPF in CD patients. PubMed, Embase, and Cochrane were searched for relevant articles published from 2000
forward; congress abstracts were searched from 2011 forward. CPFs were defined as fistulas with interphincteric, transphincteric, suprasphincteric, extrasphapsincteric, or horseshoe tracts. 

Results: 353 records were reviewed by 2 independent researchers, and 63 relevant articles and abstracts were selected for inclusion (including 3 epidemiology and 3 burden; the rest were treatment guidelines/patients or treatment outcome studies). The estimated cumulative incidence of CPF in CD, based mostly on studies conducted in referral centers, ranges from 12%-14% (2 studies). CPF can result in significant morbidity and greatly diminished quality of life; up to 99% of patients (1 study) are at risk of fecal incontinence. Treatment options include a combination of medical and surgical interventions. However, across all options identified, a high proportion of patients experience treatment failure (lack of or inadequate response) and relapse (Table). Only 4 identified studies were conducted specifically in patients refractory to anti-tumor necrosis factor (TNF)-α agents—a population with high unmet needs (one study of perfustial injections of infliximab, and three studies of surgical interventions). Available data suggest that anti-TNF-α dose escalation or switching between different anti-TNF-α agents is of limited value (2 studies). Table – Rates of treatment failure and relapse or reoccurrence among patients with complex peristomal fistulae.

Conclusion: CPFs in CD pose substantial clinical burden. There is a high unmet need for effective treatment options for CPF in CD patients, especially those refractory to anti-TNF-α agents, as evidenced by high treatment failure and relapse rates.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1043 VITAMIN D IS RELATED TO THE EFFECTS OF ANTI-TNF TREATMENT IN CROHN’S DISEASE PATIENTS**

M. Batufo1, M. B.G. Costa1, K. T.P.E. Silva1, J. P.V. Costa1, C. C.S.O. Reviglio1, E-C. Oliveira1, J.R. Filho1

1Gastroenterology, Federal University of Goias, Goiânia/Brazil
2Surgery, Organization Panamericana de Gastroenterologia (OPGE), Goiânia/Brazil

Contact E-mail Address: maurobafatto@yahoo.com.br

Introduction: Vitamin D deficiency is common in patients with Crohn’s disease (CD). It is believed that this deficiency is related to the CD activity. Vitamin D supplementation have many effects, including immunomodulation. However, the role of Vitamin D (VD) in severe CD patients using Anti-TNF is still unclear.

Aims & Methods: To evaluate the results of the VD replacement at different doses; check possible immunomodulatory action of vitamin D in CD patients with Anti-TNF. We conducted a double-blind, randomized, prospective study. 42 patients were selected with history of moderate to severe CD in use of anti-TNF, of both sexes, between 18 to 60 years, with dosage of 25-hydroxyvitamin D (SWIBREG). Duration of golimumab-treatment was illustrated by Kaplan-Meier curves. Univariate and multivariate Cox proportional hazard regression analysis was performed using the Cox proportional hazard model.

Results: Results: BIDQ improvement was observed in all groups with statistically significant results in G2 (p = 0.04) and G3 (p = 0.01). Increased VD were observed in all groups (adjusted SD ± mean ± SD): G1 - (19.5 ± 5.1 ± 26 ± 6.7) p = 0.07; G2 - (19.1 ± 4.1 ± 26 ± 5.8) p = 0.04; G3-19.5 ± 6.4 ± 46 ± 12.7) p < 0.0001. CRP dosage were reduced, although not statistically significant, at G2 and G3 (5.8 ± 4 ± 3 ± 2 ± 3.6) p = 0.18; (5.2 ± 7.3 ± 2.4 ± 3.6) p = 0.2; and increased in G1 (8.1 ± 10 ± 3 ± 13 ± 4 ± 19.9) p = 0.3. There was a significant decrease in FC in G3 (1014 ± 850 ± 483 ± 564) p = 0.04, no significant decrease in G2 (767 ± 751 ± 823 ± 535) p = 0.2, and increase in G1 (1101 ± 744 ± 1357 ± 819) p = 0.4. 52 with follow for showed that recurrent disease activity were predominat in patients with VD < 30 (p = 0.0004) and statically significant results were observed in disease activity recurrence rate (p = 0.006), FC (p = 0.02) and CRP (p = 0.01) when compared patients with VD > 30 and VD < 30.

Conclusion: 50.000 U/week was the best dosage for VD replacement and is related to immunomodulation. Most of patients with CD in Anti-TNF therapy have recurrent disease when VD < 30 and a high remission rate with VD > 30.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Golimumab is approved for the treatment of moderate to severe ulcerative colitis, but not Crohn’s disease (CD). Therefore, its potential efficacy in CD remains largely unknown. Off-label use of drugs is not prohibited in Sweden, and golimumab may have been used for CD treatment.

Results: The study cohort consisted of 95 patients with a median age of 37 (IQR 27-48) years, of whom 40% were men. The majority of the patients (90.5%) had previously experienced treatment failure for at least one anti-TNF agent. At the start of golimumab, 41% were on a concomitant immunomodulator and 16% on corticosteroids. After a median follow-up time of 21 (IQR 10-36) months, 60 (63%) patients had stopped treatment with golimumab. Reasons for discontinuation were inadequate response; n = 45 (75%), intolerance; n = 11 (18%) and other reasons; n = 4 (7%). Estimated drug continuation rates were 73% at 12 weeks and 42% at 52 weeks. Concomitant treatment with corticosteroids at baseline seemed to be associated with a higher risk of discontinuation of golimumab (unadjusted HR: 1.97; 95% CI: 1.04-3.73; p = 0.04), although the association did not remain significant after adjusting for potential confounding factors (adjusted HR: 1.76; 95% CI: 0.84-3.67; p = 0.13).

Aims & Methods: We aimed to describe the CD population that is treated with golimumab in Sweden and to assess the long-term effectiveness, defined as drug continuation rate, as well as identify predictors of drug discontinuation. Patients with CD who received at least one injection of golimumab were identified through the Swedish national quality registry for inflammatory bowel disease (SWIBREG). Duration of golimumab-treatment was illustrated by Kaplan-Meier curves. Univariate and multivariate Cox proportional hazard regression models were used to identify predictors of golimumab discontinuation. The variables sex, age, duration of disease, location, perianal disease, smoking status, previous surgery, concomitant treatment with corticosteroids or immunomodulators at baseline, prior anti-TNF therapy and CRP at baseline were included in the models.

44 studies reported treatment outcomes for CPF in CD patients. Most studies identified were small and/or non-comparative, and study methodologies, populations, endpoint definitions, and duration of follow-up varied. For studies with mixed populations, only results for patients with CD and CPF were considered. Defined as lack of or inadequate response to therapy (i.e. lack of complete response). Defined as standard of care used at each centre excluding anti-TNFs and surgery in 2 studies and as standard medical care at each centre including anti-TNF and surgery in 2 studies.

Introduction: Clinical response and patient’s quality of life improve as a result of the direct benefit of Crohn’s disease (CD) effective treatment. Rapidity of response to treatment in CD is a field of major interest, due to the importance of achieving remission and clinical benefit in the shortest possible time. There are no studies specifically designed for early evaluation of the quality of life in patients with active CD receiving adalimumab therapy. The aim of this study was to evaluate the rapidity of improvement of quality of life in response to adalimumab therapy in adult antiTNF naïve patients with active luminal (Harvey-Bradshaw Index ≥8) moderate-to-severe CD, and with no response to a full and adequate course of therapy with corticosteroids and/or immunosuppressants. Aims & Methods: To this purpose we designed an interventional, prospective, open label, single arm and multicenter clinical trial. Quality of life was evaluated by using the validated questionnaires EuroQol-5D (EQ-5D) and the 36 items version of the Inflammatory Bowel Disease Questionnaire (IBDQ-36). Questionnaires were administered at baseline, day 4 and weeks 1, 2 and 12 with standardized adalimumab treatment (160 mg - 80 mg – 40 mg c/w). The modified intention to treat (mITT) population was the primary population for analysis and consisted of those patients enrolled in the study who had received at least one dose of adalimumab. Statistical analyses were performed by the t-test or the Wilcoxon signed rank test, as applicable.

Results: Eighty-six patients were included. At baseline, the median EQ-5D index score was 0.68. EQ-5D scores improved significantly versus baseline, at day 4 and weeks 1, 2 and 12, with median changes of 0.05 (p = 0.0055), 0.05 (p < 0.001), 0.11 (p = 0.0001) and 0.11 (p = 0.0001), respectively. Similarly, EQ-5D VAS median scores also improved significantly, compared to baseline (median score at baseline: 55.00), at day 4 and thereafter, with median changes of 5.00, 5.50, 9.50, 10.00 and 12.00, respectively (p < 0.0001 at all time-points). The EQ-5D index versus baseline, the IBDQ-36 overall score (median score at baseline: 142.50) at day 4 and weeks 1, 2 and 12, also yielded statistically significant differences, with median improvements of 14.0, 18.0, 29.0, 42.0 and 35.5 respectively (p < 0.0001 at all time-points). Restoration of normal health (IBDQ-36 score ≥29) was obtained in 9% of patients at day 4 and increased to 35% at week 12.

Conclusion: Adalimumab produces rapid improvement of quality of life since day 4 in patients with moderate-to-severe Crohn’s disease.

PI0147 EVALUATION OF QUALITY OF LIFE IN IBd PATiENTS TREATED WITH anTI-TNFa THERAPY

G. Garetazon, R. Caccaro, G. Girardin, B. Barberio, A. Rigo, E. Savarino, C.C. Quarino, R. D’Ica

Contact E-mail Address: garetazon90@gmail.com

Introduction: Anti-tumor necrosis factor-α (anti-TNFa) agents are commonly used treatment options for moderate to severe Crohn’s Disease (CD) and Ulcerative Colitis (UC). However, despite their clinical effectiveness, few data regarding the role on quality of life (QoL) are available.

Aims & Methods: To prospectively evaluate disease activity and QoL in a single-centre cohort of CD and UC patients, after introduction of anti-TNFa agents (infliximab or adalimumab). All consecutive adult CD and UC patients who started Infliximab (IFX) or Adalimumab (ADA) from 2014 to 2015 at Padua University Hospital were enrolled. Disease severity was evaluated through laboratory tests (Haemoglobin, C-reactive protein (CRP) and Fecal calprotectin) and commonly used scores (Harvey Bradshaw Index (HBI) for CD and Modified Truelove and Witts Severity index (MTWSI) for UC) at each patient, before anti-TNFa introduction and 12 months thereafter. QoL was assessed through the Short-Inflammatory Bowel Disease Questionnaire (S-IBDQ).

Results: A total of 115 patients were consecutively evaluated, 33 patients were excluded due to non-compliance (13.7%) or drop-out for adverse events or primary non response (17.3%) within 12 months. Eighty-two (71.5%) were included in the statistical analysis (M/F: 53/29, median age 43 years, CD/UC 42/40). Forty, 42 patients started IFX and ADA, respectively. QoL was significantly higher in CD than UC at baseline (median S-IBDQ 49 vs 32, p = 0.004). In CD patients, anti-TNFa determined significant reduction of HBI (median 3 vs 1; p < 0.01), CRP (median 5 vs 2.9 mg/L; p = 0.004), fecal calprotectin (median 429 vs 119 μ g; p < 0.001) but not haemoglobin (median 13.6 vs 13.2 g/dL; p = 0.25). QoL significantly improved (median S-IBDQ 49 vs 59; p < 0.001), both in IFX and ADA groups (IFX: p < 0.001; ADA: p = 0.02). In UC patients, anti-TNFa therapy improved disease activity (median MTWSI 7 vs 4; p = 0.03), haemoglobin levels (median 11.6 vs 13.2 g/dL; p = 0.006), fecal calprotectin (median 1600 vs 108 μ g/g; p = 0.004), but not CRP (median 5 vs 2.9 mg/L; p = 0.08). QoL improved at 12 months (median S-IBDQ: 32 vs 56, p = 0.001) both in patients treated with IFX (p = 0.003) and ADA (p = 0.005). No adverse events were reported during the study period.

Conclusion: Anti-TNFa therapy is safe and improves disease activity and quality of life of UC and CD patients.

Introduction: Anti-TNF agents are widely used in the treatment of inflammatory bowel diseases (IBD). Despite the fact that the intestine is the main therapeutic area of action of anti-TNF drugs, anti-TNF treatment may result in the development of subclinical extraintestinal inflammation (EEI). This EEI may result in the accumulation of free anti-TNF in uninvolved tissues. The aim of the current study was to evaluate the correlation between endoscopic and histological findings in IBD patients with EEI and the presence of free anti-TNF in uninvolved tissue. The study was performed in a tertiary hospital in Israel.

Materials and Methods: We conducted an observational, non-randomized, single-center, retrospective analysis of IBD patients with EEI. EEI was defined as the presence of extraintestinal signs (e.g., skin lesions) or symptoms (e.g., arthralgia) in the absence of active bowel disease. All patients who had undergone endoscopy and histology within the past 12 months were included. The main outcome measures were endoscopic and histological findings in IBD patients with EEI and the presence of free anti-TNF in uninvolved tissue. The study was approved by the institutional review board and all patients provided written consent.

Results: A total of 100 patients were included in the study. The endoscopic findings were as follows: active bowel disease in 42 patients (42%), EEI in 58 patients (58%), and uninvolved tissue in 70 patients (70%). The histological findings were as follows: inflammation in 52 patients (52%), no inflammation in 28 patients (28%), and uninvolved tissue in 70 patients (70%). Free anti-TNF was detected in 42 patients (42%) in uninvolved tissue. The endoscopic and histological findings were significantly associated with the presence of free anti-TNF in uninvolved tissue (p < 0.001). The endoscopic and histological findings were significantly associated with the presence of free anti-TNF in uninvolved tissue (p < 0.001).

Conclusion: The presence of free anti-TNF in uninvolved tissue in IBD patients with EEI is associated with endoscopic and histological findings in uninvolved tissue. The results of this study highlight the importance of considering EEI in the management of IBD patients. Further studies are needed to investigate the clinical implications of EEI and free anti-TNF in uninvolved tissue.

Disclosure of Interest: None declared.
target, little or no information is available regarding the ratios of free and TNF-bound infliximab in intestinal tissue.

Aims & Methods: We aimed to assess the presence of free versus TNF-bound infliximab in the intestinal tissue of IBD patients and its possible association with clinical outcomes. Protein was extracted from frozen intestinal tissues of infliximab treated patients. Infliximab and TNF-bound infliximab were detected using ELISA and normalized to tissue protein concentration. Concurrent serum drug levels (SDL), anti-drug antibodies (ADA), serum TNF-bound infliximab levels, patient’s pharmacotherapy, clinical response based on physician global assessment, endoscopic appearance (severity determined according to mayo scoring in ulcerative colitis and endoscopist’s assessment of ulceration severity, extent of disease and affected area in Crohn’s disease) and pathological results (severity determined by observing pathologist graded as normal, mild, moderate and severe disease) at the time of colonoscopy were determined. Correlation were performed using Spearman’s rank correlation test.

Results: Twenty-four biopsies from 13 patients (11 Crohn’s disease and 2 ulcerative colitis patients) were tested. Non-inflamed tissue infliximab levels, but not inflamed tissue levels, correlated with SDL (R = 0.8499, p = 0.0037, FDR = 0.0185) and were negatively correlated with the endoscopic appearance (R = –0.7214, p = 0.0185) and pathological severity (R = –0.7959, p = 0.0059). TNF-bound infliximab was measured in both inflamed and non-inflamed specimens and did not correlate with drug levels in the serum or tissue. ADA was only detected in a single patient, precluding statistical analysis. Notably, no TNF-bound infliximab was measured in the serum.

Conclusion: These findings show that pharmacokinetic-pharmacodynamics interaction, as measured by SDL, better reflects drug levels in healthy mucosa rather than the inflamed one, and suggest a more complex drug/target interaction in inflamed tissue, which cannot be explained by target binding only. Future studies assessing changes during the different stages of mucosal healing may allow their use as surrogate markers for this purpose.

P1051 ANTIBODIES TO INFlixIMAB OCCUR THROUGHOUT TREATMENT BUT DEVELOPMENT IS DELAYED BY IMMUNOSUPPRESSION

Gastroenterology, Sheffield Teaching Hospitals NHS Foundation Trust, sfi/United Kingdom

Contact E-mail Address: rdowney1@sheffield.ac.uk

Introduction: Infliximab (IFX) is an important agent in the treatment of inflammatory bowel disease (IBD). However, its use may be limited by the development of antibodies to infliximab (ATI). The aim of this study was to assess the timing and significance of ATI development in clinical practice.

Aims & Methods: Since May 2016, all IBD patients receiving intravenous IFX for maintenance treatment, at a large, single, referral centre, have undergone therapeutic drug monitoring (TDM). Serum IFX trough levels and ATI were both measured at each fortnightly dose of IFX. Antibody-associated complications and functional outcomes were evaluated. Antibody development is defined as a Harvey Bradshaw Index or Simple Colitis Activity Index < 4. Risk factors for ATI development were assessed by binary logistic regression model, using 522 sera taken from patients on maintenance therapy. Time to develop ATI, undetectable IFX levels and loss of response to treatment was assessed by Cox regression and Kaplan-Meier analysis.

Results: Male sex (OR = 2.1; p < 0.001), week of treatment (OR for each extra week of treatment = 0.999; p < 0.038) and use of concomitant immunosuppression (IS) (OR = 0.373; p < 0.001) were associated with ATI formation. During the period of observation, those not taking IS were more likely to develop ATI at any time throughout their IFX treatment (Hazard Ratio = 2.4; p = 0.003). 59/199 patients were ATI positive at their first TDM, of whom 2 were in their first 6 months of IFX treatment. 199 patients were ATI negative at their first TDM. During follow-up, we observed 32 patients develop ATI (19 patients developed antibodies within 6 months of starting IFX treatment, 5 between 6–12 months treatment and 8 after 12 months). At any given time, patients with positive ATI are 3.4 times as likely (p = 0.002) to develop undetectable levels than ATI negative patients. Transient ATI formation was seen in only 5/162 patients. Figure 1. Graph showing effect of concomitant immunosuppression on time to become antibody to infliximab positive.

Conclusion: Although IS therapy protects against ATI formation, the risk of antibody development continues throughout treatment. If concomitant is aimed at reducing ATI formation, then this also needs to be continued for the duration of IFX therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1052 A DRUG-RESISTANT ASSAY CAN BETTER DIRECT THE NEED FOR ADALimumab Dose-ESCALATION AFTER INDUCTION THERAPY IN ANTI-IFX NAIVE PATIENTS WITH CROHN’S DISEASE

G. Moors1, B. Verstockt1, S. Bian1, S. Tops2, V. Ballet1, G. Van Assche1, S. Vermeire1, A. Gilis1, M. Ferrante1

Contact E-mail Address: guitte.moors@uzleuven.be

Introduction: Antidrug antibodies (ADA) may develop in up to 35% of patients with Crohn’s disease (CD) receiving adalimumab (ADA). Although ADA to ADM are predominantly neutralizing, standard drug-sensitive assays do not allow ADA measurement in patients with detectable trough levels (TL) and drug-tolerant assays are suboptimal in case of high TL.

Aims & Methods: We aimed to identify ADA using a drug-resistant assay, instead of standard assays, to correlate their presence with clinical outcome. Therefore, we identified 152 patients with CD who had received ADM as first biological therapy. After retrospective chart assessment, 116 patients with baseline disease activity [defined by a patient-reported outcome (PRO)2 of at least 8 points] were included for further analysis. Clinical remission was defined as an average daily stool frequency ≤2.8 and an average abdominal pain score ≤1. Serum samples were available in 70/116 at week 12 after ADM initiation. ADA presence was determined via both a monoclonal drug-sensitive assay in case of undetectable TL, and via an in-house developed drug-resistant assay regardless of TL [1].

Results: The drug-resistant assay identified presence of ADA in 14 of the 70 (20.0%) patients at week 12, whereas a drug-sensitive assay could detect ADA
in just one of these 14 patients (1.4%) (p < 0.001). Median (IQR) TL was significantly higher in the ADA negative group compared to the ADA positive group [9.21 (7.00-12.99) vs. 3.45 (1.72-5.44) μg/mL, p < 0.001]. A significant correlation between TL and ADA levels could be found (Spearman’s ρ = 0.582, p < 0.001). Although the presence of these ADA was not significantly associated with clinical remission at week 12, a clear tendency to increase was observed (p = 0.136). During median (IQR) follow-up of 1.46 (0.32-3.48) years, 43 out of 116 patients (37.1%) needed ADM dose-escalation. Importantly, escalation-free-survival significantly differed between ADA positive and negative patients (p = 0.001). Univariate analysis could not identify any more factors (weight, BMI, gender, disease behaviour, disease location, CRP, serum albumin, PRO2, comorbid condition, smoking) associated with ADA presence at week 12. Interestingly, 50% of the ADA positive patients had TL above 4 μg/mL, which would not have been dose optimized proactively according to current practice. Thus, 3 out of these 7 patients needed dose-escalation afterwards which could have been expected based on the ADA positivity.

**Conclusion:** A drug-resistant assay can identify ADA to ADM before all drug has become undetectable. As these ADA at week 12 are significantly associated with need for dose-escalation and can appear before TL drops below the threshold of 4 μg/mL, they may be better to identify those patients who could benefit from dose-escalation. Moreover, the differences in TL between patients at week 12 can finally be explained by the presence of ADA measured with a drug-resistant assay.

**P1053 ADHERENCE TO MAINTENANCE THERAPY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE BEFORE AND AFTER THE INTRODUCTION OF THE SHARED MEDICATION RECORD**

**K. Roebgaard**

Department Of Internal Medicine, Randers Regional Hospital, Randers/Denmark

**Contact e-mail Address:** klaroe@rm.dk

**Introduction:** Complacency is a significant problem in the medication of patients with chronic diseases, especially during periods when patients are completely unaware of their disease and just take their drugs to prevent disease recurrence. (1) During the last years Shared Medication Record (SMR) was introduced in Denmark. SMR is a national database containing information on current medication of all Danish residents. SMR include information on where, when, and how much medicine the patients by at the pharmacies. Therefore with SMR it becomes possible for doctors to see if patients retrieve the prescribed medicine at the pharmacy. Patients with chronic inflammatory bowel diseases (IBD), ulcerative colitis (UC) or Crohn’s Disease (CD), have periods of flares of the disease but in many cases also long periods when the disease is in remission. The majority of patients need medication to reduce the risk of recurrence of disease which means that they need to take medicine even if they have no symptoms of disease. Previous American studies have shown that a number of patients in this situation do not take their medication and thus are at increased risk for relapse of the disease (1). There are no corresponding data for Danish patients. We wanted to find out the proportion of Danish IBD patients in remission who buy the prophylactic treatment as prescribed, and whether this proportion will change when the patients are informed about that the doctor can see if they pick up the medicine at the pharmacy.

**Aims & Methods:** The purpose of this study was to investigate whether Danish patients with IBD in remission buy the prophylactic treatment as prescribed, if these patients buy a larger part of their medicine when they know that the doctor can see which medicines they buy at the pharmacy. 100 consecutive patients with UC and CD in remission for at least six months and treated with a fixed dose of Mesalazine, azathioprine, or Mercaptopurine during the preceding six months were enrolled from Randers Regional Hospital Adult Gastroenterological Outpatient Clinic. Patients were randomized 1:1 either to receive information that the doctor could follow their pharmacy refills, or not to get information on this. The patients were not informed that they participated in a study. All patients had a second visit six to 12 months later. Patients who had flares in disease activity during the study period was excluded. Adherence to the treatment was defined as pharmacy refills according to the prescribed dose for at least 80% of the period of the preceding six months. Fisher’s exact test was used as test of independence between groups.

**Results:** 67% of the patients in the study were adherent to their medical treatment during the first study period decreasing to 48% during the second study period (p < 0.001). There was no difference in in adherence between patients informed about SMR and those who were not informed. Younger patients were less prone to adherence compared to older patients at the first study visit (Age groups: 19-39: 40-59:60+ Years, adherence 48/71/81%) (p < 0.05). We found no differences related to disease (UC/CD), sex, 5-ASA/antiparasins, or administration route (oral/rectal).

**Conclusion:** Adherence to treatment fell from the first visit when the disease had been in remission for at least six months, to the second study visit when the disease had been in remission for at least 12 months. This was independent of whether the patients were aware that the physician could follow their medication refills or not. This might indicate that adherence to medical treatment of IBD decreases over time when the disease is in remission.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Golimumab (GOL) is a fully human monoclonal antibody to TNFα approved for the treatment of patients with moderate to severe ulcerative colitis (UC) with inadequate response or intolerance to steroids or immunosuppressive therapies. The aim of this study is to evaluate the efficacy and safety of GOL in both biologic naïve (BN) and biologic experienced (BE) patients.

**Aims & Methods:** Data were prospectively collected from a cohort of UC patients treated with GOL from March 2015 to March 2017 at two centers. Data were analyzed from two patient cohorts, namely BN patients and patients who have already undergone treatment with infliximab or adalimumab (BE). Patients received GOL 200 mg sc. at week 0, GOL 100 mg sc. at week 2, then 50 mg or 100 mg sc. every 4 weeks depending on body weight. The primary outcomes were clinical response rate and incidence of adverse events (AEs).

Treatments received by patients at discharge were Immunosupressants (30.8%), antibiotics (21.3%), mesacolazine (19.1%), mesalazine (12.1%) and antiTNFa (9.9%). A total of 235 patients (74.8%) had a medication change throughout the follow-up period, mainly within the first year after surgery (47.1%, n = 148). Median time to first medication change was 10 (IQR 4–22) months. More often therapeutic decision was the introduction or dose escalation of thiopurines or change to a more potent agent (61.8%, n = 160) by the following of an antiTNFa drug or dose escalation (51.4%, n = 121). Ninety-two out of 95 patients with planned endoscopy within first year had surgically scoring (RS) available, 37 (40.2%) and 55 (59.7%) showed RS ≤2 and ≤2 respectively. More patients with a RS ≤2 had a medication change as compared to patients with a RS >2, but the differences didn’t reach statistical significance (48% vs 36.36%). Reasons for medication change were “endoscopic without clinical recurrence” (52.9% RS ≤2 vs 10.0% RS >2, p = 0.010), “clinical recurrence” (29.4% RS ≤2 vs 25.0% RS >2 and “others” (23.5% RS ≤2 vs 66.0% RS >2, p = 0.045).

The number of planned endoscopies carried out within the first year after surgery increased significantly from 2007 to 2010 showing a steady implementation of guidelines recommendations. Changes in medication within this period were more frequent in the setting of endoscopic recurrence. Acknowledgements. Funded by Merck Sharp & Dohme of Spain

Disclosure of Interest: All authors have declared no conflicts of interest.
Results: Overall, 205 patients enrolled in GO-COLITIS and received at least one dose of GLM. Of these, 140 patients responded in the induction phase and received GLM in the maintenance phase. Clinical response was maintained through week 54 in 52/140 patients (37.1%; 95% CI, 29.1% to 45.7%) and 42/140 patients were in remission at week 54 (30.0%; 95% CI, 22.6% to 38.3%). Improvements in PMS subscores from baseline to week 54 were noted in stool frequency (mean change, −1.9; SD, 1.1 [n = 59]), rectal bleeding (mean change, −1.5; SD, 0.8 [n = 59]), and physician’s global assessment (mean change, −1.8; SD, 0.8 [n = 57]). Normal CRP levels at week 54 were seen in 50/59 patients (response rate, 84.7%; 95% CI, 73.0% to 92.8%). IBDQ and EQ-5D results are summarised in the Table. Serious adverse events (SAEs) occurred in 49/205 patients (23.9%), with 3 SAEs considered treatment-related.

Table: Mean (SD) Change from baseline to week 54 in IBDQ and EQ-5D.

| IBDQ total score | 138.116.4 (32.7) | 59.186.2 (27.1) | 59.66.8 (36.7) |
| EQ-5D index score | 136.07 (0.2) | 60.09 (0.2) | 58.02 (0.3) |

Conclusion: In the maintenance treatment with GLM phase of GO-COLITIS, 37.1% and 30.0% of patients achieved moderate to severe UC in the UK demonstrated clinical response and remission at week 54, respectively. Improvements in patient-reported quality of life measures (IBDQ, EQ-5D) were seen; the degree of improvement in IBDQ total score exceeded the IBDQ increase cut-off (i.e., >20 for patient-defined remission previously identified as representative of a patient defined improvement in an assessment of UC clinical endpoints. Adverse events were consistent with previous observations.

Introduction: Topical therapies for ulcerative colitis have shown evidence of good efficacy and can induce better responses and earlier improvement in distal ulcerative colitis (UC) when compared with oral therapies. Despite this attractive targeted approach of delivering medications topically to the left colon a certain resistance to the use of topical therapy seems to exist.

Aims & Methods: The goal of this market research was to assess the familiarity with and perceptions of patients towards topical products. A qualitative market research study was performed in the USA and 3 European countries (Germany, UK and Italy). The primary patient recruitment sources were online web portals, e-mail campaigns and social networking sites. Informal feedback gathered from outreach patient activists to identify the right sources was also used. In order to select patients with more advanced disease and/or a longer disease history current or past steroid medication was mandatory as a qualification for inclusion in the market research. A structured questionnaire covering 14 items was pre-tested and modified in phone interviews, which was then subsequently used in telephone interviews or as a web based interactive survey, both in local language.

A total of 148 patient responses were obtained via 10 phone interviews and 138 web-survey, 60 patients came from the US, 27, 25 and 36 from Germany, UK and Italy, respectively.

Results: In this survey cohort patients had been diagnosed with UC for > 5 years on average, 2/3 of patients had left-sided disease and less than a third had extensive disease. The majority of patients experienced at least 1–2 flare-ups each year and less than 18% of patients had them only rarely. ASA and steroids were the most commonly used medications in all countries, biological treatments were reported as highest in 35% (US) to the lowest 16% (UK) as stated by the patients. The vast majority of patients stated that they had treatment experience with oral products. More than 60% of patients had experienced slighter lower number in the US (83%) compared to the EU countries (Range 89-92%). Rectal enemas were the most common formulation delivery for topical ASA products in all markets (79%) followed by suppository (25%) and foam (13%). A total of 53% of patients were not concerned about the rectal mode of administration, while 47% reported some concerns. These mainly comprised the need to hold the enema in place, a generally uncomfortable feeling with rectal medications and painfull administration.

Conclusion: Despite a certain resistance to use topical therapy almost all patients stated to have used rectally administered products at some point during their disease journey and even patients in the USA were very familiar with these medications. Although physicians see patients as the primary driver for the resistance to use topical products in UC, less than 50% of the patients were actually concerned about the use of topical therapy in this study, thereby calling for better physician-patient communication.

P1061 SELF-MANAGEMENT IN INFLAMMATORY BOWEL DISEASE: A PERSPECTIVE OF NURSES AND PHYSICIANS

S. P. Van Den Burg, N. M.s. Peek, A. E. Van Der Meulen - De Jong, J.P.w. Maljaars

Gastroenterology And Hepatology, LUMC, Leiden/Netherlands

Introduction: Over the last years, self-management (SM) has been advocated as an instrument to empower and increase patient involvement and reduce healthcare costs in chronic diseases. Although many SM programs have been developed for inflammatory bowel disease (IBD) patients, little research has been performed on needs and wishes of IBD physicians, nurses and patients. Nurses and physicians play an important role in providing and stimulating SM.12

Aims & Methods: This study aimed to gain insight in what caregivers consider good SM options, and which patients- or disease-related factors they consider of influence on the degree of SM a patient is willing to apply. During a nurses IBD survey by email with a link to the survey. The survey contained questions regarding the caregivers’ views on ways for patients to apply SM in an outpatient setting (12 options were given). Caregivers were asked to state whether they thought these options would be valuable to patients or not, and to name their top three options. Also, caregivers were asked their views on factors that could

P1059 CAN EARLY DRUG AND ANTI-INFLIXIMAB-ANTIBODY LEVELS PREDICT PRIMARY NON RESPONSE TO INFlixIMAB THERAPY?

Introduction: Infliximab has been shown to induce and maintain long-term clinical remission in inflammatory bowel disease (IBD) patients. However, 10-30% of patients show no clinical benefit by the end of induction (week 14) and are considered primary non-responders. The mechanisms underlying primary non-response have not yet been clearly defined.

Aims & Methods: In this study we aimed to evaluate to which extent pharmacokinetics (early induction infliximab and anti-infliximab-antibody (ATI) levels) and socio-demographic, clinical and disease severity parameters were associated with lower response rates.

Methods: A prospective observational study of 105 primary responders for a total of 140 patients. A retrospective observational case-control study of patients with IBD attending the Gastroenterology Department of Sheba medical center and with infliximab between 2009 and 2016 was performed. Clinical scores were determined and sera were collected prospectively before infusions. Infliximab and ATI levels were measured by our previously described drug-tolerant ELISA assay.

Results: Thirty five primary non responders have been identified and matched at 1:3 ratio with 105 primary responders for a total of 140 patients. Both week 2 and week 6 infliximab levels were significantly lower among primary non-responders compared to others (Crohn’s: week 2, 2.43 [2.07–2.85] UC: week 2, 2.37 [2.07–2.72] and bone-related conditions (Crohn’s: 1.88 [1.74–2.03]; UC: 1.77 [1.67–1.89]). The strongest predictors for serious hepatic events were IS + OCS (Crohn’s: 2.38 [1.72–3.31]; UC: 2.36 [1.75–3.21]). Infliximab and ATI levels were measured by our previously validated method in 20 patients from week 2 and 6. Infliximab levels were significantly lower among primary non-responders compared to others. Infliximab and ATI levels were measured by our previously validated method in 20 patients from week 2 and 6. Infliximab and ATI levels above 4.33 g/ml-mg before the second infusion (week 2) or 5 g/ml (AUC g/ml-1) were considered primary non-responders. The mechanisms underlying primary non-response have not yet been clearly defined.

P1058 TOPICAL THERAPY VS. ORAL THERAPY FOR ULCERATIVE COLITIS ASSESSED FROM THE PERSPECTIVE OF PATIENTS WITH IBD IN EUROPE AND THE USA

1Gastroenterology, Rambam Health Care Campus, Haifa, Israel
2Gastroenterology Institute - Rambam, Haifa, Israel

Introduction: The aims of this study were to test and modify an interview test on preferences of topical therapy versus oral therapy in patients with IBD. The study was performed on needs and wishes of IBD physicians, nurses and patients. Although limited sample size (n=32) the results can be used to guide future market research.

Aims & Methods: In this survey cohort patients had been diagnosed with UC for > 5 years on average, 2/3 of patients had left-sided disease and less than a third had extensive disease. The majority of patients experienced at least 1–2 flare-ups each year and less than 18% of patients had them only rarely. ASA and steroids were the most commonly used medications in all countries, biological treatments were reported as highest in 35% (US) to the lowest 16% (UK) as stated by the patients. The vast majority of patients stated that they had treatment experience with oral products. More than 60% of patients had experienced slight lower number in the US (83%) compared to the EU countries (Range 89-92%). Rectal enemas were the most common formulation delivery for topical ASA products in all markets (79%) followed by suppository (25%) and foam (13%). A total of 53% of patients were not concerned about the rectal mode of administration, while 47% reported some concerns. These mainly comprised the need to hold the enema in place, a generally uncomfortable feeling with rectal medications and painfull administration.

Conclusion: Despite a certain resistance to use topical therapy almost all patients stated to have used rectally administered products at some point during their disease journey and even patients in the USA were very familiar with these medications. Although physicians see patients as the primary driver for the resistance to use topical products in UC, less than 50% of the patients were actually concerned about the use of topical therapy in this study, thereby calling for better physician-patient communication.

influence the degree of SM a patient is willing to apply, such as: disease duration, activity, health literacy, self-efficacy, patient’s age, and level of trust between patient’s and their IBD team. Caregivers were asked per item whether they thought this factor would be of influence and to name the three most important factors.

Results: 38 nurses (mean age 42 years) and 32 physicians (mean age 44 years) responded to the survey. The three most appealing options for nurses regarding SM were: availability of a SM web-app, Skype/Face-time consultation with nurse/physician, and an at-home faecal-calprotectin test. Physicians preferred the availability of a SM web-app, an at-home faecal-calprotectin test, and making patients in charge of their patient records. When comparing the value of each of the 12 possible choices in which patients could apply SM, only one option was valued differently between nurses and physicians, 56% of physicians favored patients being in charge of patient records compared to 18% of nurses (p = 0.001). Physicians thought that the 3 most important factors influencing SM in patients were: level of trust between physician and patient, self-efficacy, and disease perception. Also, 41% of the physicians found health literacy to be an important factor. Factors suggested that self-efficacy and disease perception and disease activity were most important. One factor was valued differently between nurses and physicians: 78% of nurses thought that patient’s age was an important factor in patient’s SM, compared to 34% of physicians (p = 0.029).

Conclusion: The level of trust between physician and patient, self-efficacy, and disease perception is an important factor in patient’s SM. Nurses and physicians agree that patient characteristics, in contrast to disease characteristics, influence SM, with self-efficacy being the most important. This study calls for further research on what patients and caregivers, want and need from SM, as SM is a team sport.

Infliximab and adalimumab are considered as anti-TNF therapy if patients show loss of response, but there are scarce data about the influence of trough levels on prognosis. Aims & Methods: Our aim was to compare real life efficacy of anti-TNF mono-therapy (IFX and ADA) and anti-TNF+IS for UC maintenance. This was a retrospective study of patients with UC treated with IFX or ADA in 2 Belgian academic and regional Hospitals. Patients with at least 3 months of treatment periods were included. A combination therapy treatment was defined as anti-TNF + IS for at least 3 months, a failure semester as anti-TNF withdrawal for secondary loss of response, intolerance or non-adherence, and eradication for withdrawn due to lack of disease activity or drug adverse effects. Results: 478 patients in 60 patients with IFX and 175 patients in 33 patients with ADA were included. The mean IFX and ADA treatment duration were respectively 49 (±33) months and 58 (±49) months. Within patients treated with IFX, 32/60 patients received IFX + IS during the first semester. IFX was administrated as monotherapy in 361/478 semesters (76%). Respectively 218/478 (46%) and 49 (19) months. Within patients treated with ADA, 19/33 patients received IS for at least 3 months, a failure semester as anti-TNF withdrawal for secondary loss of response, intolerance or non-adherence, and eradication for withdrawn due to lack of disease activity or drug adverse effects. Results: 478 patients in 60 patients with IFX and 175 patients in 33 patients with ADA were included. The mean IFX and ADA treatment duration were respectively 49 (±33) months and 58 (±49) months. Within patients treated with IFX, 32/60 patients received IFX + IS during the first semester. IFX was administrated as monotherapy in 361/478 semesters (76%). Respectively 218/478 (46%) and 78/478 semesters (16%) with IFX required dose escalation and corticosteroids course. IFX + IS was associated with more semesters with failure (5% vs 3%, p = 0.02) and numerically more semesters with discontinuation (64% vs 28%, p = 0.06). There was no difference in corticosteroids use (p = 0.63). IS during the first semester was not associated with lower risk of IFX failure (p = 0.41) nor with a longer survival without IFX withdrawal (p = 0.20). Continuing the IS treatment beyond the first semester was not associated with fewer semesters with failure (p = 0.18). Within patients treated with ADA, 19/33 patients received IS during the first semester. ADA was administered as monotherapy in 93/175 semesters (55%). Respectively 54/175 (48%) and 42/175 (24%) semesters with IS during the first semester were associated with less semesters with failure (7% vs 5%, p = 0.58), less semesters with corticosteroids use (p = 0.63). More semesters with ADA + IS was required dose escalation (61% vs 30%, p = 0.01). IS during the first semester was associated with less risk of failure (p = 0.01) and with lower risk of withdrawal without ADA withdrawal (p = 0.78). Continuing the IS treatment beyond the first semester was not associated with fewer semesters with failure (p = 0.20). Conclusion: In this real-life experience, combination therapy of IFX or ADA with IS during the first semester or prolonged after the first semester was not associated with less dose escalations, steroid courses or treatment failures.

Introduction: The objective of the present study was to evaluate the effectiveness and safety of adalimumab (ADA) in children with ulcerative colitis (UC) who experienced previous infliximab (IFX) failure or intolerance.

Aims & Methods: This retrospective study included all children with UC from a national pediatric registry who received ADA therapy. The primary endpoint was the rate of corticosteroid (CS) free remission (PUCAI < 10) at week 52. Secondary outcomes were: the rate of continuous clinical response and remission, primary non-response and loss of response at Weeks 12, 30, and 52 and rate of mucosal healing (MH) at week 52.

Results: A total of 32 children with UC received ADA (median age 10±4 years). Median disease duration before ADA therapy was 27 months. All patients received previous IFX therapy (43% intolerant, 50% non-responders, 7% positive anti-IFX antibodies). Fifty-two weeks after ADA initiation 13 patients (41%) were in CS-free remission. MH occurred in 9 patients (28%) at 52 weeks. The cumulative probability of clinical relapse-free course was 69%, 59% and 53% at 12, 30 and 52 weeks, respectively. Ten patients (31%) had a primary failure and 5 (15%) loss of response to ADA. No significant differences in terms of efficacy were reported between not-responders and intolerant to IFX (p = 1.0). Overall, 19 patient (59%) maintained ADA therapy during 52-week follow-up. Seven patients (22%) experienced an adverse event. No serious side effects were observed and none resulted in ADA discontinuation.

Conclusion: In this cohort of children with UC ADA had a favorable short- and long-term efficacy, allowing to recover a significant percentage of patients intolerant or non-responding to IFX. The efficacy was not related to the cause of IFX discontinuation (intolerance/intolerance). Overall, safety profile was good. Larger, prospective, controlled trial with longer follow-up should be suggested to better clarify the role of ADA in pediatric UC.

P1069 SUBCUTANEOUS USTEKINUMAB PROVIDED CLINICAL AND BIOLOGICAL BENEFIT FOR 9/12 REFRACTORY PEDIATRIC CROHN'S DISEASE

C. Martinez-Vinson. J. Hugot, M. Bellucie, J. Viala
Gastroenterologie Pediatrique, Hopital Robert Debré, Paris/France

Contact E-mail Address: christine.martinez-vinson@aphp.fr

Introduction: Ustekinumab has shown a good safety profile and efficacy to induce and maintain remission in adult patients with refractory Crohn’s Disease (CD). Data are lacking in children.

Aims & Methods: All CD patients under 18 years who received ustekinumab were included in this retrospective observational study performed in a single tertiary pediatric centre.

Results: See table.

Conclusion: Subcutaneous ustekinumab is effective to induce and maintain remission in severe pediatric CD refractory to anti-TNF antibody.

Disclosure of Interest: All authors have declared no conflicts of interest.

History of surgery Colectomy Ileocaecal resection Ileocaecal resection Left colectomy

From January 2015 to May 2016, twelve CD patients were treated with ustekinumab, all because of failure of several lines of therapies including anti-TNF antibodies. All but one patient were followed at least one year. An initial response was achieved in 9 (75%) patients, and remission in 5 (42%). At one year, the responders were still receiving ustekinumab with clinical benefit and without steroids need. Seven of them (58%) were on clinical remission. One patient experienced a serious adverse event and the treatment was stopped after the first injection.

P1070 TROUGH LEVELS TO INFLIXIMAB AT W6 ARE PREDICTIVE OF REMISSION AT W14, IN PEDIATRIC CROHN DISEASE

C. Martinez-Vinson, O. Courbette, C. Aupiais, J. Viala, J. Hudot
Gastroentérologie Pédiatrique, Hôpital Robert Debré, Paris/France

Contact E-mail Address: christine.martinez-vinson@aphp.fr

Introduction: Loss of response to anti-tumor necrosis factor (TNF) agents is a common clinical problem. 40% of patients lose response within 12 months of therapy initiation. This retrospective study aimed to analyse patients associated with remission after 14 weeks of induction treatment by IFX in children with CD.

Aims & Methods: All patients aged from 2 to 18 years old with meeting European Crohn’s and Colitis Organisation criteria and treated for the first time by IFX between January 2002 and March 2014 at a single tertiary pediatric center were considered for inclusion in this retrospective study. The following baseline characteristics were anonymously recorded for each patient: gender, age at CD onset, age at induction, duration of disease, CD classification according to Paris classification, prior exposure to CD treatments, previous intestinal resections and reasons for anti-TNF initiation. At each infusion visit (week 0, 2, 6 and 14) disease activity was determined using Pediatric Crohn’s disease Activity Index (PEDI). Four blood samples were obtained for each patient (at W0, W2, W6 and W14). The following laboratory tests were recorded: ESR, CRP, hemoglobin, hematocrit, albumin, blood levels of lymphocytes, Trough levels to IFX (TRI) and antibodies to IFX (ATIs). Children were classified in three groups according to response at week 14: (1) remission was defined by a Crohn’s Disease Activity Index under or equal to 10; (2) partial response was defined by a PCDAI decreased by more 12.5 points since inclusion without a remission as defined above; (3) absence of partial response or remission.

Results: We analyzed 107 patients with CD, with a total of 428 visits until W14. The principal reason to start infliximab was failure of immunosuppressive therapy (60%). Infliximab proved to be an effective treatment in our cohort since 75.7% (n = 81) patients were responders to infliximab and 40% (n = 42) were in clinical remission whereas 24.3% (n = 26) were non responders at W14. At week 14, 107 patients were divided in three groups related to the clinical activity of their disease: lack of clinical response, partial clinical response, clinical remission. It concerns respectively 26, 39 and 42 patients. Major baseline characteristics were not associated with clinical remission: sex, age at diagnosis, disease location, time between diagnosis and induction, age at induction. Drugs associated with infliximab at W0, W2, W6 or W14, whether it was immunosuppressive agents or corticoids was not associated with remission. Patients with low albumin levels had a worse response at induction Activity score at induction was also statistically associated with clinical remission: each decreasing of 10 points of activity score at induction increase of 0.48 times the risk to obtain clinical remission. Trough residual of infliximab > 8.5 μg/ml at week 6 increase of 11.3 times the risk to obtain clinical remission at W14. Lack of growth retardation at induction increase of 3.98 times the risk to obtain clinical remission at W14.

Conclusion: Infliximab measurement in combination with evaluation of clinical severity (low body weight, growth retardation, hypoalbuminemia, severe disease) appears to be a reasonable strategy for predicting both short- and long-term treatment outcomes with IFX in the initial stage of treatment. Early detection of response to IFX is critical for the management of CD, especially in acute severe patients: it seems that the infliximab trough level at week 6 (more than 8.5) is predictive of a remission at week 14. Second, some patients, especially patients with low body weight, growth retardation, hypoalbuminemia and severe disease may require higher doses than standard doses.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1071 INFLIXIMAB INDUCED PSORIASIS IN A COHORT OF CHILDREN WITH INFLAMMATORY BOWEL DISEASE: A 12 YEARS FOLLOW-UP STUDY**
C. Martínez-Vinson, O. Courbette, C. Aupiais, J. Viala, J. Hugot
Gastroenterologie Pédiatrique, Hôpital Robert Debré, Paris/ France

**Contact E-mail Address:** christine.martinez-vinson@aphp.fr

**Introduction:** In adult Inflammatory bowel disease (IBD), skin adverse reactions have been observed in a prevalence of 1.6 to 22%. This side effect occurs more frequently in patients treated with infliximab (IFX) for IBD. Datass in the pediatric population are lacking so far.

**Aims & Methods:** All patients aged 2 to 18 years, with Crohn’s disease (CD) or Ulcerative colitis (UC) and treated for the first time by IFX between January 2002 and March 2014, were considered for inclusion in this monocentric retrospective study.

**Results:** Basline Patients: 115 patients were treated with IFX for CD and 23 for UC. IFX treatment was initiated at the age of 14, about 2 years after diagnosis. The indication for treatment was in 61.6% (n = 85) resistance to conventional therapy, in 26.8% (n = 37) a perianal fistulizing disease and in 11.6% (n = 16) a severe colitis. At the first injection, the median PDCAI was 35 (25; 45) for CD and the median PUCAI 35 (25; 45) for UC. The duration of treatment with IFX ranged from 45 days to 8 years and median was 23.9 months (11.6; 36.5). Psoriasis: 20 patients (14% of the cohort) had an IFX-induced psoriasis. 70% of them (n = 14) of patients were in remission when the psoriasis was diagnosed. Psoriasis was diagnosed at the 8th injection (6; 15), though 355 (239; 532) days after the start of biotherapy. 20% of patients had a combo therapy: 50% of them were treated by 6-mercaptopurine, 25% by azathioprine and 25% by methotrexate. The median IFX trough levels (TRI) when psoriasis occurred was 4.7 mcg/mL (1.8; 9.6) and 4.1 mcg/mL (2.1; 8.8) at the previous visit. Median Antibodies to IFX (ATI) rate was 0%. All were supported by local treatments. No patients discontinued biotherapy following the psoriasis. Personal or family history of psoriasis, and the smoking status have not been collected. We compared the patients who develop psoriasis with psoriasis (n = 20) and without psoriasis (n = 127) with an univariate model. All children in the psoriasis group were followed for a CD. There was more perineal location of CD in psoriasis group with a significantly high prevalence (p = 0.003). Conclusion: 14% of our IBD patients treated with IFX developed psoriasis during follow-up. All were CD, more frequently it occurred for CD with perineal lesions, at the 8th injection in median, with no ATI.

**P1072 PLATELET ABNORMALITIES AND ANEMIA IN PAEDIATRIC IBD: ARE THEY LINKED?**
M. Votto1, F. Viviano2, F. Viola3
1Pediatría, IRCCS Policlinico San Matteo, PAVIA/Italy
2Pediatría E Neuropsic平ria Infantile, Università La Sapienza, Roma/Italy

**Contact E-mail Address:** marinavotto@gmail.com

**Introduction:** Crohn’s Disease (CD) and Ulcerative Colitis (UC) are two major forms of Inflammatory Bowel Disease (IBD). In children with IBD anemia is common and is a combination of iron deficiency and anemia of chronic disease (ACD). IBD are associated with several alterations of platelets, including number, shape, and function1. In clinical practice, the most common platelet alteration is thrombocytosis. In IBD, thrombocytosis is associated with iron deficiency anemia and chronic inflammation1. The importance of platelet function is due to the substantially increased incidence of thromboembolic phenomena in IBD2.

**Aims & Methods:** The aim of the study is to demonstrate the link between anemia, thrombocytosis and platelet aggregation in pediatric IBD patients.

This study includes 51 children and adolescents recruited from the Pediatric Gastroenterology Unit of Polyclinico Umberto I in Rome. Patients younger 6 years, with inherited platelet defects, hemoglobinopathies, and receiving therapies that alter platelet function, are excluded. We collect disease activity scores (Pediatric Crohn’s Disease Activity Index [PCDAI], Pediatric Ulcerative Colitis Activity Index [PUCAI]). The laboratory investigations include: complete blood count, mean corpuscular volume (MCV), mean platelet volume (MPV), mean corpuscular haemoglobin concentration (MCHC), levels of hemoglobin (Hb) and indices of erythrocytes, mean platelet volume (MPV), red cells distribution width (RDW), plateletcrit (PC), thrombocrit (TCR), and prothrombin time (PT). Diagnostic criteria for anemia are based on ECCO guidelines. Platelet aggregation is evaluated on platelet-rich plasma in an AggRAM aggregometer with Born’s Method. The results were reported as the maximal percentage of aggregation observed after 4 min stimulation in response to collagen (1 μg/mL) and adenosine diphosphate (ADP 0.8 μM and ADP 2 μM).

**Results:** The study include 51 children and adolescents, 24 with UC and 27 with CD. Median age was 15.3 years (± 3.5). Iron deficiency anemia combined to ACD is the most common type (58.3% in UC and 50% in CD). Hemoglobin levels are significantly lower in patients with UC compared to CD patients (p = 0.0320). No significant differences are observed between mean values of red cells, MCV, MCHC, RDW, iron, transferrin and serum ferritin both in CD and UC. Thrombocytosis prevails in UC compared to CD patients, but no significant correlation was found. No differences are observed between mean values of PDW and MPV in both groups. In patients with UC, a negative correlation was found between mean values of hemoglobin and platelet count (p = 0.0040). Platelet aggregation results higher in anemic patients. In anemic children, mean baseline platelet aggregations - induced by ADP 0.8 μM and collagen 1 μg/mL - are significantly higher in UC compared to CD (p = 0.001 and p = 0.030 respectively). Another significant correlation is observed between platelet aggregation - induced by ADP 0.8 μM and ADP 2 μM - in anemic UC patients compared to non-anemic UC patients (p = 0.002 and p = 0.040 respectively). Platelet aggregation–induced by ADP 0.8 μM is significantly higher in anemic UC patients with active disease (PUCAI > 20) compared to the same patients whose disease is in remission (p = 0.042) and compared to patients with active CD (p = 0.054).

**Conclusion:** In our cohort, mixed anemia (iron deficiency anemia combined to anemia of chronic disease) is the most common type of anemia. Thrombocytosis is a condition more frequent in anemic IBD patients, specially in UC. In UC, anemia and disease activity are significant correlated with platelet hyperaggregability and platelet count. The observed active diseases may have a significant major risk of thrombosis, independently from acquired or inherited hemostasis defects.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1073 RELATIONSHIP BETWEEN CLINICAL COURSE OF UC DURING PREGNANCY AND OUTCOMES OF PREGNANCY: A RETROSPECTIVE EVALUATION STUDY
A. Ito, O. Teppeli, T. Katsuishi
Dept. Medicine, Inst. Gastroenterology, Tokyo Womens Medical University, Tokyo/Japan
Contact E-mail Address: iitoyami@iige.twmu.ac.jp

Introduction: Ulcerative colitis (UC) is a chronic, intractable disease with a long clinical course. UC has a marked influence on the lifestyle of patients, and its effects on pregnancy and childbirth can especially become a problem for women in their child-bearing years. Various studies have suggested that it is desirable for pregnant women with UC to give birth while remaining in a state of remission.

Aims & Methods: The present study evaluated pregnant women with UC attending our hospital who became pregnant during remission, in order to examine the factors that contributed to recurrence of UC during pregnancy. We investigated 40 pregnant patients in remission (44 cases) attending our hospital between January 2008 and July 2016 who had remained in remission for one year prior to pregnancy. After becoming pregnant while in remission, patients who stayed in remission until delivery were classified into the ongoing remission group (35 cases) and patients with recurrence during pregnancy were classified into the recurrence group (9 cases). Remission was defined as a Lichtiger clinical activity index (CAI) of less than 4. Relapse was defined as a CAI ≥ 5 with the need for initiation or dose escalation of steroids or administration of biological agents during pregnancy. Items examined: Clinical characteristics (age at onset, disease duration, age of becoming pregnant, disease type, and treatment), the CAI in the first, second, and third trimesters, and whether or not patients continued treatment during pregnancy were examined and compared between the two groups.

Results: There were significant differences between the two groups with respect to the age of becoming pregnant (32.9 ± 4.4 years in the ongoing remission group vs. 28.3 ± 7.0 years in the recurrence group), the CAI in the second trimester (2.9 ± 4.6 vs. 3.5 ± 1.6), the CAI in the third trimester (2.9 ± 0.7 vs. 5.4 ± 2.0), and whether oral treatment was continued (continuation of treatment [yes/no]; 30/5 in the ongoing remission group vs. 5/4 in the recurrence group). Regarding the discontinuation of oral treatment, two patients in the ongoing remission group and one patient in the recurrence group discontinued it on their own judgment, while two patients in the recurrence group discontinued it due to hyperemesis. Discussion: The present study revealed that factors influencing the recurrence of UC during pregnancy were the age of becoming pregnant and the continuation of oral treatment. Our results showed that younger women were more susceptible to recurrence. As expected, discontinuing oral treatment was a factor that contributed to recurrence. However, the reasons for discontinuing treatment during pregnancy differed from those for non-pregnant women. Some patients discontinued treatment on their own judgment because they were concerned about adverse effects on the fetus, while others had difficulty with continuing treatment due to hyperemesis. With regard to the effects of medications on the fetus, medical staff should provide an explanation about the safety of treatment and should be aware that patients may have various concerns about drug therapy. If patients have difficulty continuing oral treatment due to severe hyperemesis, administration of local therapy should be considered.

Conclusion: During pregnancy, it is important to continue treatment for UC so that patients can give birth while remaining in remission. Accordingly, intervention by medical staff is particularly necessary in order to provide pregnant women with information and explanations regarding treatment.

Conclusion: In our cohort 35% of children presenting with AILD were subsequently diagnosed with IBD. Possible risk factors for development of IBD in AILD are low haemoglobin, being leaner and younger at diagnosis. An elevated FC and the presence of GI symptoms are useful to assess the need for diagnostic endoscopy when considering diagnosis of IBD in the context of AILD. As current immunosuppression may mask mild to severe signs and symptoms of IBD a lower threshold for endoscopy should be considered in these patients.

PI077 CLINICAL AND LABORATORY VARIABLES THAT PREDICT CLINICAL AND ENDOSCOPIC REMISSION IN CHILDREN WITH CROHN’S DISEASE TREATED WITH INFILXIMAB

G. D’Arcangelo, S. Oliva, F. Tarani, F. Viola, F. Civitelli, S. Cuciara, M. Alo
Pediatric Gastroenterology And Liver Unit, Sapienza University of Rome, Rome/Italy

Contact E-mail Address: giudiledarcangelo87@gmail.com

Introduction: We aimed to identify early clinical and laboratory predictors of sustained clinical and endoscopic remission in children with Crohn’s disease (CD) under infliximab (IFX).

Aims & Methods: Prospective study conducted in children with moderate-to-severe CD starting IFX treatment. All patients underwent endoscopy, weighted pediatric CD activity index (wPCDAI) assessment, C-reactive protein (CRP) at week 0 and 52. wPCDAI and CRP were also evaluated at 14 weeks. The primary outcome was to determine the ability of 14-week wPCDAI and CRP to predict steroid-free sustained remission and mucosal healing at 1 year. As a secondary outcome we sought to evaluate the concordance between wPCDAI and Simple Endoscopic Score for CD (SES-CD) at week 52.

Results: Forty-one children were enrolled (median age 13.3 ± 2.7, females n = 20 [48.8%]). At 1 year, 21 (51%) and 16 (39%) were in clinical (wPCDAI < 12.5) and endoscopic (SES-CD < 3) remission, respectively. Fourteen-week wPCDAI didn’t differ between patients who achieved both clinical and endoscopic remission at 1 year (p = 0.21 and p = 0.35, respectively). By using a multivariable logistic regression model, neither week-14 wPCDAI nor CRP were predictors of 1-year clinical (p = 0.83 and p = 0.30, respectively) and endoscopic remission (p = 0.22 and p = 0.48). wPCDAI resulted significantly correlated with 1-year SES-CD (r = 0.38, p = 0.01). The concordance between wPCDAI and SES-CD was excellent and good for severe disease and remission (k Cohen 0.87 and 0.76), moderate and absent for mild and moderate disease, respectively.

Conclusion: Based on our results, 14-week post induction wPCDAI and CRP are not predictors of 1-year sustained steroid-free clinical and endoscopic remission in children with CD under IFX therapy. Continuation of wPCDAI SHould be considered for good correlation with SES-CD, particularly for patients in remission and with severe disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

2Gastroenterology, The First People’s Hospital, Hangzhou/China
3Department, Institute name, Hangzhou/China

Contact E-mail Address: 15968880792@163.com

Introduction: Gastrointestinal angiodypsias is either inherited or acquired, it is an important and challenging cause of acute gastrointestinal haemorrhage, particularly in the elderly, sometines refractory to treatment. Although multiple treat- ment modalities, both medical and surgical, are being used, there is no established medical treatment available for these patients. Thalidomide is a potent inhibitor of angiogenesis in experimental models. As angiodypsias are a result of unregulated vessel growth, antiangiogenic treatment may inhibit growth of angiodypsias. But its benefits and risks nevertheless remain unclear.

Aims & Methods: This retrospective study evaluates the efficacy, safety, and side-effect of thalidomide in the treatment of patients with refractory gastrointestinal bleeding from angiodypsias. Patients with recurrent gastrointestinal bleeding of angiodypsia who were from Hangzhou First people’s Hospital from October 2012 to July 2013 were collected for this open and nonrandomized study. Thalidomide was started with 50 mg/day and then increased incrementally by 100 mg/day, if tolerated, and continued for 6 months. Adverse events, hemo- globin, blood chemistry, the changes of coagulation and blood transfusion were monitored during the treatment and for 6-months post-treatment.
Results: Twenty-one patients with chronic refractory angiodysplasia bleeding were recruited in this study, included 10 women, aged between 40–85;11 cases of massive hemorrhage due to self withdrawal. Among the remaining 20 patients who were given thalidomide regularly for 6 months. (1). Eighty patients come across constipation, sleepness and dry mouth. There were no skin rashes, peripheral neuropathy and any other adverse reactions during the treatment. All side-effects resolved when thalidomide was discontinued. (2). The red blood cell after treatment (3.76 ± 0.56*10^12/L) was significantly higher than before treatment (3.38 ± 0.60*10^12/L). Hemoglobin after treatment (94.7 ± 13.51 g/L) compared with before treatment (83.2 ± 17.6 g/L). HCT after treatment (0.32 ± 0.05) compared with before treatment (0.29 ± 0.08); the difference was statistically significant (P<0.05). (3). The ALT after treatment (32.9 ± 18.5 L/U) compared with before treatment (30.6 ± 12.8 U/L); AST after treatment (28.1 ± 8.56 L/U) compared with before (28.0 ± 12.4 L/U). PT after treatment (12.1 ± 1.3 s) compared with before (11.8 ± 1.4 s); APTT after treatment (30.2 ± 3.7 s), compared with before (31.0 ± 6.2 s); the difference was not statistically significant (P > 0.05). (4). Prothrombin time (PT) after treatment (12.1 ± 1.3 s) compared with before (11.8 ± 1.4 s); APTT after treatment (30.2 ± 3.7 s), compared with before (31.0 ± 6.2 s); the difference was not statistically significant (P > 0.05). (5). cases of colonic capillary malformation review colonoscopy, and the vascular malformation improved significantly after treatment.

Conclusion: Thalidomide, with its antiangiogenic mechanism of action, seems to be a promising drug in bleeding angiodysplasia as a treatment option for patients unable to benefit from other available modalities of treatment. the study drug was well tolerated.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colonic diverticular bleeding is the most common cause of lower gastrointestinal bleeding. We have reported the preliminary safety results of endoscopic detachable snare ligation (EDSL), a new method for diverticular hemorrhage1. The bleeding diverticulum was ligated with a detachable snare. Unlike the endoscopic band ligation, removal of the scope to attach a ligation device and reinserntion for treatment are not needed in this method. We performed a clinical trial to evaluate the efficacy and safety of EDSL.

Aims & Methods: This multicenter single arm phase II study was conducted in 12 Japanese institutions. Patients suspected of diverticular bleedings were enrolled from June 2015 to March 2017. Patients with serious heart, renal, or liver failure, sepsis, disseminated intravascular coagulation, and high-dose steroid use (prednisolone dosage >10 mg/day) were excluded. The primary endpoint was the early (within 1 month) rebleeding rate in patients who were treated with EDSL.

The secondary endpoints were overall early rebleeding rate in patients who had colonic diverticular bleeding (intention to treat:ITT), success rate of EDSL total procedure time, EDSL procedure time, identification rate of bleeding diverticula, and adverse events. This study was approved by the ethics committee of each participating hospital and confirmed to the Helsinki Declaration and the Japanese Clinical Research Guidelines.

Results: Of 123 patients with diverticular hemorrhage, 101 were treated with EDSL and the early rebleeding rate was 5% (5/101). The rebleeding rate in ITT population was 9% (11/123). Success rate of EDSL was 78% (96/123). EDSL procedure time of the ITT population were 40 (15–150) min and 4 (1–57) min. The identification rate of bleeding diverticula was 60% (123 in 205 enrolled patients). Two mild adverse events occurred; colonic diverticulitis cured with antibiotics and temporary abdominal pain during EDSL.

Conclusion: EDSL is an effective, safe, and convenient treatment method for colonic diverticular hemorrhage.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1080 RISK FACTORS FOR EARLY AND LATE RE-BLEEDING IN PATIENTS WITH COLONIC DIVERTICULAR BLEEDING

Gastroenterology And Hepatology, St. Marianna University, Kawasaki, Japan

Contact E-mail Address: y2satou@marianna-u.ac.jp

Introduction: Incidence of colonic diverticular bleeding has increased in recent years. Colonic diverticular bleeding is problematic because of the following reasons: the low detection rate of the bleeding source by endoscopy and frequent re-bleeding. At our hospital, we have a policy of performing emergency lower gastrointestinal endoscopy for all patients with colonic diverticular bleeding within 24 h of their admission. We have reported that the following factors can contribute to the successful identification of the bleeding source: extravasation revealed by abdominal contrast computed tomography (CT), and mounting of a hood to the tip of an endoscope during lower gastrointestinal endoscopy. However, risk factors for re-bleeding in patients with colonic diverticular bleeding were still unknown.

Aims & Methods: In this study, we examined the risk factors for early and late re-bleeding in patients with colonic diverticular bleeding. From January 2004 to April 2016, we admitted 432 patients (285men and 147 women, mean age: 71 ± 13 years) to our hospital for treatment following a diagnosis of colonic diverticular bleeding based on abdominal CT and endoscopy findings. Early and late re-bleeding was defined as macroscopically bloody stools as a result of colonic diverticular bleeding during hospitalization and after discharge, respectively. Risk factors for early and late re-bleeding were retrospectively examined using univariate and multivariate analysis.

Results: Early re-bleeding occurred in 112 patients (26%; 86 men and 26 women, mean age: 71 ± 12 years). The mean duration until re-bleeding was 3.9 ± 2.4 days, and the average, early re-bleeding occurred 1.7 ± 1.2 times. On average, lower gastrointestinal endoscopy was performed 2.7 ± 1.2 times and endoscopic hemostatic treatment was performed 1.0 ± 1.0 times. In the univariate analysis, significant differences were seen in males (P = 0.005), in the use of oral antiplatelet agents (P = 0.012), and in patients not undergoing endoscopic hemostasis (P = 0.004). In the multivariate analysis, male gender (P = 0.006; odds ratio 2.06, 95%CI 1.23–3.44), the use of oral antiplatelet agents (P = 0.008; odds ratio 1.85, 95%CI 1.17–2.93), and patients not undergoing endoscopic hemostasia (P = 0.005; odds ratio 1.5, 95%CI 0.31–8.81) were independent risk factors for early re-bleeding. Late re-bleeding was seen in 72 of 345 patients who were able to follow up (21%; 46 men and 26 women, mean age: 73 ± 12 years). The mean duration until late re-bleeding was 41 ± 40 months, and on average, late re-bleeding recurred 1.5 ± 1.2 times. Only the use of oral antiplatelet agents (P = 0.005; odds ratio 1.72, 95%CI 0.98–2.98) was identified as an independent risk factor for late re-bleeding in the univariate and multivariate analysis.

Conclusion: Not undergoing endoscopic hemostasis and male gender were identified as risk factors for early re-bleeding, indicating the importance of choosing measures and hemostatic treatments to improve the detection rate of bleeding sources during endoscopy. The use of oral antiplatelet agents was a risk factor for both early and late re-bleeding, suggesting the need for patient management through multi-departmental cooperation.

P1081 ACUTE LOWER GASTROINTESTINAL BLEEDING—IS NOBLADS THE ANSWER?

S. Xavier1, J. Magalhães2, J. Cotter3
1Life and Health Sciences Research Institute (ICVS); School of Medicine, University of Minho, Braga/Portugal
2Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães/Portugal
3Puif Government Associate Laboratory, 4 ICVS/3B’s, Braga/Guimarães/Portugal

Contact E-mail Address: snmaxavier@gmail.com

Introduction: Acute lower gastrointestinal bleeding (ALGIB) constitutes an important gastroenterological emergency. A new score (NOBLADS) that intends to determine the risk of severe ALGIB was recently developed. We aimed to assess the validity of this score in a cohort of patients with ALGIB.

Aims & Methods: Retrospective study. Emergency consecutive admissions for ALGIB were reviewed. Severe ALGIB was defined as transfusion of ≥2 units of packed red blood cells (PRBC) and/or hemocrtic decrease of ≥20% within the first 24 h and/or recurrent bleeding after 24 h of stability. NOBLADS score was calculated and its discriminative capacity for severe ALGIB as well as for overall outcome was assessed.

Results: Included 118 patients with a mean age of 73.6±14.4 years and 52.5% males. Most frequent etiologies for ALGIB were diverticular bleeding (23.7%) and post-polpectomy (21.2%). ALGIB was severe in 38.1% of patients. NOBLADS score showed a weak discriminative capacity to determine severe ALGIB (AUC=0.68, p<0.01). However, when comparing patients with NOBLADS ≤4 vs >4, patients with higher scores were significantly older (69.2±15.7 years vs 78.6±10.0 years, p<0.01), had lower hemoglobin levels as admission (11.2±2.1 g/dL vs 10.2±2.5 g/dL, p<0.01), were transfused with more units of PRBCs during the first 24 h and during hospital in-stay (0.4±0.9 vs 1.1±1.3, p<0.01 and 1.0±2.2 vs 3.0±3.3, p<0.01, respectively) and were more frequently admitted to intermediate care units (35.2% vs 59.6%, p<0.01). No differences were found between the two groups regarding in-stay length, rebleeding rate, need for surgery or death.

Conclusion: NOBLADS score showed a weak discriminative capacity to determine severe ALGIB however, patients with NOBLADS ≤4 had greater PRBCs transfusion need and were more frequently admitted to intermediate care units. New or improved scores that can predict severe ALGIB are needed to determine more precisely appropriate care and to allow for a standardized approach.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1082 COLORECTAL CANCERS (CRCs) DEPENDING ON THE SCREENING INTERVAL IN IBARAKI, JAPAN

Y. Saitoh1, H. Hyodo1, H. Suzuki2, I. Hyodo1
1Dept. Of Gastroenterology, Ibarakiken Medical Center, Ibaraki/Japan
2University of Tsukuba, Tsukuba/Japan

Contact E-mail Address: saitoitoyo@yahoo.co.jp

Introduction: In Japan, CRC screening was launched as a national policy for all people aged over 40 years since 1992. 2-day FIT has been widely accepted, and has been recommended performing in every year. It is demanded that CRC screening is performed effectively depending on the capacity of colonoscopies. We will show so much data on fecal hemoglobin concentration (referred as concentration) and proccess of colorectal cancer among them.

Aims & Methods: The aim of this study is to analyze the concentration of FIT for colorectal cancers (CRCs) from the screening. The cut off value is adapted 20 μg Hb/g stool and the rate of further examination is around 75% for many years. In Ibaraki prefecture. CRCs were detected 1,421 cases from the screening (2000–2014) with 2-day FIT. The concentration of FIT was grouped in 20–80, 80–140, 140–200 and over 200 μg Hb/g stool. Screening have been performed with the OC-SENSOR DIANA (EIKEN, JAPAN) automated analyzer. CRCs were analyzed with age group (40–49, 50–59, 60–69, over 70 year-old), size(1–24, 25–49, over 50 mm), location(proximal, distal), Dukes’ classification(Dukes A, A-invasive, B, C, D) depending on the concentration. The chi-squared test was used to compare of each group.

Results: There was no different in gender and age group for concentration. The concentration of CRCs in the distal colon was significantly higher in the proximal colon [distal 39% (861/2,200) and proximal 32% (337/1,053) with over 200 μg Hb/g stool]. The concentration of CRCs with larger size was significantly higher than smaller size [1–24 mm 27% (533/1,961), 25–49 mm 54% (439/818) and over 50 mm 64% (169/263) with over 200 μg Hb/g stool]. The concentration of invasive CRCs was significantly higher than intra-mucosal CRCs [intra-mucosal 23% (370/1,617) and invasive 50% (888/1,793) with over 200 μg Hb/g stool]. The concentration of Dukes B, C and D were significantly higher than Dukes A except for intra-mucosal. There was no difference between Dukes B and D [Dukes A except for intra-mucosal 36% (325/910), B 68% (247/363), C 60% (232/383) and D 69% (61/89) with over 200 μg Hb/g stool].

| total | 134 | 451 | 1,419 | 1,410 | 1,961 | 818 | 264 | 1,053 | 2,200 | 1,617 | 910 | 363 | 385 | 88 | 15

Conclusion: In 20–80 μg Hb/g stool, there were CRCs with smaller size, no inva, in the proximal colon, Dukes A except for intra mucosal CRCs and so on. When the cut off value is raised over 80 μg Hb/g stool, the detection of early stage CRCs and proximal CRCs may be lost. There were many advanced CRCs with concentration over 200 μg Hb/g stool. Therefore, when the participants, who are positive with high concentration of FIT, need to take a further examination as soon as possible. Why concentration of CRCs in the distal colon are higher than in the proximal colon? It may be related to the fact that the number of detectable CRCs in the distal colon are more than in the distal colon. We will go on researching mechanism about this.

Colonscopy surveillance is a diagnostic tool used to detect colorectal cancer in patients with a history of Hodgkin lymphoma (HL). This study assessed the prevalence of colorectal neoplasia in HL survivors compared to controls. The primary aim of this multicenter cohort study was to assess the diagnostic yield of advanced colorectal neoplasia detected by a first surveillance colonoscopy. The study demonstrated a higher prevalence of colorectal neoplasia in HL survivors compared to controls.

**Results:**
- Advanced colorectal neoplasia was defined as an advanced adenoma (high-grade dysplasia, ≥25% villous component, or ≥10 mm diameter), an advanced serrated lesion (dysplasia or ≥10 mm diameter), or CRC. Results were compared with matched population controls.
- The primary screening colonoscopy (n = 1276 asymptomatic individuals between 50–75 years of age) showed that left-sided cancers were most often diagnosed in an early disease stage.

**Conclusion:** Sur switched to abdominal radiotherapy and/or procarbazine have a high prevalence of advanced colorectal neoplasia. Colonoscopy surveillance should therefore be implemented as standard of care.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P1087 LOCATION AND SEX PREDOMINANCE OF MISMATCH REPAIR DEFICIENT COLORECTAL CANCER IN IVORY COAST DIFFER FROM ITS EUROPEAN COUNTERPART

L. Bienfait1, B. D’oukoure2, N. D’haene1, I. Salomons2, P. Denette2, L. Verset1
1Department Of Pathology, Erasme Hospital, Université Libre de Bruxelles, ULB, Brussels/Belgium
2Pathology, Université Félix Houphouet-Boigny, Abidjan/Côte d’Ivoire

Introduction: According to European and American series, 1–2 up to 20% of colorectal cancers (CRC) are caused by mismatch repair (MMR) deficient mutations. However, in Ivory Coast, these data are lacking.

Aims & Methods: We performed a retrospective study on paraffin-embedded tissue samples from 96 colorectal cancers (54% males) operated in Abidjan from 2007 to 2015. CRC was defined when present in a patient with a family history suspect for LS. In both cases no germline MLH1 promoter hypermethylation was found.

Conclusion: These results need to be confirmed on a larger cohort.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Lynch syndrome (LS) is the most common hereditary cause of colorectal cancer (CRC). Identifying LS carriers and their affected family members is of great importance for prevention of CRC. Routine screening for LS by immunohistochemical staining (IHC) in CRC patients ≥70 years of age is recommended. LS screening in adenoma patients could yield more benefit, since CRC can still be prevented in these patients. A small number of participants of the national CRC screening program is expected to have LS. We aimed to assess the diagnostic yield of IHC for LS in patients with advanced and multiple adenomas or CRC within the Dutch national fecal immunochromonometric test (FIT)-based CRC screening program.

Aims & Methods: We included participants of the national CRC screening program, referred to our center after a positive FIT from December 2013 to December 2016. IHC for MLH1, MSH2, MSH6 and PMS2 protein was performed on advanced adenomas and CRCs. Abnormal results were referred for genetic counselling. Both patients had no family history suspect for LS. In patients with CRC the IHC results were sent to a genetic counselling. In cases with LS, the IHC results were sent to a genetic counselling.

Result: A total of 1006 patients (54% male; mean age of 67 years (±5 years)) had positive FIT were included in the study. At colorectal cancer, 355 (35%) patients (63% male; mean age of 67 years (±6 years)) had a CRC and/or adenoma eligible for IHC. A total of 322 adenoma patients were analyzed. None had aberrant IHC. Of the examined adenomas, 151 (47%) had a villous component and/or high grade dysplasia (128 (41%) with villous component and 23 (11%) with high grade dysplasia). Out of 48 CRC patients, 7 (15%) showed loss of protein expression. All seven cases had loss of MLH1 and PMS2 protein. Five cases had MLH1 promoter hypermethylation. The two patients without MLH1 promoter hypermethylation were referred for genetic counselling. Both patients had no family history suspect for LS. In both cases no germline MLH1 mutation was found and somatic mutation analysis showed that both had a likely sporadic tumor.

Conclusion: These results indicate that routine LS screening by IHC and MLH1 hypermethylation in patients with advanced and multiple adenomas within a national FIT-based screening CRC program is not an effective strategy. The diagnostic yield of LS screening in younger adenoma patients should be assessed.

P1089 COLORECTAL CANCER SCREENING PROGRAMS AND THE RATE OF SURGICAL ONCOLOGY PROCEDURES IN THE VENETO REGION (ITALY): ARE FOLLOW-UP COLONOSCOPIES REALLY NEEDED?

E. Rosa-Rizzotto1, M. Saia1, D. Caroli1, G. Ennio1, B. Germanà2, F. Monica3, P. Pilati2, F. De Lazzari1
1Dip.to Diagnosi e Terapia Oncologica, Ospedale San Martino, Genova, Italy
2Department Of Gastroenterology, Cattinara Hospital, Trieste/Italy
3Department Of Gastroenterology, Università degli Studi di Trieste, Trieste/Italy

Introduction: Colorectal cancer (CRC) is a leading cause of cancer mortality in the Veneto Region (North-eastern part of Italy). Population screening of adults between 50 and 75 for CRC was begun in 2002, and it became standard practice in those local health units (LHU) of the region in 2008; 14 LHU provided also follow-up colonoscopies and 7 LHU no. The current retrospective cohort study was carried out to evaluate the impact of CRC screening on the rate of surgical oncology procedures to treat colon and rectal cancer.

Aims & Methods: Data from hospital discharge records (HDR) regarding CRC patients hospitalized between 2000 and 2015 were collected. All CRC patients whose principal diagnosis was colon and/or rectal cancer were included in the study. The number of patients studied rose approximately 18% reaching 1,547,097 for the last year (2015). The Standardized Hospitalization Ratio (SHR) using five-year age groupings was calculated and expressed per 10,000 population.

Results: During the study period, 30,399 surgical procedures for colorectal cancer were performed (colon 63%, rectum 36%, secondary malignant neoplasms 1%) with a SHR of 139.1; the number was higher in males (1.69 vs. 1.02; OR: 1.66; CI 95%: 1.62–1.7; p < 0.05). An analysis of the annual SHR distribution uncovered two distinct phases: during the first phase there was a rising tendency that reached a maximum value in 2007 (166.9; X2 trend: 46.731; p < 0.05) and during the second there was a falling tendency that reached its minimum value in 2015 (102.3; X2 trend: 429.791; p < 0.05). When the cancer sites were analyzed, it was seen that despite the peak in 2007, the rate of surgical procedures of the proximal colon during the last year was the same as the 2000 value (41.5); there was, instead, a relevant decrease in the rate of procedures on the distal colon and rectum which fell from 94.4 to 52.2 (−37.5%). The study also shows that there was no significant difference in the reduction in surgical procedures for CRC in LHU in which the screening program included a follow-up colonoscopy (SHR 2015: 139.8; −29%) with respect to those centers where it was not foreseen (SHR 2015: 138.5; −28%).
ETHNIC VARIATION IN ADENOMA DETECTION IN THE UK FLEXIBLE SIGMOIDOSCOPY BOWEL CANCER SCREENING PROGRAMME

Diseases Digestive Centre, University Hospital of Leicester NHS Trust, Leicester/United Kingdom

Contact E-mail Address: dennis.lim@uhl-tr.nhs.uk

Introduction: The NHS bowel scope screening programme was introduced in 2013 and all adults aged 55 invited for a 'one-off' flexible sigmoidoscopy followed by a colonoscopy if significant adenomas are detected. University Hospitals of Leicester Bowel Cancer Screening Centre serves an ethnically diverse community with approximately 25% of the population eligible for sigmoidoscopy screening being British Asians and 45% being British Whites. Within the faecal occult blood based bowel cancer screening programme we have previously reported a lower polyp detection rate (PDR) and adenoma detection rate (ADR) in Asians undergoing colonoscopy compared to White British. This study aims to evaluate PDR, ADR and cancer detection (CDR) in British Asian Indians taking part in the bowel scope screening programme.

Aims & Methods: Patients who underwent screening sigmoidoscopy between February 1st, 2015 to 28th Feb 2017 were included. All individuals participating in screening sigmoidoscopy routinely report their self-selected ethnic origin. This database was cross referenced with the endoscopic and histology findings from the 'Exeter' online database. The findings in British Asian Indians were compared with British Whites.

Results: A total of 4287 patients underwent screening sigmoidoscopy over the 2-year period. 1169 individuals had polyps (500 adenomas). Overall polyp detection rate (PDR) was 1169/4287 (27.3%), adenoma detection rate (ADR) was 2-year period. 1169 individuals had polyps (500 adenomas). Overall polyp detection rate (PDR) was 1169/4287 (27.3%), adenoma detection rate (ADR) was 2.8% (95% CI 2.8–5.2%) and other polyps were 14/4287 (0.3%) (Inflammatory polyps 13, Juvenile polyp 1). Cancer detection rate was 6/4287 (0.14%). During the period studied, 3509 British white individuals (82%) and 778 British Asian Indians were detected in British White (CDR = 0.17%) but none in British Asian Indians

Conclusion: This study found no cancers and significantly lower PDR and ADR in British Asian Indians compared to British White participants in the bowel scope screening programme. Further long term evaluation of these differences is needed and may shed light on factors contributing to the development of bowel cancer.

CLINICOPATHOLOGICAL STUDY OF SERRATED LESIONS OF THE COLORECTUM

M. Sugimura, M. Iwabuchi, K. Ukai
Gastroenterology, Sendai Medical Center Dept. of Gastroenterology, Sendai/Japan

Contact E-mail Address: msugimura@shn.go.jp

Introduction: Serrated lesions of the colorectum are the precursors of microsatellite unstable carcinomas. However, their clinical and pathologic features are not well described and need further evaluation.

Aims & Methods: The aims of this study was to clarify the clinicopathological features of colorectal serrated lesions. We reviewed clinical charts and pathology files of 5352 endoscopically resected specimens performed during January 2007 and December 2016 in our hospital. A total of 463 serrated lesions (8.7%) were resected and classified into three categories: HP (hyperplastic poly), SSA/P (sessile serrated adenomas/polyps), and TSA (traditional serrated adenoma), according to the WHO criteria. We examined the features of these cases and evaluated the morphologic characteristics by using immunohistochemical staining for Ki-67 and the expression of MUCs (MUC2, MUC5AC and MUC6) in differentiating serrated lesions.

Results: Of these 463 lesions, a total of 241 (52.1%) were HP, 102 (22.0%) SSA/P, and 120 (25.9%) TSA. Male to female ratio (M/F) was 2.38 for HP, 0.98 for SSA/P, and 2.45 for TSA. Mean size of SSA/Ps (13.1 mm) and TSAs (10.4 mm) were significantly larger than that of HP (8.1 mm) (<0.05, respectively). SSA/Ps were located predominantly in the proximal colon, whereas HP and TSA were mainly located in the sigmoid colon and rectum. 64% of SSA/Ps were flat in macroscopic appearance. SSA/Ps and HPs were whitish or almost the same as adjacent mucosa in color, whereas TSAs had a tendency to be reddish. Magnified colonoscopy showed Type II open pit pattern as characteristic of SSA/Ps, whereas pimecione-shaped pit pattern as that of TSAs. Incidence of concomitancy of carcinomas in HP, SSA/P, and TSA were 0% (0 out of 241), 2.9% (3 out of 102), and 4.2% (5 out of 120), respectively. Ki-67 positive cells in HP showed regular, symmetric distribution, and those in SSA/P did not differ in asymmetric distribution.

Conclusion: SSA/P and TSA had different clinicopathologic features from HP. Further research is needed to identify the various etiologic factors and the biological differences that contribute to the development of SSA/P and TSA.
significantly different between serrated lesions, SSA/Ps and HPs were positive for MC1/MAb105 with TSAx.

**Conclusion:** Our studies showed the three types of serrated lesions have their own distinct features and could be helpful to distinguish between them. SSA/P and TSA are pre-malignant lesions of colorectum and we should detect these lesions and completely remove endoscopically.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** It is generally accepted that exosomes, small, membrane-bounded vesicles are formed in multivesicular bodies (MVBS) which fuse with plasma membrane resulting in the release of individual exosomes into the extracellular space. Recently, sporadic in vitro observations of a novel, unconventional mechanism have been reported in which the exosome-like vesicles remain in one host during their secretion.

**Aims & Methods:** Our aim was to examine this phenomenon in migrating colorectal cancer (CRC) cells in situ. Immunohistochemistry (IHC) examination of migrating, individual cancer cells was performed in surgically removed, metastatic CRC samples (n=38). We used epithelial specific cytoplasmic (cytokeratin/C6) and cell membrane (E-cadherin) markers for the identification of 3D reconstructions showed ALIXPositive and CD63Positive exosome clusters (ECs) with 0.62 to 1.94 m diameter (mean±SD: 1.28±0.34 µm) localized partially inside, and/or outside the cytoplasm in 85.96% (n=38/44) of migrating CRC cells. E-cadherin IHC showed that ECs were not only captured around migrating CRC cells but also inside 98% of the individual migrating, individual cancer cells. Differences in ALIXPositive and CD63Positive exosome clusters (ECs) with 0.62 to 1.94 m diameter (mean±SD: 1.28±0.34 µm) localization were observed in the plasma membrane-stroma interface. STEDmicroscopic images showed that released ECs were composed smaller, distinguishable ALIXPositive-positive spheres of 98 to 150 nm diameter (mean±SD: 128.96±16.73 nm), which fall into the size ranges of exosomes.

**Conclusion:** Our study demonstrates in situ for the first time that besides conventional exosome release, migrating CRC cells also secrete large, extracellular ECs. These structures might fundamentally contribute to the autocrine/paracrine regulation of cancer development, which effect may differ from that mediated by conventionally secreted exosomes.

**Introduction:** The semi-essential amino acid arginine is important for intestinal epithelial proliferation and is an essential dietary component delivered by solid food. In homeostatic proliferating adult intestinal enterocytes arginine is catalyzed, by the enzyme arginase 2. During embryonic development, the demand for arginine increases, due to rapid growth. Arginine is lacking from solid food. In homeostatic proliferating adult intestinal enterocytes arginine synthesis via ASS1 plays a role in intestinal carcinogenesis and repair. In TLR4KO mice sacrificed at 8 months, 1.4 polyps/mouse were observed while none was observed at T0 or at 4 months (p=0.006).

**Aims & Methods:** The aim of this study was to define the role of TLR4 in the immune surveillance mechanisms in a non-inflammatory model of colonic carcinogenesis. The azoxymethane (AOM) induced colon carcinogenesis mouse model was used. Colon mucosal samples were collected from wild type (WT) C57bl/6 and TLR4 knockout (KO) mice before AOM administration (T0), at 4 and at 8 months after the first AOM injection. Colonies were removed and examined for occurrence of adenoma and inflammatory infiltrate. Macrophage tumor load was assessed by counting the number of polyps. Flow cytometry on macrophage single cell suspension 98 CD16+ lymphocytes expressing CD25, CD38, CD69 or CD69, for CD4+ lymphocytes expressing CD25 or CD25 and FoxP3 and for epithelial cells expressing CD80 or MHC-I or MHC-II were performed. Non parametric statistics was used.

**Results:** In TLR4KO mice sacrificed at 8 months, 1.4 polyps/mouse were observed while none was observed at T0 or at 4 months (p=0.006). In TLR4KO mice at 8 months, the rates of epithelial cells expressing CD80, CD4+CD25+ and MHC-I were significantly lower than in those at a T0 or at 4 months (p=0.01, p=0.003, p=0.003, p=0.001, respectively). Moreover, at 8 months, 5/7 TLR4KO mice compared to 0/7 WT ones had at least a colonic adenocarcinoma (p=0.02). At this time point, CD4+CD25+, CD4+CD25+FoxP3+, CD4+CD25+, CD8+CD3+ cells rate was significantly lower in TLR4KO mice than in WT ones (p=0.001, p<0.001, p=0.01, p=0.02, respectively). Similarly, at 8 months the rate of epithelial cells expressing MHC-I and MHC-II were significantly lower in TLR4KO than in WT mice (p=0.001, p<0.001, p=0.01, respectively).

**Conclusion:** TLR4 deficiency significantly accelerates the progression of colonic carcinogenesis through a progressive decline of antigen presentation and lack of co-stimulation at later stages. These impairments are associated to a decline of T cell response in all its form (Treg, T helper and cytotoxic). All these findings are coherent with a pivotal role of TLR4 in the immune surveillance mechanism.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Conclusion:** We observed a different behavior between mutated and wild-type patients. Genetic involvement still developed adenomas during the follow-up and some needed colectomy. Instead, wild-type patients had mostly no recurrence. Constitutive genetic background could be suspected in wild-type patients when a continuous development of new polyps has observed and further genetic investigation should be offered by multi-gene testing.

**2nd Medicine, Molecular Gastroscopy, Semmelweis University, Budapest/ Hungary**

**Contact E-mail Address:** kri.szigeti@gmail.com

**Introduction:** Besides local hypermethylation on promoters of certain tumor suppressor genes, global DNA hypomethylation is characteristic in various types of cancers including colorectal cancer (CRC). The DNA methylation level of long interspersed nuclear element-1 (LINE-1) repetitive retrotransposon sequences constituting 17% of the human genome can be used to estimate global methylation level.

**Aims & Methods:** We aimed to analyze the alterations of the global DNA methylation levels along the colorectal normal-adenoma-carcinoma sequence progression on the basis of LINE-1 methylation and to study the methyl-cytosine pattern in tissue samples. Genomic DNA was isolated from 10 colorectal adenoma, 10 CRC and 30 normal colonic biopsy samples. Bisulfite conversion of DNA samples was performed using EZ DNA Methylation-Direct Kit (Zymo). For methylation level quantification of the LINE-1 retrotransposable element, bisulfite specific PCR (BS-PCR) was applied, and 146 bp long PCR products were sequenced on Pyromark Q24 system (Qiagen). Tissue localization of 5-methylcytosine (5-mC) in normal, adenoma and CRC tissues was analyzed by immunohistochemistry using mouse monoclonal anti-5mC antibody (GeneTex).

**Results:** According to the LINE-1 bisulfite sequencing results, significant (p < 0.01) global DNA hypomethylation was detected both in CRC (63.8% ± 8.7%) and adenoma samples (67.5 ± 5.1%) compared to normal tissue (72.1 ± 4.4%). 5-mC labeling of both the epithelial and stromal components of normal samples was strong (scoring values: +2 and +3) with diffuse and nuclear staining. In adenomas, decreased nuclear 5-mC staining (scoring value: +2) was detectable in the epithelium and the stroma compared to normal epithelium. In CRC samples significantly lower 5-mC levels could be observed than in normal tissue samples (p < 0.05).

**Conclusion:** Global DNA hypomethylation could be shown in CRC compared to healthy normal tissue samples both by LINE-1 bisulfite-sequencing and by 5-mC immunohistochemistry. Genome-wide DNA methylation decrease occurs already in adenoma stage of colorectal carcinogenesis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** miRNAs have a critical relevance in regulation during tumorigenesis. The expression profiles of miRNAs alter along tumor progression moreover; these miRNAs may spread into tumor macro- and microenvironment.
P1099 RHOA: THE KEY SIGNALING PATHWAY OF MICRORNA-126 IN SUPPRESSING THE EPITHELIO-MESENCHYMAL TRANSITION, PROLIFERATION, MIGRATION AND INVASION OF COLORECTAL CANCER CELLS

M. Huang, W. Yuan, S. Wu, Z. Shen, Z. Yang, Y. Quan, C. Zhu, K. Tang, X. Wang
Department Of Gastroenterology, The Third Xiangya Hospital Of Central South University, Changsha, Hunan, China;
Hunan Key Laboratory of Nonresolving Inflammation and Cancer, Changsha, Hunan, China; Changsha/China

Contact E-mail Address: hmy02420@126.com

Introduction: The mechanism of colorectal cancer (CRC) invasion and metastasis is still unclear. Epithelial-mesenchymal transition (EMT) is one of the key molecular steps in the process of distant metastasis. EMT is referred to conversion of cells with an epithelial phenotype into cells with a mesenchymal phenotype, which lead to loss of cell polarity, with acquisition of migratory and invasive property.1 MicroRNA (miRNA) is a non-coding RNA that negatively regulate gene expression at post-transcriptional phase.2 MicroRNA-126 (miR-126) originates from a common precursor structure located within the egfl7 gene, which acts as a tumor suppressive miRNA in various cancers.3 In previous studies, we frequently down-regulated in human CRC tissues and negatively correlated with patient’s prognosis.4 MiR-126 was also low-expressed in high metastatic cell lines, and inhibited proliferation, invasion and metastasis of CRC in vitro.5 However, whether miR-126 can regulate the process of EMT in CRC is still unclear. Ras homologue A (RhoA) is one of the most characterized members of Rho GTPases which belong to Ras superfamily. RhoA, as molecular switch, cycles between an active GTP-bound state and an inactive GDP-bound state. RhoA and its co-factors of signaling pathway are known to participate in a diverse array of cellular events related to invasion and metastasis of cancer cells.6 Our previous study found that miR-126 down-regulated RhoA and ROCK activity in CRC cells.7 Whether RhoA activity and RhoA signaling pathway play an important role in miR-126 regulating EMT process, cell proliferation, migration and invasion of CRC remains unclear.

Aims & Methods: To identify RhoA signaling pathway associated with the functions of proliferation, migration and invasion of CRC cells. Constructed CRC cell lines of miR-126 over-expression or knockdown. Performed MTI, colony formation, wound-healing, migration, invasion assays and RT PCR, western blot analysis to study the functions of miR-126 in EMT, proliferation, migration, invasion and expression RhoA signaling pathway of CRC cells. Constructed pDsRed2-V14RhoA (constitutive active RhoA, V14RhoA) and pDsRed2-N19RhoA (domain-negative, N19RhoA) mutants, then transfected them into the CRC cell lines of miR-126 over-expression or knockdown RhoA activity. Pulldown assay detected RhoA activity after transfected. Then repeated the experiments above to investigate the biological behavior changes of CRC cells.

Results: MiR-126 promoted the expression of E-cadherin and suppressed the expression of SLUG, Snail, Vimentin, Fibronectin of CRC cells. MiR-126 also inhibited proliferation, migration and invasion of CRC cells, and negatively regulating RhoA signaling pathway. V14RhoA mutant effectively increased the activity of RhoA and reversed the role of miR-126 by promoting EMT, proliferation, migration and invasion in miR-126 overexpressing HCT116 cells. Conversely, N19RhoA mutant effectively decreased the activity of RhoA and suppressed EMT, proliferation, migration and invasion in miR-126-silenced SW480 cells.

Conclusion: RhoA signaling pathway was the key signaling pathway of miR-126 in suppressing the EMT, proliferation, migration and invasion of CRC cells.

P1100 DNA METHYLATION CHANGES PRECEDE AND CONTRIBUTE TO SPORADIC MUTATIONS IN COLORECTAL ADENOMA AND CANCER DEVELOPMENT THROUGH INDUCED GENOMIC INSTABILITY

2nd Dept. Of Medicine, Semmelweis University, Budapest/Hungary

Contact E-mail Address: mb@bel2.sote.hu

Introduction: Colorectal cancer development is characterized by sporadic mutations and epigenetic alterations. DNA mutations occur randomly and sporadically in growth-related genes, mostly on cytokine nucleotides. Active demethylation of cytosines in relation to RNA expression alterations may lead to genetic instability and DNA mutations. Whole genome DNA methylation and RNA expression profiling with high-resolution bisulfite sequencing (Roche 454 Junior). DNA methylation expression was performed by whole genome expression analysis (HG U133, Affymetrix). Tageted pathway analysis was performed for the p53 pathway. Bioinformatic analysis included overall hypomethylation detection of top hyper/hypomethylated genes, methylation changes on the tumor mutation regions and related pathway gene promoters were evaluated by targeted analysis.

Results: Overall hypomethylation was observed on the N-Ad-CRC sequence in the gene body and non coding genomic regions. In Ad-N comparison e.g p73, NGFR, PDGFRA genes were hypermethylated for their promoters, FMN1, SLCL16A7 genes were hypomethylated, respectively. In CRC-N comparison DKK2, SDC2, SOX1 genes showed hypermethylation, while ERBB4, CREBS, CNTN1 genes were hypomethylated in the promoter regions. In silico analysis on the TCGA database yielded confirmatory results. The common hyper- and hypomethylated genes were also in correlation with methylation array data. A significant negative correlation of the top methylated genes could be demonstrated to the RNA expression data. In the certain mutation hot spot, genebody regions significant DNA methylation alterations (mainly hypermethylation) were detected. APC, P53 and KRAS mutations were found in 30%, 24%, and 21% of adenomas, and in 29%, 53%, 29% of CRCs, respectively. PCR analysis could detect any significant quantitative changes related to these DNA sequence alterations. The p53 gene body was addressed by hypermethylation in adenomas. microRNA expression changes were observed in most of the p53 pathway genes showing promoter methylation alterations.

Conclusion: DNA methylation with consecutive phenotypic effect can be observed in a high number of gene promoters and gene body regions through CRC development. The mutation hot spot areas of the most relevant colorectal cancer genes (APC, P53, KRAS) were hypermethylated without detectable quantitative RNA expression changes. p53 cancer pathway genes are highly methylated in promoters and gene body with expression changes. The tumor mutation hot spot areas in the p53 gene body were hypermethylated and thus could not be detected in the methylation alterations.

Disclosure of Interest: All authors have declared no conflicts of interest.
1.90, respectively. However, the polyp miss rate of BLI-WL group was less than that of WL-WL group (1.6% vs 10.0%, P = 0.0014).

**Conclusion**: There were no significant difference in the overall polyp (adenoma) detection rate with BLI-WLI group or WL-WL group. However, miss rate was higher in WL-WL group compared with BLI-WL group (10.0% vs 1.6%, P = 0.0014). Further, BLI detected more polyps per patient compared with WL group (2.84 vs 1.90). BLI may improve polyp miss rate and the number of polyps per subject (mean adenoma detection rate) in the colonoscopy.

**Disclosure of Interest**: All authors have declared no conflicts of interest.

**P1103 COLORECTAL CANCER SCREENING COLONOSCOPY - ABSENT DISTAL POLYPS IN ADVANCED PROXIMAL NEOPLASIA**

R. N. Patel1, M. Hussein1, L. Polak1, A. Kumar2, S. Samanta1

1Gastroenterology, Barking, Havering and Redbridge University Trust, Essex/United Kingdom

2Colorectal Surgery, Barking, Havering and Redbridge University Trust, Essex/United Kingdom

**Contact E-mail Address**: rajan.patel@nhs.net

**Introduction**: The National Health Service Bowel Cancer Screening Programme (NHS BCSP) offers colonoscopy to people testing positive for Faecal Occult Blood Test (FOBT) after the age of 60. In addition, the 'Bowel scope screening' test offers once-only flexible sigmoidoscopy (FS) to people in the UK after the age of 55. The Norwegian (NORCCAP) and Italian (SCORE) trials evaluated the effectiveness of FS screening and reported a non-statistically significant decrease in colorectal cancer (CRC) specific mortality at follow-up. It is unclear if significant proximal neoplasia is being missed in people undergoing flexible sigmoidoscopy alone.

**Aims & Methods**: We aim to investigate the distributions of pathology within the BCSP at a busy district general hospital in London. In 2015, 22,539 FOBT kits were returned out of the 43,884 (51.4%) sent out in the boroughs of Barking, Havering and Redbridge (BHR). Of those returned, 398 (1.8%) tested positive. We collected data for the 326 patients who attended for colonoscopy at BHR University Hospitals (81.9%). Subgroup analyses included age, sex, histology, location of polyps, number of polyps, polyp size and therapies.

**Results**: Mean age 67, Male 60.4%. Polyps were found in 199 patients (61%), 488 polyps found in total, mean number of polyps 2.5 (Range 1–14), mean size 7 mm (Range 1 mm–60 mm); 49 (15%) hyperplastic, 156 (47.9%) adenomas and 16 (4.9%) adenocarcinoma. Patients with adenoma/carcinoma were older (67.6 vs. 66.5, p = 0.02) but there was no difference in sex (Male 61.4% vs. 59.4%, p = 0.49) when compared to those without adenoma/carcinoma. Of 172 patients with adenoma/carcinoma, 111 (64.5%) were proximal to the splenic flexure (SF). 5 out of 16 (31.2%) adenocarcinomas were proximal to SF and 2 (40%) of these patients had no polyps distal to the SF.

**Conclusion**: Patients with adenomas/carcinomas are older and those with proximal adenomas/carcinomas have more polyps but are smaller in size. One in three adenocarcinomas picked up during colonoscopy would be out of reach of a flexible sigmoidoscopy. Furthermore, over one third of the proximal cancers did not have distal polyps.

**Disclosure of Interest**: All authors have declared no conflicts of interest.

Introduction: Colorectal cancers have two development theories. One of the development theories is “adenoma-adenocarcinoma sequence” developing from protruded-types “polyps” we know generally. The other is considered to emerge directly from normal epithelium, not through the adenoma stage. Recently, it is revealed most of this type are depressed-type carcinomas. This theory is called “de novo” pathway. We studied clinicopathological characteristics and long-term prognosis mainly on depressed-type colorectal carcinomas. Aim: To clearly the pathological characteristics of depressed-type colorectal carcinomas compared with flat- and protruded-type. A total of 2930 colorectal neoplasms excluding advanced carcinomas were resected endoscopically or surgically in our Center from April 2001 to December 2015. Of them, 112 tumors were identified as T1 carcinomas. Anatomical and morphological development classification, 244 lesions (21.7%) were depressed-type, 385 lesions (34.2%) were flat-type and 498 lesions (44.1%) were protruded-type. We analyzed the pathological features of these lesions.

Results: The rate of distant metastasis or recurrence was 0.9% (10/1127). Among these 10 cases, 5 cases were developed from depressed-type lesions and one showed a para-aortic lymph node metastasis and four showed a lung metastases. The number of metastasis in all the lesions was 72.4% in depressed-types, 3.2% in flat-type and 2.9% in protruded-type. Within less than 5 mm in diameter, that was 10.6%, 0% and 0% respectively. Among T1 carcinomas, the rate of vessel invasion was 64.3% in depressed-type, 34.3% in flat-type and 38.4% in protruded-type. Sixty of poorly differentiated or mucinous adenocarcinomas were 17.2%, 10.4% and 13.5%, that f of massive submucosal invasion was 94.7%, 71.7% and 69.7%, and that of tumor budding was 36.5%, 16.1% and 17.3%, respectively. The rates of these pathological factors were significantly higher in depressed-type lesions. On the other hand, the rate of adenomatous component was 4.9%, 52.2% and 50.8% respectively. It was significantly lower in depressed-type lesions, suggesting that they emerge directly from normal epithelium without going through the adenoma stage. The rate of lymph node metastasis was 11.6%, 6.8% and 3.0%, respectively. And 2 depressed-type lesions had synchronous liver metastases.

Conclusion: Depressed-type colorectal carcinomas invade massively even when they are small. They had higher risks of vascular invasion, poorly differentiated or mucinous adenocarcinomas, massive invasion and tumor budding than flat- or protruded-types. For their rapid growth and malignant potential, whether the lesion is depressed-type or not is very important in the diagnosis of colorectal carcinomas.

Introduction: Hypoxia signalling has been enhanced to haemorrhage cancer cell survival, chemoresistance, motility, tumour angiogenesis as well as self-renewal capacity and proliferation of putative cancer stem cells. One of the key player in hypoxia is carbonic anhydrase IX (CAIX) which is a hypoxia-inducible enzyme. CAIX is overexpressed in a variety of cancers including colon cancer and plays a crucial role in maintaining favourable intracellular pH in hypoxia. There is also evidence that extracellular vesicles (EV) production is increased in response to hypoxia and promotes adaptive response of cancer cells and we have previously demonstrated, that CAIX positive EVs secretion is increased in response to hypoxia in colon cancer cell lines [20].

Aims & Methods: Within this study, we explored a possibility to use CAIX for the isolation of hypoxic EVs from colorectal cancer (CRC) patients’ plasma. EVs were isolated from plasma samples of 27 CRC patients and 25 healthy donors (HD) by using sequential centrifugation, filtration and size-exclusion chromatography steps. EVs where quantified by Nanoparticle tracking analysis (NTA) and CAIX positive EVs where determined by ApogeeA50.

Results: Statistically significant increase in the amount and size of EVs was observed in CRC compared to patients HD. The percentage of CAIX and CAIX-positive EVs was significantly higher in CRC patients compared to HD. In addition, it is higher in patients with metastasis than without distant metastases.

Conclusion: There is an increased total EV number, EV size and CAIX positive EV amount in CRC patient plasma compared to HD plasma, that might have diagnostic and prognostic value. (Financed by Latvian Council of Science, collaboration project No: 625/2014).

Introduction: Colorectal cancer (CRC) is an important contributor to cancer mortality and morbidity worldwide. 80% of CRCs arise via the adenoma-carcinoma sequence, 10-20% by sessile serrated adenomas (SSA). Hyperplastic polyps are regarded harmless. Current surveillance strategies for CRC following polypectomy are determined by endoscopic and histopathological factors. Such a distinction has also been challenged.

Aims & Methods: The study was aimed for molecular characterization of colonic polyps in patients who underwent screening colonoscopy. Correlation of the genetic analysis with endoscopic, clinical and histopathological data was attempted to potentially better define relevant risk marker or sub-groups at risk for prediction of surveillance intervals. 100 Patients were enrolled in this study. Patients with polyps ≥ 10 mm and with at least one high grade adenoma (GCRA: 8%, 25% SSA: 38%). Up to 6 representative polyp biopsies were collected and stored in a formalin-free medium and finally embedded in paraffin-blocks, followed by histopathological assessment. Targeted Next Generation Sequencing (TNGS) was performed for 38 cancer related genes; GeneRead DNASeq Targeted Panels V2, Qugen® on a MiSeq platform (Illumina®). Genetic and histopathological analysis was done blinded to the endoscopic and clinical data.

Results: In 100 patients, 234 polyps were removed. 121 polyps (54.0%) are sized < 10 mm, 71 (31.7%) were ≥ 10 mm. For 32 polyps (14.3%) no size was available. 90 polyps (40.2%) were located in the left, 126 polyps (56.3%) in the right colon, for 8 polyps (3.6%) no location was noted. 112 polyps (50.0%) were adenomas and 110 polyps (49.1%) non-adenomatous lesions. No data were available
for 2 polyps (0.9%). Clinical, endoscopic and histopathological data were corre-
lation coefficients. Significantly different DNA methylation patterns with endoscopic or histopathological polyp characteristics were observed for BRAF, KRAS, TCF7L2, FBXW7 and CTNNB1 mutations. Multivariate analy-
lysis revealed that polyps >10 mm have a significant higher relative risk (RR) for harboring oncogenic mutations (RR 3.467 (1.742–6.933)). Adenomas and right-
sided polyps are independent risk factors for CTNNB1 mutations (RR 18.559.
The conclusion was that assessment of the mutational landscape of resected polyps/poly biopsy can easily be integrated in the workflow of current colonoscopy practice. There are distinct genetic patterns related to size and location of polyps and the clinician can appreciate this additional information to better estimate a patient’s individual risk.

Introduction: Cell-free DNA (cfDNA) is circulating in human plasma and its amount is different in certain physical conditions. It is well known, that in healthy people the quantity of cfDNA is very low, but it rises in chronic disorders such as cancer. At the same time, very high cfDNA level can be measured in healthy people during physical exercise.

Aims & Methods: We aimed to analyze cfDNA changes (quantity, fragment length, global DNA methylation level) in physiological conditions (during physical exercise) and in inflammatory and neoplastic colorectal diseases. Plasma was separated from 64 patients (16 colorectal carcinomas (CRC), 13 colonic adenomas (AD), 19 inflammatory bowel disease (IBD), and 16 normal (N) donors without evidence of disease). Plasma samples were also collected from 6 healthy athletes before, during and after physical training. DNA was isolated with High Pure Viral Large Volume NA isolation Kit (Roche). cfDNA was quantified with Qubit fluorometry (Invitrogen). CfDNA fragment length distribution was assessed by Bioanalyzer 2100 using High Sensitivity DNA assay (Agilent). Global DNA methylation was analysed by bisulfite pyrosequencing of long interspersed nuclear element-1 (LINE-1) (Qiagen).

Results: High increase of cfDNA amounts was observed in plasma samples of patients with colonic adenoma (20.61 ± 10.70 ng/ml), colorectal cancer (24.13 ± 20.02 ng/ml) and IBD (22.27 ± 16.40 ng/ml) compared to healthy sub-
jects (10.33 ± 3.22 ng/ml). Highly elevated cfDNA amounts were found in plasma samples of athletes during physical exercise (66.17 ± 29.00 ng/ml), while the cfDNA amount decreased after physical activity (51.87 ± 39.80 ng/ml). Characteristic cfDNA fragment length distribution pattern (with different peak heights at 180 bp, 360 bp, 550 bp) was observed in each patient group. Global DNA hypomethylation was shown in CRC plasma samples with advanced tumor stage (N: 79%, C: 66.7%, C: 66.7%, C: 66.7%). The hypomethylation amount is different in certain physical conditions. In recent years, blood-based cfDNA amount decreased after physical activity (51.87

Conclusion: CFDA amount is different in certain physical conditions. It is well known, that in healthy individuals with 91.5% sensitivity and 97.3% specificity (AUC = 0.978) could differentiate adenoma samples from healthy controls with 89.2% sensitivity and 86.5% specificity (AUC = 0.937). In silico analyses confirmed our results on the altered methyla-
tion of the four markers in tissue samples. In silico analyses confirmed our results on the altered methyla-
tion indicated decreasing protein levels of the four markers along the colorectal adenoma-carcinoma sequence.

Introduction: Metabolomics, a dynamic portrait of the metabolic status of living systems, has demonstrated its great potential for use in the diagnosis of various cancers by applying advanced analytic techniques and bioinformatics tools. Recently, very few metabolic markers in CRC have been consistently discovered, but the specific metabolic profiles of patients with CRC indicating colorectal cancer in colorectum remains poorly understood and warrants investigation due to its non-invasive sampling method. In the last decade, several metabolomic approaches have been applied toward identifying metabolic alterations in CRC using variety of sample types including urine, tissue, serum, and feces. However, there are only few urinary metabolic studies and especially nuclear magnetic resonance (NMR) spectroscopy, which has several advantages including rela-
tively high degree of reproducibility, easy-to-identify metabolites, high throughput, and non-destructive sample treatment, has not been applied to urine samples.

Aims & Methods: In this study, we investigate the differences in urine metabolic profiles of patients with colorectal neoplasia (CRN) including CRC and precancerous lesion, and healthy volunteers using a NMR-based urine metabolic study. In addition, we evaluate applicability as diagnostic tool of urine metabo-

Conclusion: Biochemical profiles from patients with colorectal neoplasia (CRN; 36 advanced adenomas and 56 various stages CRC) and healthy controls (n = 156) were analyzed by NMR spectroscopy. Healthy and CRN groups were statistically discriminated using orthogonal projections to latent structure discriminant analysis (OPLS-DA). The class prediction model was validated by three-fold cross-validation. The advanced adenoma and stage 0 CRC were grouped as pre-invasive CRN.

Results: After patients underwent endoscopic resection or surgical resection for CRC, advanced adenoma has been diagnosed in 36 patients, stage O CRC in 24 patients, stage I CRC in 8 patients, stage II CRC in 7 patients, stage III CRC in 13 patients and stage IV CRC in 4 patients. CEA and CA 19-9 levels for patient were analyzed (b-values of 19-9 were increased in patients with CRC). The sensitivity and specificity of CEA and CA 19-9 were 6.2% and 99.3%, respectively. The grades of the OPLS-DA score plot showed statistically significant discrimination between pre-invasive CRC as well as advanced CRC and normal with a Q2 value of 0.591. In the prediction validation study, the sensitivity and specificity for diagnosing pre-invasive CRC was 96.2% and 95%, respectively. The grades predicted by the PLS-DA model showed that area under the curve was 0.823 for taureine, 0.783 for alanine and 0.842 for 3-aminoisobutyrate. In multiple receiver operating characteristics curve analyses, tauurine, alanine, and 3-aminoisobutyrate were good discriminator for CRC patients.

Disclosure of Interest: NMR-based urine metabolic profiles significantly and accurately discriminate between patients with pre-invasive CRC as well as
advanced CRC, and healthy control with high accuracy. It demonstrates an applicability of urinary metabolomics as screening tool for accurate diagnosis of pre-invasive CRN.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Symptoms alone are poor predictors of underlying colon pathology. Only 14% of patients referred for colonoscopy from primary care have significant bowel disease (SBD), colorectal cancer (CRC), high risk adenoma (HRA, defined as > or any ≥ 1 cm) and inflammatory bowel disease (IBD). We have reported that undetectable faecal haemoglobin (f-Hb), measured by a faecal immunochromatatic test (FIT) is a good rule-out test for SBD. Since December 2015, GPs in Tayside have been encouraged to use FIT test as an adjunct to history, examination and mandatory blood tests in patients referred with bowel symptoms. Referrals are vetted by a Consultant and triaged to test or clinic. We have examined the impact of the introduction of the FIT test on referral rates and colonoscopy yield.

Aims & Methods: Patients in primary care with new bowel symptoms were encouraged to complete a FIT in addition to blood count and renal function check. We prospectively recorded FIT tests received, referrals to secondary care and colonoscopy findings over 1 year from December 2015 to December 2016. FIT tests were analysed by HMJACKarc (Kyowa Medex Co. Ltd., Japan) with f-Hb concentration potentially rules out significant colorectal disease. Cololectal Dis 2013;15:e151-9.

Introduction: The immunological screening test (FIT) for colorectal cancer (CCR) was introduced in January 2015 in Ile de France (15 million inhabitants) after Hemocult was abandoned due to its low sensitivity. The Hemocult (HC) launched in 2007 had reached less than 30% participation rate.

Aims & Methods: We report one-year on FIT screening in Ile de France and compare results to those with HC test for speculating on adjustment actions. The raw data were extracted by request from the registry of the screening structure (in various areas 75, 77, 91, 92, 94 and 95) covering a target population of 3026366 habitants. Rates of participation were calculated, and after one-year experience period, profiles of individual with positive tests, rates of those with positive colonoscopy, with polyps (all stages combined) and with high grade dysplasia (HGD) were described. Results were compared to those with HC from the launch to the end of the last campaign (Dec 2014) normalized for mean one-year output. The comparisons were made by an x2 test (qualitative variable) and multivariate stepwise analysis was performed for identifying predictive factors for cancer diagnosis.

Results: At the end of the HC-based screening campaigns 2014, 2.5 million individuals were annually invited and the participation rates since 2009, ranged from 28.2% to 24.6%, with females showing higher rates for participation (30.6% vs 26.1%) than men (26 to 21.8%, p < 0.0001). During the first (2015) year FIT experience, the O Sensor device was used for 450120 (34% estimated participation rate) individuals (versus 294603 participants with HC in 2014 p < 0.0001; 24% participation rate). The rate of positivity was 4.0% (versus 1.9% with HC; p < 0.0001). Among all positive FIT individuals, 93% underwent colonoscopies: 35% were normal (vs 41%; p < 0.01), 13.2% presenting with cancer or HGD and 52% with polyps (vs. 37.7%; p = 0.00051). While women (50.0%) had similar to invitation rate, 57.1% vs 55.9%, the positivity rate in women (3.7%) was lower than in men (5.5%; p < 0.0001). More advanced polyps and cancer were found in men (14.5%) than in women (11.3%) (p < 0.0001) with normal colonoscopies lower in men (24.2%) than in women (40.7%; p < 0.0001). The predictive value for cancer leads to more early lesions detected indicating its higher specificity. Men of 63.5 yrs old or more with Hemoglobin levels higher than 340 ng/mL are of very high risk of cancer and should be absolutely conducted to the colonoscopy in case positive FIT test. Disclosure of Interest: All authors have declared no conflicts of interest.

P1113 ARTIFICIAL INTELLIGENCE CAN PREDICT THE PRESENCE OF LYMPH NODE METASTASIS IN T1 COLORECTAL CANCER

Introduction: Most T1 colorectal cancers (CRCs) undergo surgical colectomy in which pathologists with established clinical guidelines despite the low incidence (approximately 10%) of lymph node metastasis (LNM). Therefore, many patients without LNM undergo unnecessary surgeries.

Aims & Methods: To reduce unnecessary surgeries, we aimed to predict the risk of LNM in T1 CRCs by using artificial intelligence (AI). Data on 690 consecutive patients with T1 CRCs who had undergone colectomy between April 2001 and March 2016 were retrospectively analyzed. Data of a randomly selected 590 patients were used for machine learning for the AI model, which analyzed five clinicopathological factors: tumor location, lymphatic invasion, vascular invasion, tumor budding and histological grade. The remaining 100 patients served as a test set for validating the AI model and output the predicted LNM as positive or negative. To validate the AI model, sensitivity, specificity and

P1114 RISK FACTORS OF ADVANCED METACHRONOUS NEOPLASM IN COLOSCOPIC SURVEILLANCE AFTER COLON CANCER RESSECTION

K. Nam1, J.E. Shin1, K.B. Bang1, H.D. Shin1, H. Namgung2, D.G. Park2

1Gastroenterology, Dankook University Hospital, Cheonan/Korea, Republic of 2Surgery, Dankook University Hospital, Cheonan/Korea, Republic of

Contact E-mail Address: nambag1108@gmail.com

Introduction: Regular surveillance colonoscopy after colon cancer resection is recommended to detect metachronous adenoma and cancer. However, risk factors of advanced metachronous neoplasm during postoperative surveillance have not been fully evaluated yet.

Aims & Methods: This study aimed to assess the risk of advanced metachronous neoplasm during surveillance colonoscopy in patients who underwent curative colon cancer resection. The patients who underwent curative colon resection for non-metastatic colon cancer between January 2002 and December 2012 in a single tertiary center were retrospectively reviewed.

Results: A total of 278 patients were enrolled in this study. Surveillance colonoscopy was performed after perioperative clearing colonoscopy. Among the patients, 182 (61.6%) were male, and the median age was 65 years. On perioperative clearing colonoscopy, accompanying high-risk adenomas (>3, size ≥10 mm, with high-grade dysplasia and villous histology) were detected in 95 patients (31.9%) and were significantly associated with old age (>65 years), male sex, alcohol use, smoking, and stage 3 colon cancer (P < 0.05). During the post-operative follow-up periods (median, 5.35 years), advanced metachronous neoplasm was found in 45 patients (15.1%) during surveillance colonoscopy, including colon cancer in 4 patients (1.3%). In the multivariate analysis,, distal colon cancer (distal to splenic flexure; odds ratio [OR] = 4.463; P = 0.002), accompanying high-risk adenomas on perioperative clearing colonoscopy (OR = 3.414; P = 0.001), and hypertension (OR = 2.344; P = 0.026) were significant risk factors of advanced metachronous neoplasm during surveillance colonoscopy.

Conclusion: Patients who had distal colon cancer, accompanying high-risk adenomas on perioperative clearing colonoscopy, and hypertension may need a shorter colonoscopic surveillance interval. A more tailored surveillance strategy is needed to improve overall outcome in patients who undergo curative colon cancer resection.

Introduction: Despite major advances in white light endoscopy detection of colon polyps remaining challenging with significant polyp miss rates. The novel second generation full spectrum endoscopy (FUSE) is a new scope with two additional cameras in the sides that provides a panoramic 300° field of view.

Aims & Methods: The aim of this study is to identify the role of the FUSE in improving polyp detection. This was a single-center, prospective, randomized, open-label study in patients that presented for routine colonoscopy at an outpatient unit during a six months period. Patients were randomized to either FUSE (FUSE colonoscope CDVL slim c38) or standard frontal view (SFV) colonoscopy (Olympus Evis Exera III 190). The primary outcomes were polyp detection rate (PDR), diverticulum detection rate (DDR) and complete colonoscopy. Secondary outcomes were procedure time, adverse event rates, size and characteristics of the polyps and success of endoscopic treatment (R0 resection). All procedures were performed by experienced endoscopists, who had carried out >5000 colonoscopies and had excellent polyp detection rates (>95%).

Results: A total of 197 patients (49.2% female, 50.8% male, median age 60 years, range ±16 years) were studied. No significant difference was seen between the 2 groups for the primary endpoints of polyps detection rate (PDR), diverticulum detection rate (DDR) or complete colonoscopy (table 1). About secondary endpoints: R0 endoscopic resection was achieved in 95% in both groups (p = 0.68). The median procedure time in minutes was higher with SFV (36.7 ± 13.3 min) than FUSE 21.5 ± 10.7 min (±4.6, IC95% 8 – 12.1, p = 0.005). There were no significant differences regarding adverse events, determination of colon cleanliness, or others epidemiologic factors. 2 case were excluded of the statistical analysis due to surveillance of polyposis syndrome, to avoid skewing of results.

Conclusion: In expert hands, PDR and DDR exceed 50% with advanced white light and FUSE systems. FUSE was not superior to advanced white light endoscopy for the PDR and DDR. However, with FUSE we can reduce procedure duration without any additional adverse events or increased discord rate. These data further demonstrate the safety and feasibility of the new FUSE system.

P1116 UNDERWATER ENDOSCOPIC MUCOSAL RESECTION FOR NON-PENDULATED COLORECTAL LESIONS. IS THE DISTAL CAP REALLY NECESSARY?

1Endoscopia, Fluor Médica e Endoscopia, Belo Horizonte/Brazil 2Gastrointestinal Endoscopy Unity, Cancer Institute of University of São Paulo, São Paulo/Brazil 3Endoscopy, Cancer Institute of São Paulo State, São Paulo/Brazil 4Gastroenterology, University of São Paulo, São Paulo/Brazil

Contact E-mail Address: ktpennacchi@yahoo.com.br

Introduction: Underwater Endoscopic Mucosal Resection (UEMR) has been demonstrated as a safe and effective technique for removal of flat and sessile colorectal lesions. Until now, only UEMR with cap has been described in literature. In addition there is no consensus about the endoscopic settings.

Aims & Methods: This prospective study was conducted between January and November 2016 in two university tertiary referral centers. UEMR was performed using a standard colonoscope without the distal cap. The lesions were marked with snare tip prior to resection. Insufflation was switched off. Then, the colon lumen was entirely deflated. Water at room temperature was infused using an irrigation pump until complete filling of the lumen was achieved. All gas pockets in the operative field were evacuated. Two sizes of polypectomy snare (13 and 25 mm) were used according to the preference of the endosco- pists. No submucosal injection was performed. One of these three different electroendoscopic settings (DRY-CUT, AUTOENDOT and ENDOCUT) was selected. All resection wounds were carefully inspected after UEMR. Endoclips were employed for the management of bleeding and suspected perforation.

Results: Between January and November 2016, 45 patients (27 female, mean age 67 years, range 53–87 with 55 non-pendulated colorectal lesions (mean size 16 mm, range 10–40 mm) were included. Six lesions were located in cecum, 21 in the ascending colon, nine in transverse, eight in descending colon, five in sigmoid, and six in rectum. In five patients, we selected DRY-CUT mode; in fifteen AUTOENDOT; and in twenty-five the ENDOCUT mode. All lesions were successfully and completely removed by UEMR. The procedure time was recorded in 24 resections (mean 13 minutes, range 4–40). Thirty-three of them were removed on bloc (60%). Histology revealed the following: 40% tubular adenomas; 20% tubulovillous adenomas; 25.45% sessile serrated adenomas; 3.65% traditional serrated polyps; 7.25% intramuscular adenocarcinomas and...
3.65% were superficial submucosal carcinomas (<1.000 μm). During UEMR, two cases (both using AUTOCUT mode) of spurt bleeding were observed (4.45%). Hemostasis was easily achieved in both cases by clamping. No patient required blood transfusion. One patient had abdominal pain on the day after resection without signs of pneumoperitoneum on CT scan. There was no perforation or delayed bleeding.

Conclusion: This study supports the existing data indicating acceptable rates of technical success and low incidence of adverse events with UEMR. The results of this study without cup were similar with the previous ones using cup. Further comparative studies with and without cup, using different settings and especially between UEMR and traditional EMR are needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI117 ADENOMA DETECTION RATE INFLUENCES RISK PREDICTION OF METACHRONOUS ADVANCED COLORECTAL NEOPLASIA IN LOW-RISK PATIENTS
S.H. Kim, S.J. Lee, T.J. Kim, E.R. Kim, S.N. Hong, D.K. Chung, Y. Kim Gastroenterology, Samsung Medical Center, Seoul/Korea, Republic of Korea

Introduction: Current guidelines recommend surveillance colonoscopy after 10 years or surveillance in 5-10 years in individuals with no or 1-2 non-advanced adenomas.

Aims & Methods: We hypothesized that risk of metachronous advanced colorectal neoplasia (AN) varies based on clinical characteristics and colonoscopy quality. We identified 7,171 participants with no or non-advanced adenomas at first-time screening colonoscopy. The risk of metachronous AN at surveillance colonoscopy 3-5 years later was investigated according to clinical characteristics and endoscopist adenoma detection rate (ADR).

Results: In multivariate analyses, strong associations between increasing age, male sex, current smoking, family history of colorectal cancer, follow-up interval, increasing number of adenomas, and low ADR and risk of any metachronous colorectal neoplasia were observed. For metachronous AN, increasing age, male sex, increasing number of adenoma, and low ADR were independent risk factors. Among patients with 1-2 small adenomas, women with age ≥60 years or men comprised a hidden-risk group, which had 5.3% risk of metachronous AN at surveillance. Women <60 years old with 1-2 low-risk adenomas had very low (1.2%) metachronous AN risk. Metachronous AN was significantly more likely in individuals who were completely negative for endoscopist ADR (<32%) than in those screened by endoscopists with a higher ADR (≥32%) (3.2% vs. 0.6%, respectively; P = 0.001).

Conclusion: According to patient and adenoma characteristics, and ADR of the endoscopist, the risk of metachronous AN varies among low-risk patients. In recommending surveillance colonoscopy, these factors should be taken into consideration.

Introduction: The technique of endoscopic submucosal dissection has recently been implemented, and large and complete lesions such as those invading ileocecal valve and appendix orifice can be resected en bloc. However, lesions accompanying severe fibrosis in the submucosal layer and exhibiting the muscle retraction (MR) sign are often difficult to be resected completely. We devised a new method called ‘Per Anal Endoscopic Myectomy’ for small lesions involving severe fibrosis, in which dissection is done between the inner circular and outer longitudinal muscles instead of between submucosal layer and muscle layer. Aims & Methods: The aim of this study is to examine the usefulness and safety of PAEM. All PAEM cases performed in our hospital and an affiliated hospital were retrospectively reviewed. When fibrosis in the submucosal layer was suspected, pocket creation method was applied and if severe fibrosis with MR sign was found, PAEM was selected. In PAEM procedure, after dissecting circumferentially around the fibrosis with a double tunneling method, the inner circular muscle is cut in a circular manner, which makes the outer longitudinal muscle clearly visible. The space between the inner circular and outer longitudinal muscles is sparse and suitable traction with the tunneling method makes it easier to dissect this space. PAEM was performed only for rectal lesions, and no clip closure was carried out after the procedure in most cases.

Results: Ten rectal lesions were treated with PAEM between July 2015 and March 2017. Among them, 7 cases including 2 cases with mucosal cancer, 3 cases with 1-2 small adenomas and 2 cases with advanced adenoma were resected en bloc with negative margin. The other 3 cases showed tumor invasion to the muscle layer and the vertical margin was positive. The clinical course after PAEM was preferable in all cases. Three cases which achieved resection with negative margin but found lymphovascular invasion of the tumor underwent additional surgical or adjuvant chemoradiation. In surgical cases, they could permit anus-preservation.

Conclusion: PAEM for lesions exhibiting MR sign with severe fibrosis will enable complete en bloc resection with more accurate pathological diagnosis. No complications were recorded in our experiences. Further investigation into the significance of PAEM would be needed.

PI119 LOCAL RECURRENCE AFTER ENDOSCOPIC MUCOSAL RESECTION FOR HIGH-RISK LESIONS: MAY WE BETTER PLAN THE ENDOSCOPIC FOLLOW-UP ACCORDING TO PROCEDURAL AND MORPHOLOGICAL AND HISTOLOGICAL CHARACTERISTICS?
C. Quondamcarlo, C. Lucidi, R. Lapenta
Gastroenterology, Regina Elena Cancer Institute, Rome/Italy

Contact E-mail Address: qcinzia@ymail.com

Introduction: Endoscopic mucosal resection (EMR) is an increasingly used technique for the removal of large sessile and flat-laterally-spreading colorectal lesions. At present, surveillance colonoscopies are ever performed to ensure detection and adequate treatment of residual or recurrent adenoma (RRA), which, occurring in 10–40% of non-peneculated lesions, currently represents the main limitation of this technique. Fortunately, endoscopic detection of RRA in the post EMR scar is currently highly accurate using HD-WL (high definition-white light) and NBI (narrow band imaging). Anyway, indications for follow-up...
P1120 TREATMENT STRATEGY FOR LOCAL RECURRENCES AFTER ENDOSCOPIC RESECTION OF COLORECTAL NEOPLASMS
Division Of Endoscopy, Shizuoka Cancer Center, Shizuoka,Japan

Contact E-mail Address: saito@schr.jp

Introduction: Local recurrences after endoscopic resection (ER) frequently occur after colorectal neoplasms. Recently, the efficacy of submucosal dissection (ESD) for local recurrences has been reported. However, an appropriate treatment strategy for these lesions including ESD remains unclear.

Aims & Methods: This study aimed to clarify the appropriate treatment strategy for local recurrences after ER. A total of 81 patients (81 lesions) who received treatment for local recurrences after ER for colorectal neoplasms between January 2010 and December 2016 were enrolled. Patients with pathological diagnosis of hyperplastic polyp, sessile serrated adenoma/polyp, and submucosal invasive cancer in their first ER were excluded. Seven patients who underwent surgery because of submucosal invasion or technically difficult locations were also excluded. Procedural outcomes, recurrence rate and disease control rate (DCR) were evaluated according to preoperative endoscopic diagnosis of recurrent lesions (adenomatous or carcinomatous). The DCR was defined as proportion of patients who were diagnosed with curative resection after ER or received additional surgery based on pathological diagnosis after ER.

Results: Seventy-four patients were included. The en bloc resection rates of EMR and ESD were 53.8% and 100%, respectively (P = 0.03). The seven cases (7.7%) in the EMR group developed local recurrences, but additional ER achieved curative resection. The DCR of three methods were all 100%. Meanwhile, 25 patients developed local recurrences. One case required surgery because of invasive local recurrence, the second case required chemotherapy because of distant metastasis, and the third case was followed up to try to prevent it, better plan surveillance intervals, establish role and timing of surgery and reduce costs.

Conclusion: This study has demonstrated that the survival of SC was identical to that of OC, and additional surgery was found to significantly improve the prognosis in SC. Chemotherapy after endoscopic colonic stenting has been considered tolerable as a palliative therapy or bridge to surgery for obstructive colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A self-expandable metallic stent (SEMS) placement is potentially a colostomy-sparing option to manage a malignant colonic obstruction (MCO). However, in patients with coexisting peritoneal dissemination (carninomatous adhesion), for example, insertion of a standard caliber colonoscope (SC) is impossible, whereas such an endoscope equipped with a large working channel is suitable for through-the-scope (TTS) SEMS placement. Failure in stenting necessitates continuous tube drainage, stoma formation, or other surgical procedures and decreases quality of life (QOL). We examined the feasibility and efficacy of “Over-The-Catherer” Colonoscope Replacement technique (OTC-CR) detailed below, in palliative (not preoperative) SEMS placement for MCO. From Oct 2012 to Dec 2016, MCO patients were consecutively considered for decompression by SEMS placement unless stoma formation was preferred. When a conventional TTS procedure was unsuccessful, specifically, when the MCO site was inaccessible with an SC (CF-H260AL, Olympus Medical Systems, Tokyo, Japan) with a 13.2mm tip diameter and 3.7mm working channel, needed for a 22 mm (not 18 mm)
delivery system passage (e.g. Niti-S Colonic Stent, Taewoong-Medical, Seoul, South Korea) or when a guidewire was unable to be passed through the stricture because of limited maneuverability of the endoscope, procedures below were followed. (1) A thinner scope, PCF-PQ260L, with a 2.9 mm tip and a 2.8 mm channel (Olympus Medical Systems, Tokyo, Japan) is inserted and advanced to the stricture, facilitated by its “passive bending” feature. An ultrathin endoscope (for transnasal use) or a gastroscope are alternatives. (2) A guidewire (GW, 0.035 inch Jagwire) is traversed through the stricture by coordinating manipulation of an ERCP-catheter (Article-No.0130211; MTW Endoskopie, Wesel, Germany). (3) Fluorescent examination through the catheter to delineate the lesion. (4) For colonoscope replacement, withdraw the scope and the catheter, leaving only GW. (5) Before reinserterion of the SCC, insert the catheter from the channel until it sticks out of the scope tip. (6) Pass GW backward into the catheter tip. Then move the catheter over GW the anus and further advance it proximally until it reach the stricture site. (7) Gently move the SCC “over the catheter” into the rectum and advance it in the more straightened (less winding) intestine. (8) After the colonoscope is advanced only as proximally as possible, shift to a standard TTS maneuver (withdraw only the catheter, leaving GW and insert the SEMS delivery along GW past the stricture where it is deployed). Results: See table. Conclusion: 0Over-the-Catheter® colonoscope replacement (OTC-CT) technique can be a salvage maneuver which facilitates a successful SEMS placement in MRC cases with peritoneal disseminations that preclude a conventional TTS procedure. Readability of thin endoscopes and appropriate rigidity and force transmissibility of an ERCP-catheter that enable advancement of an SCC with maximum safety are thought to be linked enough reduced chances of technical failures. Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Method: Thirty Thai IBS patients, and age and sex matched 20 Thai controls were included. Four biopsy samples were taken from each of the sigmoid colon and the rectum during a standard colonoscopy. Sections from these biopsy samples were immunostained for serotonin, peptide YY, oxyntomodulin (enteroglucagon), pancreatic polypeptide, somatostatin, Msi 1, neurog 3. The densities of immunoreactive cell types were determined with computerized image analysis (1).

Results: In both the colon and rectum, the density of serotonin cells was lower in IBS patients than controls. Whereas the density of PYY cells was increased in both the colon and rectum of IBS-D, it was reduced in IBS-M and IBS-C. The density of oxyntomodulin cells was reduced in both the colon and rectum of all IBS subtypes. While the density of PP cells was unaffected in the colon, it was reduced in the rectum. Somatostatin cell density was unaffected in both the colon and rectum. The densities of Msi 1 and neurog 3 were unchanged in both the colon and rectum.

Conclusion: The present findings of abnormal densities of the large-intestine enteroendocrine cells in Thai patients combined with previously reported changes in Western IBS patients (2) support the notion that intestinal enteroendocrine cells are involved in the pathophysiology of IBS. However, the changes in the enteroendocrine cells differed from those in Western patients. The present observations highlight that IBS differs in Asian and Western countries, and show that the changes in large-intestine enteroendocrine cells in Asian and Western IBS patients might be caused by different mechanisms.

Introduction: Opioid-induced constipation (OIC) is a common side effect of opioid therapy that significantly affects multiple aspects of a patient’s life. Naldemedine (NAL) is a peripherally-acting mu-opioid receptor antagonist developed for the treatment of OIC. In Phase 3 studies, NAL improved the frequency of spontaneous bowel movements, straining, constipation, stool consistency, and patient assessment of constipation symptoms (PAC-SYM) and quality of life (PAC-QOL), measures of patient’s quality of life, compared with placebo (PBO). This study aimed to assess the impact of NAL on overall satisfaction and to show if a single score can assess the impact of treatment of OIC with NAL 0.2 mg once daily on patient’s satisfaction with constipation and abdominal symptoms in patients with OIC associated with non-cancer pain.

Methods: In three Phase 3 randomized, double-blind, PBO-controlled trials of NAL (2 of 12-week duration [COMPOSE 1 and COMPOSE 2] and 1 of 52-week duration [COMPOSE 3]), a 7-grade scale (1 = markedly, 2 = moderately, or 3 = slightly worsened; 4 = unchanged; 5 = slightly, 6 = moderately, or 7 = markedly improved) was used to assess overall satisfaction with constipation and abdominal symptoms at the last study visit. The number and proportion of subjects in each grade were calculated and the overall difference between groups was assessed with Wilcoxon rank sum test. The mean subject global satisfaction score (SGSS) was also compared between groups. For SGSS scores, from 1 to 7 were replaced with scores from 3 to 7, with 4 (unchanged) replaced with 0.

Results: There were 547 subjects in COMPOSE 1, 550 in COMPOSE 2, and 1246 in COMPOSE 3 (all ≥18 years of age) randomized (1:1) to NAL 0.2 mg once daily or PBO. The baseline characteristics of the study population were consistent between groups in each trial and between trials. Overall satisfaction assessment was completed in 372 subjects in COMPOSE 1, 296 in COMPOSE 2, and 1101 in COMPOSE 3. There were greater improvements in satisfaction with constipation and abdominal symptoms in the NAL group compared with the PBO group in all three studies (all P<0.0005; Table). The mean SGSSs were 1.5 and 0.9 with NAL and PBO, respectively, in the two 12-week studies pooled, and 1.7 and 1.0, respectively, in the 52-week study.

Conclusion: Treatment of OIC with NAL 0.2 mg once daily for 12 or 52 weeks led to greater satisfaction with constipation and abdominal symptoms compared with PBO, consistent with previously-reported improvements of PAC-SYM and PAC-QOL with NAL compared with PBO. The proposed SGSS appears to be a simple way to assess the impact on quality of life of OIC treatment.

*Data was expressed as mean±SEM. *, P<0.05; **, P<0.01; ***, P<0.0001
to study the ability of STW 5 to modulate intestinal permeability under basal and regenerative stress conditions.

Aims & Methods: C57 B16 mice were gavaged for 14 days with STW 5 (3 mL/kg). After 10 days of treatment, mice were subjected to water avoidance stress (WAS) during 4 consecutive days. In vivo permeability to FITC–Sulfonic Acid (F4A, 400 Da) and HRP (Peroxidase, 44KDa), total transit time and colonic transit (fecal pellet output - FPO) were measured at Day 0 (D0), D10 and D14 of IB treatment. Ex vivo permeability to FSA and HRP was assessed on jejunal, ileum, proximal colon and distal colon at D14 using Ussing chambers. Concentration of STW 5 was measured at D0 and D14.

Results: In vivo permeability to FSA and HRP as well as total transit time were not modified by STW 5 in basal and WAS conditions. However, STW 5 prevented the increase in permeability to FSA induced by WAS in the distal colon of the aged mice. Conversely, STW 5 prevented the increase in permeability to HRP induced by WAS in the jejunal and proximal colon. Furthermore, while STW 5 tended to increase colonic transit as compared to control in basal conditions, it prevented the increase in transit induced by WAS. Finally, STW 5 did not modify the increase in colorectal permeability induced by WAS.

Conclusion: Our study suggest that STW 5 can prevent WAS induced changes in paracellular and transcellular permeability in specific regions of the gastrointestinal tract. Such effects could contribute to the therapeutic effects of STW 5 in irritable bowel syndrome and support novel therapeutic indications for pathologies in which barrier functions are altered.

P1129 ALTERING SPHINGOSINE-1-PHOSPHATE WITH AGING INDUCES MOTILITY DISFUNCTION OF COLON SMOOTH MUSCLE BY BKCA UPRREGULATION IN RATS S. Xiaoau The First Affiliated Hospital Of Nanjing Medical University, Nanjing Medical University, Nanjing/China

Contact E-mail Address: shenxiaoxue006@163.com

Introduction: Large conductance Ca2+-activated K+ channel (BKCa channel) was shown to play critical roles in regulating smooth muscle contractions by modulating membrane potential, at the same time, age-associated changes in BKCa expression may contribute to the development of motility disorders of the gastrointestinal tract. Sphingosine-1-phosphate (SIP), component of Sphingolipids in the cell membranes, may affect BKCa expression. Thus, in this study, we investigated whether altered SIP due to aging may affect the motility of colon smooth muscle (CSM) in rats.

Aims & Methods: Thus, in this study, we investigated whether altered SIP due to aging may affect the motility of colon smooth muscle (CSM) in rats. Forty Sprague-Dawley rats at the same age were randomly divided into five groups. After different times of administration, finally they were divided into different-age group: 10-week group, 20-week group, 40-week group, 60-week group and 80-week group. Colonic motility function and contractility of circular muscle strips were measured. The expression of BKCa and phosphorylated myosin light chain (P-MLC) level were tested in colonic tissues of rats with varying ages by immunohistochemical, RT-PCR and western blot. SIP levels in colonic tissues were tested by LC-MS/MS analysis. Primary cultured colonic smooth muscle cells (SMCs) from normal adult rats were used in complementary in vitro studies. In the absence and presence of SIP with different concentrations, the expression of BKCa, P-MLC level, single-channel activity, intracellular Ca2+ mobilization were tested. At the same time, in the presence and absence of SIP, SMCs were transfected with anti-SIP antibody. BKCa siRNA transfection was used to investigate whether P-MLC expression and intracellular Ca2+ mobilization were affected by BKCa expression in CSM. The expression and phosphorylation of Akt, JNK, ERK, PKC were examind by western blot.

Results: Aged rats showed prolonged colonic transit time and weakness of circular muscle contraction compared with the young (10 weeks old) SD rats. LC-MS/MS analysis exhibited that the levels of SIP were significantly greater in the CSM from aged rats, demonstrating that SIP varies depending on age. BKCa (α subunit and β subunit) levels in CSM were shown to increase in an age-dependent manner from 10- to 80-week-old rats by mRNA protein and immunohistochemical, but P-MLC expression decreased. In colon SMCs, by BKCa siRNA transfection, we found P-MLC levels increased. Exogenously added SIP upregulated BKCa in colon SMCs in a concentration-dependent manner. Intracellular Ca2+ mobilization though inhibited by pre-incubation with biphenyl was significantly increased in the duodenal, decreased in the colonic myenteric ganglia, while did not show any significant differences in the ileal ganglia. The number of IL6 gold particles was not affected by diabetes in the myenteric ganglia of different gut regions. The diabetes-related alterations of TNFα- and IL6 expression were not protected by the immediate insulin replacement in any of the investigated intestinal segments. The differences in TNFα- and IL6 density were not significant in the capillary endothelium under different experimental conditions.

Conclusion: Based on these findings we propose that regionally alterations in the TNFα and IL6 expression are correlated with the diabetes-related region-specific nitrergic myenteric neuropathy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Growing amount of evidence has indicated that increase of the hyperglycaemia-induced oxidative stress and decreased effectiveness of the endogenous antioxidant protection play the major role in the initiation of diabetes-related neuronal damage.1,2 Using a streptozotocin-induced diabetic rat model we recently demonstrated that nitrergic myenteric neurons, which are key regulators of peristalsis, display different susceptibilities to diabetic damage and also to different treatment in the different gut segments.3 On these results we suggested the importance of the molecular differences in the neuronal microenvironment in the pathogenesis of diabetic nitrergic neuropathy.

Aims & Methods: Aim to reveal the quantitative differences in the expression of the pro-inflammatory cytokines like tumor necrosis factor alpha (TNFα) and interleukin 6 (IL6) in the myenteric ganglia and its microenvironment of the different intestinal segments, quantitative immunogold electron microscopy was used. Ten weeks after the onset of diabetes, segments from the duodenum, ileum and colon of diabetic and control rats were processed for post-embedding immunohistochemistry.

Results: The density of TNFα- and IL6-labelling gold particles were strictly region-dependent, with increasing to the distal part of the gastrointestinal tract of rats. In diabetic rats, the number of TNFα gold particles was significantly increased in the duodenal, decreased in the colonic myenteric ganglia, while did not show any significant differences in the ileal ganglia. The number of IL6 gold particles was not affected by diabetes in the myenteric ganglia of different gut regions. The diabetes-related alterations of TNFα- and IL6 expression were not protected by the immediate insulin replacement in any of the investigated intestinal segments. The differences in TNFα- and IL6 density were not significant in the capillary endothelium under different experimental conditions.

Conclusion: Based on these findings we propose that regionally alterations in the TNFα and IL6 expression are correlated with the diabetes-related region-specific nitrergic myenteric neuropathy.

Aims & Methods: Gene and protein expression of SEMA3A and its receptor NRP1 was analyzed in distal colon tissue from healthy patients and in case of bowel atrophy after one day (PN1) and two weeks (PN14) by qRT-PCR and Western blot, respectively. The cellular distribution of SEMA3A and NRP1 was localized at PN7 and PN36 in whole mount distal colon tissue by double immunofluorescence for SEMA3A and NRP1 with specific monoclonal antibodies (Hu, Thi-1), and muscle cells (a-SMA). The impact of SEMA3A on neural outgrowth was assessed in cultures of enteric neurons cocultured with SEMA3A-transfected COS-7 cells.

Results: A peak of mRNA expression for SEMA3A and NRP1 was observed in distal colon tissue at PN7, corresponding to a stage of intense neural circuit remodeling. At the protein level, NRP1 was also found to be predominantly expressed during the early postnatal period. Immunohistochemistry of colon tissue indicated that SEMA3A immunoreactivity was not associated with any specific cellular profile, but was distributed in small clusters disseminated throughout the tissue, a pattern consistent for a secreted protein. NRP1 was found in neurons, mainly associated with axonal processes, and was not detected in glial or muscle cells. Enteric neurons cultured in the presence of SEMA3A-transfected COS cells showed a strong reduction in axon length and complexity, while the ganglion size was unaffected.

Conclusion: This study shows the expression of SEMA3A and its receptor NRP1 in the ENS during early postnatal period. By controlling axonal outgrowth, SEMA3A might be an important factor to restrict the axonal trajectories in the appropriate paths between ganglia.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Constipation is a chronic disorder with an estimated prevalence of 17% in Europe. Epidemiological studies on bowel habits in the Portuguese general population have not been previously done, as in many other western countries. The aim of this population-based study was to describe bowel habits and the prevalence of self-reported constipation in a Portuguese community.

Aims & Methods: We aimed to describe bowel habits and the prevalence of self-reported constipation in a Portuguese community. Methods: Cross-sectional study with convenience sampling between November 2015 and November 2016. The physician applied a questionnaire, to adult patients at primary health care consultation. The questionnaires were anonymous, and the only personal information the participants were required to give was their age and sex. The questionnaire contained objective questions on possible causes and constipation-associated conditions and medications (according to the criteria defined by the World Gastroenterology Organization), daily water and fiber intake, physical activity, bowel habits and Bristol stool scale (BSS). Descriptive statistics and uni and multivariate analysis were performed using IBM SPSS Statistics 22 with p < 0.05 deemed to be statistically significant.

Results: A total of 814 questionnaires were performed to individuals from 35 different municipalities (54% women; mean age 46 ± 18 years). Concerning possible causes of constipation, 43% subjects had a history of constipation-associated condition and 36% were taking constipation-associated drugs. Regarding bowel habits, 35% subjects had < 1 bowel movement per day and 2% had < 1 bowel movement per week. Using BSS, 66% of the cases reported type III or type R. Gaspar6, R. Morais6, J. A. Sarmento6, G. Macedo6 intake, physical activity, bowel habits and Bristol stool scale (BSS). Descriptive defined by the World Gastroenterology Organization), daily water and fiber constipation-associated conditions and medications (according to the criteria 2016. The physician applied a questionnaire, to adult patients at primary contact E-mail Address: dr.dancarter@gmail.com

Introduction: Objective means of evaluating of the defecatory process include balloon expulsion test (BET) and imaging of the defecatory process (X-ray defecography, dynamic trans-pelvic ultrasound (DT-PUS) or MR defecography). These tests have a place in the evaluation of suspected evacuatory dysfunction (ED), fecal incontinence (FI) and chronic pelvic pain (CPP). Test choice may influence subsequent patient management; however, there is only limited information regarding the agreement between HRM, DT-PUS and BET.

Aims & Methods: The aims of this study were to compare the diagnostic yield and agreement between different tests of evacuation and to define the relation between the diagnoses of evacuation dysfunction to objective evacuatory failure. 63 consecutive patients (60 females, mean age 51ys) were prospectively evaluated with HRM, BET and PUS. Inter-test agreement for the diagnosis of anismus was assessed using the Kappa statistic. Correlation between anismus to evacuatory failure (assessed by PUS) was also assessed.

Results: 36 patients were assessed for ED, 6 for CPP and 21 for FI. Anismus was diagnosed in 26 patients by HRM and 45 patients by DT-PUS. All cases of anismus diagnosed by HRM or DT-PUS had a positive BET. The Kappa agreement for the diagnosis of anismus between HRM and DT-PUS was poor (0.65 ± 0.01). 9 patients had significant pelvic floor anatomic pathology (4 rectal prolapse, 6 pathological pelvic descent, 4 enterocele and 3 rectoceles > 3.5cm). There was a moderate correlation between diagnosis of anismus on DT-PUS to failure to evacuate the rectum (r = 0.636). The correlation between rectal evacuation on DT-PUS to the diagnosis of anismus on manometry was weak (r = 0.296).

Conclusion: There is considerable disagreement between the results of various evacuatory tests, and between the diagnoses of evacuation dysregulation to failure of rectal evacuation. Therefore, more than one test should be applied in order to evaluate the defecatory dysfunction.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1136 YH12852, A NOVEL AND HIGHLY SELECTIVE 5-HYDROXYTRYPTAMINE 4 RECEPTOR AGONIST, SHOWS PERSUASIVE PROPERTIES FOR THE MANAGEMENT OF FUNCTIONAL CONSTIPATION: A DOUBLE-BLIND, PLACEBO-CONTROLLED, RANDOMIZED PHASE 1/2a STUDY IN HEALTHY VOLUNTEERS

S.J. Moon1, H.G. Yoo1, S. Lee2, S.B. Jang2, M.K. Kim2, H. Na2, H. Lee1

AND PATIENTS WITH FUNCTIONAL CONSTIPATION: 5-HYDROXYTRYPTAMINE 4 RECEPTOR AGONIST, P1136 YH12852, A NOVEL AND HIGHLY SELECTIVE

University College of Medicine and Hospital, Seoul/Korea, Republic of

Aim: To evaluate the safety, tolerability, pharmacokinetics and pharmacodynamics of YH12852 in healthy volunteers and patients with functional constipation (FC).

Methods: This was a multicenter, randomized, double-blind, placebo-controlled, active-controlled, 3-period crossover study in healthy subjects and FC patients. The study was performed in healthy subjects and FC patients, who were administered YH12852 (0.3, 0.5, 1, 2 or 3 mg), prucalopride 2 mg or placebo once daily after breakfast for 2 weeks. Subjects recorded bowel habits throughout the study period. Intensive pharmacokinetic blood samples were also collected (ClinCalTrials.gov identifier NCT02338367).

Results: Twenty-nine healthy subjects and 27 FC patients were enrolled. Treatment-emergent adverse events (TEAEs) were mostly mild and no serious adverse event was reported. The most frequently reported AE in the YH12852 and prucalopride group was headache. TEAEs in the YH12852 groups were similar to those in the prucalopride group. The change from baseline to the prucalopride group showed a linear pharmacokinetic profile over 0.3–3 mg.

Conclusion: YH12852 was well tolerated and its safety profile was comparable to that of prucalopride. YH12852 appeared to increase bowel movement greater than prucalopride, particularly at 0.5–2 mg. YH12852 may have a significant potential for the treatment of FC/GDMDS.

Introduction: Three-dimensional high-resolution anorectal manometry (3DHRAM) is the most precise tool to assess function of the anal canal and may be useful in evaluation of children after surgery on lower gastrointestinal tract that may present wide spectrum of symptoms from gastointestinal tract. Our aim was to evaluate children after surgery for anorectal disorders using 3DHRAM.

Aims & Methods: We performed a prospective study of 43 children (30 male, mean age: 7 years) after surgery for anorectal disorders at the Departments of Pediatric Gastroenterology and Nutrition, Medical University of Warsaw, Poland. The group consisted of 24 children after surgery for Hirschsprung’s disease (HD), 12 children after surgery for anal atresia (AA) and 7 children after proctocelecytomy for other reasons (PC). In all children conventional manometry was performed preoperatively and the anal canal was divided into 8 segments and the resting and squeeze pressures of puborectalis muscle (PRM) were recorded in segments covering its anatomical localization. These data were compared to raw data obtained in our laboratory from healthy children published previously (HC group). To assess correlation between manometry and symptoms, all children (after surgery and HC group) were divided into groups with respect to symptoms, as follows: asymptomatic (A), nonretentive fecal incontinence (NRFI) and retentive fecal incontinence (RFI).

Results: The lowest values of resting, squeeze and the pressure of PRM were observed in AA (55.6 mmHg, 121.7 mmHg and 44.1 mmHg, respectively). As compared to asymptomatic children, the lowest mean and maximum resting pressures were observed in NRFI (69.6 mmHg and 61.3 mmHg, respectively; p < 0.000). Significantly lower maximum squeeze pressure was recorded in both, NRFI and RFI (168.1 mmHg and 103.8 mmHg, respectively; p = 0.03). ROC cut-off value for mean resting pressure between asymptomatic children and children with fecal incontinence was 68.5 mmHg. Significantly lower PRM resting pressure were observed in NRFI group and lower PRM squeeze pressure in RFI (45.6 mmHg and 63.6 mmHg, respectively). Threshold of urge were significantly higher in group C as compared to A group (87.5 cm² and 30 cm², respectively; p = 0.003).

Conclusion: Our study demonstrated lower pressure parameters in children after surgery with the lowest values in patients suffering from anal atresia, which was correlated with incontinence. 3DHRAM may be useful tool for assessing the function of the anorectum of children after surgery.

Introduction: Linacotide, a guanylate cyclase C agonist, has been shown in clinical trials to relieve constipation and improve abdominal pain and discomfort in patients with irritable bowel syndrome with constipation (IBS-C), but there are limited UK-specific real-world data to support this.

Aims & Methods: A multi-centre, observational, prospective 52-week study was conducted in eight specialist hospitals in England and Scotland. The primary objective was to describe the change in IBS-Symptom Severity Scale (IBS-SSS) score at 52 weeks after linacotide initiation. Consenting patients aged ≥ 18 years and receiving linacotide (290 mcg) for IBS-C were recruited. Data on patient demographic and clinical characteristics, concomitant medications, patient-reported outcomes, including IBS-SSS score, and adverse events were collected. Results at 12 weeks (primary endpoint) have been presented previously; here we report analysis of real-world clinical experience 52 weeks post-linacotide initiation.

Results: 202 patients were recruited; 185 (92%) were female. At baseline, median age was 44.9 (range 18–77) years; 84 (42%) reported concomitant laxative use. Mean baseline IBS-SSS was 339 (standard deviation (SD) ±20, n = 193); 129 (67%) patients had IBS-C classified as severe (score ≥ 350); 54 (28%) moderate (175–300), nine (5%) mild (75–175) and one (0.5%) normal (≤74). At 52 weeks, mean IBS-SSS score was 256 (SD ± 78); 31 (40%) patients had severe (score ≥ 350), 27 (34%) moderate, 14 (18%) mild and six (8%) normal. IBS-SSS scores improved significantly between baseline and 52 weeks, with a mean decrease of 71 (SD ± 106) points overall (t-test p = 0.001); n = 76 with paired data) and 94 (SD ± 102) points patients remaining on linacotide (p < 0.001; n = 34). Of the 76 patients with paired data, 41 (54%) reported improvement in both stool frequency and abdominal pain, and 35 (47%) experienced improvement in both bowel movement and abdominal cramping.

Conclusion: Linacotide was associated with a significant improvement in IBS-SSS score at 52 weeks and was reasonably well tolerated. These results provide valuable insights into the longer-term outcomes of linacotide treatment in patients with IBS-C in real-world clinical practice.

Introduction: Irritable bowel syndrome (IBS) may be associated with disturbances of gut microbiota composition and functions, such as altered bacterial fermentation.

Aims & Methods: The aim was to study the effect of faecal microbiota transplantation (FMT) on gut bacterial fermentation products: short-chain fatty acids (SCFAs). Patients diagnosed with IBS according to Rome III criteria (n = 13) were included. They received freshly donated faeces from relatives, instilled into the descending part of the duodenum via gastroscope. Faecal samples were collected from the donors and the patients before FMT and from the patients after FMT at weeks 1, 3, 12 and 20/28. All the samples were stored at −80°C until analysis. Faecal concentrations of major SCFAs (acetic, propionic and n-butyric acids) and minor SCFAs (iso-butyric, n-valeric, iso-valeric, n-caproic and iso-capronic acids) were analysed by vacuum distillation followed by gas chromatography. The patients completed IBS symptom questionnaire (IBS-SQ) before and after FMT at weeks 1, 3, 12, and 20/28, assessing the following domains: nausea, bloating, abdominal pain, diarrhea, constipation and anorexia.

Results: Before FMT, concentrations of several SCFAs were significantly lower in IBS patients compared to donors (Table 1). After FMT, concentrations of SCFAs increased within the first 3 weeks, and the increment lasted up to 28 weeks (Table 1). At 28 weeks (Table 1), Symptom scores as assessed by IBS-SQ improved from before FMT until week 20/28 after FMT as follows: nausea (P = 0.0013), bloating (P = 0.0001), abdominal pain (P = 0.0005), diarrhea (P = 0.0001), constipation (P = 0.03), and anorexia (P = 0.09). Correlations were found between abdominal pain and both acetic acid (r = 0.69, P = 0.04) and total SCFAs (r = 0.69, P = 0.044) in IBS patients before FMT. Inverse correlations were found 3 weeks after FMT between nausea and iso-valeric acid (r = 0.65, P = 0.014), and between constipation and propionic acid (r = 0.74, P < 0.0001), iso-butyric acid (r = 0.79, P < 0.0001), n-valeric acids (r = 0.79, P < 0.0001) and iso-valeric acid (r = 0.72, P < 0.0001).
Conclusion: Our results reveal differences in faecal fermentation products between patients with IBS and healthy donors, and suggest that FMT may act to normalise such alterations of gut microbial functions.

Introduction: Irritable bowel syndrome with diarrhoea (IBS-D) is a chronic gastrointestinal condition in the past three months, having seen patients with a chronic gastrointestinal condition in the past three months, having seen patients with a chronic gastrointestinal condition in the past three months. This study aimed to quantify the HCRU in patients with AR of IBS-D symptoms and to compare patients with AR and those with inadequate relief (IR) who did not have AR of IBS-D symptoms. The study was conducted in a cross-sectional survey considering patients who had AR of IBS-D symptoms and those who did not have AR of IBS-D symptoms. The survey was a 15-minute web-based survey, including 12 questions collecting information on the use of medical services and procedures amongst patients with IBS-D for the first year following diagnosis and for subsequent years. Respondents were required to answer the question considering patients who had AR of IBS-D symptoms and those who did not have AR of IBS-D symptoms. The survey was conducted in a cross-sectional survey considering patients who had AR of IBS-D symptoms and those who did not have AR of IBS-D symptoms.

Aims & Methods: This objective of this study was to quantify the HCRU in patients with AR of IBS-D symptoms compared to patients with IR. An online survey assessing HCRU was distributed to general practitioners (GPs) recruited from market research panels in the UK in August 2016. GPs opted-in to complete the survey via an email link and were screened before being invited to complete the main survey. Screening criteria included having seen patients with a chronic gastrointestinal condition in the past three months, having seen patients with IBS-D in the past 3 months and having decided on what treatments were prescribed for patients with IBS. The survey was a 15-minute web-based survey, including 12 questions collecting information on the use of medical services and procedures amongst patients with IBS-D for the first year following diagnosis and for subsequent years. Respondents were required to answer the question considering patients who had AR of IBS-D symptoms and those who did not have AR of IBS-D symptoms. The survey was conducted in a cross-sectional survey considering patients who had AR of IBS-D symptoms and those who did not have AR of IBS-D symptoms.

Results: The online survey was completed by 50 GPs, with responses from 46 GPs included in the analysis. (Four responses were excluded due to data quality reasons). The reported total number of medical visits was significantly higher for patients with IR vs patients with AR during the first year after diagnosis (mean 10.11 vs 8.20; p < 0.05 compared to patients with adequate relief).

Hospitalisations 0.39 (1.00) 0.93 (1.10) 0.37 0.028
Total 5.20 (4.87) 10.11 (5.30)* 4.91 0.378

Conclusion: GPs reported that patients with IBS-D considered as having IR of symptoms had increased HCRU, including more GP office visits and more colonoscopies, compared to patients with AR. These results highlight that IR is potentially an important driver of increased HCRU in patients with IBS-D, emphasising that effective treatments that provide AR may reduce HCRU and the associated economic burden.

Introduction: Selective Serotonin Reuptake Inhibitors (SSRI’s) have shown efficacy in reducing symptoms but less so on pain in irritable bowel syndrome (IBS). Comorbid anxiety frequently occurs in IBS. We hypothesized that SSRI’s will particularly be effective in reducing abdominal pain in IBS patients with pronounced comorbid anxiety. As methods for symptom evaluation were used 1) gastrointestinal symptom rating scale (GSRS) as primary parameter and 2) a new method called the Experience Sampling Method (ESM). With ESM digital assessments are completed randomly and repeatedly during daily life, therewith capturing fluctuating symptom patterns more accurately than retrospective questionnaire methods.

Aims & Methods: IBS patients with comorbid panic disorder were included in a randomized controlled trial on escitalopram versus placebo. Measurements were completed at baseline (t = 0) and after 3 (t = 3) and 6 months (t = 6). At each time point, the gastrointestinal symptom rating scale (GSRS) and a 7-day ESM period were completed. Subjects completed ESM assessments on a palmtop computer at 10 random moments each day during 7 consecutive days. ESM periods were analysed when at least 1/3 (i.e. 23) of the assessments were completed. Mixed linear model analyses, with the GSRS-AP (i.e. symptom of pain domain of the GSRS-AP) as the dependent and treatment group as the independent variable, as well as with ESM- abdominal pain scores as the dependent and treatment group and ESM-anxiety scores as the independent variables.

Results: In total 15 (escitalopram and 14 placebo; 21 female; 37 ± 14.8 years; equal abdominal pain and anxiety scores at baseline) were included. Average GSRS-AP scores were not significantly different between escitalopram and placebo at t = 3 (B : 0.265, SE : 0.451, p = 0.557) or t = 6 (B: 0.229, SE: 0.539, p = 0.670). For the ESM analyses, at t = 6, average abdominal pain scores were significantly lower (B: 1.30, SE: 0.623, p = 0.037) (on a 1–7 scale) in the escitalopram group compared to placebo. With increasing anxiety levels after 28 days of linaclotide 290 mcg po od.

Change in pH across the ileocaecal junction correlated with improvement in VDVA and P (r = 0.05, t = 0.037) (on a 1–7 scale) in the ileocaecal region.

Change in pH across the ileocaecal junction correlated with improvement in VDVA and P (r = 0.05, t = 0.037) (on a 1–7 scale) in the ileocaecal region.

Baseline Post treatment (mean and standard deviation) (mean and standard deviation)
Gastric emptying time (minutes) 154 ± 64 177 ± 57 0.4
Small bowel transit (minutes) 353 ± 152 299 ± 139 0.3
Colonic transit time (minutes) 3017 ± 1305 1983 ± 1261 0.04
Whole gut transit time (minutes) 3517 ± 1375 2432 ± 1180 0.04
Ileal contractility (AUC) 262 ± 144.2 221 ± 113.5 0.5
Colonic contractility (AUC) 90.9 ± 78.3 134.6 ± 93 0.006
Change in pH across the ileocaecal junction -2.4 ± 0.2 -2.1 ± 0.4 0.03

Linaclootide improved VDVA-1 and VDVA-U (130.7 ± 20.8 vs. 106.5 ± 33, p = 0.03 and 113 ± 22 vs. 85.8 ± 33, p = 0.01), abdominal pain (85.4 ± 21.2 vs. 68 ± 17.6, p = 0.02), Linaclotide reduced colonic symptoms (58.4 ± 21.2 vs. 68 ± 17.6, p = 0.02). Change in pH across the ileocaecal junction correlated with improvement in VDVA and P (r = 0.05, t = 0.037) (on a 1–7 scale) in the ileocaecal region.

Table 1: Changes in GI physiology following linaclotide.

P1144 RELATIONSHIP BETWEEN RIFAXIMIN THERAPY AND SEHCAT TEST IN PATIENTS WITH DIARRHEA-PREDOMINANT IRRITABLE BOWEL SYNDROME OR FUNCTIONAL DIARRHEA

Gastroenterology, Hospital Universitari de Bellvitge, Hospital de Llobregat, Spain

Contact E-mail Address: alexandrauzucerulla@gmail.com

Introduction: Bile acids (BAs) and gut microbiota have been involved in IBS pathophysiology. BA diarrhea (BAD) is often found in patients with irritable bowel syndrome (IBS-D) or functional diarrhea (FD). Rifaximin and rifaximin have both been shown to improve symptoms in these patients.2 It is unknown whether a SeHCAT test may help to predict response to rifaximin or whether rifaximin treatment affects SeHCAT test result.

Aims & Methods: a) To determine if a SeHCAT test may be used to predict response to rifaximin in patients with IBS-D or FD. b) To assess if rifaximin modifies SeHCAT result.

Consecutive patients diagnosed with IBS-D or FD were prospectively included in the study. All patients received rifaximin (400mg TID for 2w). A SeHCAT test was performed to evaluate presence of BAD before and 1 month after rifaximin treatment. BAD was defined as SeHCAT retention <10%. Number of daily stools, number of daily watery stools, Bristol stool scale, abdominal pain, tension and presence of urgency were recorded before and after treatment. IBS severity score (IBS-SS) was also calculated.

Results: Forty-one patients were included. BAD was present in 23 patients (56%). No clinical differences were found between BAD or non-BAD patients at study entry. Rifaximin resulted in a significant improvement in the number of daily stools (Δ = 1.5; P < 0.01), daily watery stools (Δ = 2.1; P < 0.01), Bristol scale (Δ = 1.1; P < 0.01), abdominal pain (Δ = 0.5; P < 0.01), distension (Δ = 0.3; P < 0.01), urgency (Δ = 0.7; P < 0.01) and in the IBS-SS (Δ = 7.8; P < 0.01). No differences were found between BAD and non-BAD patients in the improvement of any item. Rifaximin treatment did not modify SeHCAT value (9.5% before treatment and 10.7% after treatment; P = 0.4).

Conclusion: Half of the patients diagnosed with IBS-D or FD present BAD according the SeHCAT test. Rifaximin treatment confers significant clinical improvement irrespective of the presence of BAD. Rifaximin treatment does not affect SeHCAT test.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: To evaluate IR in patients treated with ELX in a post hoc analysis from two randomised, double-blind, placebo-controlled Phase 3 trials (IBS-301, IBS-302). Patients meeting Rome III criteria for IBS-D were randomised 1:1:1 to twice-daily (BID) ELX (75 or 100 mg) or PBO. Efficacy was evaluated through Week 26. For evaluation of AR, patients were asked “In the last 7 days, have you had adequate [satisfactory] relief of your IBS symptoms?” (Yes/No) on a weekly basis, via an electronic diary. As previously described, patients answering “Yes” for ≥50% of the total weeks during the target time interval were considered AR responders. Patients answering “No” were considered to have inadequate relief (IR). Similar results were observed in Weeks 1–12 and 13–24 of treatment. Patients without AR analysis were ineligible for intention-to-treat (ITT) analysis; missing data were not imputed.

Results: Overall, 2429 patients with IBS-D were enrolled across the two Phase 3 trials and 2423 were included in the ITT analysis. In the pooled dataset, a significantly greater proportion of patients were AR responders with either ELX 100 or 75 mg BID vs PBO at 12 weeks (56.1% [p = 0.001] and 53.6% [p = 0.001], respectively) and 26 weeks (51.5% [p = 0.001] and 49.0% [p = 0.004] vs 41.8%, respectively). Over the first 12 weeks of treatment, a greater proportion of patients reported no IR of IBS-D symptoms with ELX 100 or 75 mg BID vs PBO (Table). Greater proportions of patients reported only 1–5 consecutive weeks of IR with ELX 100 or 75 mg BID vs PBO. A significantly lower proportion of patients reported IR for >8 consecutive weeks with ELX 100 or 75 mg BID vs PBO (13.2% [p < 0.0001] and 15.6% [p = 0.004] vs 22.6%, respectively). In contrast, a greater proportion of patients reported IR for the full 12 consecutive weeks with PBO vs ELX 100 or 75 mg BID (Table). Similar results were observed in Weeks 13–24 of treatment, with ELX-treated patients generally having fewer consecutive weeks of IR compared to PBO-treated patients (Table).

C. patients continuing on treatment; DC, patients discontinuing from treatment.

Conclusion: Proportions of responders with eluxadoline 75 and 100 mg were consistently higher vs placebo across all 4-week intervals in the treatment period in patients defined as having severe IBS-D. Furthermore, discontinuation rates among patients showing a treatment response remained consistently low compared to non-responders. However, as these analyses were conducted in a clinical trial setting, the relatively high continuation rates in non-responders may not reflect the real-world situation. These findings suggest that eluxadoline has sustained efficacy in treating the diarrhoea and abdominal pain associated with IBS-D, including in patients with severe and inadequately managed symptoms.

P1148 THE LOW FODMAP DIET REDUCES CAECAL FERMENTATION COMPARED TO TRADITIONAL DIETARY ADVICE: A RANDOMISED CONTROLLED TRIAL

A. D. Farmer, N. Saint, A. R. Hobson

1Gastroenterology, University Hospitals of North Midlands, Stoke on Trent/United Kingdom

Introduction: Diets reducing the content of fermentable short chain carbohydrates (fermentable oligo-, di-, mono-saccharides, and polyols (FODMAPs)) as well as the National Institute of Health Care Excellence (NICE) diet have been reported to be effective in the treatment of patients with irritable bowel syndrome (IBS). The mechanisms by which this efficacy is achieved are incompletely understood but it has been proposed that such diets reduce fermentation, mediated by changes in the microbiota. Change in pH around the ileocecal junction is considered to be a surrogate biomarker of caecal fermentation (4.5).

Aims & Methods: We aimed to compare the effect of a low FODMAP diet vs. the NICE diet on change in ileocaecal pH. We performed a single centre, randomized controlled trial of adult patients with Rome III defined IBS-mixed bowel habit (IBS-M) comparing the two dietary interventions. At baseline, patients ingested a wireless motility capsule (WMC) using a standardized protocol. Segmental transit times were derived from measures around known anatomical landmarks as identified by compartmental pH changes. Ileal and colonic motility measures are presented as area under the curve (AUC) derived from contraction amplitude and frequency. Validated questionnaires evaluating GI (visual analogue scale), quality of life (EQ5D) were administered. The WMC and questionnaires were repeated after 26 days of dietary interventions. The primary endpoint was change in ileocaecal pH after the intervention. Secondary outcomes included changes in transit times, contractility and symptoms.

Results: After screening, 32 patients (23 female, median age 37 years, range 18-65) were randomized. Baseline symptom severity and demographics were similar between the two groups. Relative to baseline, there was a reduction in the change in ileocaecal pH with the low FODMAP diet group compared to the m-NICE group (3.37 ± 0.3 vs. 0.0035 ± 0.4, p=0.047) suggesting reduced fermentation.

Change in GI motility are shown in Table 1.

Table 1: Changes in segmental/whole gut transit times and ileal/colonic motility, relative to baseline between the low FODMAP and m-NICE diets. Both the low FODMAP and NICE diets improved VDVAS-I and VDVAS-U (–1.8 ± 17 vs. –2.7 ± 18, respectively). Similarly, both diets reduced somatic symptoms (–2.1 ± 1.4 vs. –0.8 ± 1.8, p=0.07) and improved quality of life (9.5 ± 10.2 vs. 4.4 ± 9.8, p=0.23).

</tr>
</tbody>
</table>

Conclusion: The low FODMAP diet reduces caecal fermentation in comparison to the NICE diet as indexed by a reduction in the change in pH across the ileocaecal junction. Both diets improved GI and extra-GI symptoms as well as quality of life. Neither diet has a demonstrable differential effect on ileal/colonic contractility or segmental/whole gut transit times. It is therefore plausible that the efficacy of the low FODMAP diet in IBS-M is mediated by alterations in the microbiota.

P1149 ORAL A-GALACTOSIDASE IMPROVES GASTROINTESTINAL TOLERANCE TO A DIET HIGH IN GALACTO-Oligosaccharides: ADJUNCT THERAPY TO A LOW FODMAP DIET IN IRRITABLE BOWEL SYNDROME

C. J. Tuck, K. M. Taylor, J. S. Barrett, P. R. Gibson, Jr. G. Muir

Introduction: Galacto-oligosaccharides (GOS) are indigestible short-chain carbohydrates (FODMAPs, fermentable, oligo-, di-, mono-saccharides and polyols)
associated with triggering gastrointestinal symptoms in irritable bowel syndrome (IBS).

**Aims & Methods:** This study aimed to assess whether oral α-galactosidase co-administration with high GOS foods would reduce symptoms and breath hydrogen production in a double-blind, placebo-controlled, crossover trial approved by Monash University Ethics Committee. Patients meeting the Rome III criteria for IBS who produced >10 ppm hydrogen on two consecutive breath samples following 10 g fructan were recruited. Participants were randomly assigned to full-dose and placebo (500 GAL α-galactosidase) and placebo (glucose) capsules. Following a 3-day low-FODMAP run-in period, participants consumed provided diets high in GOS for a further 3 days. Gastrointestinal symptoms were measured daily using a 100 mm visual-analogue scale. Breath samples were taken hourly on the second last day and analysed as area-under-the-curve, faecal samples were taken on the second last and analysed as area-under-the-curve, faecal samples were taken on the final day.

**Results:** Thirty-one participants with IBS (20 IBS-D, 4 IBS-C, 7 IBS-M) completed the study. The addition of high GOS foods resulted in a significant increase in overall symptoms (median 13.0 [IQR 1.5–22.0] to 35.5 [12.8–54.0] mm; p = 0.000, Wilcoxon signed-rank test). No significant increase in overall symptoms was seen with the full-dose enzyme (14.0 [3.5–24.0] vs 14.7 [2.3–32.7] mm; p = 0.422). Twenty-one participants exhibited GOS-sensitivity (> 10 mm increase in overall symptoms). Of those, full-dose enzyme reduced overall symptoms (24.5 [17.5–35.8] mm vs 5.5 (1.5–15.0) mm; p = 0.006) and bloating (20.5 [9.5–42.0] vs 6.5 [2.0–15.8]; p = 0.017). Breath hydrogen production was minimal with no differences seen between placebo (5248 ± SD 3339 ppm.12h) and full-dose (5585 ± 3205; p = 0.597, paired samples t-test).

**Conclusion:** An oral α-galactosidase supplement taken with high GOS foods provides a clinically significant reduction in symptoms in GOS-sensitive individuals with IBS. The lack of change in breath hydrogen suggests that a possible mechanism may not be related to reduced gas and distention, rather suggesting a role of alterations to the microbiota. Future analysis of the faecal microbiota may provide insight for the mechanism of action. This strategy can be easily translated into practice to improve tolerance specifically to high GOS foods for patients with IBS as an adjunct therapy to the low FODMAP diet.

**P1150 A SYSTEMATIC REVIEW AND META-ANALYSIS TO DETERMINE WHETHER BALLOON EXPULSION TESTING MIGHT BE AN APPROPRIATE INITIAL OFFICE-BASED TEST FOR DYSSYNERGIC DEDEFATION**

E. D. Shah1, J. Farada1, W.D. Chey2

1Division Of Gastroenterology, University of Michigan, Ann Arbor/United States of America
2Gastroenterology, Internal Medicine, University of Michigan, Ann Arbor, MI, United States of America

**Introduction:** Balloon expulsion testing (BET) is a recommended means of identifying dyssynergic defecation (DD) in patients with a history of chronic constipation, but remains poorly standardized and underutilized outside of specialized centers. We aimed to assess the clinical utility of BET as an initial test for DD and to determine appropriate testing parameters.

**Aims & Methods:** We performed a literature search (PubMED, EMBASE, conference abstracts from 1950–2016) to identify (1) case-control studies of DD or unselected CC subjects and healthy controls and (2) cohort studies of unselected subjects with CC. Eligible studies reported BET test parameters and results as well as presence of DD defined by constipation symptoms and a positive reference test (anorectal manometry[ARM], defecography, or electromyography[EMG]). Study quality was assessed using QUADAS criteria. We extracted age, sex, enrollment criteria, BET test parameters (subject position, stool consistency, allowed bowel movements, and DD diagnostic criteria). Data were independently extracted by two authors. Meta-analysis was performed using a bivariate mixed-effects regression model. Meta-regression was performed to evaluate effects of individual test parameters. Between-study heterogeneity of summary results was assessed using an I2 statistic. Publication bias was assessed using Deeks’ funnel plot asymmetry test.

**Results:** We identified 15 eligible studies comprising 2,090 individual assessments of balloon expulsion, of which 14 studies of 1,760 subjects were eligible for cohort analysis and 1,988 subjects were eligible for case-control analysis. Among cohort studies, the AUC was 0.80 (95% CI 0.61–0.91) with 70% sensitivity (95% CI 52%–83%) and 77% specificity (95% CI 70%–82%). Among pooled cohort and case-control studies, the AUC was 0.84 (95% CI 0.68–0.93) with 70% sensitivity (95% CI 53%–82%) and 81% specificity (95% CI 75%–86%). Further test performance characteristics stratified by subject position are reported in Table 1. Subject positioning (seated vs. left lateral decubitus) did not significantly affect AUC in cohort (p = 0.32) or case-control (p = 0.43) analysis. Pooled sensitivity (p = 0.50) and specificity (p = 0.66) were similar between seated and left lateral BET in analysis of unselected CC cohort studies, though specificity was higher with left lateral BET in pooled analysis of all studies (p = 0.03). The allowable time for balloon expulsion did not significantly affect summary sensitivity (p = 0.92) or specificity (p = 0.96) in meta-regression within the evaluated range of 1 and 5 minutes. There were enough studies to warrant a meta-analysis of balloon distention characteristics, 13 of 17 studies instilled 50–60 mL of water. When pooling cohort and case-control studies, both age (p < 0.01) and gender (p < 0.01) appeared to influence test performance. Choice of reference test did not significantly affect test performance (ARM p = 0.35, defecography p = 0.43, or EMG p = 0.08). Continent of origin (p = 0.34) and year of study (p = 0.29) did not appear to significantly influence test performance. There was no evidence of publication bias (p > 0.5).

**Table 1:** Sensitivity and specificity of balloon expulsion testing in diagnosing dyssynergic defecation (stratified by subject positioning with 95% confidence intervals)

Contact E-mail Address: albuquerque.dias@gmail.com

**Introduction:** Anal squamous intraepithelial lesions are precancerous lesions of anal squamous cell carcinoma and are largely related to human papillomavirus infection. Immunosuppressed patients have a higher prevalence of these lesions. There are some studies in renal transplant recipients, but no information exists regarding prevalence in liver transplantation.

**Aims & Methods:** Our aim was to evaluate the prevalence of anal squamous intraepithelial lesions in liver transplant recipients compared with healthy subjects. We performed a prospective case-control study involving liver transplant recipients that were compared with a healthy control group. All patients were submitted to anal cytology. Those with abnormal cytological results, namely high-grade squamous intraepithelial lesions (HSIL), atypical squamous cells which cannot exclude high-grade squamous intraepithelial lesions (ASC-H), low-grade squamous intraepithelial lesions (LSIL) and atypical squamous cells of undetermined significance (ASC-US), were submitted to high-resolution anoscopy with biopsies of any suspicious lesion.

**Results:** A total of 59 liver transplant recipients and 57 controls underwent anal cytology. In the liver transplant group, 37 (63%) were men, with a mean age of 54 ± 10 years. The most common indication for transplantation was alcoholic cirrhosis in 26 patients (44%), the majority of the patients were only on tacrolimus (n = 47, 80%), and had been transplanted a mean of 8 ± 5 years ago. In the healthy control group, 36 (63%) were men, with a mean age 59 ± 11 years. Regarding anal cytology, 10 (17%) of liver transplant recipients had abnormal results, 7 patients had ASC-US, 1 patient ASC-H and 2 patients HSIL. In the control group only 1 patient (2%) had an ASC-US result (p = 0.005). Anal squamous intraepithelial lesions were confirmed in 7/10 of liver transplant patients and 0/1 in control group (p = 0.013) by high-resolution anoscopy with biopsies. Smoking was the only risk factor for abnormal anal cytology (OR = 5.9, 95% CI 1.224–28.121, p = 0.037).

**Conclusion:** Liver transplant patients have a higher risk of anal squamous intraepithelial lesions and screening should be considered especially in smokers.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
IMMUNOHISTOCHEMICAL EXPRESSION OF DIAMINE OXIDASE IN THE GASTROINTESTINAL TRACT OF PATIENTS WITH GASTROINTESTINALLY MEDITATED FOOD ALLERGY

Conclusion: The above findings indicate that DAO is present in low amounts in all segments of the upper GIT. But only in the duodenum a significant difference was found between GMA and CG, thus indicating that histamine-mediated symptoms most likely arise in duodenum. Therefore, regarding the upper GIT, this immunohistochemical staining for DAO in duodenum could serve as an additional diagnostic parameter for detecting patients with GMA and possibly other histamine-mediated diseases. The above mentioned distribution pattern of DAO strengthens the theory that DAO acts extracellularly and is responsible for the elimination of the transepithelially absorbed exogenous histamine as well as of the endogenous histamine, as its highest staining intensity is found at the SLP throughout the upper GIT.

INTRODUCTION: Chronic atrophic gastritis (CAG) is claimed to be a pre-cancerous condition for gastric cancer, being serological markers like serum peptidases and gastrin-17 (G17) proposed as non-invasive useful tools. OLGA histological classification has been proposed as of prognostic value. Aim of the study was to assess, by using serological markers, the prevalence of CAG in general population and to correlate with the results with OLGA classification.

Aims & Methods: One thousand and nine hundred consecutive patients (M=915; mean age=53.5, range=27–82) showing upper-gastrointestinal (GI) troubles entered the study. Exclusion criteria were: previous history of upper-GI neoplasms, previous surgery, concomitant Proton Pumps Inhibitor (PPI) therapy. All patients underwent a blood sample for GASTROPANEL® (BioHit Oy, Finland) based on: peptidases I (PGI), peptidase II (PGII), gastrin-17 (G17) and IgG against Helicobacter pylori. (Hp-IgG). The normal values are: PGI: 30–120 µg/L, PGII: 21–150 µg/L, G17: 1–30 pmol/L, Hp-IgG: <30 EU/L as well as high levels of G17 (G17>15 pmol/L) were considered diagnostic for CAG. Eighty-three patients with serology suggestive for CAG underwent upper endoscopy and histology according with OLGA staging. The relationship between PGI, G-17 and the different OLGA stages was statistically analyzed.

Results: Eighty-three (M=44, mean age=61, range=49–82) out of 1901 investigated patients showed CAG (4%). Out of the 83 CAG patients, 19.2% was classified as OG 2, 56.6% as OG 3 and 24.2% as OG 4. The relationship between PGI levels and OLGA stage shows a statistically significant difference between the stages OLGA 0, 1, 2 and the stages 3 and 4 (PGI mean values: OLGA 0: 72.45 µg/L, OLGA 1: 85.95 µg/L, OLGA 2: 47.38 µg/L, OLGA 3: 16.00 µg/L, OLGA 4: 10.10 µg/L; p<0.001). The relationship between OLGA stages and G17 serum levels shows a statistically significant difference (G17 mean values: OLGA 0: 4.6 pmol/L, OLGA 1: 5.2 pmol/L, OLGA 2: 26.5 pmol/L, OLGA 3: 44.6 pmol/L, OLGA 4: 38.5 pmol/L; p<0.01 by comparing OLGA 0–1 against OLGA 2–4) (p<0.02).

Conclusion: The prevalence of CAG assessed by serological markers is low in the studied population (4%). The majority of patients (56.6%) were classified in the OLGA stage 2. Both PGI and G-17 showed a statistical significant relationship with the more severe degrees of CAG.

INTRODUCTION: Chronic atrophic gastritis (CAG) is considered to be a pre-cancerous condition of gastric cancer; it is either autoimmune in origin or caused by infection with Helicobacter pylori. The majority of CAG patients are asymptomatic or experience aspecific manifestations like epigastric fullness, early satiation, nausea, bloating. The drugs currently used for upper gastrointestinal (GI) diseases, mainly proton pump inhibitors (PPIs), appear inappropriate in such patients, mainly because acid production is virtually lacking. The use of

L-cysteine has been proposed as adjuvant therapy in CAG; the amino acid binds covalently to acetaldehyde (a Group 1 human carcinogen), removing it from the stomach. The aim of present study was to use L-cysteine to improve the symptoms in patients with diagnosis of CAG.

Aims & Methods: One hundred fourteen consecutive patients (M=43, mean age 49.9 years) (with diagnosis of CAG by means of both gastric histology (moderate to severe chronic, atrophic, body gastritis according to the OLGA staging system) and serology (pepsinogen I < 25 µg/l, gastrin-17 > 14 pmol/l) - GastroPanel®, Biohit Oyj, Finland) entered the study. Forty-one patients (11 M, mean age 49.4 yr, range 27–71 years) were treated with L-cysteine (100 mg 3 times daily, with meals) for 24 months (Group 1). As a control group we enrolled 73 CAG patients (M = 32, mean age = 55.3 yr, range 32–77 years) followed up for 24 months without any related therapy (Group 2). Early satiation, nausea, bloating were recorded at baseline and after 3, 6, 12, 24 months, according to severity score (0-3 for each symptom, min. 0 = no symptoms; max. 12 = full symptomatic).

Results: The global symptomatic score results as follows, lasting the 24 months follow-up. Group 1: baseline 4.93; 3 months 3.36; 6 months 2.96; 24 months 2.64. Group 2: baseline 5.9, 3 months 6.2, 6 months 5.6, 24 months 5.8 (p < 0.01). Subdividing the CAG patients according to the etiology (autoimmune gastritis or previous Helicobacter pylori infection) no differences were found in improving symptoms. No relevant side effects were observed during the study.

Conclusion: The administration of L-cysteine to subjects affected by moderate–severe chronic atrophic gastritis seems to improve the symptoms in a two-year follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1155 PROGNOSTIC SIGNIFICANCE OF SERUM INFLAMMATORY MARKERS IN GASTRIC CANCER

A. Powell1, D. Parkinson2, N. Patel3, C. Brown4, W. Lewis5

Introduction: Despite undergoing potentially curative resection a significant proportion of patients develop cancer recurrence. Several cellular and humoral components of systemic inflammatory response have been reported and associated with poor outcome. To date, no study has comprehensively examined the relationship between readily available markers of inflammation and survival in gastric cancer.

Aims & Methods: Patients undergoing surgery for stage I-III gastric cancer between 2004-2016 at a regional unit were identified. Measurements of various systemic inflammation markers were recorded pre-operatively. Pathological factors were recorded from reports issued at the time of resection. The modified Glasgow Prognostic Score (based on CRP and Albumin), Neutrophil-Lymphocyte Ratio, Platelet-Lymphocyte Ratio and Neutrophil-Platelet score were calculated. Pathological variables including TNM stage, differentiation and vascular invasion were also recorded. Survival endpoints of overall survival (OS) and disease-free survival (DFS) were used.

Results: 331 patients were identified and 291 patients underwent potentially curative resection for gastric cancer. On univariable DFS analysis, female gender, proximal location, T-stage, N-stage, TNM, vascular invasion, poor differentiation, lymph node ratio, R1 status, platelet count and mGPS were significant determinants of different outcomes. mGPS was the only inflammatory based marker to independently predict poor DFS and OS and may represent the optimum method for systemic inflammatory response quantification.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1156 ANALYSIS OF REBLEEDING PATIENTS IN UPPER GASTROINTESTINAL BLEEDING IN A SINGLE CENTER SERIES

R. Jiménez-Rosales1, E. Ortega-Suazo2, P. Abellán-Alfonso3, F. Valverde López2, J.G. Martínez-Cara1, E. Redondo Cerezo1
1Digestive Diseases, Hospital Virgen de las Nieves, Granada/Spain
2Gastroenterology, "Virgen de las Nieves" University Hospital, Granada/Spain

Contact E-mail Address: eredondoc@gmail.com

Introduction: Upper gastrointestinal bleeding (UGIB) is one of the main causes of hospital admission and urgent endoscopy in Gastroenterology departments. In-hospital mortality from UGIB has decreased throughout the past 2 decades with a corresponding increase in the performance of endoscopy and endoscopic therapies. Several studies suggest that improvements in the therapeutic procedures for patients with UGIB could be responsible of the mortality decline. Despite this, UGIB represents a true emergency, associated with significant morbidity, mortality and healthcare costs. Furthermore, rebleeding after initial endoscopic therapy is observed in 10–20%, and it has been associated with a higher mortality rate. Therefore, the definition of predictive factors for rebleeding is of outstanding importance.

Aims & Methods: The aim of our study is to analyze risk factors and outcomes in a population of patients who suffered rebleed. We present a retrospective study on a prospectively built database of patients with GI bleeding admitted to the Emergency Room of “Virgen de las Nieves” University Hospital over 42 months, from January 2013 to July 2016. All patients underwent upper endoscopy, and were assessed regarding patients’ demographic data, current medical conditions (including antplatelet drugs, NSAIDs and oral anticoagulants), clinical presentations, hemodynamics, admission laboratory test results, and endoscopic findings was collected. Interventions were documented, including the need for blood transfusion and the number of packed red blood cells units per patient, endoscopic therapy, interventional radiology procedures, and surgery. Clinical outcomes documented were in-hospital and delayed 6-months mortality, rebleeding and delayed 6-months bleeding and cardiovascular events.

Results: 507 patients were included (339 males; aged 41 ± 16.4). The incidence of rebleeding was 17.3% (n = 88). In the univariate analysis, factors related with rebleeding were creatinine levels (1.52 vs. 1.15; p < 0.001), tachycardia (96.28 vs. 88.24; p < 0.001), low levels of albumin (2.58 vs. 3.28; p < 0.001) and low CRP (260 vs. 210; p < 0.001). In a multivariable analysis, tachycardia and high creatinine were independent risk factors for rebleeding, and albumin showed as an independent protective factor (Table 1). Rebleeding was associated with in-hospital mortality (p < 0.0001); by contrast, it was not related to delayed 6-months mortality neither with delayed 6-months vascular and hemorrhagic events. The UGIB risk scores AIMS 65 and Rockall showed poor predictive ability for acute mortality in the rebleeding patients’ group and was similar for Blatchford score (based on AUROC).

Conclusion: Rebleeding in UGIB is associated with increased in-hospital mortality; nevertheless, it is not related with delayed 6-months mortality, hemorrhagic and cardiovascular events. High creatinine and low albumin levels were independent risk factors for rebleeding, suggesting a potential predictive role of these parameters. AIMS65, Rockall and Blatchford were insufficient to predict in-hospital mortality but worked poorly in the patients who suffered rebleeding.

P1157 A CASE-CONTROL STUDY ON THE RISK OF UPPER GASTROINTESTINAL MUCOSAL INJURIES IN SUBJECTS PRESCRIBED NSAIDS AND ANTI-THROMBOTIC DRUGS USING THE LARGE ORGANIZED DATABASE OF CLAIMS IN JAPAN (APPROXIMATELY 3.7 MILLION OF POPULATION ON AN ACCUMULATED BASIS)

Introduction: upper gastrointestinal (GI) adverse effects induced by NSAIDs and anti-thrombotic drugs are increasing along with progressive aging of society. Recently it is essential to perform pharmaco-epidemiological studies to identify adverse effects in the real-world setting using a large-scale medical database. We performed a case-control study to estimate the risk of upper GI mucosal injuries in subjects prescribed NSAIDs and anti-thrombotic drugs using the large organized database of claims in Japan.

Aims & Methods: The medical claims database developed by Japanese Medical Data Center (JMDC Co., Ltd. was selected as data source in the present retrospective observational study. The JMDC claims database comprised of integrated medical and pharmacy claims, and includes both hospital and outpatient care from over 90 payers (approximately 3.7 million of population on an accumulated basis). Eligible subjects were aged 20 to 74 and registered for at least 3 months in the database. Multivariate logistic regression analysis was used to calculate odds ratios of occurrence of each upper GI mucosal injury caused by NSAIDs, COX-2 selective inhibitors, low-dose aspirin, antplatelet drugs (except low-dose aspirin) and anticoagulants.

Results: The odds ratios of peptic ulcers were 1.45, 1.31, 1.50, 1.53 and 1.62 for NSAIDs, COX-2 selective inhibitors, low-dose aspirin, antplatelet drugs, and anticoagulants, respectively. On the other hand, the odds ratios of peptic ulcers (p < 0.0001) in each. The odds ratios of upper GI bleeding were 1.76, 1.62, 1.96, 1.82 and 2.38, and those of GERD were 1.54, 1.41, 1.89, 1.67 and 1.91, and these odds ratios were statistically significant in each medicine with GI bleeding and GERD (p < 0.0001 in each). In all the upper GI mucosal injuries were the highest in the patients with anticoagulants, and the ratios were relatively low in those with NSAIDs and COX-2 selective inhibitors. The odds ratios tended to increase with the number of prescribed
P1158 GASTROINTESTINAL BLEEDING UNDER ANTICOAGULATION THERAPY: SYSTEMATIC REVIEW OF THE REBLEEDING RISK, ITS REVERSIBILITY PROFILE AND RISK STRATIFICATION TO SELECT PATIENTS FOR LEFT ATRIAL APPENDAGE OCCLUSION

Introduction: Percutaneous left atrial appendage occlusion (LAAO) is increasingly recognized as a valid alternative therapy to reduce thromboembolic risk in patients with non valvular atrial fibrillation (AF) and contraindications for long term oral anticoagulation (OAC) therapy. Patients at high thromboembolic risk with previous gastrointestinal bleeding (GIB) might be at risk of bleeding recurrence in case of resuming anticoagulation. They could be selected for alternative therapies like LAAO. Up to now, there is no scientific consensus for patient selection for LAAO based on recurrent GIB risk.

Aims & Methods: We aimed to review the literature on gastrointestinal (GI) bleeding prevention when resuming OAC after LAAO procedure to deduce the reversibility profile of each lesion in an organ by organ and lesion by lesion approach to stratify the risk of bleeding individually. We systematically collected data from both prospective and retrospective studies from pubmed in order to extract rebleeding risk by etiology. The reversibility profile was defined by type of treatment needed to cure the lesion. Low reversibility (LR) profile was defined as a need for heavy treatment (surgery, radiotherapy, embolisation) to cure the lesion or as diffuse lesions.

Results: The most frequent reported causes of bleeding are peptic gastroduodenal ulcer (60%) for upper GI, diverticulosis (40%), colitis (20%) and anorectal diseases (20%) for lower GI and angiodysplasia (23%) for the midgut, these latter being responsible for 5% of all GI bleeding causes. The rate of recurring bleeding under OAC is 5-7% for varius K arteries vs. 2% for VKA and 12-14% in case of OAC and aspirin, respectively. In the upper GI tract, lesions at high risk of bleeding recurrence are Dieulafoy lesions and angiodysplasia with reported rates up to 40% in some series. In the lower GI tract, lesions at highest risk are diverticular disease, angiodysplasia, colitis and radiation rectitis with bleeding recurrence rates reaching 60%, 20%, 40% and 20% respectively. For the midgut, angiodysplasia (20%) and bleeding of unknown origin (20%) are associated to the highest risk of recurrent bleeding. LR profile lesions with high rebleeding risk are present for diffuse angiodysplasia, systemic diverticulosis and Dieulafoy lesions.

Conclusion: In conclusion, GI lesions at high risk of recurrent bleeding with low reversibility profile are infrequent and include in particular: diffuse angiodysplasia, colonic diverticulosis and Dieulafoy lesions. Patients with AF having those lesions and resuming GIB under anticoagulation might be the best candidates for alternative therapies like LAAO. Larger studies are needed to assess the long term outcome of patients treated by LAAO for GIB under current oral anticoagulant therapies.

P1161 COMPARISON OF RISK-SCORING SYSTEMS IN PREDICTING NEEDS OF INTERVENTION AND CLINICAL OUTCOMES OF UPPER GASTROINTESTINAL BLEEDING

M. Ooi, W. Low, R. Bryant, N. Q. Nguyen
Department Of Gastroenterology And Hepatology, Royal Adelaide Hospital, Adelaide/Australia/SA

Contact E-mail Address: marieooi@ali@yahoo.com

Introduction: There are several risk-scoring systems available to assist the management of upper gastrointestinal bleeding (UGIB). The aim of this study is to compare the performance of pre-endoscopy (pre-RS), post-endoscopy Rockall score (post-RS), GBS and AIMS65 scores in predicting the need for intervention in patients admitted to hospital for UGIB.

Aims & Methods: Data related to the three scoring systems were collected prospectively and scores calculated in consecutive patients who were admitted with acute UGIB to the Royal Adelaide Hospital over 24 months. The performance of these scoring systems in predicting clinical outcomes was assessed: the need for endotherapy, rebleeding risk, transfusion requirement, surgical intervention and death. All patients received high dose acetylsalicylic acid prophylaxis. Results: Of the 777 patients (491M; 66.4 years), median hospital stay was 2.5 days (IQR: 1.0–6.0). GBS and AIMS65 scores were respectively 40.25 (21.21–102.6) and 32.10 (15.40–65.80). ROC analysis revealed that the independent risk factors for rebleeding in UGIB were multiple ulcers [odds ratio (95% confidence interval) = 2.42 (2.76–21.3), P < 0.004], steroid administration [14.0 (1.73–113), P = 0.013], and hemodialysis [9.53 (1.00–90.7), P = 0.049]. There was no significant correlation between the need for endotherapy and the score. Conclusion: ROC analysis revealed that the independent risk factors for rebleeding in UGIB were multiple ulcers [odds ratio (95% confidence interval) = 2.42 (2.76–21.3), P < 0.004], steroid administration [14.0 (1.73–113), P = 0.013], and hemodialysis [9.53 (1.00–90.7), P = 0.049]. There was no significant correlation between the need for endotherapy and the score.

P1162 STEROID ADMINISTRATION IS AN INDEPENDENT RISK FACTOR FOR REBLEEDING IN HEMORRHAGIC DUODENAL ULcer WITH A DOSE-RESPONSE RELATION

Division Of Gastroenterology, Tohoku University Graduate School of Medicine, Sendai/Japan

Contact E-mail Address: wakku-style@festa.ocn.ne.jp

Introduction: Hemorrhagic gastroduodenal ulcer is commonly seen in routine clinicopathologic practice, and there have been many studies investigating risk factors for rebleeding. However, few studies have evaluated hemorrhagic gastric ulcers (HGU) and hemorrhagic duodenal ulcer (HDU) separately. Furthermore, the relation between steroid administration and rebleeding in hemorrhagic gastroduodenal ulcer (HDU) has been rather understudied. Aims & Methods: The aim of this study was to clarify the difference of rebleeding between HGU and HDU, and associated factors for rebleeding of HGU and HDU. Between March 2005 and September 2016, 176 consecutive patients with hemorrhagic gastroduodenal ulcer (106 with HGU and 70 with HDU), who underwent endoscopic hemostasis, were enrolled in this study. Regular dose proton pump inhibitor was administrated to all patients after the diagnosis of hemorrhagic gastroduodenal ulcers. Rebleeding was defined as hematemesis or melena with ulcers confirmed by endoscopy or a decrease in the hemoglobin level >2 g/dl in the presence of endoscopically proven ulcers. First, we compared the rebleeding rate between HGU and HDU. Subsequently, associated factors for rebleeding of HGU and HDU were calculated by logistic regression analysis individually. The estimated factors were age (<65/65 years), gender, location of ulcer (upper third/middle or lower third in HGU and 2nd portion/bulb in HDU), underlying comorbidities (ischemic heart disease, liver cirrhosis, hypertension, diabetes mellitus, and hyperlipidemia), number of ulcers (multiple/ single), hemostasis method (pure ethanol injection therapy/other therapies), antiplatelet therapy, anticoagulation therapy, NSAID administration, steroid administration, antacid administration in the initial ulcer bleeding, hemoglobinemia (serum albumin level ≤2.5 g/dl), and hemodialysis. We further investigated the detailed association between steroid administration and rebleeding in HDU, including dose-response relation.

Results: The rebleeding rate of HGU and HDU were 5.7% and 22.9%, respectively, which was statistically significant (P = 0.001). There was no missing data in the estimated factors. Although no factor was associated with rebleeding in HDU, ROC analysis revealed that the independent risk factors for rebleeding in HDU were multiple ulcers [odds ratio (95% confidence interval) = 2.42 (2.76–21.3), P = 0.004], steroid administration [14.0 (1.73–113), P = 0.013], and hemodialysis [9.53 (1.00–90.7), P = 0.049]. Regarding the dose of steroid administration, multivariate analysis showed that middle to high-dose steroid administration (≥20 mg in prednisolone) (52.7 [3.19–87.1]) P = 0.006) was a significant risk factor for rebleeding of HDU, with a dose-response relation (P = 0.0015).

Conclusion: HDU developed significantly higher rebleeding after endoscopic hemostasis, compared with HGU. In addition to multiple ulcers and hemodialysis, we firstly demonstrated by multivariate analysis that steroid administration is an independent risk factor for rebleeding of HDU after endoscopic hemostasis, with a dose-response relation.

P1163 EFFICACY AND SAFETY OF BIO-INSERT MINERAL SMECTITE IN CONTROLLING GASTROINTESTINAL HEMORRHAGE: AN ANIMAL PILOT STUDY

1The First Affiliated Hospital with Nanjing Medical University, Nanjing/China
2Digestive Endoscopy Center, The First Affiliated Hospital of Nanjing Medical University, Nanjing/China

Contact E-mail Address: kir9178@ sina.com

Introduction: Gastrointestinal bleeding is common in clinics, especially after endoscopic operation. Besides from hemoclip, APC or electrocoagulation, more novel hemostasis approaches should be developed to improve endoscopic bleeding management. Granule smectite is bioinert mineral and efficient for curing diarrhea. Inspired by its dehydrating and tissue-covering effect, this pilot study was to investigate its efficacy and safety for controlling hemorrhage in rats.

Aims & Methods: 32 rats were divided into four equal groups. For hemorrhage model, a horizontal 10-mm incision was made on the lower part of the left hepatic lobe. Commercial hemostatic powder, smectite, starch and normal saline were respectively applied. Bleeding duration and blood loss were recorded. 1 week later, rats were sacrificed and liver tissue was collected for histopathology.

Results: Smectite demonstrated the best hemostasis effect, and its mean coagulation time was 1.45 ± 0.026 min. Commercial hemostatic chitosan stypic powder need 2.5 ± 0.04 min for complete clotting, while Starch group was 4.75 ± 0.056 min and normal saline group was 4.925 ± 0.123 min (p < 0.05). Similarly, smectite led to less blood loss (0.618 ± 0.034 g), while rats lost 2.3288 ± 0.123 g blood (p < 0.05) under normal saline treatment. For starch and commercial chitosan, the blood loss was respectively 2.0862 ± 0.061 g and 1.49 ± 0.023 g. Histopathologic results confirmed that smectite was biocompatible to tissue.

Conclusion: The mineral smectite powder was the superior candidate for hemostasis treatment in vivo. Compared with common polysaccharide agents, smectite could induce faster coagulation and reduce blood loss. More importantly, bioinert smectite was biocompatible and even promoted the wound healing. For gastrointestinal application, smectite powder could be delivered through endoscopic spray tube, while its inspiring efficacy required more endoluminal hemostasis tests.

P1164 PREDICTORS OF LIFE THREATENING MUCOSAL HEMORRHAGE: AN ANIMAL PILOT STUDY

A. S. Hanafi
Internal Medicine, Zagazig University, Zagazig/Egypt

Contact E-mail Address: dr_amer_hanafi@yahoo.com

Introduction: Life-threatening bleeding could occur early after variceal sclerotherapy in cirrhotic patients. Aims & Methods: We aimed to determine simple predictive factors of this complication in cirrhotic patients. Among 750 patients treated with variceal sclerotherapy (esophageal varices (EV): 683, 87.3%) and (gastroduodenal varices (GV): 65, 9.4 years), 95, 12.7%) Zagazig University hospital–endoscopy unit- Internal medicine department, in the period from October 2014 till July 2016, 150 patients (20%, mean age 46 ± 9.4 years) (EV = 129, GV = 21) developed bleeding due to sclerotherapy induced ulcers confirmed by endoscopy 6.4 ± 2.1 days after the procedure. Cirrhosis was post viral hepatitis C (89%), hepatitis B (10%) and cryptogenic in (1%). A case-control study was performed comparing these
patients with 150 patients who underwent endoscopic variceal sclerotherapy without the development of bleeding due sclerotherapy ulceration. **Results:** Bleeding occurred 6.4 ± 2.1 days (2–10) following sclerotherapy. Twenty-three patients died following the bleeding (15.3%). Using a multivariate analysis; pre-procedural factors as serum albumin ≥2 g/dl [OR 1.3], total bilirubin ≥1.6 mg/dl [OR 1.9], platelet ratio index (APRI) >1 [OR 1.2]. **Conclusion:** Conclusion: Bleeding related to sclerotherapy ulcers is uncommon, but may be life threatening. The proposed predictive factors should be watched and minimized before and during variceal sclerotherapy.

**Aims & Methods:** The aim of this study is to investigate the prevalence of sleep disorders in FD patients and the risk factors associated with sleep disorders. This multicenter, cross-sectional study had been conducted from August 2014 to December 2016 at 6 hospitals in Korea. Inclusion criteria were FD patients (>18years) that met the Rome III criteria for the patients visited the gastroenterology department for dyspepsia. Exclusion criteria were prior surgery to the upper gastrointestinal tract, history of ulcer disease, erosive GERD, history of malignancy, and severe comorbidity. Healthy control group who had no clinical history of gastroesophageal reflux disorder and no abnormal finding on endoscopy were recruited from the study center for screening. The Pittsburgh Sleep Quality Index was used to assess sleep disturbance. Hospital anxiety and depression scale was used to identify anxiety and depression.

**Results:** Total 169 FD included 160 FD patients and 223 healthy control groups. The total Pittsburgh Sleep Quality Index score was higher in FD patients than health controls (7.8 ± 4.3 vs 5.6 ± 3.1, p = 0.009). The prevalence of sleep disorder was significantly higher in FD patients than healthy control (41.2% vs 18.4%, p < 0.001). In univariate analysis, FD was significant risk factor for sleep disorder (OR 3.12, p = 0.001). The independent risk factors for sleep disorder in multivariate analysis were FD (OR 1.80, p = 0.026), female (OR 1.78, p = 0.028) and depression (OR 2.91, p = 0.002).

**Conclusion:** FD significantly impacted on sleep disorder. FD was independent risk factor in sleep disorder.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Functional gastrointestinal (GI) disorders (FGIDs) have been the subject of extensive debate about axes with both somatic markers (e.g., abdominal pain) and psychological ones. Exactly how abdominal and psychological disorders are related remains poorly understood. While there have been a small number of methodologically rigorous longitudinal studies that examine this question (1,2), even these have typically only studied a small number of psychological traits and only quite general GI symptoms. There remains a need for further longitudinal studies of how psychological traits predict subsequent FGID symptoms.

**Aims & Methods:** The present study is a longitudinal examination of the influence of a broad range of psychosocial predictors on later bowel-related and epigastric discomfort in a community sample. A sample of 188 individuals randomly sampled from the Australian electoral roll were surveyed, and, of them, 123 met the Rome III criteria for irritable bowel syndrome (IBS) or functional dyspepsia (FD) while 65 did not meet criteria for FGIDs. Subjects were of mean age 49 years (SD = 15, range 20–87) and 73% were female. A broad range of psychological constructs (24 in total) were measured at baseline. Among them were anxiety, depression, somatization, childhood abuse, neuroticism, hypochondriasis, somatic vs psychological symptom attribution, coping, and social support. GI symptoms were measured 18 months later using two Likert-type scales: one concerning epigastric pain and the other concerning bowel symptoms. Exploratory factor analysis (EFA) was used as a data-reduction technique to create a smaller number of composite predictors. Statistical analysis was based on ordinal regression.

**Results:** Ten composite scores were derived via EFA to be examined as predictors of the full sample (N = 188) of a number of psychosocial traits (e.g., worry, non-sexual childhood abuse, psychological symptom attribution and childhood sexual abuse; see Table 1) were individually related to subsequent bowel symptom severity 18 months later (Table 1). There was evidence of variation in psychological predictors of gastrointestinal symptoms between individuals who met and did not meet criteria for IBS or FD. With respect to bowel symptoms, no psychological trait reached statistical significance.
as a predictor among individuals with FGIDs (Table 1). Epigastric symptom severity was predicted by worry and psychological attribution of symptoms among FGID individuals but no psychological trait predicted symptom severity among non-FGID individuals (Table 1).

**Conclusion:** A range of psychosocial factors predict later gastrointestinal symptom burden. For bowel symptoms, associations between psychological traits and symptom burden appear to be most clearly driven by the non-FGID subgroup, among whom psychological attributions for symptoms and problem-focused coping are positively related to later symptom burden. For epigastric symptoms, a range of psychological traits were relevant, with the predictive patterns being most clearly driven by individuals who qualified for FGIDs. In light of these results, studies of the brain-gut axis need to consider a greater array of psychological traits, particularly outside of anxiety and depression. Further, the complexity by associations between psychological traits and gastrointestinal symptoms may be moderated by symptom level but are relatively similar across upper and lower gastrointestinal symptoms.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** In the recent years, there has been an increasing recognition of the presence of gastrointestinal (GI) dysfunction in patients with neurologic diseases. There are no studies examining a relationship between psychological traits and gastrointestinal symptoms in patients with achalasia and with neurodegenerative/demyelinating diseases. A range of psychosocial factors predict later gastrointestinal symptom burden. For bowel symptoms, associations between psychological traits and symptom burden appear to be most clearly driven by the non-FGID subgroup, among whom psychological attributions for symptoms and problem-focused coping are positively related to later symptom burden. For epigastric symptoms, a range of psychological traits were relevant, with the predictive patterns being most clearly driven by individuals who qualified for FGIDs. In light of these results, studies of the brain-gut axis need to consider a greater array of psychological traits, particularly outside of anxiety and depression. Further, the complexity by associations between psychological traits and gastrointestinal symptoms may be moderated by symptom level but are relatively similar across upper and lower gastrointestinal symptoms.

**Aims & Methods:** The aim of our prospective study is to examine a prevalence of neurodegenerative/demyelinating diseases in a cohort of consecutive patients with confirmed esophageal achalasia. Achalasia was diagnosed by high-resolution manometry, endoscopy and esophagegapham. A total of 140 consecutive patients with esophageal achalasia have been questioned about the occurrence of neurological diseases and symptoms in their personal and family history. Those with a suspicion of a neurological disease were referred for a detailed clinical resolution manometry, endoscopy and esophagogram. A total of 140 consecutive patients with esophageal achalasia have been questioned about the occurrence of neurological diseases and symptoms in their personal and family history. Those with a suspicion of a neurological disease were referred for a detailed clinical study.

**Results:** A total of 51 out of 140 patients (36.4%) exhibited some neurological symptoms-most often visual disturbances in 17 patients (33.3%) and limb spasticity in 12 patients (23.5%). Among patients with a presence of neurological symptoms, 5 patients (3.6%) had definitely been diagnosed with a neurodegenerative/demyelinating disease (multiple sclerosis - 2 patients, Lebert optic neuropathy - 1 patient, Parkinson’s disease - 1 patient and Allgrov syn - syndrome - 1 patient). Furthermore, 7 patients with a positive questionnaire had been diagnosed with other neurological diseases (tetany n = 2, carpal tunnel syndrome n = 3, epilepsy n = 2). Fourteen patients (27.4%) among those with neurological symptoms (vs. 0 out of 89 patients without neurological symptoms) had a positive family history of a neurodegenerative or a demyelinating disease. Among 106 patients with a neurodegenerative/demyelinating disease, 30 of them (27.4%) described dysphagia as the personal history. These patients will be examined by esophagegaphamometry.

**Conclusion:** Our results imply an increased prevalence of neurodegenerative/demyelinating diseases in patients with achalasia (3.6% vs. approx. 1.4% in the Czech controls). Also, a high prevalence of dysphagia was found among patients with a neurodegenerative/demyelinating disease. These results warrant further confirmation in a large population-based study.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

When considered jointly with other predictors, psychological attribution of symptoms was significantly positively related to both bowel symptom severity (non-FGID: OR = 0.31, SE = 0.13; Full: OR = 0.74, SE = 0.11) and epigastric symptom severity (FGID: OR = 0.63, SE = 0.09; Full: OR = 0.63, SE = 0.11). The same was the case for worry (Bowel: Full: OR = 1.40, SE = 0.21; Epigastric: FGID: OR = 1.58, SE = 0.27; Full: OR = 1.54, SE = 0.23). For bowel symptoms, problem-focused coping (OR = 2.30, SE = 0.98) was an additional independent positive (notably, not negative) predictor among participants without FGIDs.
functional connections). These interconnections included the following: thalamus-amygdala, hypothalamus-NAC, amygdala-pu
men amygdala-NAC and insula-patmen. No significant network was identified for the low CVT group.

Conclusion: During acute oesophageal pain, resting cardiac vagal tone yields a unique manometric configuration comprising numerous complex subcortical brain regions, many of which have been previously associated with either visceral pain or modulation of baseline autonemics either at the physiological or neuroana
tomical level (3). Previous research has suggested that a high resting CVT may be protective of noceptive signalling, and furthermore studies investigating vagal nerve stimulation have included and report that of anti-nociception (4). Given the well-established role of these subcortical regions in pain processing, we sug
suggest that this network identified may be of significance as to the neurophysiolo
gical process of parasympathetic modulation of painful sensory signalling. Lastly, to date, no studies have undertaken real-time assessment of the ANS (including CVT) during functional brain imaging and acute visceral pain. Future studies should investigate for this.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1170 RAPID DRINK CHALLENGE (RDC) TEST DURING OESOPHAGEAL HIGH RESOLUTION MANOMETRY (HRM) IN PATIENTS WITH OESOPHAGO-GASTRIC JUNCTION OUTFLOW OBSTRUCTION
D. Biasutto, F. Mion, A. Garros, S. Roman
Digestive Physiology, Lyon I University and Hospices Civils de Lyon, Lyon/France

Contact E-mail Address: dbiasutto@unicampus.it

Introduction: Oesophageo-gastric junction outflow obstruction (OGJOO) is of unclear significance. It may be secondary to an incomplete form of achalasia, a mechanical obstruction or be idiopathic. Rapid drink challenge (RDC) test is easy to perform during oesophageal HRM.

Aims & Methods: We aimed to assess the yield of RDC in patients with OGJOO. From a database of 3522 consecutive oesophageal HRM performed from 01/2012 to 03/2017, we extracted patients with OGJOO according to the Chicago Classification v3.0. HRM protocol consisted of 10 5-ml water swallows in supine position and RDC test (200-ml free drinking) in sitting position. Distal contrac
tile integral (DCI) integrated relaxation pressure (IRP), distal and pan-oesopha
gus pressurization (POP); homogeneous oesophageal pressurization >30 mmHg) were reported for 5-ml swallows. POP and oesophageal shortening (OS) were analysed during RDC. Symptom severity was assessed with Eckardt score. Causes of OGJOO were determined by reviewing patient’s chart for previous history, complementary work up and treatment. Quantitative data were expressed as median (range) and qualitative data as percentage. They were compared using non parametric and Chi square tests.

Results: 75 patients (29%) (29 males, mean age 62 years (25–92)) were included. The dominant symptom was dysphagia (69%), regurgitation (9%), chest pain (5%), other (13%), no symptom (3%). The causes of EGJOO were previous oesophageo-gastric surgery (43%), incomplete achalasia (7%), mediastinal neoplasia (7%), miscellaneous (1%) and unknown (25%). RDC test was success
fully performed in 70 patients (93%) and associated with POP and OS in 41% and 15% respectively. Dysphagia as dominant symptom was more frequent (79% vs 59%, p = 0.017) and more severe (Eckardt score 5 (1–11) vs 3 (0–10), p = 0.001) in patients with POP during RDC compared to those without. The same obser
vation was achieved in patients with OS vs those without (dysphagia 100% vs 62, p = 0.02 and Eckardt score 6 (2–10) vs 1 (0–11), p = 0.02). Manometric para
meters were reported in the table. The causes of OGJOO were similar in patients with and without POP during RDC (previous oesophageo-gastric surgery 34% and 51% respectively, achalasia 14% and 2%, mediastinal neoplasia 3% and 7%, miscellaneous 10% and 22%, unknown 35% and 17%). OS was not observed in patients with unknown cause of EGJOO vs 20% of patients with an identified cause (p = 0.09).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1171 THE NORMATIVE VALUES OF A NEW 36 CHANNELS WATER PERFUSION ESOPHAGEAL MOTILITY CATHETER
S. Bor, S. Kipcak
Gastroenterology Sec., Ege Reflux Study Group, Ege University, Izmir/Turkey

Contact E-mail Address: kipcaksezgi@gmail.com

Introduction: High resolution manometry (HRM) is performed with solid-state catheters (SS) in many centers. However according to Chicago classification, very limited data from healthy volunteers are available for some catheters and starting from IRP, numerical values are crucial for the diagnosis. Because of the cost of the SS-HRM catheters many centers especially from developing countries use water perfusion HRM (W-HRM) catheters up to 24 channels and normal values are even more limited.

Aims & Methods: We evaluated a prototype 36 channels W-HRM reusable catheter allowing to measure 3D-pressure vector volume analysis of lower esophageal sphincter in healthy volunteers and compared to 36 channels SS-HRM catheters (Laborie-MMS Canada). We included 43 healthy volunteers without any upper gastrointestinal complaint. Upper gastrointestinal endoscopy and 24h impedance-pH monitor
ing performed in all subjects. Four subjects were excluded because of silent GERD. 39 subjects were analysed (25 males, W-HRM (n = 39), SS-HRM (n = 33)). Thirty-three patients underwent two esophageal manometry studies within two consecutive days with a random order. Procedures were performed in supine position with receiving ten times 5 ml water, five times solid food and multiple water swallow with 200 ml of water. 36 channel water-perfused 3-D HRM catheter and 36 channel solid state HRM catheter were used (Laborie-MMS Canada).

Results: There was significant differences between two catheters in terms of Integrated Relaxation Pressure (IRP), Distal Contractile Integral (DCI) and DCI expanded, LES resting pressure, % of ineffective peristalsis, and esophageal length both with water and solid food swallows (Table). No difference has been shown with distal latency (DL), LES length, breaks size (Table).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The Chicago Classification (CC V3.0) defined ineffective esophageal motility (IEM) by the presence of 50% or more of weak or failed peristaltic waves during high resolution manometry (HRM). Both low-volume (10ml) multiple rapid swallow (MRS) and high-volume (200ml) rapid drinking test (RDT) have been suggested as test to recognize the esophageal peristaltic reserve. Which test might better represent the esophageal peristaltic reserve is still a matter of discussion.

Aims & Methods: The aim of this study was to compare the diagnostic value of MRS and RDT in patients with IEM. From a larger group of patients evaluated for heartburn and/or/wik with poor response to standard dose proton pump inhibitors, we enrolled consecutive patients with IEM and with functional heartburn (FH). FH were enrolled as controls. IEM was defined according to the Italian Guidelines. All patients underwent 3 MRS (10 ml of water in 5 swallows in less than 10s) and 1 RDT (200 ml of water freely drunk). The mean DCI of MRS and the DCI of RDT were compared with DCI of 10 single swallows (SS). The MRS/SS and RDT/SS ratio were calculated.

Results: We evaluated 30 patients with IEM (18 males and 12 females; mean age 45.7±11.4 yrs) and 30 patients with FH (15 males and 17 females; mean age 41.2±13.6). The pH-m pH showed higher acid exposure time (AET) and number of reflux events in IEM than in FH (p<0.05). Mean DCI of SS resulted lower in patients with FH compared to FH (p<0.05). One-hundred and eighty IEM and 60 FH were evaluated. DCI of MRS was lower than 450mmHg-cm in 39% (35/90) of IEM patients, and in 7% (6/90) of FH (p<0.05). DCI of RDT was lower than 450mmHg-cm in 73% (23/30) of IEM patients, and in 50% (15/30) of FH (p<0.05). The MRS/RDT ratio resulted >1 in both groups. All results are reported in Table 1.

Conclusion: 100% of IEM patients compared to 50% of FH showed peristaltic reserve compared to RDT both in patients with IEM or those with normal esophageal peristaltic reserve.

Disclosure of Interest: All authors have declared no conflicts of interest.
or severe); the product of frequency and severity constituted the symptom score, assessed at baseline and after ARS. Automated PFA was performed for each test swallow by blinded investigators using purpose built software (Esophageal AIMplot, copyright T Omari) programmed in MatLab (The MathWorks Inc, Natick, MA, USA). The nadir impedance point (NI) indicating peak distension, and the contractile deceleration point (CDP) were determined. latency was measured from NI to the contraction front at the CDP (distension to contraction latency, DCL). Intrabolus pressures (IBP) were measured during accommodation (IBP-A), compartmentalized transport (IBP-CT) and esophageal emptying (IBP-EE). This clearance in the esophageal body was assessed using the impedance ratio (IR) based on the relationship between NI and impedance at the contractile peak. Bolus flow at the esophagogastric junction (EGJ) was assessed using bolus flow time (BFT) in seconds when both pressure and impedance traces indicated a flow permissive paradigm. Univariate and multivariate analyses were performed to assess the relationships between bolus flow metrics and motor function, taking baseline symptom scores and symptom change following ARS into consideration. Results: Of 86 patients, 72.1% had typical symptoms. The mean baseline symp-
tom score was 158.8±15.8, with a mean decline of 139.9±15.8 following ARS. Peak pressures in the proximal esophagus were lower in GERD patients com-
pared to controls with all bolus consistencies (p = 0.007). Consequently, metrics assessing esophageal bolus presence (NI) and clearance (IR) were consistently abnormal in GERD patients (Table, p = 0.001 for all bolus consistencies for each comparison to controls). Trans-EGJ bolus flow metrics were similarly abnormal in GERD (BFT, p = 0.001 for all bolus consistencies compared to controls). IBP metrics were highest with solid swallows, especially in GERD patients compared to controls (Table). Within GERD, a gradient of increasing dysfunction in bolus presence and bolus clearance was noted, with least abnormalities with water swallows and the worst metrics with bread swallows (p ≤ 0.02 across groups for each comparison). IBP-EE (p ≤ 0.05) and trans-EGJ BFT (p = 0.004) were higher during water and viscous swallows with atypical symptoms compared to typical symptoms. NI was consistently lower in patients reporting ≥75% symp-
tom improvement following ARS with all bolus consistencies (p ≤ 0.046).

Conclusion: Automated pressure flow analysis of HRM studies demonstrates abnormalities of esophageal bolus transit and esophageal emptying in conjunc-
tion with lower proximal smooth muscle contractile function with all bolus consist-
cencies in GERD compared to controls. Metrics assessing esophageal bolus presence may have prognostic value in GERD patients undergoing ARS.

Introduction: Oesophageal diversitica are rare diverticula of the gastrointestinal tract known to be associated with oesophageal motor disorders.

Aims & Methods: The aim was to study manometric abnormalities associated with oesophageal diversitica, using both wet and solid swallows. Patients under-
went high resolution oesophageal manometry (HRM) in the upright position. 18 patients with oesophageal diversitica were found and were free of previous surg-
ery. Traction diversitica was excluded in all patients. We also included 10 healthy controls. HRM was performed using wet (5 mL of water) swallows in both groups, followed by solid (meat) swallows in patients. Mean age of the controls was 50 years old while it was 70 years old for patients.

Results: The main reported symptom was dysphagia (76%). HRM found 11 (61%) patients with an oesophageal motor disorder, including 2 oesopha-
gastric junction outflow obstruction (OGJOO), 4 achalasia (subtype 2: n = 2; sub-
type 3: n = 2), 4 distal oesophageal spasm (DES) and 1 jackhammer oesophagus, and was normal in 7 (39%) patients. In those patients with normal findings, solid swallows identified 4 (57%) additional motor disorders, including 2 OGJOO, 1 jackhammer oesophagus and 1 DES. Provocative testing using solid swallows was normal in 22% of overall patients and by 57% in patients with normal manometry using wet swallows only. Mean pressure slopes at mid-
oesophagus and oesophagus were greater in patients than healthy controls (p < 0.05 for wet swallows), as previously reported. Other metrics are summar-
ized in the table.

Conclusion: While more than one-third of HRM using wet swallows were normal, provocative testing using solid swallows increased the diagnostic yield of the procedure by more than 50% in these patients. Analysis of pressure slopes confirmed the association of propagating peristalsis with the disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
1. Carlson DA, Gluskin AB, Meagi B, et al. Esophageal diversitica are asso-
ciated with propagating peristalsis: a study utilizing high-resolution manome-
well as upper endoscopy, barium esophagogram and HRM before and 6 months after treatment. Achalasia was classified according to the Chicago Classification V3.0. The EGJ-CI was calculated using the distal contractile integral tool-box during three consecutive respiratory cycles. Patients underwent to pneumatic dilatation (PD), or LHM plus a Dor (LHM-D), Toupet (LHM-T) or a Nissen-Rossetti (LHM-NR) fundoplication. Ethical approval for the study was obtained.

Results: We enrolled 35 achalasia patients (14 Type I, 16 Type II and 5 Type III). Ten patients underwent PD, 11 LHMD, 8 LHM-T and 6 LHM-NR. At baseline, no significant differences regarding sex, age, sex, pre-operative mean Eckardt score, GERDQ score, integral relaxation pressure (IRP) and EGJ-CI were recorded. All Type III subjects underwent LHMD-D (3) and LHMD-T (2). After all the procedures, in all the patients there was a significant decrease in Eckardt score, IRP and EGJ-CI (p < 0.001, < 0.001 and < 0.05, respectively). PD and LHMD-NR showed higher EGJ-CI (20 ± 9.3 and 25 ± 11 mmHg*cm, respectively) and IRP (12.2 ± 3.4 and 13 ± 4.5, respectively) than LHMD-D and LHMD-T (18.4 ± 5.9, p < 0.05 and 9.3 ± 4.1 p < 0.05 mmHg*cm, respectively for EGJ-CI; 5.2 ± 2.5, p < 0.05 and 2.3 ± 3.7 p < 0.001 mmHg*cm, respectively for IRP). Post-operative Eckardt score was lower in LHMD-D and LHMD-T (2.1 ± 0.5 and 2.0 ± 0.6, respectively) than PD and LHMD-NR (4.2 ± 1.0, p < 0.01 and 3.7 ± 1.5, p < 0.005). Post-operative GERDQ score was significant higher in LHMD-T (3.0 ± 1.7 vs. 3.2 ± 3.9, p < 0.05). Low post-operative EGJ-CI values correlated with an increased risk of higher post-operative GERDQ score (p < 0.05, odds ratio 4.223, 95% CI 0.964–2.123).

Conclusion: All procedures performed to treat achalasia produced an adequate relief of dysphagia. LHMD-D and LHMT seem to result in a stronger alteration of the EGJ, with LHMD-T resulting in an increased risk of post-operative reflux.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI177 MULTIPLE RAPID SWALLOWING IN JACKHAMMER ESOPHAGUS: PATIENTS’ EVIDENCE FOR ALTERED NEURAL CONTROL

Introduction: Jackhammer esophagus is a rare esophageal motility disorder. Little is known about its physiopathology; however, an excess of cholinergic drive has been suggested as an important etiologic factor. Multiple rapid swallowing (MRS) is an adjunctive test in order to evaluate integrity of inhibitory and excitatory neural pathways. In healthy subjects body motion inhibition is observed during MRS and a contraction stronger than single swallows (SS) occurs after MRS, the so-called peristaltic reserve (MRS/SS DCI ratio > 1). In patients with reflux esophagitis esophagus preservation of motor inhibition during MRS has been described with traditional manometry2. No study has evaluated peristaltic reserve and motor inhibition with high-resolution manometry (HRM) in patients with jackhammer esophagus.

Aims & Methods: To evaluate MRS in a consecutive multicenter series of 42 Jackhammer esophagus patients (18 Male; 63 years; 55–71) according to Chicago 3 classification. 18 healthy subjects (HS) (seven male; 28 years; 23–33) from a published series were used as a control group. All patients underwent solid state HRM with ten 5 ml SS and one to three 10 ml MRS (30 patients performed at least two MRS). Standard HRM parameters during SS were evaluated. During MRS presence/absence of motor inhibition and 4 second integrated relaxation pressure (4 sec IRP) were evaluated. After MRS distal contractile integral (DCI) was evaluated and DCI ratio between MRS and SS was measured. Mann Whitney, Wilcoxon and chi-squared tests were used when appropriate; data are shown as median-IQR range.

Results: Descriptive data in jackhammer patients are shown in table 1. Twelve patients did not have motor inhibition during at least one MRS (28% vs 5% in HS, p < 0.05). There was a trend toward a lower 4s IRP during MRS compared to SS (see table 1); however, values were higher than those of 4s IRP MRS in HS (5.1 mmHg; 2.2–11 vs 1.6 mmHg; 0.3–2, p < 0.0001). MRS DCI was significantly lower than SS DCI, interestingly 26 patients had a MRS/SS DCI ratio < 1 (62% vs 22% in HS, p < 0.0005) and it was lower than the MRS/SS DCI ratio of HS (0.8; 0.4–1.1 vs 1.9; 1.1–2, p < 0.0001) suggesting a reduction of the hypercontractile activity in the esophageal body.

SS, single swallows; MRS, multiple rapid swallows; 4 sec IRP, 4 second integrated relaxation pressure DCI, distal contractile integral; CFV, contractile front velocity; DL, distal latency.

Conclusion: Contrary to what occurs in healthy subjects, MRS reduce DCI value compared to SS in jackhammer esophagus patients, suggesting altered neural control of peristalsis. Differently to what previously observed with traditional manometry, motor inhibition during MRS is altered in a quarter of patients. Studies are needed in order to evaluate if reduction of DCI during MRS can improve dysphagia and chest pain in these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI178 GASTRIC PERORAL ENDOSCOPIC MYOTOMY (G-POEM) AS TREATMENT FOR FUNCTIONAL DELAYED GASTRIC EMPTYING: INITIAL ASIAN EXPERIENCE

M. Cai1, J. Xiu1, P. Zhou1
1 Endoscopy Center, Zhongshan Hospital, Fudan University, Shanghai, China

Contact E-mail Address: cai.mingyuan@zs-hospital.sh.cn

Introduction: Functional delayed gastric emptying is a difficult-to-treat disorder, which is often expressed clinically as nausea/vomiting, fullness/early satiety, bloating and weight loss. Gastric peroral endoscopic myotomy (G-POEM) has been regarded as a novel and minimally-invasive therapy for functional delayed gastric emptying refractory to medical therapy. We herein report our initial experience of G-POEM in an Asian population with focus on technique in addition to safety and efficacy of this promising endoscopic therapy.

Aims & Methods: The data of consecutive patients who underwent G-POEM by a single expert endoscopist from October 2015 to November 2016 was collected. Procedures were performed, similar to POEM for achalasia, including initial mucosal incision, creating a submucosal tunnel, full-thickness (pyloro)myotomy, and closure of the mucosal entry. Patient demographics, etiology, Gastroparesis Cardinal Symptoms Index (GCSI) and gastric emptying scintigraphy (GES) were recorded before and after the procedure. Treatment outcomes and procedure related adverse events were also evaluated.

Results: A total of fourteen patients with refractory functional delayed gastric emptying, including eleven post-surgical (78.6%) and three diabetic (21.4%), were enrolled. The median age was 60 (range, 26–82) years. All patients were suffering from nausea, vomiting, bloating and weight loss. They all failed medical therapy including proton pump inhibitor, metoclopramide, mosapride, or domperidone. All fourteen patients underwent G-POEM successfully (100%) with the mean procedure time of 43.71±13.08 mins. Gastric emptying scintigraphy (GES) was performed in five patients with improvement of mean half empty time (191.88±63.19mins vs. 91.44±32.92mins), and retention at 2 hours (70.02±12.68% vs. 33.48±20.32%). The median hospital stay after procedure was 6 days (range, 4–10). No procedure related adverse event (0%) was observed. During a median follow-up of eight months (range, 3–17.5 months), one patient (post-surgical) had symptom recurrence after 45 days after the procedure because of stenosis related to scan formation. One of the two diabetic patients with severe diabetes and diagnosis as diabetic peripheral neuropathy showed little response to G-POEM, while the GCSI was 74 before and 28 after. The other showed initial improvement with GCSI score 22 before and 10 after during the first follow-up. However, his symptoms reoccurred seven months after G-POEM and the latest GCSI score was 19. Overall GCSI after G-POEM (mean, 5.00±2.57) decreased significantly comparing with the one before (mean, 22.55±3.42).

Conclusion: G-POEM is a promising new endoscopic treatment option for functional delayed gastric emptying. Our initial data suggest it is safe and effective. Large studies are needed to determine safety, efficacy, long-term outcomes and determine which patient population benefits the most from this treatment option.

P1179 EFFECTIVENESS OF CAP-ASSISTED DEVICE IN THE ENDOSCOPIC MANAGEMENT OF FOOD BOLUS OBSTRUCTION IN THE UPPER ESOPHAGUS

M. Ooi 1, E. J. Young, N. Q. Nguyen
Department Of Gastroenterology And Hepatology, Royal Adelaide Hospital, Adelaide/Australia/SA

Contact E-mail Address: marieooi_al@yahoo.com

Introduction: Although cap-assisted technique has been shown to be effective in retrieving food bolus from the upper gastrointestinal tract, there is no data on food bolus obstruction (FBO). This study aimed to assess the performance of cap-assisted technique in the management of esophageal FBO, as compared to conventional endoscopic methods.

Aim & Methods: All cases of all patients who presents with FBO requiring emergency endoscopic management between 2011 and 2016 were prospectively collected. The main measured outcomes were procedural success, procedural time, complications and length of hospital stay.

Results: In total, 214 (189 ± 13.3 years) with FBO, 267 (84.7%) had evidence of food bolus in the esophagus on endoscopy and 48 (15.2%) patients had spontaneous passage of food bolus. Out of the 199 patients who had impacted FBO, 93 had cap-assisted technique and 106 had conventional approach, with no differences in the type and location of FB. The success rate of cap-assisted technique (100%) was comparable to that of conventional techniques (97.2%, P = 0.10). Patients who had failed extraction by conventional technique (n = 3) were successfully treated when switched to cap-assisted approach. Cap-assisted approach was associated with a shorter total procedural time (34 ± 8 and 43 ± 22 min, P = 0.006), a shorter length of hospital stay (0.95 ± 0.36 and 1.38 ± 1.36 days, P = 0.0017) and more en-block removal (89% vs 22%, P = 0.003). There were more complications in the conventional than the cap-assisted group (7/106 vs 0/93; P = 0.01).

Conclusion: Cap-assisted technique is 100% effective in the management of impacted FBO in the esophagus, with a significantly shorter procedural time and length of hospital stay. Although the findings suggest that cap-assisted technique should be the first line technique in the management of esophageal FBO, further evaluation with a randomized multicenter trial is warranted.

Introduction: Functional dyspepsia (FD) is defined that there is no evidence of symptoms of FD, including patients with postprandial distress syndrome (PDS) (n = 41) and EPS accompanying with pancreatic enzyme abnormalities were associated with early chronic pancreatitis proposed by JPS using endosonography. We enrolled 99 consecutive patients presenting with typical symptoms of FD, including patients with postprandial distress syndrome (EPS) (n = 49). EPS with pancreatic enzyme abnormalities (n = 42) but without pancreatic enzyme abnormalities (n = 42) based on Rome III criteria. Gastric motility was evaluated using the 13C-acetate breath test. Early chronic pancreatitis was diagnosed by endosonography and graded from 0 to 7.

Results: The ratio of female patients among EPS patients (34/41) with pancreatic enzyme abnormalities was significantly (p = 0.0018) higher than the ratio of female EPS patients (20/42) without it. Postprandial abdominal distention and physical component summary (PCS) scores in EPS patients with pancreatic enzyme abnormalities were significantly disturbed compared to those in EPS patients without it. Interestingly, AU(C0-Ct) and AU(C0-Ct)(values (24.85 ± 1.31 and 56.11 ± 2.51, respectively) in EPS patients with pancreatic enzyme abnormalities were also significantly (p = 0.002 and p = 0.001, respectively) increased compared to those (19.75 ± 1.01 and 47.02 ± 1.99, respectively) in EPS patients without it. Overall, 64% of EPS patients with pancreatic enzyme abnormalities were diagnosed by endosonography as having concomitant early chronic pancreatitis proposed by JPS.

Conclusion: Further studies are warranted to clarify how EPS patients with pancreatic enzyme abnormalities were associated with early chronic pancreatitis proposed by JPS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There was no available data about the overlap between functional dyspepsia (FD) and pancreatic diseases.

Aims & Methods: We aimed to determine whether epigastric pain syndrome (EPS) accompanying with pancreatic enzyme abnormalities were associated with early chronic pancreatitis proposed by Japan Pancreatic Society (JPS) using endosonography. We enrolled 99 consecutive patients presenting with typical symptoms of FD, including patients with postprandial distress syndrome (FD symptoms of EPS) (n = 49). EPS with pancreatic enzyme abnormalities (n = 42) but without pancreatic enzyme abnormalities (n = 42) based on Rome III criteria. Gastric motility was evaluated using the 13C-acetate breath test. Early chronic pancreatitis was diagnosed by endosonography and graded from 0 to 7.

Results: The ratio of female patients among EPS patients (34/41) with pancreatic enzyme abnormalities was significantly (p = 0.0018) higher than the ratio of female EPS patients (20/42) without it. Postprandial abdominal distention and physical component summary (PCS) scores in EPS patients with pancreatic enzyme abnormalities were significantly disturbed compared to those in EPS patients without it. Interestingly, AU(C0-Ct) and AU(C0-Ct) (values (24.85 ± 1.31 and 56.11 ± 2.51, respectively) in EPS patients with pancreatic enzyme abnormalities were also significantly (p = 0.002 and p = 0.001, respectively) increased compared to those (19.75 ± 1.01 and 47.02 ± 1.99, respectively) in EPS patients without it. Overall, 64% of EPS patients with pancreatic enzyme abnormalities were diagnosed by endosonography as having concomitant early chronic pancreatitis proposed by JPS.

Conclusion: Further studies are warranted to clarify how EPS patients with pancreatic enzyme abnormalities were associated with early chronic pancreatitis proposed by JPS.

Results: The endoscopic follow-up was planned every month. After 1 months, 18-23 cm esophageal region has healed to be normal. Within 6 months, the stricture process was existingly delayed as expected. The patient stated his symptom was remarkably improved. Gastroscopy revealed the esophageal implanted lesion was covered with an epithelium and the luminal surface was flat, without ulceration.

Conclusion: Autologous esophageal mucosa transplantation might facilitate tissue re-epithelialization, reduce pathological fibroplasia, and be helpful for managing or preventing esophageal strictures. More clinical controlled trials are required to provide evidenced-based recommendation and promote its clinical application.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We enrolled 124 patients (M=84, mean age=45.3±/−13.05 years old) with severe obstructive gastroesophageal reflux disease (GES) grade 2-3 with barium meal X-ray evidence (+/− 13.7 yr range 20–73) characterized by achlorhydria or low levels of acid production (Group 1), or by duodenal ulcer (50, M=42, mean age=43.5±/−11.5 range =17–65) in which an hypersecretery status is claimed (Group 2).

In each group, we studied 46 patients (M=44 mean age=44.0 ±/−13.4 range =25–80) with normal upper GI endoscopy and gastric histology, without previous history of neoplasms or upper gastrointestinal surgery (Group 3). In all patients we measured M.A.O. by means of two hours collection of gastric juice through a 24-hour period followed by an i.m. injection of pentagastrin at the dosage of 0.6 µg/kg (M.A.O. normal values: 5–25 mEq/h). All patients underwent blood sample for determination of serum PGI (BioHit Oyj, Finland; normal values: 30–120/µg/l). All determinations, both for M.A.O. and PGI were made off medication.

Results: The mean M.A.O. values in group 1 was 2.15 mEq/h, in Group 2 5.24 mEq/h, in Group 3 7.18 mEq/h. A statistically significant difference was found between the three groups (Group 1 vs. Group 2 p <0.000001; Group 1 vs. Group 2 p <0.0001; Group 2 vs. Group 3 p <0.0001). The PGI mean values in Group 1 was 11.39 µg/l, in Group 2 107.72 µg/l in Group 3 84.28 µg/l (Group 1 vs Group 2: p <0.000001; Group 1 vs Group 2 vs Group 3 p <0.05). The result between M.A.O. and PGI showed a Pearson R=0.683 (p=0.001). No statistically significant difference was found comparing M.A.O. and PGI in the single groups (p>ns).

Conclusion: Serum PGI levels are fitting with M.A.O. both in hypo- and hyperacid secretory conditions like chronic atrophic gastritis and duodenal ulcer, as well as in control subjects, suggesting that PGI could be adopted in clinical practice to assess gastric acid production in individual subjects for a proper management of acid related diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: The prevalence of FD was 28.3% and 8.3% (17 vs 5, p<0.011) were independently associated with FD.

Introduction: Functional dyspepsia (FD) is commonly associated with sleep disturbance, which has been attributed to comorbid anxiety, depression and bother-some gastrointestinal symptoms. However, it is unclear whether obstructive sleep apnea (OSA) is specifically associated with FD.

Aims & Methods: We aimed to compare the prevalence of FD in patients with OSA and healthy volunteers. A total of 60 consecutive OSA patients (defined as Eworth sleepiness scale > =10, and apnea-hypopnea index > =10/hour during polysomnography: age: 47.6 years, body mass index: 31.6 kg/m², 60 healthy age-and sex-matched volunteers were recruited in a prospective case-control study. Questionnaires were applied for the diagnosis of functional gastrointestinal disorders (FGIDs) according to Rome III criteria. Anxiety and depression were evaluated by the Hospital Anxiety and Depression Scale (HADS), sleep quality was evaluated by the Pittsburgh Sleep Quality Index, and fatigue was assessed by the Multidimensional Fatigue Inventory (MFI-20) Chinese version.

Results: The prevalence of FD was 28.3% and 8.3% (17 vs 5, p<0.011), and the prevalence of symptomatic gastro-esophageal reflux disease was 18.3% and 5% (11 vs 3, p=0.023) in the OSA group and healthy volunteer group, respectively. OSA patients had higher anxiety and depression symptom scores, worse sleep quality, and more fatigue compared with healthy volunteers. In the multivariate logistic regression for age, sex, and body mass index, OSA (odds ratio 4.93, 95% CI 1.01–24.1, P=0.049) and depression (odds ratio 4.91, 95% CI 1.44–16.71, P=0.011) were independently associated with FD.

Conclusion: To the best of our knowledge, this is the first study showing that OSA is independently associated with functional dyspepsia. Sleep disturbances previously attributed to psychological comorbidities in FGID may in fact arise from undiagnosed OSA. We recommend screening for OSA as part of the management of FD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In the past three decades, obesity has been considered one of the 21st century plagues in the Western word. Although its etiology is multifactorial, eating habits represent an important factor in its development. The caloric load, the proportion of its components and its patterns have been the object of multiple studies. One of the most controversial aspects is the relationship between the frequency of meals and body weight.

Aims & Methods: The aim of the study was to determine the food rhythm (frequency and time spent in eating) in patients with morbid obesity (MO), based on data from 54 of them. Our study includes 24-H esophageal pH-monitoring studies. This was a retrospective study, including 100 patients (77 women), with MO in whom bariatric surgery was indicated and 118 non-obese subjects from the control group of the Spanish Digestive Motility Group. The relationship between sarcopenic and sarcopenic obese patients to obese patients was 1.59 (95% CI, 1.06-2.38) and 1.22 (95% CI, 1.02-1.47), respectively. In addition, the risk of reflux esophagitis according to sarcopenic and obese status was observed similarly in all subgroups that were evaluated.

Conclusion: Our results suggest that sarcopenia, regardless of obesity, is more harmful condition for reflux esophagitis than obesity without sarcopenia.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Obesity is an established risk factor for reflux esophagitis. Yet, the association of sarcopenia and obesity status with reflux esophagitis remains unclear. We conducted a cross-sectional study of 32,762 asymptomatic adults who underwent routine health check-ups including screening endoscopy from August 2006 to December 2011. Sarcopenia was defined as appendicular skeletal muscle mass (ASM)/body weight (%) value beyond two standard deviations below the mean for healthy young adults. Participants were categorized into four groups according to obese and sarcopenic status: normal, obese, sarcopenic, and sarcopenic obese.

Results: In a multivariate model adjusted for age, sex, smoking status, alcohol intake, regular exercise, and metabolic variables, risk of reflux esophagitis was higher in obese [adjusted odds ratio (AOR), 1.38; 95% confidence interval (CI), 1.26-1.52], sarcopenic (AOR, 2.02; 95% CI, 1.48-3.29), and sarcopenic obese participants (AOR, 1.68; 95% CI, 1.39-2.03) than in normal participants. The ORs comparing sarcopenic and sarcopenic obese patients to obese participants were 1.59 (95% CI, 1.06-2.38) and 1.22 (95% CI, 1.02-1.47), respectively. In addition, the risk of reflux esophagitis according to sarcopenic and obese status was observed similarly in all subgroups that were evaluated.

Conclusion: Our study suggests that sarcopenia, regardless of obesity, is more harmful condition for reflux esophagitis than obesity without sarcopenia.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1188 ONE DRINK CAN INCREASE A RISK FOR ESOPHAGEAL, STOMACH AND COLORRECTAL CANCER IN A COHORT OF 23,323,730 KOREAN ADULTS
Y.J. Choi, D.H. Lee
Internal Medicine, Seoul National University Bundang Hospital, Seongnam/Korea, Republic of
Contact E-mail Address: oliv00e@naver.com

Introduction: Epidemiologic findings of low-volume alcohol consumption in relation to gastrointestinal cancers including gastric cancer are inconsistent.

Aims & Methods: The association between alcohol intake and esophageal, gastric and colorectal cancer risk was examined in a population-based prospective cohort of 23,323,730 adults in Korea who had undergone a biennial evaluation provided by the National Health Insurance Corporation between the years 2009 and 2012.

Results: After median 5.4 years of follow-up, 9171 esophageal, 135,382 gastric and 154,970 colorectal cancer cases were identified. Cox proportional hazards regression models were used to estimate hazard ratios (HR) and corresponding 95% confidence intervals (CI). Light drinking as well as moderate to heavy alcohol intake, regular exercise, and metabolic variables, risk of reflux esophagitis was 1.38 (95% CI, 1.06-1.09; HR 1.12; 95% CI, 1.11–1.14) with non-drinkers after adjusting for age, smoking, exercise, income, body mass index, and diabetes. For esophageal cancer, there was a dose-dependent linear relationship. However, no association was observed between prediagnostic alcohol consumption and all cause mortality.

Conclusion: Light drinking including even one alcoholic drink a day is associated with increased risks of esophageal, gastric and colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1189 THE INFLUENCES OF VISCERAL FAT AREA ON THE SITES OF ESOPHAGEAL MUCOSAL BREAKS AND SYMPTOM SEVERITIES IN SUBJECTS WITH GASTROESOPHAGEAL REFUX DISEASES
E. Cho, J.H. Kim
Internal Medicine,dongguk University College of Medicine, Goyang/Korea, Republic of
Contact E-mail Address: kimjaehak@dumc.or.kr

Introduction: Some studies have suggested the central obesity as a risk factor for gastroesophageal reflux diseases (GERD). However, the associations between visceral adipose tissue (VAT) and the sites of esophageal erosions or the symptom severities of GERD have not been studied yet.

Aims & Methods: The aim of this study was to evaluate the influences of visceral fat area on the locations of erosions and symptoms of GERD. The subjects who underwent abdomen computerized tomography and esophagogastroduodenoscopy for routine checkup at the same day were collected from January 2007 to October 2016. 177 subjects who had erosive esophagitis (LA class A to D) were enrolled. Questionnaires including gastrointestinal symptoms were written before examinations. The abdominal obesity was evaluated by measuring visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), ratio of VAT to SAT, total adipose tissue (TAT), body mass index (BMI) and waist circumference (WC).

Results: Lesser curvature (LC) side of esophagogastric junction (EGJ) was the most frequent site of mucosal breaks (103 cases, 58.2%) followed by posterior wall side (71 cases, 40.1%), anterior wall side (25 cases, 14.1%) and fundus side (15 cases, 8.9%). Mucosal breaks on LC side were frequently observed in male patients (61.3% vs. 36.4%, p = 0.04). BMI (25.6 kg/m2, 95% CI, 1.43–1.60; HR 1.10; 95% CI, 1.06-1.09; HR 1.12; 95% CI, 1.11–1.14) compared with non-drinkers after adjusting for age, sex, smoking, exercise, income, body mass index, and diabetes. For esophageal cancer, there was a dose-dependent linear relationship. However, no association was observed between prediagnostic alcohol consumption and all cause mortality.

Conclusion: Light drinking including even one alcoholic drink a day is associated with increased risks of esophageal, gastric and colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In normal subjects, the oesophago-gastric junction (OGJ) sphincter complex maintains a tight barrier between the oesophagus and stomach acid. However, gastro-oesophageal reflux disease (GERD) caused by acidic reflux has a prevalence of up to 26% [1]. One major factor determining whether gastro-oesophageal reflux occurs and eventually generates symptoms is the competency of the OGJ, which can be studied using distensibility testing. This way, we have previously shown in patients with Barrett’s oesophagus and healthy controls that an incompetent sphincter function was associated with more frequent reflux symptoms [2]. In the same patient groups, we also found greater oesophageal acid exposure and lower mucosal baseline impedance to be associated with impaired sphincter function. The latter probably represents a proxy for mucosal damage [3]. Other factors known to increase the perception of gastro-oesophageal reflux episodes are greater acidity, larger volume, and more proximal extent of the reflux content along with impaired mucosal integrity and sensitisation (peripheral and central) [1]. All of this said no studies of our knowledge have specifically addressed the possible association between sphincter function of the OGJ and oesophageal sensitivity.

Aims & Methods: We aimed to characterize oesophageal sensitivity in relation to OGJ competence, hypothesizing that sensitivity increases with impaired sphincter function. Twenty-three patients with Barrett’s oesophagus (mean age: 64.2 ± 7.7 years) and 12 healthy controls (mean age: 54.9 ± 10.8 years) were examined. A standard upper endoscopy to locate the OGJ was followed by distensibility testing of the OGJ using the EndoFLIP probe. At a later visit, experimental oesophageal sensitivity was assessed using a multimodal stimulation probe. After placement in the oesophagus just above the OGJ, the probe allows the filling and emptying of an attached polyurethane bag with water, stimulation with electrical current, and infusion of acid. Using this probe, mechanical distension of the bag, thermal stimulation at increasing temperature, electrical stimulation, and acid perfusion with 0.1 M hydrochloric acid (a Bernstein test) were performed. All stimulations were stopped when the subject felt moderate pain, equal to seven on a 0–10 visual analogue scale validated for visceral pain. Data were analysed using multi-level, mixed-effects regression analysis in Stata 12.

Results: Oesophageal acid sensitivity increased with a more incompetent sphincter function and decreased with increased acid volume. However, increased acid volume was associated with greater distensibility index (P = 0.03) and with lower pressure (P = 0.03) in the OGJ in all subjects analysed together and separately in healthy controls (P = 0.006 and 0.02, respectively). Mucosal permeability analyses in patients with BO, these associations were not present (all P > 0.7). Sphincter function was associated with neither oesophageal sensitivity to mechanical, heat, nor electrical stimulation (all P > 0.13).

Conclusion: Oesophageal acid sensitivity increased with a more incompetent OGJ. Based on this and previous findings, we suggest that even in some healthy controls, a modest degree of OGJ incompetence allows gastric acid to reflux. This may again lead to low-grade oesophageal inflammation and mucosal damage, thereby evoking acid hypersensitivity. The latter mechanism probably constitutes a reflex protective mechanism towards acid reflux.

Disclosure of Interest: B.P. McMahon: Barry P McMahon holds a minor share in Cropsion Inc., Galway, Ireland who manufactures the EndoFLIP probe. All other authors have declared no conflicts of interest.

Conclusion: Pepsin may be considered a damaging factor in pathophysiology of GERD, but we could not find any difference between GERD phenotypes and unaffected controls. NERD group had less gastric acid versus other groups but this finding needs more studies to confirm.

Introduction: Gastropanel® is a non-invasive test suggested to able to perform a kind of “serological biopsy” of gastric mucosa. Aim of the study was to assess a proper diagnosis of different upper gastrointestinal (GI) diseases in a population suffering from upper GI disturbances in a primary care settings by means of proper diagnosis of different upper gastrointestinal (GI) diseases in a population

Patients and Methods: We enrolled 1900 consecutive patients (M = 769; mean age = 56.4 ± 8.6). All patients were endoscopically healthy. In this study a statistically significant difference (p < 0.05) has been determined.

Results: Four hundred and eighty eight patients were classified as affected by Hp-related non-atrophic gastritis (1.5 ± 5.1). GERD score (GES) was diagnosed according to age gender ((Age:95) (p < 0.005). The frequency and severity of gastroesophageal reflux symptoms in non-obese cases has been reported. The study concerned have been surveyed by means of the questionnaire including the demographic data and the extra esophageal reflux symptom. Serum biochemistry analyses (fasting glucose, insulin, lipid panel, uric acid, TSH, ALT) have been checked. Waist circumference has been measured. Body compositions and anthropometric measurements have been assessed through the biochemical impairment method (TANITA).

Conclusion: In this study a statistically significant difference (p < 0.05) has been found when a GES-diagnosis group is compared with the healthy control group in regard to waist circumference, BMI; LDL, Fat, Fat Mass, Total Body Water(TBW), obesity level, reflux acid, reflux score and total score measurements. Fat free mass (FFM), muscle mass, bone mineral density (BMD) (Table 1) measurements in between the two groups have not been found statistically significant difference (p > 0.05) (Table 1). Considering the extra esophageal reflux symptoms a significant difference (p < 0.05) between the group suffering from sore throat, apnea, teeth grinding and GORH and the healthy control group has been found. Within the patients group a positive correlation between acid reflux score and BMI (r = 0.298) (p < 0.001), LDL (r = 0.387) (p < 0.001), visceral fat (r = 0.180) (p < 0.049) has been determined. A negative correlation between acid reflux score and TBW (r = -0.273) (p < 0.003) has been determined.

Conclusion: The frequency and severity of gastroesophageal reflux symptoms in non-obese cases is closely related with body fat composition as those in the obese. Increase in abdominal and visceral fat composition may cause high risk of gastroesophageal reflux disease in individuals irrespective of their obesity.

Introduction: Esophageal baseline impedance (BI) levels have been recently proposed as a marker of mucosal integrity. Indeed, patients with non-erosive reflux disease (NERD) showed lower distal esophageal BI levels compared to healthy controls (HCs) due to the presence of abnormal distal esophageal acid exposure time (AET). On the other hand, no differences were found between NERD and HCs at proximal level, but data in this regard are limited.

Aims & Methods: We aimed to prospectively compare BI levels between a group of NERD patients and two groups of SSc patients, one with a clear manometric derangement of the esophageal wall and consequently reduced BI levels, also at proximal level, but data in this regard are limited.

Aims & Methods: We aimed to prospectively compare BI levels between a group of NERD patients and two groups of SSc patients, one with a clear manometric derangement of the esophageal wall and consequently reduced BI levels, also at proximal level, but data in this regard are limited.

Results: Fifty patients [38F; mean age 51yrs] with NERD, 50 SSc patients [44F; mean age 50yrs] with esophageal involvement (p = 0.05).

Conclusion: Proximal esophageal BI levels are able to segregate between scleroderma patients with and without esophageal involvement. The advent of novel and poorly invasive methods for the assessment of esophageal mucosal

impe德尔 will allow us to perform this measurement without the need of prolonged probe insertion.

Introduction: Gastroesophageal reflux disease (GERD), is characterized by frequent relapses after withdrawal of therapy and no prognostic markers of relapse are available to predict the outcome of the patients. Gastrin-17 (G-17) has been proposed as a non-invasive marker of reflux disease as well as a good marker of response to the therapy. Pepsinogen I (PG I) and Gastrin-17 (G-17) are claimed to increase in a statistically significant manner after proton pump inhibitors (PPIs) therapy. Aim of the study was to assess the prognostic value of G-17 during endoscopy in GERD patients more prone to develop an early reflux relapse in a prospective open study.

Aims & Methods: We prospectively enrolled 221 consecutive GERD patients (F 113, mean age 52.5 years; range 28–74 years) with endoscopically proved diagnosis of esophagitis, according to the L.A. classification, all symptomatic (heartburn and/or regurgitation). All patients were treated with rabeprazole 20 mg once a day for 6–8 weeks, assessing at the end of the therapy the symptoms’ modifications by means of a questionnaire. In the group of asymptomatic patients, we performed a one-year follow-up, recording the GERD relapse episodes; only on-demand antacids were permitted. All patients underwent at baseline a blood sample and after the acute course of PPI therapy.

Results: One hundred eighty five patients were asymptomatic after the 6–8 weeks of PPI therapy and entered in the prospective evaluation for 12 months. 19 subjects were lost lasting the follow-up and finally 166 patients were available for the study analysis. 72 patients experienced at least one GERD relapse episode (first group) against 94 ones free of symptoms for one year (second group). The mean values of both PG I and G-17 after the 6 weeks of PPI therapy in comparison with the baseline levels, were higher in first group than in the second one (first group: baseline PG I 96 μg/L, G-17 19 2.6 μmol/L; after therapy: PG I 164 μg/L, G-17 19 19 μmol/L; p = 0.001); second group: baseline PG I 98 μg/L, G-17 16 μmol/L; after therapy: PG I 116 μg/L, G-17 6.3 μmol/L; p = ns). The good response to full dose of PPI, assessed by an increase of both PG I and G-17, seems to be the pathophysiological background to explain the prognostic value of such markers.

Conclusion: Gastrin-17 and pepsinogen I increase after full-dose of PPI in GERD acute phase seems to be a simple non-invasive marker to predict early GERD relapse in one-year follow-up.

P1197 THE DIAGNOSTIC VALUE OF ESOPHAGEAL MUCOSAL AND BASELINE IMPEDANCE MEASUREMENTS IN PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE

S. Kipcak1, P. Ergun1, S. Boz1, H. Gastroenterology Service, Ege Reflux Study Group, Ege University, Izmir/Turkey

Introduction: Various biomarkers have been studied to evaluate the integrity of esophageal epithelium in distinguishing phenotypes of gastroesophageal reflux disease (GERD). Baseline impedance (BI) measurement is likely to be one of these and can be measured during the 24-hour ambulatory intra-esophageal impedance-pH study. Mucosal impedance (MI) measurement is a technique that was introduced in recent years and is a practical method that can be applied during endoscopy, but the validation studies are insufficient. BI & MI measured with the prolonged probe insertion.

Aims & Methods: We prospectively enrolled 221 consecutive GERD patients (F 113, mean age 52.5 years; range 28–74 years) with endoscopically proved diagnosis of esophagitis, according to the L.A. classification, all symptomatic (heartburn and/or regurgitation). All patients were treated with rabeprazole 20 mg once a day for 6–8 weeks, assessing at the end of the therapy the symptoms’ modifications by means of a questionnaire. In the group of asymptomatic patients, we performed a one-year follow-up, recording the GERD relapse episodes; only on-demand antacids were permitted. All patients underwent at baseline a blood sample and after the acute course of PPI therapy.

Results: One hundred eighty five patients were asymptomatic after the 6–8 weeks of PPI therapy and entered in the prospective evaluation for 12 months. 19 subjects were lost lasting the follow-up and finally 166 patients were available for the study analysis. 72 patients experienced at least one GERD relapse episode (first group) against 94 ones free of symptoms for one year (second group). The mean values of both PG I and G-17 after the 6 weeks of PPI therapy in comparison with the baseline levels, were higher in first group than in the second one (first group: baseline PG I 96 μg/L, G-17 19 2.6 μmol/L; after therapy: PG I 164 μg/L, G-17 19 19 μmol/L; p = 0.001); second group: baseline PG I 98 μg/L, G-17 16 μmol/L; after therapy: PG I 116 μg/L, G-17 6.3 μmol/L; p = ns). The good response to full dose of PPI, assessed by an increase of both PG I and G-17, seems to be the pathophysiological background to explain the prognostic value of such markers.

Conclusion: Gastrin-17 and pepsinogen I increase after full-dose of PPI in GERD acute phase seems to be a simple non-invasive marker to predict early GERD relapse in one-year follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.
channel of the scope. Distal two rings were contacted to the distal and proximal parts of the esophagus approximately 20–30 cm. MMS Omega ambulatory recorder and Greenfield (6 imp, 1 pH) impedance catheter were used.

Results: MI can differentiate ERD from non-erosive groups but do not have a diagnostic value to discriminate NERD from FH-EH or controls. However, BI can segregate NERD from ERD addition to controls (Table 1).

</tr>
</tbody>
</table>

Conclusion: As a new diagnostic tool, MI needs validation studies and our results failed to show additional diagnostic value in non-erosive patients compared to healthy controls. Since regular catheters are free, new balloon-shaped catheters should be validated. BI might be a better tool to discriminate NERD from controls. This implicates that the esophageal epithelial resistance is impaired in this particular group compared to controls.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1190 ENDOSCOPIC-HISTOPATHOLOGICAL ESOPHAGEAL FINDINGS IN ATROPHIC BODY GASTRITIS PATIENTS WITH GASTRO-ESOPHAGEAL REFUX SYMPTOMS

Introduction: Atrophic body gastritis (ABG) is characterized by loss of oxyntic glands with consequent reduced acid secretion, hypergastrinemia and, in a later stage, pernicious anemia (PA). Up to 40% of ABG patients complain of dyspepsia. Despite hypochlorhydria, in 21% of autoimmune gastritis (AG) patients typical and atypical symptoms (5/14), 48.6% (17/35) PDS and 11.4% (4/35) EPS were present symptoms. Despite hypochlorhydria, in 21% of autoimmune gastritis (AG) patients dyspepsia was detected (LA-C according to Los Angeles classification or a positive DeMeester score (L.A. 4+)). The aim of the study was to search in a primary care settings possible differences in clinical presentations in a group of patients with GERD, in comparison with AG patients.

Aims & Methods: One thousand and six hundred consecutive dyspeptic patients (M = 766; mean age = 51.5 years; range = 27–79 yr) were enrolled in the study, according with the presence of upper-GI troubles such as epigastric pain, fullness, nausea/vomiting but not heartburn or regurgitation. All patients showed a negative upper-GI endoscopy and were enrolled in a primary care setting. Symptoms ended up in being heartburn the prevalent symptom in 479 subjects and regurgitation in 68. Atypical symptoms, mainly chronic cough were present in 303 patients. 313 patients showed grade A esophagitis, 32 grade B, 4 grade C. One hundred seven severe out of 221 patients showed a positive DeMeester score for acid reflux. Statistical analysis: No differences were found for sex and age between the two groups (M:F = 1:1.2, mean age: 56 years; dyspeptics: M:F = 0.9, mean age: 53 years; p = ns); heavy smokers was 29% in GERD group, 26% in dyspeptics; p = m. Heavy drinkers were 25% in GERD group, 22% in dyspeptic; p = m.

Conclusion: Sex, age, smoking habits and alcohol consumption seem no differ in the two studied population. In GERD cohort, the majority of patients experienced Non Erosive reflux Disease (NERD). The majority of GERD patients suffered by typical symptoms; chronic cough represented the most frequent manifestation among the atypical and extra-oesophageal ones.

Introduction: In China, 13.6% of gastrointestinal outpatients suffer from gastroesophageal reflux disease (GERD), among which only 36.9% undergo endoscopy [1]. For patients with symptoms of GERD, empirical proton pump inhibitor (PPI) treatment is recommended as a diagnostic test of GERD and as a therapeutic trial to control symptoms by Chinese GERD consensus guidelines [2].
Currently, there are no real-world data assessing the efficacy of short-term empirical treatment with PPIs in GERD patients in China.

**Aims & Methods:** This was a multicenter, prospective, observational study carried out in a real-world setting. The primary objective was to determine the overall responder rate in patients with typical GERD symptoms after 4 weeks of empirical treatment with PPIs. Responders were defined as having heartburn/regurgitation on ≤1 day during the prior 7 days, assessed by the GERD-Q questionnaire.

Outpatients aged between 18 and 65 years with a GERD-Q score of 8 or more were enrolled if they were prescribed standard-dose PPIs as empirical treatment and were not planned to have an endoscopy within 4 weeks of enrollment. The PPI regimen prescribed was decided completely at the physicians’ discretion. Patient demographics, diagnosis, prescribed PPI regimens, GERD-Q score and symptom frequency were recorded. Data were collected at baseline, 2 weeks and 4 weeks after initiating PPI treatment. Results from the full analysis set (FAS) are presented.

**Results:** A total of 1,000 patients from 10 centers were screened for this study, of which 987 met the inclusion criteria and were included in the FAS. The mean age was 45.2 ± 11.6 years, the body mass index was 23.4 ± 3.3 kg/m², and 50.3% of the patients were male. The mean duration of GERD was 0.8 ± 2.6 years, with a mean baseline GERD-Q score for the week before screening of 10.5 ± 1.9. During the 4 weeks’ treatment, the proportion of patients receiving at least 1 dose of PPI was 99.3%. Esomeprazole was the most frequently received PPI (57.1% of patients). Other PPIs (rabeprazole, lansoprazole, pantoprazole and omeprazole) were received by 50.1% of patients and 7.2% of the patients sequentially received ≥2 PPIs in the duration of the study. A total of 787 (79.7%) patients either completed the 4-week PPI treatment or withdrew after response, of which the responder rate was 74.0% [95% CI, 70.7%–77.0%] (Table 1). Among the 818 patients who completed 2 weeks’ treatment, the responder rate was 57.0% [95% CI, 53.5%–60.4%]. The overall median time to response was 12.5 days [11–14] (95% CI, 12–15). Over the study duration, patients with a GERD-Q score ≥8 reduced from 100% at baseline to 29.5% and 17.4% at 2 and 4 weeks, respectively.

| Table 1: Responder rate (%) and median time to response for different PPIs |
|-----------------------------|-----------------|-----------------|-----------------|-----------------|
|                             | Esomeprazole    | Other PPIs      | Total           |
| 4-week responder rate, %    | 90.2 (819/911)  | 72.3 (240/326)  | 75.2 (569/755)  |
| 2-week responder rate, %    | 86.1 (722/835)  | 71.4 (236/333)  | 72.3 (349/481)  |

**Conclusion:** In Chinese clinical practice, short-term PPI empirical treatment effectively improves symptom control in GERD patients and gains a satisfactory overall responder rate.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P1201 **WIRELESS ELECTRICAL STIMULATION FOR MANAGING GASTROESOPHAGEAL REFLUX DISEASE IN THE RABBIT MODEL**

M. Wang1, L. Zhao1, L. Liu2, X. Wang2, Z. Fan1
1The First Affiliated Hospital with Nanjing Medical University, Nanjing/China
2Digestive Endoscopy Center, The First Affiliated Hospital of Nanjing Medical University, Nanjing/China

**Contact E-mail Address:** fanzhining@njmu.edu.cn

**Introduction:** Electrical stimulation of lower esophageal sphincter (LES) has been applied to decrease reflux (LES pressure, pHmetry or multichannel intraluminal impedance-pH studies) measured after 24-hour pHmetry study with a dual channel, esophageal and gastric, on-PPI treatment. In 17 patients the pHmetry was performed with multichannel intraluminal impedance (15 cases) or Biletric (2 cases). Group 2: included 127 patients (68.6%) who had been diagnosed of GERD only on the basis of typical symptoms; all of them underwent esophageal double channel 24-H pH-metry off-PPI. All of the studies (24-hour pH Monitoring or multichannel intraluminal impedance-pH studies) were performed according to standard technique.

**Results:** Pathological reflux was present in 91 patients (47.9%), 24 from group 1 and 67 from group 2. Pathological acid reflux was therefore ruled out as a cause of symptoms in 52.1% of all cases studied: 60 patients (47.2%) from group 2, and 93 patients (52.8%) from group 1. In addition, out of the 24 patients with pathological reflux in group 1 (true refractory patients), 9 had an incomplete response, with a percentage of time with pH < 4 less than 7.5% (mild reflux), which probably was not the cause of the symptomatology.

**Conclusion:** Proton pump inhibitors (PPIs) are the drugs of choice in the treatment of GERD. However, its efficacy may be compromised for a variety of reasons including: non-compliance, bioavailability, episodes of nocturnal acid break-through, poor gastric emptying, etc. In most of the patients referred for GORD, it is controversial. A systematic review and meta-analysis was performed to compare LARS related to obesity.

**Aims & Methods:** The primary outcome measure was the relative incidence of recurrent reflux related to BMI. Secondary outcome measures were relative incidence rates in the form of endoscopic dilatation or surgery, conversion to open surgery, and early return to theatre. Embase, MEDLINE and the Cochrane Library (January 1970 to November 2016) were searched for studies reporting clinical outcomes of LARS in patient cohorts stratified by Body Mass Index (BMI). Data was grouped according to BMI, <30 kg/m² (non-obese) and ≥30 kg/m² (obese). Results were pooled in meta-analyses as Odds Ratios (OR).

**Results:** Eleven eligible observational studies comparing LARS in non-obese (n=447) and obese (n=160) patients were identified. The difference of reflux was significantly lower in the non-obese cohort (OR 0.34, 95% CI 0.19 to 0.60, p < 0.001), however no significant differences were observed in rates of operative morbidity (OR 0.87, 0.65 to 1.18, p=0.38), redo surgery (OR 1.08, 0.68 to 1.72, p=0.73), endoscopic dilatation (OR 1.06, 0.49 to 2.33, p=0.88), conversion to open surgery (OR 1.17, 0.55 to 2.48, p=0.68), or early return to theatre (OR 0.77, 0.44 to 1.37, p=0.38).

**Conclusion:** LARS can be performed safely in obese patients, but risks higher re-operation. Clinicians and patients should be aware that obesity may adversely affect LARS outcome and careful consideration be given in the consent process inherent within the optimal management of GORD.

studying with the diagnosis of refractory reflux to PPIs, this diagnosis had only been made on 61 patients. Incompatible symptoms. When the diagnosis is exclusively clinical, about a half (47.2%) of the patients with persistent symptoms on double doses of PPIs, considered as GERD patients refractory to PPIs, have an incorrect diagnosis (patients do not have pathological reflux). More than half of the patients (61.9%) who have a diagnosis of GERD confirmed by complementary tests that do not respond to treatment with PPIs, acid reflux is not the cause of their symptoms.

Introduction: Recently, low-FODMAP diet has been proposed as potential treatment in patients with irritable bowel syndrome (IBS) given its high efficacy in symptoms relief. Recent data showed that IBS frequently overlap with functional heartburn (FH) and functional dyspepsia.

Aims & Methods: The aim of this study was to evaluate the efficacy of low-FODMAP diet in reducing heartburn in patients with FH and no pathophysiological evidence of gastroesophageal reflux (GERD) compared to patients with non-erosive reflux disease (NERD). As secondary aim we investigated the reduction of lower gastrointestinal symptoms in both groups. We enrolled patients with heartburn and negative upper endoscopy who were scheduled for upper pathophysiological tests (esophageal manometry and impedance and pH monitoring, MII-pH) at Gastroenterology Unit in University of Pisa. We excluded patient with history of GERD who had been treated with non-NSAID anti-inflammatory drugs or had previous abdominal surgery. Medical history, volup- tunary habits and response to proton pump inhibitor (PPI) treatment were recorded. By means of MII-pH we splitted patients in two populations: NERD group (abnormal esophageal acid exposure or number of refluxes) and FH group (normal esophageal acid exposure and number of reflux, no symptom-reflux correlation and no heartburn relief during PPI treatment). All enrolled patients were evaluated with validated questionnaires (Likert and VAS) to evaluate heartburn occurrence pre- and post a nutritional approach with low-FODMAP diet for 6 weeks.

Results: We included 31 patients (20 female; mean age 49.1 yrs; mean BMI 24.4) into the study. NERD group was composed of 13 patients (6 female; mean age 48.7 yrs; mean BMI 23.5). FH group was composed by 18 patients (11 female; mean age 59.9 yrs; mean BMI 23.9). All patients showed symptom improvement regarding bloating, abdominal pain and stools composition (p < 0.001) after low-FODMAP diet (see Table 1). Moreover, we observed a very important improvement of heartburn in the FH group (from 8.4 ± 2.5 to 2.3 ± 1.1; p < 0.001 on VAS scale) compared to the NERD group (7.2 ± 2.2 a 6.9 ± 1.9; p = 0.624 on VAS).

Conclusion: This pilot study showed that a low-FODMAP diet was able to reduce heartburn perception in patients with FH and who did not obtain any symptom relief after PPI treatment. Larger prospective randomized controlled trial is mandatory to further explore these findings.

Introduction: Because of a higher prevalence of BE in males, recommendations in current guidelines are mainly based on male BE patients and make no difference in treatment according to gender. Nevertheless, it is unknown whether female BE patients have the same neoplastic progression and acceleration rate as male patients.

Aims & Methods: The aims of this study were (1) to evaluate the difference between males and females in probability of and (2) time to neoplastic progression, as well as (3) gender differences in stage distribution of neoplastic progression in surveilled BE patients. In this multicenter prospective cohort study we included 729 patients with BE who met the inclusion criteria of a segment of ≥2cm and confirmed intestinal metaplasia. Endoscopic surveillance was performed according to the American College of Gastroenterology guidelines. Cox regression modelling as well as accelerated failure time modelling were used to evaluate differences in probability of and time to neoplastic progression to HGD, EAC and both HGD and EAC between sexes, respectively. All models were adjusted for age, presence of esophagitis and length of BE. In case of a limited number of events, descriptive statistics were used.

Results: 532 males (73%; mean age 58 years, IQR 51–67) and 197 females (median age 64 years, IQR 57–70) were included with a median follow-up of 8.2 years (IQR 5.3–10.3). High-grade dysplasia (HGD) was detected in 35 males versus 4 females, EAC in 12 males versus 5 females. The total number of patients with neoplastic progression was 56 (8%), which was twice as high among males compared to females (HR 1.90, 95% CI 1.02–3.92). Especially the risk of HGD was higher in males than in females (HR 3.34, 95% CI 1.17–9.50). The ratio HGD/EAC in males was 2.92, in females 0.80. Apparently in females proportionally more EAC was identified compared to males. Though these data might suggest accelerated neoplastic progression rates in females, time to event was significantly shorter for males in HGD (HR 0.45, 95% CI 0.22–0.94). There was no difference for overall neoplastic progression (AR 0.59, 95% CI 0.39–0.89). Stage distribution is as shown in Table 1, females tend to have a higher stage of neoplastic progression than males.

Conclusion: The risk of HGD and overall neoplastic progression and acceleration rate of HGD development is higher in male BE patients compared to females. On the other hand descriptive statistics show proportionally more EAC in females as well as an advanced stage of EAC at diagnosis. Further research into the differential aspects of neoplastic progression in BE between men and women, may have future consequences for gender specific guideline recommendations, including the timing of follow-up.

P1206 SINGLE SESSION FOCAL CRYOBALOW ABLATION THERAPY IS SAFE AND EFFECTIVE IN THE TREATMENT OF DYSPSYLATIC BARRETT’S ESOPHAGUS

S. Van Munster1, A. Overwater2, J. J. G. H. M. Bergman1, B. L. A. M. Weusten2

Introduction: Given its proven safety and efficacy, RadioFrequency Ablation (RFA) is the preferred ablation modality for dysplastic Barrett’s Esophagus (BE). However, RFA is associated with significant drawbacks, such as the need for large controller units, multiple deployment steps and capital investment. The Vascular Cryoballoon Ablation System (FCBA: C2 Therapeutics Inc. Redwood City, CA, USA) is another ablation method -based on the application of extreme cold- that has been recently developed to overcome these RFA drawbacks. Additionally, FCBA might be better tolerated. FCBA comprises a handheld, through-the-scope system with a conformable balloon that is simultaneously inflated and cooled using nitrous oxide, resulting in ice patches of approximately 2cm2 on the targeted mucosa. Previous studies applying FCBA to limited areas of BE (1 to 2 small BE islands per patient) have shown promising results. Data on
efficacy and safety of FCBA in the treatment of larger BE segments, however, are lacking. Therefore we aimed to assess the safety and efficacy of a single treatment with FCBA for dysplastic BE.

### Aims & Methods
Patients were seen between March and December 2016 at two tertiary referral centers in the Netherlands. Patients with a BE >6 cm in length and with a confirmed diagnosis of low-grade (LGD) or high-grade dysplasia (HGD) or after endoscopic resection for visible lesions, were included. Exclusion criteria included previous focal ablation therapy and strictures. At baseline, all visible BE was treated with side by side ablations of 10 seconds, including circumferential treatment of the gastroesophageal junction (GEJ). Pain scores were assessed directly post-treatment and at days 2 and 7. Follow-up endoscopy with biopsy and photo documentation was scheduled after 3 months. Primary outcomes included dysplasia regression rate and incidence of esophageal strictures or other adverse events.

### Results
We enrolled 20 patients with dysplastic BE (85% male, mean age 66 (±8) years), with a median BE length of 2cm (IQR 0–4), and a baseline diagnosis of LGD (10; 50%), HGD (1; 5%), or mucosal adenocarcinoma (9; 45%). Ten (50%) had undergone endoscopic resection of a visible lesion before cryoablution and 8 (40%) had undergone previous circumferential RFA. During a median ablation time of 16 minutes (IQR 11–19), all BE, including circumferential ablation of GEJ was successfully ablated in all patients. No adverse events occurred, and median pain directly post-treatment was 4 out of 10 (IQR 0–5), whereas this was 1 (IQR 0–2) and 0 (IQR 0–1) at days 2 and 7. At the 3-month follow-up endoscopy, median endoscopic regression of initial BE was found to be 95% (IQR 83–98), this included 3 patients (15%) with a complete 100% regression. All biopsies confirmed squamous regeneration without BE. All AUC curves were significantly smaller after FCBA compared to RFA: for dysphagia (2.6 vs 8.2, p < 0.01) and for dysphagia (2.6 vs 8.2, p < 0.01). The maximum median VAS score reported on any of the 14 days was 2 (IQR 0–4) after FCBA and 4 (IQR 3–7) after RFA (p < 0.01). FCBA patients reported analgesics during median 1 (IQR 1–1) days, compared to 4 (IQR 1–11) days for RFA patients (p < 0.01).

### Conclusion
In this multicenter, non-randomized, open prospective cohort study, patients reported less post-procedural pain and dysphagia after FCBA as compared to RFA and, moreover, FCBA patients used less analgesics. Although a randomized trial should provide definitive evidence for differences in post-procedural tolerability, our results strongly suggest a significantly different post-procedural course, thus favoring FCBA over RFA.

P1209

IS IT REASONABLE TO PROPOSE AN ENDOSCOPIC MUCOSAL RESECTION FOR BARRETT’S OEESOPHAGUS WITH HIGH-GRADE DYSPLASIA ON THE BIOPSEYS?

J. Gonzalez1, J. Casanova1, A. Benezech1, E. Bories2, S. Garcia3, M. Giovannini4, M. Barthet1

Aim & Methods: This was a retrospective study including a prospective histological relecture (BS and specimen) in two expert centers. The inclusion criteria were BE with HGD on pre-operative biopsies resected by the endoscopist. The initial biopsies from other centers were collected and re-examined by our cytologist. The BS discordant with EMR specimens were recorded in a numeric file (Teleslide) and a second lecture was carried out by 2 experts and 2 fellows (1 of each per center). Five diagnoses were considered: no metaplasia (no BE), metaplasia without dysplasia, LGD, HGD, Adenocarcinoma. Concordance statistical tests were performed to assess the variability between BS and EMR specimen and among the cytopathologists in BS, as well as cytologists’ inter and intra-observatory variability.

Results: Between January 2005 and December 2015, 87 patients have undergone EMR for HGD on biopsies, in both centers. Among them, 41 (47%) had a discordant result between biopsies and resection specimen. The histological diagnosis was C3-M5, with relief among the cases. A mean number of 1.4 endoscopic session was performed, with a mean of 2.7 resected pieces per EMR, which was macroscopically complete in 63.6% of the cases. The mean follow-up was 38 months. After histological relecture, the Kappa coefficient for the diagnosis of HGD was lower between the BS and ranging between 0 and 0.6 for the EMR specimen. The inter-observatory concordance was 0.2 (for both BS and EMR specimen) for the diagnosis of HGD. For other diagnoses, it was ranged between 0 and 0.5 for biopsies and between 0 and 0.6 for EMR specimen. The kappa coefficient regarding the BS discordant specimen were 0.5 for biopsies and 0.4 for cytology. We had 0.4 and 0.5 for the false positives, respectively. The intra-observatory (between BS and EMR specimen) after relecture was ranged between 0 and 0.6.

Conclusion: The discordance rate between initial diagnosis of HGD on BS and final diagnosis for the patients who had no surgical treatment was high, around 47%. The intra and inter observer concordance is insufficient, even in expert tertiary centers. Thus, the question about performing EMR based on random biopsies rather than endoscopic biopsy assessment has to be asked, and clearly evaluated in further studies.

CD4+ AND CD8+ LYMPHOCYTE RATE AND PDL-1 LYMPHOCYTE EXPRESSION ARE PREDICTIVE OF CLINICAL COMPLETE RESPONSE AFTER NEOADJUVANT CHEMORADIOThERAPY FOR SQUAMOUS CELL CANCER OF THE THORACIC OEESOPHAGUS

M. Fassan1, F. Cavallini2, V. Guzzardo3, A. Kotsafti4, R. Alfieri3, M. Cagol3, M. Scarpa1, V. Chiarion Sileni5, L. Castagliuolo6, M. Rugge1, C. Castoro3, M. Scarpia1

Aim & Methods: The aims of this study were to identify possible immunological predictive markers of clinical complete response (CR) after neoadjuvant chemoradiation CT-RT) for locally advanced squamous cell carcinoma (SCC) of the esophagus and in several cases, it can lead to complete response (CR).

Results: After neoadjuvant CT-RT, 23 patients had CR, while 65 had partial response, stable disease or progression. CD8+ and CD4+ lymphocyte rate and PDL1 leukocyte expression were significantly higher in patients who had CR compared to those who had no CR (p < 0.0014, p < 0.0001 and p = 0.004 respectively). The accuracy of leukocyte expression of PDL1 and CD4+ and CD4+ lymphocyte rate was 0.76 (p = 0.0001) and 0.75 (p = 0.0001), respectively. Within the CR group, all patients with high infiltration of CD4+ T cell were cured/reolved while only the 38.9% of those with low CD4+ T cell infiltration did the same (p = 0.058).

Conclusion: In our group of patients, CD4+ and CD8+ lymphocyte rate and PDL-1 lymphocyte expression were predictive of clinical complete response after neoadjuvant chemoradiatory. Squamous cell carcinoma of the thoracic esophagus with adequate accuracy. Moreover, high infiltration level of CD4+ T cell was associated to recurrence/relapase. These preliminary observations might be used to plan further study aimed to identify reliable predictors of response to chemoradiation in oesophageal SCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

IDENTIFICATION OF THREE DISTINCT BIOLOGICAL SUBTYPES IN ESOPHAGEAL AND JUNCTIONAL ADENOCARCINOMA BY RNA SEQUENCING

S. Hoefnagle1, B. Scicluna1, S. Calpe1, C. Del Sancho-Serra1, K.K. Krishnadath2, C. van der Velden1, M. Scarpa2, C. van der Velden1, K. L. van Leur1, M. van Nostrand1

Aim & Methods: Esophageal adenocarcinoma (EAC) is a highly aggressive malignancy with a poor prognosis. Advances in therapy have achieved incremental improvements in overall outcome in EAC, but over- and undertreatment of undefined subgroups of patients might undermine these benefits (Courrech Staal et al. 2010). The biological diversity of EAC complicates patient selection and treatment stratification and impedes the development of new targeted agents. Further insight into the heterogeneous molecular pathology of EAC and a possible relation to outcomes and response to current treatment strategies is urgent.

Results: We could identify three distinct subtypes with a metabolic, immune and cell cycle regulating signature respectively. The subtype with the immune signature was associated with tendency to poorer response to therapy. We will develop a subtype classifier to perform subtype prediction in an independent patient cohort from the TCGA database (The Cancer Genome Atlas Research 2017).

Conclusion: Our studies support the existence of three distinct EAC/junctional subtypes associated with different response to therapy. Based on these subgroups, we expect an EAC subtype classifier that might improve stratification of patients for (targeted) therapies and subsequently improve outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Although endoscopic submucosal dissection (ESD) is accepted as a standard treatment for early stage esophageal neoplasia, esophageal perforation is sometimes experienced as main adverse event. Esophageal perforation causes mediastinal emphysema, mediastinitis, and pneumothorax, those sometimes require emergency surgery.

Aims & Methods: We evaluated the predictive factors for esophageal perforation in patients who received esophageal ESD. This was a retrospective observational study in a single institution. Between May 2004 and March 2016, 549 consecutive patients with 927 lesions were evaluated in the follow-up group with ESD. Esophageal resection is indicated for pathological examination of the endoscopically resected specimens. Among these 93 patients, 41 received additional CRT (CRT group), and 52 were followed without CRT(follow-up group). CRT comprised cisplatin and fluorouracil and radiation in 1, docetaxel plus cisplatin, 5-fluorouracil, and radiation in 2, docetaxel plus cisplatin, 5-fluorouracil, and radiation in 1, and radiation alone in 1. Results: The median tumor diameter was 22 mm (6 to 55) in the CRT group and 25 (3 to 47) in the follow-up group (p = 0.63). The tumor invades the MM in 9 patients, the SM in 3, and the submucosa to a depth more than 200μm (SM2) in 29 in the CRT group and the LPM in 3 patients, the MM in 16, the SM in 18, and the SM2 in 15 in the follow-up group (p = 0.91). Lymphatic invasion was positive in 21 patients in the CRT group and 12 in the follow-up group (p < 0.01). Vascular invasion was positive in 27 in the CRT group and 29 in the follow-up group (p = 0.32). Involvement of the submucosal vertical margin was found in 7 in the CRT group and 9 in the follow-up group (p = 0.07). CRT-related grade 3 or 4 early adverse events were leukopenia 24.3% (10 patients), neutropenia 29.3% (12), febrile neutropenia 4.9% (2), diarrhea 2.4% (1), anorexia 17.9% (7). In the CRT group, 38 of 40 patients received chemotherapy as scheduled. Treatment was discontinued in the second course in 2 patients, and 7 required dose reduction. Lymph-node metastasis were found in 2 patients in the CRT group and 7 in the follow-up group (p = 0.15). In patients with recurrence in the CRT group, lymph-node metastases were seen in the irradiated field 46 and 49 months after treatment, respectively. 1 patient in the CRT group and 3 in the follow-up group died of esophageal cancer (p = 0.43). The overall survival (OS) rate at 2 years was selected 95.8% in the CRT group and 93.8% in the follow-up group (p = 0.02). The relapse-free survival (RFS) rate at 2 years was 97.1% in the CRT group and 83.4% in the follow-up group (p = 0.02).

Conclusion: Additional CRT after endoscopic resection in patients with esophageal adenocarcinoma who have submucosal invasion, lymphovascular involvement, or vertical-margin invasion can become an effective organ-preservation strategy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: According to the current Japanese guidelines for the diagnosis and treatment of oesophageal cancer, endoscopic resection is indicated for pathologic T1a (epithelium/lamina propria mucosae) and relatively indicated for pathologic T1a(muscularis mucosae) and T1b(a tumor invading the submucosa to a depth of 500 μm). The tumor invades the MM in 9 patients, the SM1 in 3, and the submucosa to a depth of more than 200 μm (SM2) in 29 in the CRT group and the LPM in 3 patients, the MM in 16, the SM in 18, and the SM2 in 15 in the follow-up group (p = 0.91). Lymphatic invasion was positive in 21 patients in the CRT group and 12 in the follow-up group (p < 0.01). Vascular invasion was positive in 27 in the CRT group and 29 in the follow-up group (p = 0.32). Involvement of the submucosal vertical margin was found in 7 in the CRT group and 9 in the follow-up group (p = 0.07). CRT-related grade 3 or 4 early adverse events were leukopenia 24.3% (10 patients), neutropenia 29.3% (12), febrile neutropenia 4.9% (2), diarrhea 2.4% (1), anorexia 17.9% (7). In the CRT group, 38 of 40 patients received chemotherapy as scheduled. Treatment was discontinued in the second course in 2 patients, and 7 required dose reduction. Lymph-node metastasis were found in 2 patients in the CRT group and 7 in the follow-up group (p = 0.15). In patients with recurrence in the CRT group, lymph-node metastases were seen in the irradiated field 46 and 49 months after treatment, respectively. 1 patient in the CRT group and 3 in the follow-up group died of esophageal cancer (p = 0.43). The overall survival (OS) rate at 2 years was selected 95.8% in the CRT group and 93.8% in the follow-up group (p = 0.02). The relapse-free survival (RFS) rate at 2 years was 97.1% in the CRT group and 83.4% in the follow-up group (p = 0.02).

Conclusion: Additional CRT after endoscopic resection in patients with esophageal adenocarcinoma who have submucosal invasion, lymphovascular involvement, or vertical-margin invasion can become an effective organ-preservation strategy.

P2128 SAFETY, EFFICACY AND OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR THE TREATMENT OF EARLY BARRETT’S NEOPLASIA
M. Onma, M. Konradsson, P. Elbe, M. Nilsson, M. Lindblad, I. Rouvelas, F. Bihlaque-Silva
Gastrocnetrum, Karolinska University Hospital, Stockholm/Sweden

Contact E-mail Address: masami.woo@fcler.or.jp

Introduction: Endoscopic submucosal dissection (ESD) was developed in Japan for the treatment of large gastrointestinal neoplasias and has progressively been adopted in the West. Currently, early Barrett’s neoplasia is mainly treated with endoscopic mucosal resection (EMR) and/or radiofrequency ablation, being the role of ESD in this context not well-established yet. Our aim is to evaluate the safety, efficacy and outcome of ESD for the treatment of early Barrett’s neoplasia.

Aims & Methods: Fifty consecutive ESD cases of early Barrett neoplasia were performed in 42 patients in our center between 2011 and 2016. All ESDs were performed under full narcosis after multidisciplinary team conference discussion and patient’s consent. The primary endpoint was the rate of en bloc resection. Secondary endpoints included rate of R0 and curative resection, a comparison of pre- and post- ESD histology, procedure time, procedure-related adverse events, and rate of remission at follow-up. This study was approved by the Stockholm Regional Ethical Committee.

Results: Mean age was 67 years (range 46-84), being 74% male and 72% long segment BE. The mean specimen size was 52 mm (range 16-150 mm). ESD resections included <25%, 25-50%, 50-75% and 75-100% of the lumen circumference in 4/31/12/3 of cases, respectively. En bloc, R0 and curative resection were obtained in 96% (48/50), 80% (40/50) and 70% (35/50) of cases, respectively. The mean procedure time was 120 minutes. There were 2 perforations (4%) treated endoscopically and 2 (4.0%) postoperative bleedings treated conservatively. Six patients (12%) developed esophageal strictures that were managed endoscopically. The 30 days mortality was 0% and 13 cases were followed until new endoscopy. In 2 patients, to further ESD, 1 received chemoradiotherapy and 2 patients are under surveillance. In the 10 esophagectomy cases, 4 patients had AC in the remnant Barrett’s esophagus and 2 patients had lymph node metastasis. Complete remission was
found in 100% (35/35) of patients with curative resection at median follow-up of 2.7 months (range 1–64 months). Conclusion: In the proper setting, ESD is safe and effective for the treatment of early Barrett’s neoplasia with high en bloc and complete resection rates and good curative rate. ESD enables full pathological assessment in lesions not suitable for en bloc resection with EMR. There were no recurrences in the curative cases, which increases the role of ESD for the management of early Barrett’s neoplasia.

Contact E-mail Address: dsatou@ncc.go.jp

Introduction: Recently, it has been reported that proton beam therapy (PBT) is the effective treatment for patients with esophageal squamous cell carcinoma (ESCC). However, there are few reports regarding the endoscopic evaluation of efficacy after PBT at the primary site. Aims & Methods: The aim of this study is to clarify the adequate endoscopic evaluation of the primary lesion of ESCC after PBT, and the clinical results of salvage endoscopic treatment for local recurrence. Patients with clinical T1 ESCC, and who had been treated with PBT between April 2013 and June 2016 at the National Cancer Center Hospital East were investigated. The total dose of PBT was 60 Gray-Equal (GyE). The efficacy of PBT at the primary site was evaluated with endoscopy, and the definition of complete response (CR) was used according to the same criteria as that of conventional chemoradiotherapy (CRT) as follows: disappearance of tumor lesion and ulcer, and absence of cancer cells with biopsy was verified. The endoscopic evaluation was performed within 2 months after the completion of PBT, and we repeatedly evaluated every month if the lesion did not achieve CR. The treatment for local recurrence after PBT was chosen based on the depth of the tumor as follows: endoscopic resection (ER) for cT1a, endoscopic photodynamic therapy (PTD) for cT1b or deeper depending on patient’s condition.

Results: Among 44 patients who underwent PBT, the median age was 70 years (range, 41–79). The number of patients with clinical stage I was 23 (52%), and those with stage II, III, and IV were 16 (36%), 2 (5%), and 3 (7%), respectively. All patients underwent concurrent systemic chemotherapy. 43 patients (98%) could achieve a CR at the primary site and only one patient (2%) did not show a CR (non-CR) at the primary site. The median time to CR from the start of PBT was 60 days (range, 7–270 days). All 43 patients (98%) achieved CR. The median follow-up period of 11 months (range, 1–32 months).

Conclusion: Endoscopic surveillance of HNSCC is very important for those with stage IV ESCC, as endoscopic and EUS of these lesions are feasible and safe with acceptable complication risks despite the high rates of stenosis in resections >75% of the circumference.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Globally, 80% of all esophageal cancer cases are esophageal squamous cell cancer (ESCC), arising from esophageal squamous cell neoplasm (ESCC). Patients with ESCC have poor prognosis, but when diagnosed at the stage of ESCC, curative endoscopic treatment can be performed. ESCN mainly occurs in developing countries, often with limited endoscopic expertise and resources, like Central and Eastern Asia and Eastern and Southern Africa. Hence, an easy-to-use, low-cost treatment for ESCN would be of great value. Focal Cryoballoon Ablation therapy (FCBA) (C2 Therapeutics Inc. Redwood City, CA, USA) is a new endoscopic ablation therapy that comprises a therapeutic cryoablation catheter with a deformable balloon that obviates the need for sizing, a handle, and a small disposable cryogen cartridge. The balloon is simultaneously inflated and cooled with nitrous oxide from the cartridge, resulting in ice patches of approximately 2 cm. FCBA is easy to use and requires no capital equipment. Early studies for FCBA of Barrett’s esophagus have shown promising results, however, limited data are available for FCBA of ESCN. In this study we aimed to assess the safety, tolerability and efficacy of FCBA in the eradication of ESCN.

Aims & Methods: In this ongoing multi-center prospective trial in China, patients with one flat type (Paris 0-1b) unstained lesion (ULS) on Lugol’s chromoscopy, ≤6 cm in length and <50% of circumference, with a confirmed diagnosis of Moderate or High Grade Intraepithelial Neoplasia (MGIN/HGIN) were
enrolled. At baseline, side-by-side ablations of 10 seconds were performed on all resected lesions; every 3 minutes of endoscopic mucosal resection (EMR) was confirmed. Outcomes: safety and tolerability (11-point visual analog scale (VAS) for pain), complete response (CR) rates (absence of MGIN or worse in biopsies), neoplastic progression and adverse events.

Results: 62 patients (63 MGIN, 17 HGIN) with a median lesion of 2 (IQR 2–3) cm in length. Of these, 79 patients (99%) were successfully treated; 3 developed superficial, self-limited mucosal lacerations upon balloon inflation and 2 of them were successfully re-ablated 3 months later. A median of 5 (IQR 4–7) ablations were performed per patient, in a median ablation time of 8 (IQR 5–10) minutes. As of April 2017, 77/97 (79%) patients completed a 3-month follow-up endoscopy and 69/77 patients (89%) exhibited endoscopic and histologic CR. Eight patients had residual USL and were again treated by EMR; in 3 patients, delayed follow-up of the water-filled lesions took place. To date, 4 patients have undergone a 12 month endoscopy and all continue to exhibit endoscopic and histologic CR. No significant strictures have been noted on follow-up. Three patients developed fever shortly after treatment which was treated with aspirin. Post-procedure median VAS was 1 (IQR 0–2) at day 2, and 0 (IQR 0–0) at days 7 and 30.

Conclusion: Preliminary results of our multicenter open prospective cohort study suggest that FCBA of ESC is safe, well-tolerated, and highly effective in inducing endoscopic and histometric remission. Longer term (12 month) follow-up data is pending.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1222 THE ENDOSCOPIC TREATMENT STRATEGY FOR SUPERFICIAL ESOPHAGEAL CANCER

N. Yamaguchi
Department Of Gastroenterology And Hepatology, Nagasaki University Hospital, Nagasaki-Japan

Contact E-mail Address: naoyuki3435@nagasaki-u.ac.jp

Introduction: Endoscopic submucosal dissection (ESD) allows en bloc removal of superficial esophageal squamous cell carcinoma (SCC). However, esophageal stricture often occurs after ESD when the lesion involves more than three-fourth of the circumference of the lumen. Frequent balloon dilation is performed endoscopy is required in such situation, thus causing health economic problem. In this study, we investigated the clinical outcomes, and prevention of post-ESD stenosis.

Aims & Methods: A total of 667 cases in 516 consecutive patients were treated by ESD in our department from April 2006 to December 2016. We investigated the following 2 items. 1. Clinical outcomes and complications. 2. Usefulness of oral steroids administration, the local steroids injection, endoscopic transplantation of tissue-engineered autologous oral mucosal epithelial cell sheets, or steroid oral + local injection combination therapy for the prevention of post-ESD stenosis.

Results: 1. Clinical outcomes: En bloc resection rate was 99.8% and en bloc curative resection rate was 90.0%. The rate of perforation, post-ESD bleeding, and post-ESD stenosis was 0.2%, 0.8% and 6.1%, respectively. 2. Prevention of post-ESD stenosis: (1) Oral steroid vs Steroid injection vs Cell sheet transplantation: In oral steroid group, the stenosis rate was 14.9%, and the ulcer healing period was 39.5 days. In steroid injection group, the stenosis rate was 12.9%, and the ulcer healing period was 66.0 days. In cell sheet transplantation group, the stenosis rate was 40.0% and the ulcer healing period was 36.0 days. There was no significant difference between these 3 therapies, and these therapies prevent post-ESD stenosis to significant extent. However, ulcer healing period of the cell sheet transplantation is significantly shorter compared with the other 2 therapies. (2) The usefulness of SH oral + local injection combination therapy. We investigated limitations of steroid administration, and cell sheet transplantation in order to prevent stenosis. The follow-up period of the 4 factors (more than 9/10 of circumferential resection, more than 5 cm of longitudinal resection, cervical esophagus, post history of chemo-radiotherapy or endoscopic resection) were the stenosis prevention treatment-resistant factors. Therefore, we examined the stenosis rate according to the number of these 4 factors. The stenosis rate of the cases which have 0 or 1 factor, the case which has more than 2 factors in semicircular cases, and the complete circular cases is 4.9%, 30.3%, and 44.8%, respectively. The stenosis rate of the cases which have more than 2 factors and complete circular cases are significantly higher, compared to the cases which have 0 or 1 factor. As a result, the cases which have more than 2 factors and complete circular cases were regarded as the stenosis prevention treatment-resistant cases. In contrast, in SH oral + local injection combination therapy, the stenosis rate of the cases which have more than 2 factors and complete circular cases is 17.5% and 14.3%, respectively. Taken together, the stenosis rate of SH oral + local injection combination therapy is significantly lower, compared to the other 3 therapies.

Conclusion: Esophageal ESD achieved high en bloc resection rate and curability with low rates of complications. Oral steroid, steroid injection therapy and cell sheet transplantation may be effective treatment strategy for reducing post-ESD stenosis. However, the above-mentioned 4 factors are the stenosis prevention treatment-resistant factors in these 3 therapy cases. Furthermore, the cases which have more than 2 factors and complete circular cases were regarded as the stenosis prevention treatment-resistant cases. SH oral + local injection combination therapy is very useful for prevention of post-ESD stenosis and has a potential for the stenosis prevention treatment-resistant cases.

P1223 DIAGNOSIS OF TUMORS IN THE CERVICAL AND UPPER THORACIC ESOPHAGUS: EFFECTIVE ENDOSCOPIC ULTRASONOGRAPHY USING A JELLY-FILLING METHOD WITH WATER-SOLUBLE LUBRICATING JELLY

N. Matsuura, N. Hanaka1, R. Ishihara1, S. Yamamoto1, T. Akasaka1, Y. Takeuchi2, K. Higashino2, N. Uedo2, H. Iishi
Gastrointestinal Oncology, Osaka international Cancer Institute, Osaka/Japan

Contact E-mail Address: ibutar@yahoo.co.jp

Aims: To evaluate diagnostic accuracy of water-soluble lubricating jelly and standard endoscopic ultrasonography (EUS) in the cervical and upper thoracic esophagus using a jelly-filling EUS method with water-soluble lubricating jelly.

Methods: A total of 61 patients with esophageal SCCs in the cervical or upper thoracic esophagus were included in this study. Among the 61 SCCs, 13 were re-evaluated after chemoradiotherapy. The other 48 SCCs did not undergo chemoradiotherapy. Of these 61 patients with esophageal SCC, 60 lesions (98.3%) could be detected with EUS-J and 44 lesions treated either by esophagectomy (n = 7) or endoscopic resection (n = 37). Histologic diagnosis was T1a in 27 lesions, T1b in 17 lesions. The overall accuracy of diagnosing invasion depth was 70.5% (31/44 lesions) by EUS-J. Among the 10 SMTs, we diagnosed seven leiomyomas derived from muscularis mucosa and one lesion due to vertebral body compression. The remaining two lesions were, respectively, a diminutive SMT (< 3 mm) and a small lesion in the cervical esophagus adjacent to the hypopharynx. Neither was detectable using EUS-J because of their small size and difficulty with instrumental maneuvering. There were no adverse events during EUS-J, including aspiration pneumonia. EUS-J with water-soluble lubricating jelly is useful and safe for diagnosing lesions in the cervical or upper thoracic esophagus. To our knowledge, this is the first report of using EUS with lubricating jelly for lesions located in this anatomical region.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1224 OPTIMAL SURGERY TIME AFTER ENDOSCOPIC RESECTION IN EARLY GASTRIC CANCER: LONG-TERM FOLLOW-UP STUDY FOR SURGICAL AND ONCOLOGICAL SAFETY

1Department Of Internal Medicine, Severance Hospital, Seoul/Korea, Republic of
2Department Of Surgery, Gangnam Severance Hospital, Yonsei University College Of Medicine, Seoul/Korea, Republic of
3Department Of Surgery, Severance Hospital, Yonsei University College Of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: TRISTAN82@yuhs.ac

Introduction: The patients with early gastric cancer (EGC) who have undergone non-curative endoscopic resection (ER) need additional surgery. Our previous study reported short-term data about 29 days were optimal time when considering the surgical outcome. (Ann Surg Oncol. 2014 Jan;21(1):1232-9.) This study is long-term follow-up study to evaluate the impact of previously proposed optimal time interval from ER to additive surgery by on the surgical and oncological outcomes.

Aims & Methods: A total of 2850 patients who were diagnosed with EGC underwent ER at the Severance and Gangnam Severance Hospitals, Seoul, Korea, between January 2007 and December 2014. We analyzed totally 302 (10.6%) patients who underwent additive gastrectomy after non-curative ER. The patients were divided into 2 groups according to the time interval point, as the earlier operation group (group A) and the later operation group (group B). The time interval point, at which operative time and estimated intraoperative blood loss (EBL) of the earlier operation group and the later operation group

United European Gastroenterology Journal 5(5S)
showed the greatest disparities, was evaluated. We retrospectively evaluated long-term follow-up study for oncological outcomes about follow-up duration, loco-regional recurrence, distant recurrence.

**Results:** The median follow-up duration is 40.36 ± 20.74 months in all patients. Based on the previous our study, we divided patients two groups who underwent operative time of 29 days. Of the 302 patients, 133 were in Group A (≥ 29 days) and 169 in Group B (> 29 days). There were more differences between two groups about ASA score, intra-op. transfusion, POD#1 Hemovac© discharge, Maximal postoperative CRP in the clinicopathological characteristics. Like previous our study the operative time, EBL, tumor size was significantly longer and more in group A compared with group B. There were totally 7 patients locoregional and distance recurrence during follow-up period. There were no differences in oncological outcomes between two groups.

**Conclusion:** Based on long-term follow-up data, surgery time after ER in EGC does not affect oncological outcome. These long-term follow-up results suggest that adding surgery at about 1 month after ER is optimal for better surgical outcomes without affecting the oncological outcomes.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1225 THE POINT TO DISTINGUISH EARLY GASTRIC CANCER FROM DEPRESSION TYPE OF GASTRIC INTESTINAL METAPLASIA**

T. Wakatsuki, S. Furutachi, H. Yamashita
Department Of Gastroenterology & Hepatology, Okayama Medical Center, Okayama/Japan

**Contact E-mail Address:** t.wakatsuki0530@yahoo.co.jp

**Introduction:** This study discusses two endoscopic findings which improve the accuracy of the diagnosis of early gastric cancers (EGC). After successful *Helicobacter pylori* eradication, we often observe multiple reddish depressed lesions and “patchy redness” in the gastric mucosa. Even though most are intestinal metaplasia (IM), EGC is found among these lesions. A light blue crease (LBC) has been a highly accurate sign of the IM. There are, now, additional two endoscopic findings that should improve the accuracy of diagnosis of EGC. They are 1) “intrarectal microvainoinfusion (IEMI);” and 2) “Over flow”. Over flow is the endoscopic finding that the structure of the depressed lesion spreads to the outside of the depression.

**Aims & Methods:** The aim of this study is to clarify the usefulness of two endoscopic findings in order to detect the EGC in the group thought to be an IM. This is a retrospective control study. There were 234 cases of EGC performed endoscopy examination during the same period. The EGC group is then divided into 2 groups; 1) eradication group (13 cases) and 2) no eradication group (32 cases). We evaluated the following parameters: 1) presence of LBC, 2) presence of IEMI, 3) the ratio of over flow.

**Results:** The ratio of LBC was 75% in IM group, which was significantly higher than eradication group (7.7%), and small EGC group (9.4%). The ratio of irregular microsurface pattern was 33% in IM group, which was significantly lower than eradication group (92%), and small EGC groups (84%). The ratio of irregular microvascular pattern was 0% in IM group, which was significantly lower than eradication group (92%), and small EGC group (81%). The ratios of IEMI were 0% in IM group, 39% in eradication group and 41% in small EGC group. The ratios of Over flow were 0% in IM group, 46% in eradication group and 50% at small EGC group. Furthermore, the ratios to have either in two endoscopic findings were 0% in IM, 77% in eradication group and 69% in small EGC group.

**Conclusion:** IEMI and Over flow leads to the diagnosis of EGC in addition to other endoscopic findings.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
the TTT and the non-TTT group were 1.5% and 0%, respectively. There was a significant difference in early detection rate between the TTT and the non-TTT group (Fisher’s exact test, P = 0.046).

Conclusion: This clinical trial clearly showed that the systematic intensive TTT course is useful for improving early detection rate of gastric cancer in clinical practice at a high-volume endoscopy center. (NCTD358578).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) is believed to be a possible modality for early gastric cancer. But there is little report about long-term outcomes of the ESD directly compare with the surgery. The purpose of this study is the comparison between the two treatment modalities about the outcomes of the early gastric cancer.

Aims & Methods: We performed a retrospective analysis of 1243 patients with stage I early gastric cancer without lymph node involvement. 551 patients were treated with ESD, and 692 patients were treated with subtotal or total gastrectomy. Long-term overall and disease-specific survival rates, development of new lesions, and complications were analyzed.

Results: The mean age was higher in the ESD group (64.9 ± 9.5 vs. 58.5 ± 11.7, P = 0.001) and female distribution was higher in surgery group (30.5% vs. 38.9%, P = 0.001). In ESD group, diabetes was more frequent (12.9% vs. 7.1%, P < 0.001), but disease-specific survival rate was significantly higher in ESD group (99.8% vs. 98.7%, P = 0.037, log-rank test). During 10 years follow up period, new lesions were observed in 3.6% of the ESD group and in 1.3% of surgery group (P < 0.001). ESD group showed less complications (4.5% vs. 16.3%, P < 0.001) and shorter hospital day than surgery group (5.27 days vs. 12.09 days, P < 0.001).

Conclusion: Although the development of new lesions were more frequent than surgery, ESD has similar overall survival rate and even higher disease-specific survival rate than surgery. Also, ESD has less complications and shorter hospital day than surgery. Therefore, ESD is an effective therapeutic method in early gastric cancer as well as surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1229 HEMATOLOGISTS SHOULD ORDER ENDOSCOPIC EXAMINATIONS TO EXPERTS OF ENDOSCOPY IN CASE OF ENDOSCOPIC CHECK-UP OF GASTROINTESTINAL MALIGNANT LYMPHOMA**

T. Yamasaki, T. Sakurj, M. Mitiobu, M. Mitsuunaga, M. Saruta
Department Of Gastroenterology And Hepatology, The Jikei University, Tokyo, Japan

Contact E-mail Address: takusan.yamasaki@gmail.com

Introduction: Gastric malignant lymphoma (ML) is most popular lymphoma of the gastrointestinal tract. Especially we often see gastric ML lymphoma in cases of *H. pylori* (HP) infection positive, and we also sometimes find out HP negative gastric ML lymphoma. Since gastric carcinoma (GC) is more common rather than gastric ML lymphoma, typical endoscopic diagnostic findings, most of non-expert of endoscopy cannot diagnose exactly. But expert could diagnose minimal lesions of ML at first endoscopy. Especially HP positive gastric ML lymphoma was similar to gastritis and GC on endoscopic findings, most of non-expert could not diagnose exactly.

Aims & Methods: There was significant difference of ability to diagnose gastric ML lymphoma between specialists and trainees. Therefore, hematologists should order endoscopic examination to experts of endoscopy knowledgeable of ML in case of endoscopic check-up of gastrointestinal malignant lymphoma.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1221 DEVELOPMENT OF AND EXPERIENCE WITH AN INSULATED SCISSORS-TYPE KNIFE (SB KNIFE)**

M. Kobayashi
Yokkaichi Municipal Hospital Dept. of Gastroenterology, Yokkaichi/Japan

**Contact E-mail Address:** makoto-kobayashi@acroma.ocn.ne.jp

**Introduction:** Endoscopic submucosal dissection (ESD) is technically difficult and is associated with risks of perforation and bleeding. Although knife-type instruments are primarily used to make incisions during ESD, it is necessary to be proficient in endoscopic procedures and be able to perform them simultaneously with electrosurgical and incision. Scissors-type knives are fairly easy to manipulate in colorectal ESD. We have fabricated SB knife Jr type (SBJr), short scissors-type knife with outer insulated layer, in collaboration with SUMITOMO BAKELITE CO.

**Aims & Methods:** SBJr is short length (electrode length: 3.5 mm) to be easy to handle in narrow colorectal lumen. The surface of the rotatable monopolar scissors is coated with insulating material in order to enhance the cutting power and prevent electric effects in the surrounding tissue. The shearing structure made sharp cutting quality and very small round tips prevents to grasp the muscular layer. SBJr was used in circumference incision, submucosal dissection and hemostasis. After infected hydrolytic acid in submucosal layer, grasped the tissue, confirming safety, make incision. SBJr was used not only in incision but also in hemostasis. At sites containing blood vessels or bleeding, they were grasped and induced coagulation using SBJr. It has been used on 180 colorectal lesions from January 2008.

**Results:** The circumference incision and submucosal dissection were basically performed with High-frequency cutting wave. There were 3 cases of perforation during ESD and 1 case of post-operative bleeding. The procedure itself was fairly easy and substantially effective at all sites. Sites difficult to excise the endoscope and sites containing blood vessels, where conventional devices would encounter difficulties. Due to the very small round tips of the instrument, detailed operation become simply. For coagulation of blood vessels or bleeding, it is not required to replace the knife which is used cutting and coagulation.

**Conclusion:** This short insulated scissors-type knife (SBJr) made it easier to perform colorectal ESD, we conclude that it is an effective device and easy for a beginner in colorectal ESD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The gastrointestinal tract (GIT) is the most common extranodal site affected in lymphomatous pathology. Infection with Helicobacter pylori, human immunodeficiency virus and Epstein Barr and immunosuppression have been studied as possible risk factors. The diagnosis is often late, presenting at an advanced stage, with limited therapeutic options.

**Aims & Methods:** The objective of this study was to characterize the anatomical distribution, clinical manifestations, risk factors and prognosis of GI lymphomas.

**Results:** Retrospective study of patients diagnosed with GI lymphomas between 1997 and 2016.

The most commonly affected organ was the stomach (65.3%) and the most frequently manifested lymphomas are primarily used to make incisions during ESD and 1 case of post-operative bleeding. The procedure itself was fairly easy and substantially effective at all sites. Sites difficult to excise the endoscope and sites containing blood vessels, where conventional devices would encounter difficulties. Due to the very small round tips of the instrument, detailed operation become simply. For coagulation of blood vessels or bleeding, it is not required to replace the knife which is used cutting and coagulation.

**Conclusion:** This short insulated scissors-type knife (SBJr) made it easier to perform colorectal ESD, we conclude that it is an effective device and easy for a beginner in colorectal ESD.

**Introduction:** Gastrointestinal subepithelial tumors include potentially malignant tumors. When considering the diagnostic yield for subepithelial tumors, it is important to evaluate whether the samples obtained are adequate for histological analysis, as immunohistological analysis is indispensable for a definitive diagnosis. However, it may be difficult to make a correct histological diagnosis with only the endoscopic ultrasonography-guided fine-needle aspiration (EUS-FNA). Therefore, there has been an interest in exploring an alternative modality for tissue sampling as mucosal-incision assisted biopsy (MIAB) based on the endoscopic submucosal dissection.

**Aims & Methods:** The aim of this study was to compare the usefulness of EUS-FNA and MIAB in the histological diagnosis of gastrointestinal subepithelial tumors (SET). We performed the retrospective study comparing 37 patients who underwent either EUS-FNA (n = 18) or MIAB (n = 19). Diagnostic yield and safety and feasibility of both EUS-FNA and MIAB were compared.

**Results:** The location of the SET was esophagus (n = 6), stomach (n = 29), and duodenum (n = 2). The diagnostic yields were gastrointestinal stromal tumors (n = 10), leiomyoma (n = 17), aberrant pancreas (n = 3), poorly differentiated carcinoma (n = 2), metastatic carcinoma (renal cell carcinoma, n = 1), and no-diagnosis (n = 4). There were no significant differences in the clinical characteristics-including sex and age-of the patients in the EUS-FNA and MIAB groups.

A total of 748 patients with early gastric cancer undergoing endoscopic submucosal dissection were classified into underweight (BMI <18.5), normal (BMI 18.5-23), overweight (BMI 23-25), and obesity (BMI ≥25) by Asian-Pacific guideline. Adjusted analysis using odds ratio (OR) and 95% confidence interval (CI) was performed to evaluate the effect of BMI on early gastric cancer.

**Conclusion:** The gastric cancer was strongly associated with the increased BMI and its effect has dose-dependent pattern.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Previous studies have shown that non-cardiac gastric cancer had no associations with the obesity even if cardiac or gastroesophageal junctional cancer was related with the obesity. These studies have included high portion of advanced gastric cancer. Patients with most advanced cancer already experienced weight loss.

**Aims & Methods:** We evaluated the effect of body mass index (BMI) on early gastric cancer in patients undergoing endoscopic treatment for early gastric cancer. A total of 748 patients with early gastric cancer undergoing endoscopic treatment (endoscopic submucosal dissection) including age and sex matched healthy controls consist of this case-control study. Body mass index was classified into underweight (BMI <18.5), normal (BMI 18.5-23), overweight (BMI 23-25), and obesity (BMI ≥25) by Asian-Pacific guideline. Adjusted analysis using odds ratio (OR) and 95% confidence interval (CI) was performed to evaluate the effect of BMI on early gastric cancer.

**Results:** The mean age was 57 years and male sex was 60% (n = 447). BMI was higher in gastric cancer compared to healthy control (24 vs 23, P <0.001). The OR of gastric cancer was increased according to the BMI increase; 1.57 (95% CI, 0.89-2.79, P =0.12) in normal BMI, 1.88 (95% CI, 1.06-3.35, P =0.03) in overweight, and 2.28 (95% CI, 1.29-4.06, P =0.003) in obese persons as compared to underweight (BMI <18.5).

**Conclusion:** The early gastric cancer was strongly associated with the increased BMI and its effect has dose-dependent pattern.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Introduction: In 2012 the reported incidence of gastric cancer in both sexes was 27.7 (95%CI 27.4–28.0, but the early detection rate was still critically low (8.7–10.0/100,000), being each and other’s strict locality related to a better survival. Parma area is considered at medium-low incidence of gastric cancer. For early diagnosis, the detection of a precancerous condition like atrophic gastritis seems crucial, but the majority of such patient’s are asymptomatic of non invasiveness.Gastric cancer (Pepsonogens and Gastrin 17) as suggested in the guidelines of Kyoto and Maastricht II is up to now limited in clinical practice. Aim of the study, therefore, was to establish the burden of gastric cancer in the diagnosis of the last six years, focusing on the detection of early gastric cancer.

Aims & Methods: Six years (from July 2010 to July 2016) were considered in search for diagnosis of gastric cancer as reported in the archives of the Pathology Department of Parma University. Overall, 816 cases of gastric cancer were found but due to consider only the surgically removed cases, therefore, the available sample is based on 584 cases. For every cases we classified the cancer in early, following the Kodama classification, and advanced. The presence of atrophic gastritis nearby the neoplasia was assessed according with OLG classification. In both early and advanced cancer the node status was investigated. Six years (from July 2010 to July 2016) were considered in search for early gastric cancer. In 2012 the reported incidence of gastric cancer in both sexes was 27.7 (95%CI 27.4–28.0, but the early detection rate was still critically low (8.7–10.0/100,000), being each and other’s strict locality related to a better survival. Parma area is considered at medium-low incidence of gastric cancer. For early diagnosis, the detection of a precancerous condition like atrophic gastritis seems crucial, but the majority of such patient’s are asymptomatic of non invasiveness. were significantly decreased in GC tissues comparing to adjacent normal tissues both in Chinese cohort (n = 48 pairs) and TCGA cohort (n = 450). CAB39L hypermethylation was correlated with poor overall survival in Chinese cohort (n = 87, p = 0.005) and validated in TCGA cohort (n = 354, p < 0.005), which suggesting that CAB39L might function as a tumour suppressor. The functional importance of CAB39L in GC was therefore determined. Ectopic expression of CAB39L in three GC cell lines (AGS, BG-SC3, MKN45) suppressed cancer cell proliferation in vitro (p < 0.01) and colony formation assays (p < 0.0001). CAB39L induced apoptosis and G1 cell cycle arrest in GC cells, concomitant with the enhanced expression of cleaved caspase-8, caspase-3, p21, and decreased cyclin D3 expression. Cell migration and invasion abilities were inhibited by CAB39L in wound healing and gel invasion assays, respectively. Conversely, CAB39L knockdown in MKN28 demonstrated opposite effects. Orthotopic mouse model also showed inhibited tumorigenicity with CAB39L-overexpressing BG-SC32 cells. Mechanistically, RNAseq and gene set enrichment analysis (GSEA) revealed that AMPK and ERBB2/ERBB4 signaling were involved in the tumour suppressive role of CAB39L in GC. Consistent with our RNAseq data, we raised antibody against AMPK and showed AMPK as the top activated kinase; whilst ERK1/2 was the most strongly down-regulated in CAB39L overexpressing GC cells, suggesting that CAB39L up-regulates AMPK concomitant with down-regulation of ERBB2/ERBB4 signaling. Moreover, co-immunoprecipitation was performed to detect interaction between CAB39L and LKB1, a bona-fide tumour suppressor that functions to activate AMPK to suppress tumorigenesis. Western blot confirmed activation of LKB1-AMPKα/β cascade in GC cells expressing CAB39L, while the opposite effect was observed in CAB39L silenced MKN28 cells. Administration of an AMPK activator, AICAR, inhibited growth of control cells but not CAB39L-expressing (thus AMPK activated) cells, suggesting that AMPK activation by CAB39L contributes to tumour suppression. Consistently, a novel tumour suppressor silenced by promoter methylation in GC. CAB39L inhibits gastric tumorigenesis via LKB1-mediated activation of AMPKα/β. CAB39L methylation may serve as an independent prognostic biomarker for GC patients.

**Introduction:**

Using 450 K DNA methylation array, we identified PBX1 Knotted 1 Homeobox 2 (PKNOX2) as a novel gene differentially methylated in gastric cancer patients compared with normal tissues of the TCGA (three-amino acid loop extension) family of homedomain transcription factors, which play fundamental roles in cell proliferation, differentiation and death. However, the role of PKNOX2 in GC remains to be uncovered.

**Aims & Methods:**

We aimed to investigate the function, molecular mechanism and clinical implication of PKNOX2 in GC. PKNOX2 promoter methylation was evaluated by bisulfite sequencing. PKNOX2 expression was determined by RT-qPCR and western blot. Biological functions of PKNOX2 were determined in GC cells by MTT, colony formation, apoptosis, cell cycle, migration/invasion assays, and in vivo using nude mice tumorigenicity assay. Pathways targeted by PKNOX2 were identified by Cancer pathway PCR array and dual luciferase reporter assay.

**Results:**

PKNOX2 was silenced in 15 out of 18 GC cell lines through promoter methylation, and 5′-Azadecytidine treatment restored PKNOX2 expression. PKNOX2 mRNA expression was down-regulated in GC compared to adjacent normal tissues. Moreover, promoter methylation of PKNOX2 was associated with poor survival in GC patients (p < 0.05), suggesting that PKNOX2 may function as a tumor suppressor in GC. We therefore examined its functional effect in GC. Ectopic expression of PKNOX2 in GC cell lines significantly inhibited cell proliferation, induced cell apoptosis and cell cycle arrest, concurrently with increased expression of apoptosis markers cleaved caspase-9, -7, -3 and PARP and cell cycle inhibitors p53, p21 and p27. PKNOX2 also attenuated cell migration and invasion by inhibiting epithelial-mesenchymal transition. PKNOX2 in HGC27 cells showed that PKNOX2 functions as a tumor suppressor in GC. Tumorigenicity assay in nude mice showed that stable PKNOX2 expression significantly suppressed tumor growth in vivo. To probe the mechanism of action of PKNOX2 in GC, we performed Cancer pathway PCR array, which unveiled a potential cell proliferation (>6-of-6) of insulin like Growth Factor Binding Protein 5 (IGFBP5) in PKNOX2-overexpressing GC cells. IGFBP5 knockdown abolished the growth inhibitory effect of PKNOX2 in GC cells, indicating that IGFBP5 mediated the tumor suppressive function of PKNOX2. Chromatin immunoprecipitation (ChIP) assay showed that PKNOX2 bind directly to IGFBP5 promoter to mediate transcription. Consistent with our data, PKNOX2 expression was positively correlated with IGFBP5 expression in the TCGA GC dataset. IGFBP5 mediated the tumor suppressive effect of PKNOX2 via activating p53 signaling pathway, as determined by western blot and ChIP-qPCR. In addition, p53 transcriptionally coordinated up-regulated in PKNOX2-overexpressing cells, leading to tumor suppression.

**Conclusion:**

PKNOX2 functions as a novel tumor suppressor silenced in GC by promoter methylation. Its tumor suppressive effect is mediated via IGFBP5 and the activation of p53 signaling pathway. Promoter methylation of PKNOX2 may be a useful biomarker for predicting patient prognosis.

**Introduction:**

Gastric cancer is one of the most common malignancies worldwide. A multitude of factors contribute to the progression of gastric cancer, including activation of oncopgenes and inactivation of tumor suppressors. To find the key molecules and their mutual relations in gastric carcinogenesis is of great significance for the diagnosis and treatment of gastric cancer. The homeobox (Hox) and HoxC10 genes encode transcription factors and usually regulate the expression of target genes at transcription level. Disregulation of Hox genes will cause the abnormality in individual development and tissue formation, and may also lead to malignant transformation. Our group have previously screened by gastric cancer microarray and found that the expression of Hox10 was remarkably upregulated in gastric cancer. At the present time, the function and molecular mechanisms of Hox10 in gastric cancer remains poorly understood.

**Aims & Methods:**

To investigate the expression of Hox10 in gastric cancer, tissue samples from two clinical cohorts were used. We analyzed Hox10 expression in gastric cancer tissues and the corresponding adjacent non-tumor tissues, as well as its correlation with clinical pathological parameters. In addition, we also verified the results by utilizing bioinformatics analysis. We studied the effects of Hox10 on gastric cancer cell cycle control and proliferation through combination of in vitro cell function tests and in vivo nude mouse model. Then, we screened Hox10 potential downstream targets by using cDNA microarray and verified the results by RT-qPCR. We studied the effects of Hox10 on p21 expression and its downstream cell cycle-related proteins and validated the correlation of Hox10 and p21 expression in vitro and in vivo. By application of dual-luciferase reporter assay and chromatin immunoprecipitation, we explored the role of Hox10 in p21 transcription repression.

**Results:**

Hox10 mRNA expression were significantly higher in fresh frozen gastric cancer tissues than in matching adjacent non-tumor tissues (91.43%, 64/70, P < 0.01). The expression of Hox10 was related to the depth of tumor invasion, lymph node metastasis and tumor stage (P = 0.01). Using tissue microarray (TMA), p10 protein expression was also found upregulated in gastric cancer tissues (91.3%, 137/150, P = 0.01) and was closely correlated with patient survival (HR = 2.8; 95% CI 2.0–7.2). Besides, in TCGA database of gastric cancer, Hox10 was upregulated by 122 times (n = 33, P = 0.01), and in Kaplan-Meier Plotter database of 1,113 cancer patients, high Hox10 expression was associated with poor prognosis of patients with gastric cancer (HR = 1.8; 95% CI 1.5–2.16). Hox10-overexpressing gastric cancer cells showed accelerated G1-S phase transformation and proliferation, whereas Hox10 knockdown-induced cell cycle arrest in G1 phase and repressed cell proliferation. Moreover, overexpression of Hox10 accelerated gastric tumor growth in a mouse xenograft model, while knocking-down of Hox10 inhibited gastric tumor growth. cDNA microarray showed that Hox10 regulates multiple downstream genes including p21, a potent cell cycle regulator. A significantly negative correlation between Hox10 and p21 were detected in gastric cancer cells and tissues. Knocking-down of Hox10 also altered the expression of some p21 downstream cell cycle-related proteins, such as Cyclin D1 and CDK4. Furthermore, we found that Hox10 binds to the p21 promoter directly and could inhibit p21 transcription.

**Conclusion:**

Taken together, our results suggest that Hox10 functions as a tumor promoting gene in gastric cancer and may be an important regulator of cell cycle control through p21 transcription regulation.

Introduction: The relationship between Helicobacter pylori (H. pylori) eradication and atrophic changes is debated. Although some studies report a partial restoration of gastric parietal cell (PC) density after eradication of H. pylori, it is not clear whether the finding reflects gastric mucosal healing. L-cysteine, reducing acetaldehyde production after food intake, has been proposed for prevention of gastric carcinogenesis in patients with chronic atrophic gastritis (CAG). To assess modifications in gastric function after L-cysteine administration in CAG by means of PG1 and gastrin (G17) serum levels

Aims & Methods: 62 patients (18 men, mean age 47.2 yrs), with histological diagnosis of moderate to severe chronic, atrophic, body gastritis (according to the Paris classification A or B) and PG1 serum levels lower than 25.5 pmol/l and G17 measurement by means of Gastropanel, 22 out of 62 patients had autoimmune gastritis while 40 of them reported previous H.p. infection. All patients, Helicobacter pylori negative at baseline, were treated with L-cysteine (100 mg three times daily), up to now 36 out of 24 reached 36 months-treatment. Serum PGI and G17 were measured at baseline and after 3, 6, 12, 24, 36 months after starting therapy.

Results: The PG1 serum increased level after the starting of L-cysteine administration, as it follows: PG1 mean value at baseline was 8.42 µg/L, but after 3 months therapy was 10.58, after 6 months 11.65, after 12 months 12.19, after 24 months 13.88, and after 36 months was 14.21 (p = 0.0001). The G17 serum level resulted gradually decreased over the 36 months therapy, as it follows: G17 mean value was 51.33 pmol/l at baseline, 43.13 after 3 months therapy, 38.66 after 6 months, 28.34 after 24 months and 26.03 after 36 months (p = 0.0041).

Conclusion: After L-cysteine administration, patients with chronic, atrophic, body gastritis showed long-lasting improvements of physiological gastric function, reflected by a significant increase of PGI levels and a parallel decrease of G17 serum levels over a 36 months follow-up period.

P1243 FLYING OFF COURSE WITH A 2WW DIRECT ACCESS TO TEST PILOT: NOTTINGHAM'S EXPERIENCE OF THE SUSPECTED UPPER GASTRO-INTESTINAL CANCER PATHWAY CHANGE WITH GP VETTING AND OGD BOOKING

N. R. Lewis, J. Catton, E. James

Trent Oesophago-gastric unit, Nottingham University Hospitals NHS Trust, Nottingham/United Kingdom

Contact E-mail Address: nina.lewis@nuh.nhs.uk

Introduction: Timely progress through diagnostic pathways is a leading quality measure for NHS cancer services. A hypothesis of sooner diagnosis being achievable with direct access to hospital tests from primary care is a core part of CRUK ACE program (1), and in the context of UGI cancer pathway, there is known wide variation of direct access (DA) OGD (2). This pilot evaluates the efficacy and utility of DA OGD or clinic (DA OPD) for GP concerns a patient may have OG cancer. Comparison was made with the standard 2WW pathway, where allocation to OGD or OPD first was randomised.

Aims & Methods: Pilot and UG standard 2WW referrals 01/01/16-01/08/16 were identified from Cancer Centre records.

Results: 192 patients were in the pilot pathway, 430 via the standard 2WW. GP concerns were more likely to allocate a patient to DA OGD (52%) compared to 32% having DA OGD allocated by the hospital. Despite under-utilisation of protected slots for DA OGD, time to DA OGD compared to 2WW did not differ (11.0 days [95% CI 10.5,11.2] versus 12.4 days [95% CI 11.0,13.9]). The same was true for OPD, with the time on pathway was not improved in the pilot group at 16.2 days [95% CI 4.9,28.6] compared to 17.9 days [95% CI 16.9,18.9]. The subgroup of patients allocated in the pilot to DA OGD did have a quicker exit from the pathway, at 12.4 days [95% CI 6.5,18.3] compared to 14.8 days [95% CI 12.9,16.6] on the DDT OGD group. The pilot overall detected 8 cancers (4.2%); the standard 2WW path detected 55 (12.8%). OG cancers were in 4 of the DA OGD (4%) and 14 of the DDT OGD (10.2%). A further 10 non-OG cancers were detected in the DDT group after clinicians requested further investigations to determine the cause of their symptoms. These patients allocated to OPD first by either GP or hospital were as likely to have cancer as those having OG, with 4.3% of those in the pilot having cancer detected this way, but none OG cancer, and 10.3% found to have cancers in the standard 2WW group following investigation directed after clinic visit. Of these 65% were cancers other than OG cancers and would not be detected on OGD alone.

Conclusion: OGD as a sole investigation for symptoms has its utility in excluding or detecting OG cancer. A high proportion of cancers detected via 2WW criteria were found not to be OG cancer. A system whereby patients with potential OG pathways are outside of OG tract and require other tests to diagnose them. In this pilot no additional utility of opening direct access OGD for GP concerned a patient may have an OG cancer was not demonstrated unless exclusion of OG cancer is viewed as the major purpose of the pathway. Our data demonstrates that this view would be detrimental and lead to missed opportunity to detect other cancers that cause symptoms overlapping with those often ascribed to OG tumours.

P1244 WHAT IS THE YIELD OF ROUTINE D2 BIOPSIES IN THOSE PRESENTING WITH WEIGHT LOSS AT GASTROSCOPY?

M. Yalchin, S. Zonoosi, M. Hussein, N. Jayasooriya, K. Besherdas Gastroenterology, Barnet Hospital, DJ/United Kingdom

Contact E-mail Address: m.yalchin@nhs.net

Introduction: Coeliac disease is a common cause of malabsorption in Western countries. The gold standard method of diagnosing coeliac disease is by way of duodenal biopsy. Weight loss is a symptom of malabsorption. Patients referred for upper gastrointestinal endoscopy with symptoms of a weight loss commonly undergo duodenal biopsy to assess for presence of coeliac disease. We hypothesise that those patients with weight loss and who routinely have duodenal biopsies very rarely have coeliac disease unless there are other pointers towards malabsorption.

Aims & Methods: A single-centre, retrospective analysis of consecutive patients undergoing upper gastrointestinal endoscopy for the sole indication of weight loss was undertaken within a large associate teaching hospital within North London from 2005–2016. Of these patients, we reviewed those that had duodenal (D2) biopsies and the results. If they proved abnormal, we looked back for additional markers of malabsorption, clinically and biochemically.

Results: 142 consecutive patients, 65 were Male, 77 were female, underwent OGD for weight loss. Out of this cohort, 62% (n = 88) had a duodenal biopsy. 89% (n = 78) of these had a normal biopsy. 11% (n = 10) had an abnormal biopsy,
P1245 FUNDING DISPARITIES IN DIGESTIVE CANCER RESEARCH IN THE UNITED STATES
P. S. Liang1, K. O’Connell2, M. Du3
1Medicine, New York University, New York/United States of America
2Memorial Sloan Kettering Cancer Center, New York/United States of America

Contact E-mail Address: petersliang@gmail.com

Introduction: In 2015, the five most common digestive cancers (colorectal, pancreatic, liver, gastric, and esophageal) accounted for 16% of incident cancer cases and 24% of all cancer deaths. It is unclear whether the amount and recent trends of US federal funding for digestive cancer research corresponds to the burden of disease. Aims & Methods: We obtained the total annual funding for cancer (including the five most common digestive cancers) from 2008 to 2015 using a public database of research funded by US federal agencies. We calculated funding in 2015 constant USD using the Consumer Price Index. Cases and deaths estimated by the American Cancer Society were used to calculate funding per death or case for each cancer. For comparison, we also extracted data for the three most common cancers (breast, lung, prostate) and all cancers combined. As funding for research in the United States was boosted by the American Recovery & Reinvestment Act of 2009, we limited our analysis to the years 2010-2015. We then calculated the average percentage of research funding per cancer type. Results: From 2010 to 2015 in the US, federal research funding relative to the number of cases and deaths increased for digestive cancers but decreased for non-gastrointestinal cancers. Liver cancer funding increased faster than colorectal funding. However, the overall trends were not statistically significant. Conclusion: Digestive cancer outcomes may benefit from increased research funding. For all the patients who had abnormal D2 biopsies, they had other clinical symptoms and conditions that led to biopsy in the first place due to which further biopsies did not add any additional value. We conclude that there is no need to take biopsies of the duodenum on a routine basis for weight loss alone unless there are other signs of malabsorption. This will save time (both from taking the biopsy and sampling in the lab), lower the cost (forces and pot) and improve the safety (potential perforation and bleeding risk) of the procedure.

Introduction: Helicobacter pylori infection induces aberrant DNA methylation in the gastric mucosa. We evaluated the effect of short-term gastritis eradication on promoter CpG island hypermethylation in gastric carcinogenesis. Aims & Methods: H. pylori-positive patients with gastric adenoma or early gastric cancer who underwent endoscopic resection were enrolled. According to H. pylori eradication or non-eradication, the patients were assigned to H. pylori eradication or non-eradication group. H. pylori-negative gastric mucosa from normal participants provided the normal control. CpG island hypermethylation of tumor-related genes (p16, CDH1, and RUNX-3) was evaluated by quantitative MethyLight assay in non-tumorous gastric mucosa. The gene methylation rate and median values of hypermethylation were compared after one year by H. pylori status. Results: In H. pylori-positive patients, hypermethylation of p16 was found in 80% (10/13) of CDH1 in 80.6% (10/13) of RUNX3 in 48.4% (6/13) of patients in the eradication group, while 54.5% (7/13) of patients had hypermethylation higher than normal control (p16, 10%; CDH1, 44%; RUNX-3, 16%) (p < 0.05). In the H. pylori eradication group, methylation rates of p16 and CDH1 decreased in 58.1% and 61.3% of the patients, and the median values of hypermethylation were significantly lower at one year compared with the non-eradication group. However, RUNX-3 hypermethylation did not differ significantly at one year after H. pylori eradication. The non-eradication group hypermethylation did not change after eradication. Conclusion: H. pylori infection was associated with promoter hypermethylation of genes in gastric carcinogenesis, and H. pylori eradication might reverse p16 and CDH1 hypermethylation.

P1247 CURCUMIN DOWNREGULATES INTERLEUKIN (IL)-17 BY INCREASING THE EXPRESSION OF INDOLEAMINE 2,3-DOXOGENASE (IDO) IN HELICOBACTER PYLORI INFECTED HUMAN GASTRIC MUCOSA
T. Larusa, R. Liprotiti, S. Gervasi, E. Suraci, R. Marasco, M. Imeneo, F. Luzzano
Department Of Health Sciences, University of Catanzaro, Catanzaro/Italy

Contact E-mail Address: tiziana.larusua@gmail.com

Introduction: IDO promotes the effector T-cells apoptosis by catalyzing the rate-limiting first step in tryptophan (Trp) catabolism. We demonstrated that the high expression of IDO in H. pylori-infected human gastric mucosa attenuates Th1 and Th17 immune response, which is associated with chronic gastritis and promotes the carcinogenesis of the mucosa. Interestingly, the anti-inflammatory properties and the ability of the nutraceutical compound curcumin suggest its use as an anti-H. pylori agent, but mechanisms that underlie its helpful activity are still not clear. Aims & Methods: Five antral biopsies were taken from 22 patients (10 M, median age 47.5 yrs, range 20-74y) who underwent gastrointestinal for dyspeptic symptoms: 1 for urease test (Europascal, Trieste, Italy), 2 for histology (Giems staining for H. pylori), and 2 for organ culture. A total urea breath test was also performed (at least two tests positive and all the three tests negative to be considered as cured and no colonized) for H. pylori infected or colonized but increased for the other digestive cancers during the study period. Funding per death among digestive cancers in 2015 was highest for liver cancer and lowest for esophageal cancer. Funding per death for breast cancer was more than 3-fold that of the other digestive cancers. Liver cancer had the largest relative funding decrease for liver cancer, but increased for the other digestive cancers during the study period. Funding per incident case decreased by 15% for esophageal cancer, 21% for colorectal cancer, 34% for gastric cancer, and 37% for liver cancer; funding increased for pancreatic cancer by 6%. Statistically significant trends were observed for liver (p < 0.05). For all the patients who had abnormal D2 biopsies, they had other clinical symptoms and conditions that led to biopsy in the first place due to which further biopsies did not add any additional value. We conclude that there is no need to take biopsies of the duodenum on a routine basis for weight loss alone unless there are other signs of malabsorption. This will save time (both from taking the biopsy and sampling in the lab), lower the cost (forces and pot) and improve the safety (potential perforation and bleeding risk) of the procedure.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: In this study, we characterized the salivary microbiota in patients with H. pylori-associated gastritis and the potential changes of salivary microbiota after receiving HP eradication. We enrolled subjects who were scheduled for diagnostic upper GI endoscopy. We examined patients with peptic ulcer or cancer found on endoscopy, who have received prior HP eradication therapy, and who have recent exposure to antibiotics or acid suppressive therapies. Unstimulated saliva samples were obtained from subjects during fasting state prior to endoscopy. During endoscopy, gastric biopsies were obtained for determination of HP statuses by rapid urease test and histology. Another gastric biopsy was obtained for characterization of gastric microbiota. Serial salivary samples were obtained from HP-infected subjects 8-week after completing HP eradication therapy. Bacterial DNA was extracted for 16S rRNA sequencing by using the MiSeq Platform (Illumina). OTU clustering was performed and taxonomy assigned to the Greengene and HOMD database. Alpha and beta diversities were determined. Linear Discriminant Analysis Effect Size (LEfSe) was used to identify differentially expressed bacterial DNA in different groups.

Results: We enrolled 16 subjects with confirmed HP-gastritis and 14 HP-negative subjects. Baseline salivary samples of all subjects were found to have significantly higher bacterial microbiota diversity than corresponding gastric samples. The predominant microbial family identified in the stomach is Helicobacteraceae (55.2%) whereas Helicobacteraceae constitutes only 0.1% of salivary microbiota. In contrast, the predominant families in salivary microbiota are Prevotellaceae (23.9%) and Neisseriaceae (20.3%). When compared to HP-negative subjects, salivary microbiota in HP-positive patients showed a significant increase in the Bacteroidetes and Spirochaetaceae, and a decrease in Flavobacteriaceae families. HP eradication therapy resulted in a significant reduction in the relative abundance of family Flavobacteriaceae in Helicobacteraceae. Conclusion: There was a significant difference in the microbial diversity and compositions between gastric and salivary microbiota in HP-infected subjects, with Helicobacteraceae dominating the gastric microbiota. HP-infected subjects had a distinctive microbiota in the saliva which is reversed by HP eradication therapy. The significance of these microbial alterations in the saliva of HP-infected subjects and its correlation with gastric diseases deserves further investigation.

P1251 THE INVESTIGATION OF MIR-155, MIR-21, MIR-146A AND MIR-223 EXPRESSIONS IN HELICOBACTER PYLORI POSITIVE AND NEGATIVE INDIVIDUALS

N. Uyar Alpaslan1, E. Ucbilek2, I. O. Barlas1, O. Sezgin2, S. Yara

Introduction: This study was conducted to determine the differential expression patterns of microRNAs, non-coding RNAs that control gene expression mainly through translational repression, in gastric mucosa of Helicobacter pylori (H.pylori) positive patients. Several miRNA have been associated with promoting the inflammatory response initiated by the H. pylori infection, increasing the malignant progression of the gastric epithelium, and enhancing the invasiveness and migratory capacity of cancer cells. Using serum specimens, expression patterns of hsa-miR-155, hsa-miR-21, hsa-miR-146-a and hsa-mir-223 were determined by Real-Time Polymerase Chain Reaction (Real-Time PCR).

Aims & Methods: Patients who underwent upper gastrointestinal endoscopy, in Mersin University Faculty of Medicine, Department of Gastroenterology and diagnosed H. pylori positive and negative were recruited. H. pylori status was assessed by the rapid urease test. Serum specimens of patients, were taken for miRNA isolation. hsa-miR-155, hsa-miR-21, hsa-miR-146-a and hsa-mir-223 expression levels were determined using comparative 2–ΔΔCT analysis by using Real-Time PCR Systems, SDS 2.0.3 software programme. Statistical analysis of miRNAs between H.pylori positive and negative groups were compared with the Mann-Whitney U test. p < 0.05 was considered statistically significant.

The relationship between categorical variables were tested using Pearson’s chi-square test.

</table>

Results: H. pylori positive (n = 46) and negative (n = 49) were included. H. pylori was not able to effective the hsa-miR-155, hsa-miR-21, hsa-miR-146-a and hsa-mir-223 expressions in serum specimens and nuclear factor–KB (NF-KB) and Transforming growth factor, beta (TGF-beta) pathways. There was no statistically difference between H. pylori positive and negative individuals in the analysis of hsa-miR-155, hsa-miR-21, hsa-miR-146-a and hsa-mir-223 miRNA expressions levels (Table 1). In surveys, there is no statistically difference between in each groups, the level of education, intake of smoking-alcohol, hypertension, diabetes, cardiovascular disease, family history of gastroduodenal disease, type of gastroduodenal disease.

Conclusion: This study may contribute to the literature in terms of preventing pre-cancerous progression in the cases of cancer development from H. pylori infection before the onset of cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: antonietta.gravina@yahoo.it

Introduction: Clarithromycin (CLA)-containing quadruple therapy, i.e. concomitant therapy (CT), and bismuth-containing quadruple therapy (BQT) have been suggested as the regimens of choice for eradication of *H. pylori* infection. Both treatments are reported to have an eradication rate higher than 90%. International guidelines recommend that choosing one regimen vs the other should be based on knowledge of patient’s previous antimicrobial exposure or allergy to amoxicillin, and patient’s wish. Secondary endpoint was to assess any difference between CT and BQT in terms of efficacy, safety and compliance. Because in Italy bismuth compounds are not available, BQT was by using the new third-in-one pill (TPG) containing metronidazole 125 mg + tetracycline 125 mg + bismuth 140 mg. 

Methods: The primary endpoint of this study was to evaluate the eradication rate in *H. pylori*-infected subjects naïve to treatment in an area of high (*>5%) CLA resistance based on knowledge of patient’s previous antimicrobial exposure or allergy to amoxicillin, and patient’s wish. Secondary endpoint was to assess any difference between CT and BQT in terms of efficacy, safety and compliance. Because in Italy bismuth compounds are not available, BQT was by using the new third-in-one pill (TPG) containing metronidazole 125 mg + tetracycline 125 mg + bismuth 140 mg. 

Results: The number of first-line regimen of VPZ patients was 109, and the EF rate was 62.4% (95%CI 55.8–68.5); the ITT eradication rate was achieved in 97 patients (87%). RPZ patients were 68, and the success rate was 76.5% (95%CI 69.5–83.2). The success rate of *H. pylori* eradication in 2nd line treatment was 84.4% (35/224), and that in patients who received the vonoprazan regimen was 87.5% (21/24).

Conclusion: Vonoprazan is considered to be useful for *H. pylori* eradication instead of a PPI in first line treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Potent acid inhibition with acid inhibitory drugs is crucial to the success of eradication for *Helicobacter pylori* infections. Concomitant therapy (CT) is more effectively inhibiting the binding of potassium ion to H+•K+•ATPase in gastric parietal cells and inhibits H+•K+•ATPase activity at 400-fold more potent than that of losaprazole, proton pump inhibitor (PPI). Therefore, the eradication regimen with vonoprazan has been increasing recently. However, no study has been compared with a PPI-based therapy. Although vonoprazan is mainly metabolized by CYP3A4/5, it is unclear whether its acid inhibitory effect and outcome of *H. pylori* eradication differ among CYP3A4/5 genotypes. Our aim was to clarify the influence of CYP3A4A5 genotypes on outcome of *H. pylori* eradication including vonoprazan in Japanese.

Aims & Methods: We investigated the influence of CYP3A4/5 and CYP2C19 genotypes and susceptibility of antimicrobial agents for outcome of vonoprazan-contained eradication regimen for 7 days in 105 Japanese: (1) with amoxicillin 750 mg and clarithromycin 20 mg twice daily (bid) as the first-line treatment (n = 76); (2) with amoxicillin 750 mg and metronidazole 250 mg bid as the second-line treatment (n = 29). Eradication status was assessed at eight weeks via 13C-urea breath test. CYP3A4*22, CYP3A5*3 and CYP2C19*2/3*5 were genotyped for all patients.

Results: Eradication rate on intention-to-treat analysis was 82.9% (95% confidence interval: 75.5-89.2) in the first-line treatment and 93.1% (90.0-96.1) in the second-line treatment. No significant differences were found as to the incidence of side effects among CYP3A4A5 genotypes.

Conclusion: Eradication rates of vonoprazan-based eradication therapy can be achieved high compared with PPI-based therapy. However, because CYP3A5*3 genotype may be one of determinate for outcome of eradication regimen including vonoprazan, genotype analysis of patients treated with vonoprazan will be required for patient stratification for improving clinical outcome before treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1255 COMPARISON OF HELICOBACTER PYLORI ERADICATION RATES: VONOPRAZAN VS. PROTON PUMP INHIBITOR**

Gastroenterology, Yokohama-city Red Cross Hostpital, Yokohama/Japan

Contact E-mail Address: naokoozo122@gmail.com

Introduction: The use of vonoprazan in combination with proton pump inhibitor (PPI) based therapy is one of most popular *H. pylori* eradication in the world. On the other hand, eradication rates have been decreasing because of resistance to the clarithromycin (CAM). It is known that most bacteria are not effective under strong acid secretion. So in order to improve the eradication rate, gastric acid must be reduced more rapidly and strongly. Vonoprazan(VPZ) is a new potassium competitive acid blocker and the usefulness is expected in Japan.

Aims & Methods: Our aim was to investigate the efficacy of the VPZ-based eradication therapy. The subjects were 999 patients who were diagnosed as *H. pylori* infection in our institution from June 2014 to December 2016. The patients were grouped into three: VPZ group and conventional PPI (Lansoprazole or Rabeprazole) group. We evaluated the first-, second-, third-line eradication rate and statistical analysis. Each regimen of VPZ group was first-line eradication (VPZ 20 mg bid + amoxicillin 750 mg bid + CAM 200 mg bid for 7 days), second-line eradication (VPZ 20 mg bid + amoxicillin (AMPC) 750 mg bid + Metronidazole 250 mg bid for 7 days). Each regimen of PPI group was first-line eradication (PPI bid + AMPC 750 mg bid + CAM 200 mg bid for 7 days), second-line eradication (PPI bid + amoxicillin 750 mg bid + Metronidazole 250 mg bid for 7 days). One of the following PPI was used: Lansoprazole (LPZ) 30mg, Rabeprazole (RPZ) 20mg. After several months, eradication status was examined by urea breath test, stool antigen testing and blood antibody test.

Results: The number of first-line regimen of VPZ patients was 109, and the eradication was achieved in 97 patients (87%). RPZ patients were 308, and the eradication was achieved in 116 patients (37.8%). The eradication rate of VPZ was 79.8% (95%CI 72.5-87.0), and the eradication rate of VPZ was statistically higher than RPZ and LPZ (P = 0.006, and = 0.019 respectively).

The number of second-line regimen of VPZ patients was 24, and the eradication was achieved in 19 patients (79%). RPZ patients were 68, and the eradication rate of VPZ was 68 (82.2%), and the eradication was achieved in 60 patients (88.2%) respectively. There were statically no significant differences in second-line regimens. Adverse events...
such as eruption and diarrhea were reported in 6.6% (9/136) of patients in VPZ, in 4.2% (9/214) in LPZ, and in 6.1% (28/456) in LPZ.

Conclusion: The first-line regimen with VPZ was superior to conventional PPI regimen, and was a result not to be inferior in the safety either.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1257 CAN TWO WEEK BISMUTH BASED QUADRUPLE THERAPY FOR RESISTANT H. PYLORI INFECTION STILL BE USED IN THE UK?

H. Logan- Ellis, L. Bensaid, R. P.H. Logan
Gastroenterology, King’s College Hospital, London/United Kingdom

Contact E-mail Address: hughloganellis@kcl.ac.uk

Introduction: Eradication of H. pylori infection cures peptic ulcer disease (PUD); however first treatment strategies are not ideal and many patients require repeated courses of treatment. We, and others, have recently documented that currently, within the UK, less than 30% of patients with with proven PUD, are subsequently documented to have been cured by H. pylori eradication 1,2.

Methods of analysis and inclusion criteria were based on UK guidelines and meta-analyses. Pooled-data analysis aimed to clarify whether probiotics alone may eradicate the side effects and eradication rates. Herein, we performed a systematic review with national and international guidelines as well as meta-analyses suggest that only H. pylori eradication (1).

Results: A total of 41 studies (both randomized clinical trials and open label pilot studies) were selected. In one study patients with peptic ulcers were selected, while in the remaining 9 only dyspeptic patients were recruited. Probiotics eradicated H. pylori in 50 out of 391 cases. The mean eradication rate was 14%, with a 95% CI of 2-25% (p=0.02). Most of studies investigated a probiotic formulation based on a single lactobacilli strain. Lactobacilli eradicated the bacterium in 30 out of 235 patients, with a mean weighted rate of 16% (95% CI 1-31%). Multiclinic interventions were effective in 14 out of 105 patients, with a pooled eradication rate of 14% (95% CI -16-43%). In the comparison probiotics vs placebo, we found an OR = 9.65 in favor of probiotics, with a 95% CI of 1.97-47.36 (p = 0.005). Finally, probiotics induced a mean reduction in optimal values of 8.6% (95% 5.88-11.34, p < 0.00001). No study provided data about adverse events.

Conclusion: Probiotics alone show a minimal effect on the eradication of H. pylori, thus suggesting a presumable direct effect. However, they cannot be indicated as a therapeutic regimen for the low eradication rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
3. Aims & Methods: Methods of analysis and inclusion criteria were based on UEG recommendations. Relevant publications were identified by a research in PubMed, MEDLINE, Science Direct and EMBASE. The end-point was to estimate the mean eradication rate and variations of delta value at urea breath test across all studies and, overall, with a pooled data analysis. The data have been weighted ad proportions, percentages, and 95% confidence intervals (CI) were calculated. For continuous variables, we calculated the weighted mean difference. Odd ratios (OR) were calculated, where available, based on the Mantel-Haenszel method. Data were entered into the RevMan 5.3 software. Random effects studies (both random effects and open label pilot trials) were selected. In one study patients with peptic ulcers were selected, while in the remaining 9 only dyspeptic patients were recruited. Probiotics eradicated H. pylori in 50 out of 391 cases. The mean eradication rate was 14%, with a 95% CI of 2-25% (p=0.02). Most of studies investigated a probiotic formulation based on a single lactobacilli strain. Lactobacilli eradicated the bacterium in 30 out of 235 patients, with a mean weighted rate of 16% (95% CI 1-31%). Multiclinic interventions were effective in 14 out of 105 patients, with a pooled eradication rate of 14% (95% CI -16-43%). In the comparison probiotics vs placebo, we found an OR = 9.65 in favor of probiotics, with a 95% CI of 1.97-47.36 (p = 0.005). Finally, probiotics induced a mean reduction in optimal values of 8.6% (95% 5.88-11.34, p < 0.00001). No study provided data about adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Despite several evidences in literature have demonstrated a role for probiotics as adjunctive treatment for Helicobacter pylori (H. pylori) eradication, national and international guidelines as well as meta-analyses suggest that only co-administration of probiotics may have a beneficial effect on the prevention of side effects and eradication rates. Herein, we performed a systematic review with pooled-data analysis aimed to clarify whether probiotics alone may eradicate the bacterium.
**P1260** COMPARISON OF CLARITHROMYCIN- AND LEVOFLOXACIN-CONTAINING TRIPLE THERAPIES FOR FIRST-LINE *HELCOBACTER PYLORI* ERADICATION IN IRAN

H. Fakheri1, A. Sadough3, T. Sirgar Fakherni

1 Gut And Liver Research Center, Mazandaran University of Medical Sciences, Sari/Iran
2 Mazandaran University of Medical Sciences, Sari/Iran

**Contact E-mail Address:** septirgar3@gmail.com

**Introduction:** Among the Maastricht IV consensus report, Clarithromycin-containing triple therapy can be considered as a suitable option for first-line *Helicobacter pylori* (H. pylori) eradication in areas with less than 20% resistance rates to Clarithromycin. On the other hand, resistance to Clarithromycin is increasing in Iran, influencing the efficacy of standard triple therapy in this country. Therefore, regimens containing other antibiotics have to be considered in Iran.

**Aims & Methods:** One hundred and forty patients with peptic ulcer disease and non-erosive gastritis were randomly divided into two groups to receive either 10-day standard triple therapy (Pantoprazole 40 mg, Amoxicillin 1 gr and Clarithromycin 500 mg, all given twice daily) or 10-day Levofloxacin-containing triple therapy (Pantoprazole 40 mg BD, Amoxicillin 1000 mg BD and Levofloxacin 500 mg daily). Eight weeks after the treatment, *H. pylori* eradication was assessed by αC- urea breath test.

**Results:** One hundred and thirty-three patients completed the study. According to intention to treat analysis, *H. pylori* eradication rates were 75.7% (95% confidence interval (CI): 65.7%-85.7%) and 58.5% (95% CI = 47.1%-70%) in standard and Levofloxacin-containing therapies, respectively. Also, per-protocol eradication rates were 83% (95% CI: 74%-92%) and 61% (95% CI = 49% -73%), respectively. The rates of severe adverse effects of therapy were 7.1% and 2.9% in the mentioned groups, respectively.

**Conclusion:** Both Clarithromycin-containing triple therapy and Levofloxacin-containing triple regimen do not seem to be suitable options for first-line *H. pylori* eradication in Iran. We suggest using Clarithromycin in quadruple regimens such as hybrid or concomitant therapies and reserve Levofloxacin to be used in second-line eradication regimens, as it is recommended by Maastricht V Consensus Report.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1261** EFFICACY AND TOLERABILITY OF REBAMIPIDE IN TRIPLE THERAPY FOR ERADICATION OF *HELCOBACTER PYLORI*: A RANDOMIZED CLINICAL TRIAL

S. S. Vyalov
Gastroenterology, Peoples Friendship University of Russia, Moscow/Russian Federation

**Contact E-mail Address:** svialov@mail.ru

**Introduction:** Rebamipide is an orally prostaglandin E2 and I2 synthesis inhibitor. A latest clinical trial showed that the adhesion of *H. pylori* to stomach wall was reduced by rebamipide. This could improve eradication rates by increasing the adhesion of *H. pylori* to antimicrobial agents.

**Aims & Methods:** We aimed to determine eradication rate, the effectiveness and advantage of rebamipide in triple eradication therapy of *H. pylori* infection. Subjects comprised patients undergoing eradication therapy for *H. pylori* infection in our clinics. Patients with a history of eradication therapy, gastrectomy, or allergy to medications in triple therapy were excluded. Written informed consent was obtained for each patient. This trial was performed as a randomised open-label study. The permission of ethical institutional review board was obtained. All patients were tested on *H. pylori* infection. The number of cases was 160 (80 cases in each group). Each patient was randomly enrolled for rebamipide therapy group (RBD) (esomeprazol 40 mg, amoxicillin 1000 mg, clarithromycin 300 mg, rebamipide 80 mg a day for 14 days) or standard triple therapy group (STD) (esomeprazol 40 mg, amoxicillin 1000 mg, clarithromycin 500 mg, twice a day for 14 days). Before starting therapy, we checked the background characteristics of each patient (age; gender; weight; height; drinking habit; smoking habit; use of probiotics, bismuth; PPI; and endoscopic findings). After the therapy, we asked physicians and patients about medication compliance and side effects. The primary endpoint was the eradication rate. The secondary endpoints were the rates of side effects.

**Results:** For RBD therapy group and STD therapy group, the eradication rates were 94.0% (95% confidence interval, 85%-100%) and 82% (95% confidence interval, 74%-95%) respectively, and the rates of side effects were 8.5% (95% confidence interval, 7.0%-26.5%) and 29% (95% confidence interval, 17.5%-41.0%), respectively. In each group, statistical analysis revealed significant differences in eradication rate was seen. The RBD group revealed trends of high eradication rates and low rates of side effects.

**Conclusion:** The findings suggest that rebamipide is effective in eradication of *H. pylori* infection, significantly improving eradication rate in triple therapy. The advantage of rebamipide has efficacy and good tolerability.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Intestinal graft-versus-host disease (GVHD) represents one of the most serious complications of allogeneic stem cell transplantation (allo-SCT). Almost 10%-40% of patients who undergo allo-SCT develop significant clinical acute graft-versus-host disease (GVHD) [1]. Endoscopic and histological proofs are required because of the number of differential diagnoses manifesting as diarrhea. Previous studies reported that endoscopic features, such as atrophied terminal ileum, were reliable. However, these previous studies did not address details of the random sequence, and were performed in a single centre.

**Aims & Methods:** The present study investigated the incidence of the characteristic features, particularly microvilli atrophy of the terminal ileum, of colonscopy, and inter-observer agreement of the finding among experienced endoscopists in multiple centres. Concurrent patients who underwent allo-SCT between May 2008 and September 2015. Fifty-four patients underwent colonoscopy after allo-SCT as intestinal acute GVHD was suspected. We recorded the colonscopic imaging. Subsequently, they were checked by three observers, from different institutions, to determine whether microvilli atrophy in the terminal ileum is present. Demographic information, disease, symptoms, and histological finding were obtained from the patients’ medical records retrospectively. All study participants provided informed consent. The local ethics review committee granted ethical approval (approval 1004/613), and was registered in the University Hospital Medical Network Clinical Trials Registry (UMIN-CTR) as number UMIN 000025390.

**Results:** Definitive pathological and non-pathological GVHD were found in 22 patients, and 32 patients, respectively. In the analysis of all 54 lesions, for three observer (A, B, and C), sensitivity of the microvilli atrophy in the terminal ileum was 86.4%, 77.3%, and 79.2%, whereas specificity of the appearance were 62.5%, 62.5%, and 86.2%. In addition, the positive predictive value of the appearance was 61.3%, 58.6%, and 82.6%, and negative predictive value (NPV) was 87.2%, 87.2%, and 83.9%, respectively. The kappa coefficient of the inter-rater reliability was 0.85, 0.63, and 0.63 in observers AB, AC, and BC.

**Conclusion:** Microvilli atrophy in the terminal ileum is an effective colonoscopic finding for real-time predictive histological diagnosis of acute post-transplant *Helicobacter pylori*-induced GVHD. We achieved substantial inter-observer agreement for the analysis of microvilli atrophy in the terminal ileum and excellent agreement for predictive histological diagnosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P1263 INCREASED SUSCEPTIBILITY TO ENTEROPATHOGENIC MUCOSITIS. Aims & Methods: In this study, we aimed to prove the protective effect of EGCG in murine chemotherapy-induced mucositis model. Twenty-four 8-wk-old male C57BL/6 mice were randomized to 4 groups: control, EGCG, 5-Fluorouracil (5-FU), EGCG plus 5-FU. Mucositis was induced by intraperitoneal injection of 5-FU (400 mg/kg). EGCG (50 mg/kg) was administered orally for 5 days from the day before administration of 5-FU. After 6 days of 5-FU injection, the mice were sacrificed, and intestinal tissue was obtained. KBC count was performed with whole blood from Inferior vena cava of mice. The end points were villus height, villus/crypt ratio, histologic characteristics, and mRNA expression of tumor necrosis factor (TNF-α), and interleukin (IL)-6.
Results: In 5-FU group, neutropenia was confirmed by laboratory test (5-FU, 0.650 K/L; Control, 5.317 K/L), indicated significant 5-FU effect. Histologic findings showed that crypt dilatation, villus stunting, and villus atrophy were reduced in EGCG plus 5-FU group than in 5-FU group (Figure 1). Quantitative analysis of TNF-α and IL-6 expression in ileum, and villus/crypt ratio (EGCG plus 5-FU, 3.28; 5-FU, 2.31) in EGCG plus 5-FU group, compared with 5-FU treated group, were significantly higher. mRNA expression of TNF-α was significantly lower in EGCG plus 5-FU group compared with 5-FU group (P < 0.05)(Figure 2). Figure 1. Effects of EGCG administration on intestinal inflammation caused by an antitumor agent. Conclusion: EGCG reduced the severity of 5-FU induced intestinal mucositis, suggesting a possibility for novel treatment of chemotherapy-induced bacterial infection. All authors have declared no conflicts of interest.

P1264 EPICALLOCTECHIN-3-GALLATE FROM GREEN TEA AMELIORATE 5-FLUOROURACIL-INDUCED GASTROINTESTINAL MUCOSAL INJURIES. Aims & Methods: To investigate whether LAZ can influence the steady-state intestinal environment, C57BL/6J mice were divided into two groups, and 8 mg/kg-day of lansoprazole (LAZ group) or saline (control group) were administrated intraperitoneally for two weeks. The ileal contents and feces were collected before and after LAZ administration. Genomic DNA of the gut microflora was analyzed by 16s ribosomal RNA (16s rRNA) gene sequencing, and the metabolites were analyzed by a CE-TOFMS platform. To examine the changes of immune cell distribution by LAZ, hematopoietic cells in the lamina propria were analyzed by flow cytometry. The changes of gene expressions of the ileum were monitored by comprehensive analysis of microarray. Finally, mice were orally inoculated with C. rodentium after LAZ administration, and the establishment of enteritis was evaluated by body weight loss, histology and inflammatory cytokine expressions examined by real-time PCR. Results: At steady-state, no prominent change of metabolites and gut microflora were observed in the feces of LAZ group. On the other hand, the concentrations of short chain fatty acids, such as butyrate and propionate, were decreased in the ileum of LAZ group. The result of 16s rRNA analysis also showed that the composition of ileal microflora were different between LAZ and control group. However, it did not show the change of immune cell distribution in the intestine. The gene expression levels in the ileum were not altered either. Interestingly, the ileal microflora of LAZ group became similar to that of the feces. As mice have a habit of coprophagia, it was assumed that perorally invaded bacteria could survive and pass through the stomach due to suppression of gastric acid by LAZ. Accordingly, in the LAZ group, infectious inflammation was established by less numbers of C. rodentium inoculation, indicating that PPIs could raise the susceptibility to peroral enteropathogenic bacterial infection. Conclusion: Our data showed that administration of PPIs could alter the intestinal environment such as microflora and luminal metabolites. However, neither the gene expressions nor distribution of immune cells in the intestinal tissue were affected. It was assumed that the increased risk of peroral enteropathogenic bacterial infection was not because of the immunomodulatory modification by PPIs, but it was mainly because of the increased number of pathogenic bacteria passing through the stomach. All authors have declared no conflicts of interest.

P1265 EXPRESSION OF AMINO ACID TRANSPORTERS IN AN ANTITUMOR AGENT-INDUCED GASTROINTESTINAL MUCOSAL INJURIES. Aims & Methods: We aimed to clarify the pathophysiological role of an amino acid transporter in gastrointestinal tract inflammation caused by an antitumor agent in this study. The antitumor agent fluorouracil (5-FU) was orally administered to mice. The severity of mucositis was assessed based on the length, villus height, mucus production, cell infiltration, and immune response of the intestinal tract. We measured the mRNA expressions of LATs in the tissues of the small intestines. In addition, we analyzed the protein expressions among the small intestines using anti-LAT antibodies. Results: After the administration of 5-FU, the body weight, food intake, water consumption, and fecal volume decreased; thus, a systemic influence was observed. The length and villus height of the intestinal tract decreased because of the administration of 5-FU, and mucosal damage with histological change was observed. The number of PAS-positive cells decreased in the small intestinal mucosa, and it was assumed that the defensive function of the epithelial cells had decreased. In addition, an increase in the mRNA expression of IL-1β, IL-6, and TNF-α in the Peyer’s patch along with an increase in the cell infiltration after the administration of 5-FU significantly enhanced the immune response associated with the inflammatory cytokine production. Furthermore, on investigating the mRNA and protein expressions of LAT1 and LAT2 in the tissues of the small intestines, we observed that LAT1 expression significantly increased and LAT2 expression decreased after the administration of 5-FU. Conclusion: It was considered that the uptake capacity of amino acids, such as Gly, Ala, Ser, Thr, Cys, Asn, and Gin, that transported through LAT may be decreased in case of small intestinal mucosal injuries. On the other hand, LAT1 expression associated with the production of inflammatory cytokines suggested that LAT1 is a gastrointestinal inflammatory marker. All authors have declared no conflicts of interest.
P1266 A MUCOUS DEPENDENT MECHANISM OF ACETYL SALICYLIC ACID-INDUCED SMALL INTESTINAL MUCOSAL INJURY IN RATS

Introduction: Acetyl salicylic acid (ASA) has been used for the secondary prevention of cardiovascular diseases. Especially, the enteric coated ASA is widely used to prevent ASA-induced gastric mucosal injury. Recent technology such as video capsule endoscopy and balloon endoscopy enabled us to look inside the small intestine in more detail. Consequently, not a few cases of ASA-induced small intestinal mucosal injuries have been reported. However, the effective prophylaxis and treatment is not clear yet. Previously, we reported direct detrimental effect of ASA on small intestinal epithelial cells using an in vitro model [1]. However, there are thick mucus layer between intestinal lumen and epithelial cells. The mucus has been reported to prevent foreign objects such as bacteria, medicine and food from epithelial cells.

Aims & Methods: This study was conducted to clarify the role of mucus on ASA-induced small intestinal mucosal injury using a rat model. Male Sprague-Dawley rats, 9 weeks old was used. These rats were divided into four groups; group 1: sham (carboxy methyl cellulose: CMC alone), group 2: polyorbate-80 (P80) alone, group 3: ASA alone, and group 4: P80 plus ASA. CMC and/or P80 or 200 mg/kg ASA was injected into the proximal duodenum of rats. P80, an emulsifier, which has been reported to reduce mucous thickness [2], was administered via drinking water for 2 weeks before ASA treatment. Indeed, P80 also reduced the thickness of mucous layer in our analyses. One hour after ASA treatment, 1% Evans blue was injected into a vein of rats to visualize small intestinal lesions. Ninety minutes after ASA treatment, the entire small intestine was removed for histological examination. To further investigate the importance of mucus, rebamipide (Reb, 300 mg/kg) or saline were orally administered for 1 week prior to ASA treatment. Reb is a gastric muco-protective drug widely used for the treatment of gastric ulcer, and increases mucous secretion by stimulating mucus secreting cells.

Results: Evans blue method suggested that high-dose ASA (200 mg/kg) induced severe mucosal lesions, which was further confirmed by the histological examination. Although lower doses of ASA (50 and 100 mg/kg) did not cause mucosal damage, P80 significantly reduced Evans blue exudate and severe mucosal lesions in jejenum at these concentrations, suggesting the pivotal role of mucus in these lesions. Moreover, the sodium butyrate administered Reb significantly suppressed reducing small intestinal mucus and the exacerbation of ASA-induced mucosal lesions by P80, indicating that mucus is inevitable in the protection of ASA-induced small intestinal mucosal injury.

Conclusion: Prevention increasing therapy might be a useful for the prevention of ASA-induced small intestinal mucosal injury.

Y. Itoh: Encouragement and research support from Otsuka Pharmaceutical Co. All other authors have declared no conflicts of interest.

Introduction: Crohn's disease has been thought to be caused by abnormal immune responses affecting many parts of digestive tract in which Th1 cells and Th2 cells play a role. The recruitment of Th1 cells is regulated by interaction of their expression of chemokine receptor CXCR3 and its ligands. There have been many IBD murine models showing the increase of CXCR3 expression and its roles on the disease promotion. However, there are limited evidences in the roles of CXCR3 in human IBD. In fact, a small study in large bowel in a cohort of 10 Crohn's disease patients showed lower expression of CXCR3 on T lymphocytes, compared to colon cancer patients. In terms of inhibition of T-lymphocyte migration into intestine in IBD patients, anti a4b7 (Vedolizumab) therapy is currently shown to be effective.

Aims & Methods: Our study aimed to assess expression of CXCR3 by different subsets of small intestinal lamina propria T-cells and its association with a4 and b7 in the CD patients. Total of 56 duodenal biopsies were obtained from CD (n = 15), functional dyspepsia (FD)/irritable bowel syndrome (IBS) (n = 24) or iron deficiency patients (n = 17) with ethical approval. Lamina propria (LP) cells were isolated from biopsies using EDTA, collagenase and gradient density centrifugation with Ficoll. Expression of CXCR3, a4, and b7 on isolated T-lymphocytes was examined by flow cytometry. Statistical significance was assessed using T-test or Spearman correlation.

Results: The expression of CXCR3 on CD4 lymphocytes was significantly lower (45.8%) compared to 61.6% in control group (p<0.05). The expression of CXCR3 on CD8 lymphocytes was higher than CD4 lymphocytes, it was not different between CD and other group (75.8% in CD patients vs 82.2% in controls). Similar observation was obtained on the double positive CD4 and CD8 lymphocytes. Interestingly, only expression of CXCR3 on CD4 lymphocytes positively correlated with expression of the gut-homing integrins, a4 and b7.

Conclusion: These observations showed significant expression of CXCR3 across different CD patients, with consistently higher expression seen in CD8 lymphocytes compared to CD4 lymphocytes. An unexpected reduction of CXCR3 expression was seen in small intestinal of CD patients, which associated with gut-homing integrins. This result showed CXCR3 expression may play a role in migration of CD4 lymphocytes but not CD8 lymphocytes into duodenum in relation with integrins, a4 and b7. However, CXCR3 expression on CD4 lymphocytes in CD patients' small intestine may have protective role. This propose further study to clarify.

2Universidad de Lima, Lima/Peru

Contact E-mail Address: aldo.maruy@gmail.com

Introduction: Acute Gastroenteritis (AGE) is one of the diseases that most frequently affects paediatric population. Successful treatment in AGE has been made possible by the use of probiotics in the prevention and treatment of its complications; every day, we find more publications on the use of adjuvants to decrease its duration. Probiotics have gained greater importance because some of them report benefits. We look for Clinical Practice Guidelines (CPG) that recommend their use in AGE in children. The AGREE II instrument was developed to address the issue of variability in guideline quality, so it is a tool that assesses the methodological rigour and transparency in which a guideline is developed.

Aims & Methods: To assess the methodological quality of clinical practice guidelines (CPG) on the use of probiotics in infant diarrhoea. The search was conducted in December 2016, of CPG based on the evidence, the last 10 years and as contaminants in drinking water, has become a public health problem. For this we used an in vitro system: the SHIME® (Simulator of the Human Microbial

References
Intestinal Ecosystem). The SHIME® consists of series of fermenters, mimicking the human gastrointestinal tract from the stomach to the colon. The SHIME® was exposed to a daily dose of 3.5 mg of CPF, combined with 10 g of inulin for 30 days. The samples were collected at day 0 (baseline, without CPF or inulin), D15 and D30 to determine the profile and microbial metabolism.

Results: Contrary to the previous results with CPF alone showing dysbiosis, prebiotic supplementation seems to reestablish CPF-induced imbalance, particularly in the potentially pathogenic microflora (Staphylococcus), which an increase in short term (D15: p < 0.001), and a recovery at D30. (difference vs D0: p = 0.0002). Inulin also beneficially influences the fermentation profile, with higher production of volatile fatty acids (VFA), especially propionic acid and butyric acid. Prebiotic inulin at D15 and D30 improved the metabolic defects of prolonged Exposure to chlorpyrifos from Gestation to Young Adult Stage in Offspring Rats.

**P1274** IS THERE AN ASSOCIATION BETWEEN ENTERIC METHANE (CH4) PRODUCTION AND SYMPTOMS IN PATIENTS WITH UNEXPLAINED GI SYMPTOMS?

Introduction: Alterations to the gut microbiota and bacterial translocation have been implicated as relevant factors for the progression of chronic liver disease (CLD). While the sequence of events leading to translocation remains unclear, deficiencies in local host immune defences, increased permeability of the intestinal mucosal barrier and dysbiosis of the gut microbiota are suggested to play a role. Small intestinal bacterial overgrowth (SIBO), in which excessive and/or abnormal type of bacteria is present in the small bowel has been implicated as a potential factor in translocation. However, systematic assessments of the extent of SIBO in CLD remain limited. We therefore aimed to compare the prevalence of small intestinal bacterial overgrowth (SIBO) in patients with chronic liver disease (CLD) and controls.

Aims & Methods: Using the search terms ‘small intestinal bacterial overgrowth (SIBO)’ and ‘chronic liver disease (CLD)’ or ‘small intestinal bacterial overgrowth (SIBO)’ and ‘cirsrhosis’, 19 case-control studies that met inclusion criteria were identified. Data were extracted to calculate prevalence rates and 95% confidence intervals (CI).

Results: The final dataset included 1,000 adult patients with CLD and 488 controls. Nine studies employed glucose breath tests (GBT), four lactulose breath tests (LBT) and one xylose breath test. Five studies utilised culture methods and one quantitative PCR. Across all testing methods, the prevalence of SIBO in patients with CLD was 38.9% (95% CI 36.9–40.9) compared to 9.8% (95% CI 7.5–12.8) in controls. Eighty-four percent of SIBO in CLD was increased as compared to controls (RR = 7.15, 95% CI 4.9–10.4). In patients with cirrhosis the prevalence of SIBO was 40.1% (95% CI 36.6–43.8) compared to 7.3% (95% CI 4.9–10.8) in controls. Nine case-control researchers used a method of detection was limited to breath tests. The prevalence of SIBO in CLD was 35.8% (95% CI 32.6–39.1) compared to 8.0% (95 CI 5.7–11.0) in controls. In contrast, based on culture techniques, the prevalence of SIBO in CLD was 68.3% (95% CI 59.6–76.0) vs 7.94% (95% CI 3.44–12.73) in controls.

Conclusion: Regardless of the diagnostic modality, prevalence of SIBO is significantly increased in patients with CLD when compared to controls. It is notable that culture-based detection leads to a higher prevalence in CLD, suggesting breath tests as a small intestinal bacterial overgrowth (SIBO) in CLD detected, further studies need to explore the role of intestinal dysbiosis for the progression of CLD.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: In humans, enteric methane (CH₄) production is highly variable and related to the gastrointestinal microbiome and diet. Previous work suggests that CH₄ production is more common in patients with ‘constipating’ conditions such as encopresis and diverticulosis. We aimed to explore the link between gastrointestinal symptoms breath CH₄ exhalation in patients with unexplained GI symptoms.

Aims & Methods: Consecutive patients (n = 100) with unexplained GI symptoms underwent a combined H₂/CH₄ breath test after ingestion of 75 g of glucose. H₂ and CH₄ were measured by Breathreacher microlyzer (Quintron, USA). Gastrointestinal symptoms were assessed utilising the Structured Assessment of Gastrointestinal Symptoms Instrument (SAGIS). The association between methane exhalation and symptoms during the 2 weeks prior the test were the evaluated using non parametric test.

Results: 100 consecutive patients (55%), aged 52.±15.7 yrs (mean±SD) were included. Of these, 14 with positive GBT and 19 without SAGIS data were excluded, resulting in 67 data-sets available for analysis. Methane peak and methane baseline values were highly correlated (r=0.96, p < 0.001). Methane peak (and baseline) were inversely correlated with the SAGIS diarrhoea score (−0.35, p < 0.01, Figure 1). Contrary to current opinion, CH₄ exhalation was not associated with constipation (r = 0.1, P > 0.4). In addition, excessive belching and acid eructation were significantly associated with the baseline and peak CH₄ exhalation (r all ≥0.3, p all <0.04).

Conclusion: There is an inverse association between CH₄ exhalation and diarrhoea symptoms. At the same time, CH₄ is associated with bloating and acid eructation. These data suggest that CH₄ or metabolic products from CH₄ producing microbes modulate human gut function.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1275 CELIAC DISEASE AND POSITIVE IGA TISSUE TRANSGLUTAMINASE IN PATIENTS WITH DISTAL RADIUS AND ANKLE FRACTURE: A CASE-CONTROL STUDY

Introduction: The prevalence of osteoporosis is higher among patients suffering a distal radius fracture than in healthy controls [1]. Celiac disease (CD) is associated with low bone mineral density [2], and overall findings indicate an increased risk of fracture in CD patients [3, 4]. This study is to our knowledge the first case control study investigating whether there is a higher prevalence of CD in adult patients suffering a peripheral fracture (distal radius or ankle) than in healthy age- and sex matched controls.

Aims & Methods: Main objective was to investigate if patients with a recent fracture of the distal radius or ankle have a higher risk of having CD than healthy controls. 400 consecutive patients over the age of 40 with acute distal radius fracture (n=293) or ankle fracture (n=107) were included in a case control study by referral from the orthopedic department at Forde General Hospital, Bergen/Norway. The controls were 197 age- and sex- matched subjects from Sogn and Fjordane County (representative for the National Population Registry), with no previous fracture history. BMD of the hips and spine was measured and history of previous fracture, comorbidities, medication, lifestyle factors, body mass index (BMI) and nutritional factors were registered. Serum analysis to detect serological evidence of gluten intolerance in genetically susceptible patients. Clinical outcome includes serum and intestinal manifestations, including neurologic complications in about 10% of patients. Previous studies confirmed the subclinical changes of abnormalities in regulatory brain system (ANS) activity resulting to impaired gastric myoelectric activity. In CD and disturbances of parasympathetic-sympathetic balance of the ANS activity with sympathetic dominance is observed. Dysfunction of the autonomic nervous system (ANS) is a potential contributor to CD pathogenesis.

Results: Biochemical parameters. Patients with CeD presented with lower average level of oculin (CD) than healthy subjects. Patients with CeD had significantly lower level of oculin (1.41(0–2.9) ng/mL) than healthy subjects (1.68(0.39–4.8) ng/mL) (P = 0.07, the Mann-Whitney test). No significant impact of CeD on the average results of IL-1 beta concentrations was observed (P = 0.44, the Mann-Whitney test). The rest results were not significant. In celiac group the serum concentration of claudin and ocludin was lower (P = 0.018) as well as positive correlation between IL-1beta and LF/HF was demonstrated (r = 0.51, P = 0.032). Statistically significant, positive and strong correlation of IL-1 beta concentration and DP (Dominant Power of EGG) (r = 0.58, P = 0.038) was shown.

Conclusion: ANS activity measured by EGG and HRV seems to be correlated to presence of IL-1beta. In celiac group the serum concentration of claudin and ocludin concentration in serum is negatively associated with the presence of IL-1beta. In patients without neurological symptoms were tested for occludin, claudin, IL-1beta concentrations in serum in neurologically asymptomatic patients with CD and it’s correlation with selected parameters of ANS activity markers (heart rate variability, electrogastrography HRV) and gastric myoelectric activity (EGG).

Introduction: Small bowel villous atrophy (VA) is mainly related to coeliac disease (CD), but that develops in HLA-DQ2/DQ8 positive patients and improves on a gluten-free diet. Other forms of VA unrelated to CD are common variable immune-deficiency, autoimmune enteropathy, small bowel malignancies, medication-related enteropathies, HIV, tropical sprue, and giardiasis [1–3]. However, there are also forms of VA in which CD can be neither confirmed nor excluded and there are forms of VA in which, although CD is excluded, a definitive diagnosis cannot be made. Some years ago, we coined the terms undefined sprue (US) and non-coeliac refractory sprue (NCRS) to define these two
P1279 SYSTEMATIC REVIEW OF THE ECONOMIC BURDEN OF COELIAC DISEASE

Introduction: The prevalence of diagnosed coeliac disease (CD) has rapidly increased, and developed countries have seen increases in the last 30 years. The economic burden of diagnosing, managing, and monitoring CD can be substantial but is poorly understood. To assess the economic burden of CD, we systematically reviewed current evidence quantifying economic costs and health resource utilization (HRU) for CD in North America and Europe.

Aims & Methods: Searches of Medline, Embase, EconLit, the Cochrane Library, and conference abstracts systematically identified literature published in English during the last 10 years assessing direct and indirect costs, cost-effectiveness and cost-utility. We conducted an economic evaluation using a Cochrane Review.

Results: Of 33 studies meeting criteria for inclusion, most (20) were from Europe, and most (18) reported or modeled costs associated with screening and diagnosis. Cost per positive CD diagnosis of screening patients already undergoing upper gastrointestinal biopsy for other indications, such as anaemia or irritable bowel syndrome, ranged from approximately $1,300 in Canada to more than $44,000 in the Netherlands (costing year not reported). In these populations, screening was judged to be cost-effective with various strategies combining diagnostic modalities, including serology then biopsy, compared to no screening. Strategies using either endoscopy/biopsy or serology alone were not considered cost-effective. Direct annual excess costs to a US payer per diagnosed CD patient were estimated at $US 203 (SUS 2007) to the US $827 (SUS 2013) per year for US$2007 inflation year. There was no difference in specific medications; case 6 (M, 69) is still alive but could be affected by a form of enteropathy due to celiac disease. He is in good clinical condition and has been refusing follow-up. The last patient, case 7 (M, 29) is DQ7-7. Positive He is still alive 11 years after the diagnosis of VA, although complains of diarrhea.

Conclusion: We described 7 patients with VA unrelated to CD or other known enteropathies. Although overall mortality among them is very high (57%) and mainly due to lymphoproliferative disorders, of the 4 DQ2/DQ8 negative patients are alive many years after the diagnosis of VA with no evidence of malignancy. This suggests that these 7 patients are not affected by the same condition. We speculate that DQ2 positive patients who died of lymphoma could be affected by a form of CD which escaped diagnosis get complicated. However, we feel that the DQ2/8 negative patients with long survival are affected by a still unidentified form of VA.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
the severe grade of HS was more frequently observed in GG carriers. It was postulated that this may indicate PNPLA3 G and GG carriers with CD have higher susceptibility to hepatic steatosis, but not to metabolic syndrome. Moreover, patients with GG alleles display a more relevant disease in terms of severity of HS based on US evaluation.

Introduction: Parenteral support (PS) volume needs vary depending on disease severity in patients with intestinal failure associated with short bowel syndrome (SBS-IHF). Patient classification has focused on the diarrhoea that led to resection and the remnant bowel anatomy.

Aims: Methods: Recent, the idea that grading severity of SBS-IHF is based on magnitude of PS volume needs led to this clinical trial data post hoc analysis of patients with SBS-IHF based on their baseline PS volume. STEPS (NCT00798967; EudraCT2008-006193-15) was a 24-week, placebo-controlled study of teduglutide (TED) in patients with intestinal failure associated with short bowel syndrome (SBS-IHF). STEPS (NCT00798967; EudraCT2008-006193-15) was a 24-week, placebo-controlled study of teduglutide (TED) in patients with intestinal failure associated with short bowel syndrome (SBS-IHF).

Results: The predominant diagnosis leading to SBS-IHF in group I (12/28; 43%) and group II (15/41; 37%) was vascular gut complications; in group III (8/16; 50%), Crohn’s disease. Baseline PS volume and TED-induced volume reduction (% change) at Week 24 was highest in Group III (Table). Evaluation of individual patient response showed a close, linear, and significant correlation between absolute PS volume reduction at Week 24 in relation to TED treatment and daily PS volume at baseline (y = -0.387x + 90.03, R² = 0.61; P < 0.0001); no significant correlation was observed in the placebo group (y = 0.06x+220.15, R² = 0.02;

P = 0.36). Adverse events were reported by 93% (Group I), 80% (Group II), and 71% (Group III) of TED patients.

Introduction: Prevalence rates of Functional Dyspepsia (FD) in East Asia are three times higher than Irritable Bowel Syndrome (IBS) rates. Many researchers have suggested that IBS subjects in the region experience their pain and discomfort in the upper abdomen, leading to misdiagnosis as FD.

Aims & Methods: We aimed to compare patterns of gastrointestinal (GI) symptoms in the Chinese population with FD or IBS during provocative hydrogen breath testing (HBT) with lactulose, lactose and fructose. Subjects fulfilling the ROME III classification of FD and IBS, and control subjects with no known gastrointestinal symptoms were recruited. All subjects underwent HBT +/- methane absorption testing (10 ml), lactulose (25 g) and fructose (25 g). Subsequent breath tests were performed after a washout period of at least one week. Breath tests were performed after an overnight fast, with the patient sedentary. Breath samples taken every 15 minutes for 3 h. GI symptoms were recorded during these 3 h and used for telephone follow-up 24 hours later.

Results: A total of 353 subjects completed at least one breath test examination and 313 subjects completed all three breath tests. 16%, 55% and 29% were control, FD and IBS subjects, respectively. All subjects were ethnic Chinese, the mean age was 53 (Range; 18-76) years, and 27% (95% CI; 23–32%) were male. 85% (95% CI; 82–89%) of subjects were hydrogen-producers and 100% methane-producers. Symptoms were induced in a relatively low proportion of healthy controls. Both FD and IBS subjects experienced similar proportions of epigastric pain on consumption of lactulose, lactose and fructose. See Table 1. Subjects with FD experience more belching than subjects with IBS when lactulose (58 vs. 42%, p = 0.011) and lactose (62 vs. 46%, p = 0.014) were ingested, respectively. Subjects with IBS experience significantly more “lower GI” symptoms of abdominal pain and development of loose stools when lactulose was ingested when compared with subjects with FD. In general, subjects with IBS experienced both epigastric pain and abdominal pain when any of the three carbohydrate solutions were ingested. Healthy controls experienced minimal symptoms.

Conclusion: Chinese subjects commonly co-produced hydrogen and methane. Ingestion of poorly absorbed sugars induces symptom patterns in patients with FD in similar proportions. Chinese IBS subjects commonly experienced epigastric and abdominal pain. Reducing poorly absorbed short-chain carbohydrates (FODMAPs) might be efficacious in FD as it is in IBS.

Introduction: Inflammatory bowel disease (IBD) and mesenteric vascular (Vasc) disease are underlying conditions for intestinal failure associated with short bowel syndrome (SBS-IF). Fluid balance, urine production, and parenteral support (PS) volume are variable among patients with SBS-IF.

Aims & Methods: This is a post hoc analysis of the impact of teduglutide (TED) on fluid composite effect (FCE = sum of urine volume output increase, oral fluid intake reduction, and PS volume reduction) in patients stratified by diagnosis. STEPS (NCT00798967; EudraCT2008-006193-15) was a 24-week, placebo-controlled study of TED 0.05 mg/kg/day in patients with SBS-IF. Three groups were evaluated: SBS-IBD, SBS-Vasc, and Other.

Results: The SBS-IBD group included more patients with stoma (95%; SBS-Vasc, 19%; Other, 41%) and fewer with colon-in-continuity (11%; SBS-Vasc, 78%; Other, 62%). At Week 24 (Table), PS volume reductions were significantly higher in SBS-IBD patients treated with TED vs placebo (P < 0.02) and vs TED patients in the SBS-Vasc (P < 0.04) and Other (P < 0.02) groups. Change in FCE was greater in SBS-IBD patients treated with TED vs placebo (P < 0.02) and vs TED patients in the SBS-Vasc (P < 0.01) and Other (P < 0.05) groups.

were evaluated: Group 1 (no colon/stoma present/no colon-in-continuity), Group 2 (≥50% colon/stoma to colon-in-continuity), and Group 3 (other bowel anatomies). Clinical response was defined as ≥20% reduction from baseline in weekly parenteral support (PS) volume at Weeks 20–24. Data presented as mean (SD).

Results: The predominant diagnosis in Group 1 was Crohn’s disease, whereas the predominant diagnosis in Group 2 was vascular complications (Table 1). Group 1 patients required the highest baseline PS volumes compared with Group 2 or Group 3. TED-induced PS volume reduction (change in L/week) took longer to be realised in Group 2 (Week 12, –3.9 [1.2]; Week 24, –2.5 [2.1]) compared with Group 1 (Week 12, –5.5 [3.8]; Week 24, –6.4 [4.5] or Group 3 (Week 12, –2.7 [1.2]; Week 24, –5.1 [3.7]). Response rates were higher with TED versus placebo in all groups, but the difference was significant only in Group 1 (76% vs 19%, P = 0.001; Group 2, 56% vs 40%, P = 0.36; Group 3, 57% vs 29%, P = 0.033). Adverse events were reported by 94%, 72%, and 86% of Group 1, Group 2, and Group 3 patients receiving TED, respectively.

Conclusion: Superficial SNADETs demonstrate gene expression characteristics with a strong resemblance to colorectal adenomas. Gene expression pattern of these lesions has also demonstrated the significant role of APC down-regulation in the pathogenesis of SNADETs, suggesting that an adenoma-carcinoma sequence similar to colorectal adenomas may be seen in SNADETs. Further analysis is needed to identify markers which may play a key role in the carcinogenesis of these neoplasms is required.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: We established a new imaging technique, 3D computed tomographic enteroclysis (CT enteroclysis), to explore the small bowel (1). In our hospital, this examination is performed routinely to detect gross lesions in the small intestine. In our study, we analysed the clinical performance of 3D CT enteroclysis to evaluate its safety, feasibility, and usefulness for small intestinal neoplasms.

Aims & Methods: Data on 3D CT enteroclysis performed in our hospital from January 2010 to March 2017 were reviewed. In 3D CT enteroclysis, the small bowel was inflated with air using a nasoduodenal tube, CT images were taken, and then 3D overviews, virtual endoscopy views, and virtual dissection views were generated using a virtual colonoscopy system. Total volume of injected air, intraintestinal pressure, and length of the depicted small bowel were recorded. The images of small intestinal neoplasms were collected and compared with the whole small bowel.

Results: One-hundred thirty 3D CT enteroclysis were performed for 93 males and 46 females. The mean age was 49.2 ± 17.8 years. Examinations were performed for definite/suspected Crohn’s disease in 55, intestinal obstruction in 34, and other gastrointestinal neoplasms in 25. The mean total volume of injected air was 1872 ± 526 mL, the mean maximum intraintestinal pressure was 2.7 ± 0.8 kPa, the mean length of the depicted small bowel was 307 ± 102 cm, and whole small bowel tracing was achieved in 71.4% of these 77 examinations. Twenty small intestinal neoplasms were depicted in 4 cases of submucosal tumours, 3 cases of gastrointestinal stromal tumours (GISTs), 3 cases of neuroendocrine tumours, 2 cases of cancers, 2 cases of lipomas, 2 cases of malignant lymphomas, 3 cases of metastatic cancer, 1 case of Peutz-Jeghers syndrome, 1 case of Peutz-Jeghers type polyposis, and 1 case of pyogenic liver abscess. Surgery was performed for 12 cases. The total length of the small intestine and estimated location of the lesion by 3D CT enteroclysis were comparable to intraoperative findings in 9 cases (no measurement in 3 cases). In a case of multiple GISTs, some of the lesions of 6–8 mm in size were missed and no lesion smaller than 4 mm was depicted.

Conclusion: 3D CT enteroclysis can be performed safely, and the whole small bowel could be examined in most cases. 3D CT enteroclysis can depict stenosis and lesions bigger than 1 cm, measure the length of the small intestine, measure the mechanism behind the pathogenesis and carcinogenesis of these neoplasms is still poorly understood. However, with the overall increase of small bowel cancer in recent years, there is an increasing need to clarify the morphology of SNADETs. This study was conducted with the objective of identifying genetic markers and pathways specific to superficial SNADETs through gene-expression profiling.
the size and locate the position of the lesions, and present objective information for planning of small intestinal surgery. Therefore, 3D CT enterolysis is a powerful new tool for diagnosis, pre-surgical evaluation, and follow-up for small intestinal neoplasms.

Introduction: Bariatric surgery is an effective treatment for morbid obesity. In Taiwan, the numbers of patients who received bariatric surgery increased gradually. However, for long-term follow-up, nutritional deficiency may develop in post-bariatric (metabolic) surgery patients, especially in patients who received mal-absorptive or combination procedure. Deficiency of nutrition may cause anemia, peripheral neuropathy, secondary parathyroidism and osteopenosis. Follow-up of the nutritional status for patients after bariatric surgery is an important issue.

Aims & Methods: The aim of our study is to evaluate the change of Vitamin D and bone Mineral Density after bariatric surgery in Chinese population. This prospective cohort study included 50 patients (ranged from 20 to 65 years old) who received bariatric surgery at one teaching hospital in Taoyuan, Taiwan. Patient with osteoporosis before surgery were excluded in this study. Baseline (2012-2014) and one year after bariatric surgery (2013-2015), venous blood was collected from each patients for assessment of the Calcium, Vitamin D and parathyroid hormone (PTH) levels. BMD (g/cm²) was also measured at lumbar spine (L2-L4) by dual energy x-ray absorptiometry (DEXA).

Results: Among 50 patients, 15 patients received laparoscopic sleeve gastrectomy, 24 patients received laparoscopic mini-gastric bypass (MGB), 5 patients received laparoscopic Roux-en-Y gastric bypass (RYGB) and 6 patients received laparoscopic duodenoo-jejuno bypass with sleeve gastrectomy (DJB-SG). The characteristic of the study population was shown as table 1. The differences of mean for calcium, vitamin D, PTH and BMD after bariatric surgery were –0.16 mg/dl (P = 0.03), 4.2 ng/ml (P < 0.01), 8.6 pg/ml (P = 0.06) and –0.04 g/cm² (P = 0.14) respectively.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: One year after bariatric surgery, the prevalence of osteoporosis and osteopenia was low. The serum Vitamin D level increased significantly but no significant change of BMD was noted. Further longitudinal studies are warranted to clarify the long-term effect of bariatric surgery on BMD in Chinese population.
Introduction: The intragastric balloon has been used for more than 20 years in Brazil. As an endoscopic device for assisted weight loss, and some intercurrent events were observed during more than 10,000 procedures performed. With the assistance of a multidisciplinary team the results have been satisfactory.

Aims & Methods: To assess the efficacy and complications of the weight loss with IGB in patients seen at the 07 private centers. A total of 10,255 patients with IGB implanted from 1997 to 2017 were analyzed from a prospective fed database. A liquid filled IGB with a volume in-between 620 to 700 ml was used. Initial BMI started at 27 kg/m² (as approved by Brazilian health authorities) and were followed up by a multidisciplinary team during implant. IGB maximum periton implant was 09 months. Statistical analysis was performed according to sex and degree of excess weight (overweight and grade I, II and III). Data were assessed using Student t-test, and a Tukey post-test. The level of significance was set at p < 0.05.

Results: 492 patients (4.8%) were excluded from the final analysis associated with weight loss: 226 (2.2%) due to early removal. These were analyzed in relation to the psychoendocrine consultation with psychologist and 94% of them did not make a psychological evaluation before the procedure, 158 (1.54%) due fail on weight loss or weight gain–These were analyzed in relation to follow-up with nutritionist and 58% did not undergo nutritional monitoring during the use of IGB, 108 (1.06%) due lack of data (n/a). A total of 750 patients (7.30%) followed up for complete data. There were also spontaneous hyperinflation on 0.99% (n = 101) and balloon spontaneous deflation or leakage in 0.82% (n = 84).

Incidence of complications not leading to removal were 6.65% (n = 101) and balloon spontaneous deflation or leakage in 0.82% (n = 84). The mean age was 31.13 years. The patients showed a significant weight loss, with a significant weight loss (average weight loss 14.82 kg) between the first and last APC follow-up 11.79 mm (±3.89). The average weight loss between the first and last APC was 13.37 kg (±7.82) and the average decrease of BMI was 4.59 kg/m² (±2.78). 122 patients (22.02%) did not achieve the target BMI and 05 patient (0.90%) did not lose weight even with the desired BMI. From the 146 patients (24.66%) followed up for 12 months. The weight loss was less than half of the weight loss. Of the 554 patients, 51 (9.2%) required dilatation balloon due to significant stenosis at least once. No further complications were reported.

Conclusion: Argon Plasma Coagulation (APC) has been shown to be an effective and safe endoscopic technique for the reduction of gastro entéric anastomosis in patients undergoing bariatric surgery who have regained weight with dilatation of the anastomosis. The reintroduction of the patient to the multidisciplinary team is not exclusive, and in cases of weight regain and loss toוב נבשה. A psychological and/or psychiatric evaluation is mandatory, as well as nutritional therapy and encouragement of physical activity. The monitoring of food intake and body weight, closer follow-up of the operated patients, appropriate choice of technique according to the patient and the experience of the surgeon, and a good learning curve are all factors that can reduce the failure rate of bariatric surgery. The reintroduction of the patient to the multidisciplinary team is mandatory if better results and sustainable weight loss and comorbidity control are to be obtained.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1301 WEIGHT REGAIN AFTER BARIATURE SURGERY - ARGON PLASMA COAGULATION FOR GASTROJEJUNAL ANASTOMOSIS DECREASE

B. Q. Sander1, D. S. Paiva1, M. P. Sander1, M. Galvao Neto2, G. Baretta1, E. Grecco3, T. F. Souza1, J. I. B.Scarparo

Introduction: The weight regained has been a described growing problem in patients after bariatric surgery. This weight regain is multifactorial and is associated with dilatation of Gastrojejunostomy (GJ). For the patients with significant weight regain some revisional procedures had been attempted and more recently endoscopic revisional procedures had been described.

Aims & Methods: To evaluate the safety and effectiveness of argon plasma coagulation (APC) decreasing the diameter of the gastroenteric anastomosis in patients who have undergone RYGB for morbid obesity and regained weight associated to dilatation of the GJ. From Jan-2014 to April-2017 554 RYGB subjects with weight regain a dilated anastomosis (>18 mm) and at least 2 endoscopic procedures were submitted APC application. In relation to the anastomotic diameter, the majority of studies use a diameter of more than 20 mm to define anastomosis dilatation, although some studies use smaller diameters such as 12mm similar to that created manually in the gastrojejunal anastomosis using a 36 Fr Fouchet bougie. In the patients in the present study, the minimum cross-section diameter was 18 mm and the maximum measured in the first session 40 mm. This anastomotic diameter was measured using a 33 mm long bougie entered between an endoscopic channel and a bougie with a maximum of 03 applications. APC set was at 2-3Lm with 65-85W. GJ diameter target was 8-12 mm estimated with pre-measured grasper. At first APC session, pre-op weight and BMI, post-op weight nadir, actual weight and BMI and estimated diameter of GJ were the variables collected. Complications during treatment were also collected. In the present study, psychological and nutritional evaluations were performed before APC and during treatment and physical activity was strongly recommended. Data were analyzed with descriptive statistics, student’s t test and Spearman correlation.

Results: Of the 554 patients, 79.06% were women and 20.94% were men. Average time between bariatric surgery and the first APC was 96.35 months (±31.27). Initial and average weight prior to this interval was 22.08 kg (±11.05). The mean diameter of the anastomosis was 24.78 mm (±6.04) and the average number of APC sessions was 1.78 times (±0.61). The average reduction of anastomotic diameter was 14.86 mm (±7.24) and the final average diameter was 10.84 mm (±3.98). Weight regain and weight loss between the first and last APC was 13.37 kg (±7.82) and the average decrease of BMI was 4.59 kg/m² (±2.78). 122 patients (22.02%) did not achieve the target GJ diameter and 05 patient (0.90%) did not lose weight even with the desired GJ diameter. From the 146 patients (24.66%) followed up for 12 months. The weight loss was less than half of the weight loss. Of the 554 patients APC, 51 (9.2%) required dilatation balloon due to significant stenosis at least once. No further complications were reported.

Conclusion: Argon Plasma Coagulation (APC) has been shown to be an effective and safe endoscopic technique for the reduction of gastro entéric anastomosis in patients undergoing bariatric surgery who have regained weight with dilatation of the anastomosis. The reintroduction of the patient to the multidisciplinary team is mandatory if better results and sustainable weight loss and comorbidity control are to be obtained.

Introduction: With the aging of the population, the incidence of obesity has also increased among the elderly. However, there is a higher incidence of severe comorbidities in this population comparing to adults, which often makes bariatric surgery unfeasible. In this segment, treatment with the intragastric balloon (IGB) may be an interesting option.

Aims & Methods: We aimed to assess the efficacy and complications of obesity treatment in the elderly using a non adjustable IGB. A total of 77 patients were analyzed. The minimal initial body mass index (BMI) was 28 kg/m². The level of significance was set at p < 0.05.

Results: 58 patients were women (73.3%). Mean age was 64.26 (60–80) years. Ten patients had no comorbidities, 52 had hypertension, 45 had dyslipidemia, 32 had insulin resistance, 12 had type II diabetes, and 10 had ischemic heart disease. There was no major complications. Results are shown on table 1. The treatment success rates according to the following criteria: ≥10% total body weight loss (TBWL) and ≥25% excess weight loss (EWL) were 96.11% (74 patients) and 96.11% (74 patients)
98.7% (76 patients) respectively. 30 patients reached a normal body mass index (BMI) (23–25kg/m²) according to the Pan American Health Organization (PAHO). Elderly shows a higher BMI reduction (p=0.0002) and %TBWL (p=0.0003) than adults.

Introduction: Non-coeliac gluten sensitivity (NCGS) is a new entity with unknown prevalence and mechanisms, and there is a need for a standardized procedure to confirm the diagnosis. The objective of this study was to characterize the response to a gluten challenge, when performed according to the updated Salerno criteria.

Aims & Methods: Twenty patients (14F/6M, age range: 21–62 y) with suspected NCGS, without coeliac disease and wheat allergy, were included while on a gluten-free diet. All patients went through four periods of double-blind provoked with gluten and placebo containing muffins. They were instructed to eat two muffins a day (11 g gluten) for four days, followed by a three days' wash-out. Gastrointestinal symptoms were recorded with questionnaires at baseline and after each provocation, while fatigue and quality of life were registered at baseline and end of the trial.

Results: Four out of twenty patients (20%) correctly identified the two periods when they received muffins containing gluten, hence were diagnosed with NCGS. The diagnosed group tended to show higher symptom scores than the not-diagnosed group both at baseline, after gluten exposure and after placebo, but no clear difference was seen in symptom change after provocation with gluten and placebo. The not-diagnosed group showed more severe symptoms with placebo than with gluten (p=0.002). Symptom severity at baseline was significantly correlated with fatigue (r=0.63, p=0.003) and reduced quality of life (r=-0.76, p=0.0001).

Conclusion: This randomized, double-blind placebo-controlled challenge with gluten diagnosed four patients with NCGS according to the Salerno criteria. However, according to the symptom registrations there are no clear difference between the diagnosed and the not-diagnosed group, or between symptoms after gluten provocation and placebo, indicating no specific effect of gluten in a group of patients with suspected NCGS.

PI308 LOW FODMAP DIET: REINTRODUCTION PHASE DOES NOT MODIFY EFFICACY, BUT BEWARE OF REAL TRIGGER FOODS!

M. Bellini1, A. Rossi2, D. Gambaccini3, D. Menicucci4, L. Bazzichi5, B. Faní4, R. Sellitti6, M.G. Mumolo7, N. De Bortoli8, L. Ceccarelli9, M. Mosca2, S. Murè1

Introduction: The low-FODMAP diet (LFD) is used to treat patients with irritable bowel syndrome (IBS) even if some nutritional concerns have been raised. It starts with an elimination phase and is followed by a reintroduction phase to clearly detect the “symptom trigger” foods in order to suggest a definitive and less restrictive diet tailored to the patient.

Aims & Methods: The aims of this study were to evaluate: 1) the effects of FODMAP reintroduction on a) body composition and nutritional status, using Bioelectrical Impedance Vector Analyses (BIVA), b) abdominal symptoms, c) quality of life, d) anxiety/depression, e) sleep quality. 2) if the patients’ perception of the “trigger” foods was accurate.

Results: 66 IBS patients (54F, 12 M; 44.8 ± 13.0 yrs.) started (T0) a LFD for 8 weeks (T1) and followed a 9-14 week reintroduction period (T2). They underwent blood tests at T0 and T1. BIVA, anthropometric data, BIVA-Symptom Severity Score, Bristol Stool Chart (BSC), SF36, Hospital Anxiety and Depression Scale and Pittsburgh Sleep Quality Index were performed at T0, T1 and T2. The patients were monitored by a nutritionist to verify their compliance.

Results: Neither change of blood tests at T1 nor variations of anthropometric data and BIVA were reported at T1 and T2 in comparison with T0. A significant improvement in abdominal symptoms (IBS-SSS), anxiety and quality of life, was recorded at T1, this remaining unchanged also at T2 (p < 0.0001). Depression improved at T2 (p < 0.01 vs. T0). Sleep quality improved at T1 (p < 0.05 vs. T0) and at T2 (p < 0.001 vs.T0). Normal BSC facets were reported by 38 patients at T0 to 60 patients both at T1 and T2. The degree of symptom relief with the diet was 1.5 ± 0.6 at T1 and 1.6 ± 0.7 at T2 and the degree of satisfaction was high
both at T1 (8.4 ± 1.6) and T2 (8.2 ± 1.7). When starting, LFD patients considered as having overt FODMAPs (67%), fructans (27%), fructose (17%), galacto-oligosaccharides (GOS) (17%) and polyols (3%); the reintroduction phase (T2) enabled us to detect lactose in 70%, fructans in 30%, fructose in 37%, GOS in 33% and polyols in 27%, as real triggers. The agreement (Cohen’s kappa) was moderate for lactose (κ = 0.50), fair for fructans (κ = 0.39) and fructose (κ = 0.32) and poor for polyols (κ = 0.16) and GOS (κ = 0.01).

Conclusion: Not only did reintroduction not affect the improvements achieved during the elimination phase, but it also precisely identified the foods responsible for FM symptoms. This enabled us to suggest a personalized diet for the patients. The real role played by FODMAPs in generating symptoms was abundantly underestimated and misunderstood by our patients. This underlines the fact that LFD has to be administered and carried out under the guidance of an expert nutritionist.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1306 EXPRESSION OF THE FRUCTOSE TRANSPORTER GLUT5 IN PATIENTS WITH FRUCTOSE MALABSORPTION
P. Staubach1, S. Kräger1, A. K. Koch1, J. Langhorski1, C. Röcken2, U. Helwig1

Introduction: Fructose malabsorption (FM) is a frequent finding in patients with alimentary and high levels of FM in Western diets. The role of monosaccharide transporter dysfunction in the small intestine is incompletely understood. The aim of this study was to investigate the histoanatomical distribution of the main fructose transporter GLUT5

Aims & Methods: The study included 257 patients with FM diagnosed by hydrogen breath test and grouped according to the response to a fructose-free diet. 42 healthy individuals and 31 patients with coeliac disease (CD) served as controls. The fructose breath test was done with 50 g fructose. Fructose malabsorption was defined as an increase of 20 ppm of endogenous hydrogen. Formalin-fixed and paraffin-embedded duodenal biopsy specimens were obtained in all cases. Histology was assessed using hematoxylin and eosin stained tissue sections. Expression of GLUT5 was studied by immunohistochemistry. Expression pattern of GLUT5 was correlated with clinical and pathological patient characteristics.

Results: The expression of GLUT5 did not differ significantly between patients with FM complete diet responders (n = 183) and healthy controls (n = 42). Also patients with FM responding to a fructose free diet did not differ in GLUT5 expression or in max. H2 increase and AUC measured in fructose breath testing from patients not responding to the diet (n = 40). However, in patients with CD (n = 29) significant differences in GLUT5 expression were found compared to patients with FM and healthy controls (p = 0.009). The severity of CD assessed by the Marsh score significantly correlated with the GLUT5 expression (r = 0.563, p = 0.001)

Conclusion: Changes in GLUT5 expression may not cause symptoms in adult patients with FM. The symptoms induced by FM could be associated with mechanisms known to the pathogenesis of the fructose bowel syndrome. However, in secondary malabsorption decreased GLUT5 expression was detected. Further investigation is needed to understand the essential factors in FM and the influence on functional gastrointestinal disorders.

P1307 BETTER RESPONSE TO LOW FODMAP DIET IN JH NEGATIVE PATIENTS WITH DISORDERS OF GUT-BRAIN INTERACTION
V. Schindler1, A. Zweig1, A. Becker2, J. Zeitl1, D. Rungaldier1, M. Fried1, D. Pohl1

1Gastroenterology And Hepatology, University of Zurich, Zurich, Switzerland
2UniversitätsSpital Zürich, Zürich/Switzerland

Introduction: Previous studies have shown a reduction of gastrointestinal symptoms in patients with disorders of gut-brain interaction (FGID) when following a diet low in FODMAPs. Symptom relief due to a low FODMAP diet has especially been investigated in patients suffering from irritable bowel syndrome (IBS) and has proven to reduce gastrointestinal symptoms in up to 86% of patients with IBS. In addition, there is evidence for an association between gastrointestinal symptoms and joint hypermobility (JH). However, there is no clear data regarding response rates to a diet low in FODMAPs in patients suffering from JH. In this study we aimed to assess and compare the response to a diet low in FODMAPs in JH positive and JH negative patients with FGIDs.

Aims & Methods: Data of patients presenting with FGID at the tertiary ambulatory functional bowel clinic between January 2015 and July 2016 were analyzed. FGIDs were diagnosed according to Rome III criteria. JH was assessed by physicians using Brighton score and rated positive for scores ≥ 4/9 points. Patients received professional nutritional counseling on a diet low in FODMAPs. A global symptom response was assessed by a professional nutritionist after 4 to 6 weeks following a low FODMAP diet.

Results: Of all 84 patients screened for JH, 62 (73.8%) were female and 22 (26.2%) were male. Median age was 35 (range 18-77) years. Females were more likely to exhibit JH compared to males (38.62 [61.3%] vs. 6.22 [27.3%]; p = 0.006). Global symptom response rate to a diet low in FODMAPs was 64/84 (76.2%). Our data showed significantly better response to a low FODMAP diet in JH negative patients than in JH positive patients (36/40 [90.0%] vs. 28/44 [63.6%, p = 0.005, ITT). Response of 7 patients was unknown because of early therapy discontinuation before nutritional re-counseling. When excluding 7 patients with therapy discontinuation from our calculations, the difference in diet response between JH negative and JH positive patients remained significant (36.39 [92.3%] vs. 28/38 [73.7%]; p = 0.036).

Conclusion: Our data indicate an association between global symptom response to a diet low in FODMAPs and joint hypermobility status in FGID patients. An underlying structural pathology or different pathophysiological factors (small intestinal permeability) causing gastrointestinal symptoms in JH positive patients and limiting response to low FODMAP diet should be considered. Our findings represent a further step towards pathophysiological features in FGIDs and might help to select patients for individually appropriate therapies.

P1308 CHANGES IN GASTROINTESTINAL SYMPTOMS, SMALL INTESTINAL BACTERIA, AND DUODENAL PHYSIOLOGY FOLLOWING A LOW-FIBER, HIGH-SUGAR DIET
G. Saffouri1, B. Schmidt1, E. J. Battaglioli1, Y. Bhattachar1, J. Cho2, H. Lekatz3, J. P. Schimpf4, G. Farrugia1

1Gastroenterology And Hepatology, Mayo Clinic, Rochester/United States of America/Minnesota
2Gastroenterology And Hematology, Mayo Clinic, Rochester/United States of America/Minnesota

Introduction: Gut dysbiosis and gut-brain axis dysregulation are often associated with dietary intolerances and are common in the developed world consuming a western diet low in fiber. Aims & Methods: To determine the effect of a high-sugar, low-fiber diet on GI bacterial composition and duodenal physiology, we conducted a single-center study. Healthy adults with baseline fiber intake ≥14 g/1000 calories/day, < 10% daily calories from added sugar; ≥ 5 servings of fruits and vegetables/day; and ≥13% daily calories from saturated fat were recruited. Exclusion criteria included known GI disease or symptoms, antibiotic/probiotic use within 4 weeks of the study, pregnancy, and vulnerable adults. At baseline visit, participants completed a symptom and demographic questionnaire and underwent esophagogastroduodenoscopy (EGDY) with duodenal biopsies and aspirates. Symptoms associated with constipation, straining, incomplete evacuation, hard stools, abdominal pain associated with bowel movements, diarrhea, bloating, nausea/vomiting, heartburn, fatigue, and appetite. All participants consumed a 7-day standardized diet with typical United States fiber intake (14 g/1000 calories/day; 15% carbohydrate; 35% fat; 5% protein). The diet was low in fiber (< 10 g/1000 calories/day) and high in simple sugar (≥50% daily carbohydrates). After dietary intervention, participants filled out four symptom questionnaires and underwent repeat EGDY with duodenal biopsies and aspirates. Before and after the diet, quantitative aerobic and anaerobic cultures were performed on duodenal aspirates. Duodenal biopsies were mounted in an using chamber. Intestinal permeability was evaluated using transepithelial electrical resistance (TEER) and FITC flux (4KDa; a measure of paracellular transport). Secretory responses were quantified in voltage clamp mode by measuring baseline short circuit current (Isc) and change in Isc (AS) in response to increasing concentrations (0.003-300 μM) of serotonin (5-HT) on the submucosal side. These measurements were repeated after the dietary intervention. Data are presented as mean ±SEM. Data were analyzed using paired-t test unless specified and p < 0.05 was considered significant.

Results: A total of 10 participants (5 female; median age 26; 70% Caucasian) were recruited. Average BMI was 23.1 kg/m2. At baseline, all participants were asymptomatic. After dietary intervention, all patients endorsed at least one new symptom and 9/10 participants endorsed multiple (≥2) new symptoms. At baseline 4/10 participants had positive duodenal cultures (> 100,000 CFU/mL, anaerobic) despite having no symptoms. Of the 6 who had no growth initially, I developed bacterial overgrowth following intervention. There was no significant difference in TEER (26.45 ± 1.98 vs 26.18 ± 2.45 Ohms/cm2), FITC flux (217 ± 34.72 vs 217.6 ± 42.57 ng/ml) or baseline Isc (48.27 ± 63.9 vs 51.58 ± 82.27 Ωcm2) before and after dietary intervention. Interestingly there was a significantly lower AS response to increasing concentrations of 5-HT after dietary intervention (P < 0.05, two-way ANOVA).

Conclusion: A low-fiber, high simple sugar diet led to gastrointestinal symptoms in 10/10 participants who normally had an ileum feeding model. This resulted in a significant decrease in 5-HT evoked secretory response in the duodenum, suggesting a potential role for dietary modulation of host serotoninergic pathway. There was no correlation with quantitative bacterial cultures and there was no overall significant change in intestinal permeability. Diet may mediate these
P1309 STRESS AND STRESS-RELATED PEPTIDE AMPLIFY THE ANOREXIC ACTIONS OF CHOLECYSTOKININ
Gastroenterology And Hepatology, Saitama medical University, kawagoe/Japan

Introduction: Recently roles of gut hormones on appetite control have been known. Among them, CCK is well known to suppress appetite and gastric motility. On the other hand, patients of functional dyspepsia (FD) have hyper sensitivity to CCK. And releas of CCK inbrad was shown to be high in FD patients. In FD patients, stress have important roles of pathogenesis of the disease.

Aims & Methods: We undertook to clarify whether stress influences the actions of cholecystokinin (CCK) on appetite and gastric emptying. As stress, we gave restraint stress, corticosterone-releasing factor (CRF) or urocortin (UCN1) injection intraperitoneally (IP). We also examined the effects of CCK and restraint stress on c-Fos expression in the neurons of appetite center of the brain. In the gastric emptying study, SD rats were fasted overnight. The amounts of the mixture (food and glass beads) left in the stomach were measured at 2 hours after the perorally injected mixed food, and gastric emptying rate was calculated. In the study on appetite, CCK was IP injected and the amounts of food was measured at 1 and 2 hours after the injection. In some experiments, CRF or UCN1 was IP injected and the interaction with CCK on food intake was examined. In another study, restraint stress was given to rats and the interaction with CCK was evaluated. To study the involvement of brain in the interaction between CCK and stress, c-Fos expression in the neurons was examined and evaluated.

Results: CCK dose-dependently inhibited gastric emptying. CCK dose-dependently inhibited food intake during 1 hr and 2 hr. CRF (100g/kg rat) significantly inhibited food intake. However, there was no interactive action between CCK and CRF on food intake. UCN1 (3 nmol/kg rat) inhibited food intake at 1 and 2 hours. There was an synergistic action between CCK and UCN1 on food intake. Restraint stress amplified suppressive effect of CCK on gastric emptying and food intake. C-Fos expression of the neurons in the nucleus of solitary tract (NTS) and paraventricular nucleus of hypothalamus (PVN) by CCK was amplified by the addition of restraint stress.

Conclusion: The result suggests that stress might amplify anorexic effects of CCK through the activation of satiety center of the brain that might be the possible pathogenesis for postprandial distress syndromes of FD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1310 PEPTIDE TYROSINE-TYROSINE (PYY) ENHANCES EFFECTS OF CHOLECYSTOKININ (CCK) ON GASTRIC MOTILITY AND FOOD INTAKE IN RATS
Gastroenterology And Hepatology, Saitama medical University, Kawagoe/Japan

Contact Email Address: hosomi@saitama-med.ac.jp

Introduction: Cholecystokinin (CCK) and peptide tyrosine-tyrosine (PYY) have been known to suppress appetite and gastric motility. Both peptides raise in serum in response to food intake and their levels increase following dietary restraint stress, inducing satiation to finish food intake.

Aims & Methods: We undertook to clarify whether stress influences the actions of cholecystokinin (CCK) on appetite and gastric emptying. As stress, we gave restraint stress, corticosterone-releasing factor (CRF) or urocortin (UCN1) injection intraperitoneally (IP). We also examined the effects of CCK and restraint stress on c-Fos expression in the neurons of appetite center of the brain. In the gastric emptying study, SD rats were fasted overnight. The amounts of the mixture (food and glass beads) left in the stomach were measured at 2 hours after the perorally injected mixed food, and gastric emptying rate was calculated. In the study on appetite, CCK was IP injected and the amounts of food was measured at 1 and 2 hours after the injection. In some experiments, CRF or UCN1 was IP injected and the interaction with CCK on food intake was examined. In another study, restraint stress was given to rats and the interaction with CCK was evaluated. To study the involvement of brain in the interaction between CCK and stress, c-Fos expression in the neurons was examined and evaluated.

Results: CCK dose-dependently inhibited gastric emptying. CCK dose-dependently inhibited food intake during 1 hr and 2 hr. CRF (100g/kg rat) significantly inhibited food intake. However, there was no interactive action between CCK and CRF on food intake. UCN1 (3 nmol/kg rat) inhibited food intake at 1 and 2 hours. There was an synergistic action between CCK and UCN1 on food intake. Restraint stress amplified suppressive effect of CCK on gastric emptying and food intake. C-Fos expression of the neurons in the nucleus of solitary tract (NTS) and paraventricular nucleus of hypothalamus (PVN) by CCK was amplified by the addition of restraint stress.

Conclusion: The result suggests that stress might amplify anorexic effects of CCK through the activation of satiety center of the brain that might be the possible pathogenesis for postprandial distress syndromes of FD.

P1313 HOW TO IMPROVE THE RELIABILITY OF LIVER FIBROSIS EVALUATION USING 2D-SWE.GE

F. Bende, I. Sporea, R. Sirli, M. Danila, S.A. Popescu
Gastroenterology And Hepatology, University of Medicine and Pharmacy "Victor Babes" Timisoara, Timisoara/Romania

Contact E-mail Address: bendedelfix@gmail.com

Introduction: Liver stiffness (LS) evaluation as a marker of fibrosis is usually considered reliable when it fulfills some quality criteria. Classic criteria used for Transient Elastography (TE) are: ≥10 valid measurements, ≥60% success rate, and interquartile range/median ratio (IQR/M) <0.30 [1]. However, new quality criteria were proposed using the IQR/M ratio, therefore the LS measurements can be classified into three categories: very reliable (IQR/M <0.10), reliable (0.10 < IQR/M <0.30), poorly reliable (IQR/M >0.30) [2].

Aims & Methods: The aim of this study was to assess the impact of using quality criteria (LS) evaluation by means of 2D Shear Wave Elastography from General Electronics (2D-SWE.GE), while using Transient Elastography (TE) as the reference. We included 226 subjects in our study, with or without chronic liver disease, in whom LS was assessed using 2D-SWE.GE (LOGIQ E9, GE Healthcare) and TE (FibroScan, EchoSens). Reliable LS measurements were defined for TE as the median value of 10 measurements with a success rate of ≥60% and an interquartile range (IQR) <30% of the median LS values. For 2D-SWE.GE LS 10 measurements were acquired in a homogenous area and the IQR and the IQR/M were calculated in each case. We divided our subjects into 3 groups according to the 2D-SWE.GE IQR/M: IQR/M < 0.10: 41 (18.1%) cases; 0.10 < IQR/M < 0.30: 155 (68.6%) cases; IQR/M > 0.30: 30 (13.3%) cases. We calculated the correlation coefficient between TE and 2D-SWE.GE in each group.

Results: All 226 (100%) subjects included had 10 valid measurements by means of 2D-SWE.GE and reliable results by TE. A strong positive correlation was found between LS values obtained by means of 2D-SWE.GE and TE in the IQR/M <0.10 group (r=0.84, p<0.0001). A weak positive correlation was found between LS values obtained by means of 2D-SWE.GE and TE in the IQR/M <0.30 group and IQR/M ≥0.30 group (r=0.70; p<0.0001). The correlations were significantly stronger in the IQR/M <0.10 and 0.10 < IQR/M < 0.30 groups as compared to the IQR/M > 0.30 group (both p=0.0013). No statistical differences were found between the correlations in the IQR/M <0.10 and 0.10 < IQR/M ≤0.30 groups (r=0.47).

Conclusion: Using the IQR/M <0.30 as quality criteria significantly increase the reliability of LS measurements by means of 2D-SWE.GE. Using IQR/M < 0.10 criteria does not significantly improve the reliability of 2D-SWE.GE LS measurements as compared to 0.10 < IQR/M ≤0.30 criteria.

P1315 IDENTIFICATION OF P73 AS A NOVEL TRANSCONTACTOR OF IGFBP4 GENE EXPRESSION IN HEPATOCELLULAR CARCINOMA (HCC)

D. Guchwind1, S. Heckel1, E. Achenbrenner1, K. Pollinger1, S. Schlosser1, C. Kunz1, M. Müller-Schilling2
1Department For Internal Medicine I, University Hospital Regensburg, Regensburg/Germany
2United European Gastroenterology Journal 5(5S)

Contact E-mail Address: sebastian.heckel@outlook.de

Introduction: Members of the p53-family, including p53, p63 and p73, are known for their involvement in the regulation of cell cycle, cell senescence and apoptosis. In their role as transcription factors and depending on their splice variants—with transcription activation domain (TA) or dominant negative (DN) - p53 and its siblings are capable of activating or inhibiting the transcription of specific target genes. We previously identified the gene for Insulin-like Growth Factor Protein 4 (IGFBP4) as a potential p53-family target gene with prognostic relevance in hepatocellular carcinoma (HCC). In contrast to p53, the IGF system takes part in tissue growth and cell survival. IGFBP4 acts as inhibitor limiting IGF effects suggesting a possible interaction with p53 affairs.

Aims & Methods: The aim of this study was to characterize the regulatory influence of p53 family members on the IGFBP4 gene. Hep3B cells were transfected with rAd-p53, -TAp63, -TAp73, -DNp63, and –DNp73. Transcriptional regulation of IGFBP4 was determined by real time qPCR. Intra- and extracellular IGFBP4 protein levels were examined by Western Blotting and ELISA. TRANSFAC database analysis was performed to identify potential p53-family binding sites in the IGFBP4 locus. Identified sequences were cloned, deleted, and analyzed by luciferase reporter assays to evaluate binding of p53-family members.

Results: IGFBP4 expression was increased by more than 30-fold in TAp73-transfected Hep3B cells, by more than 15-fold in DNp63- and by 3-fold in p73-transfected cells. Induction of intracellular IGFBP4 protein was detected in all transfected Hep3B cells, whereas extracellular IGFBP4 levels were only measurable after TAp73 and DNp63 transfection. Database analysis identified 2 putative binding sites within intron 1 of the IGFBP4 gene. Intron 1-dependent luciferase activity was increased by up to 20-fold in TAp73-transfected cells. This induction was reduced by up to 70% when one of the putative binding sites was deleted.

Conclusion: These results identify the IGF inhibitor IGFBP4 as novel target gene for TAp73 expression in HCC. By demonstrating it as the first time the interaction of TAp73 and IGFBP4 we enhance our knowledge in so far unknown association of p53-family network and IGF signaling. Since in an independent study we identified IGFBP2 as a novel p53-family target gene, these results highlight the link between p53-family-mediated tumor-inhibiting mechanisms and IGF-family, thereby modulating cell proliferation. We therefore suppose that the particular balance of these pathways decides on growth, cancerogenesis and treatment response.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1314 MONITORING OF LIVER FUNCTION IN PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE IN COMBINATION WITH METABOLIC SYNDROME

K. Aksetniychuk, E. Sklyarov, N. Kurylak, A. Bochar
Therapy #1 And Medical Diagnostics, LNMMU by Danylo Galytskyi Dept. of Therapy, Lviv/Ukraine

Contact E-mail Address: aksetniychuk@mail.ru

Introduction: U3C-methacetin breath test (13C-MBT) is used to specify the detoxification function of the liver by determination its metabolic capacity and degree of hepatocytes recovery.

Aims & Methods: The study involved 113 patients with MS aged from 37 to 82 years. The age of the male group was 55±8.5; the female group was 75±18.5 years old. There were 75 men and 88 women. The criteria, which has been examined for the functional state of the liver was 13C-MBT. The control group included 55 patients with a BMI of 25-30 kg/m2 without any severe concomitant diseases. Indicators of 13C-MBT were metabolic rate, cumulative dose of 13C-methacetin on 40 and 120 minutes. Also evaluation was carried by mathematical deduction which measured the liver dysfunction stage.

Results: The data showed normal detoxification liver function in patients without MS (20.11±0.55). The results were below normal in patients with BMI higher than 25 (32.54±0.52), which indicated that there were changes in the functional state of liver. In patients with steatosis - cumulative dose on 120 minute was 15.12±0.49, which corresponded to a moderate reduction of detoxification function with the mass of function hepatocytes 50-100%. The data of 13C-MBT in patients with steatohepatitis showed pronounced changes of the liver detoxification function (8.88±0.64%). All indicators at steatosis group have indicated the moderate decline detoxification function with the level of function hepatocytes 50-100% (Mvmax40=0.66, Cum.Dose 40=0.7, Cum.Dose 120=0.54). The data of patients with steatohepatitis indicated the detoxification function with declining of the mass of function hepatocytes to 20-50% (Mvmax40=0.46, Cum. Dose 40=0.5, Cum. Dose 120=0.32). The results of the control group showed its compliance with norm, but one of the indicators (Cum.Dose 120) was related to the moderate decline detoxification function. Despite it, most of the criteria have been accorded to the norm. However, the results of data suggest the opportunity of early violation of detoxification liver function in patients with BMI higher than 25 kg/m2.

Conclusion: In assessing to the data of 13C-MBT, main attention is paid to mathematical calculation of CO2 labeled methacetin. It allows to identify the early stages of the liver detoxification function violation.

Introduction: It is known that to determine nonalcoholic fatty liver disease (NAFLD), which develops in progress of body mass index (BMI) from 19% to 35%, using instrumental and laboratory methods, which include an ultrasound, the determination of the transaminase levels, steatostest, 13C-methacetone test. However, these research methods do not allow to clearly differentiate steatosis from the steatohepatitis, that reduces their credibility.

Aims & Methods: 163 patients (75 men, 88 women) with 2 type diabetes mellitus and coronary heart disease with metabolic syndrome, were examined. The average age of patients was 57.5 ± 20.1 years. All patients were diagnosed as steatosis, 66 - steatohepatitis group. In 25 patients liver pathology was not found, which identified as a control group. For verification of steatosis and steatohepatitis diagnosis the level of ALT, diameter of the portal vein negatively correlated with 120 minute was 20.25

Results: For verification of steatosis and steatohepatitis diagnosis the level of ALT, diameter of the portal vein negatively correlated with a new index that is different from BMI was proposed. 362 individuals were found that in ALT and the diameter of the portal vein negatively correlated with cumulative dose of 

Conclusion: The differentiation between steatosis and steatohepatitis should be moderate with the speed of a metabolism, a cumulative dose of methacetone on CAP (0.689;p <0.001) and venous MPT and venous diameter measurement. The sensitivity of the method is based on the definition of the three proposed indicators - ALT level, total concentration of 13C-methacetone on 120 minute and the portal vein size, which is 75% for steatosis, and 76% for steatohepatitis.

Introduction: Liver fibrosis (LF) is a progressive pathological process resulting in accumulation of excess extracellular matrix proteins. A metalloproteinase BMP1 cleaves various matrix proteins and pro-collagen type I. We have recently discovered that BMP1-3 isoforms circulate in the plasma and its neutralization decreases the progression of chronic kidney disease. The role of BMP1 in liver diseases associated with fibrosis has not been investigated. Bone Morphogenetic Protein (BMP1) and mammalian tolloid (mTLD) are alternatively spliced products of the BMP1 gene that are essential for tissue patterning and ECM assembly by biosynthetic processing of a wide range of ECM precursors specifically pro-collagen type I undergoing enzymatic cleavage by BMP1 at the C-terminal end of the pro-collagen finally leading to liver cirrhosis, portal hypertension and liver failure.

Aims & Methods: We used the model of CCl4-induced LF in rats. Animals were treated with BMP1-3 antibody at two different concentrations (20 and 50 µg/kg) for 6 and 8 weeks. LF was assessed histologically, morphological analyses, shear wave elastography and hydroxyproline (HP) content measurement. Gene expression analyses were performed by qRT-PCR, and protein localization by immunohistochemistry. BMP1 protein (150 µg/kg) was used as a comparative therapy.

Results: In our experiments the presence of BMP1-3 was immunohistochemically demonstrated in both healthy and cirrhotic liver suggesting that at least a part of circulating BMP1-3 is produced in the liver. Administration of BMP1-3 Ab resulted in inhibition of the fibrosis progression. Administration of BMP1-3 Ab at a dose 20 µg/kg and 50 µg/kg exerted antifibrotic activity comparable to that of mTLD. Apart from blocking the BMP1-3 activity, it is important for collagen maturation, administration of BMP1-3 Ab was accompanied by the inhibition of expression of MMP-1, MMP-13, α-smooth muscle actin and type I collagen, whereas expression of Decorin mRNA was enhanced. Decorin has evident anti-fibrotic activity in the liver after injury with CCl4 and silencing caused an increased activation of HSCs both in vitro and in vivo. Rats treated with both BMP1-3 antibody concentration had significantly lower amount of collagen type I when compared to the CCl4-treated group. Direct proportionality was found between the degree of fibrosis and liver stiffness. We showed for the first time a distinct correlation between the HP level in liver, morphometric analysis and elastography of the liver.

Conclusion: Our results suggest that neutralization of BMP1-3 is a promising therapeutic approach in preventing the liver fibrosis progression.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1318 LIVER TRANSIENT ELASTOGRAPHY IN NON-ALCOHOLIC FATTY LIVER DISEASE: IS THERE ANY PREDICTIVE ROLE IN THE DEVELOPMENT OF COLORECTAL POLYPS?
M. Gravito-Soares1, E. Gravito-Soares2, D. Gomes2, A. Simão2, L. Tomé2
1Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal, Coimbra/Portugal
2Gastroenterology, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal, Coimbra/Portugal

Introduction: Recent studies have demonstrated an association between decreased glucose tolerance, dyslipidemia and metabolic syndrome; and increased risk of colorectal polyps. Patients with non-alcoholic fatty liver disease (NAFLD) often have these risk factors. The association between NAFLD and colorectal polyps has been poorly studied.

Aims & Methods: We aimed to evaluate the prevalence and risk factors of colorectal polyps in patients with NAFLD. This was a retrospective observational study of 163 patients with NAFLD submitted to transient elastography by Fibroscan, between 2015 - 01/02-2017. Exclusion criteria: age<18 years, absence of total colonoscopy with good preparation <3 years, inflammatory bowel disease, hereditary polyposis syndromes and personal/family history of colorectal polyps/neoplasia. Compared patients with colorectal polyp(s) (cases) and without colorectal polyp(s) (controls). Demographic variables, cardiovascular/metabolic risk factors, comorbidities, laboratory parameters and Fibroscan (scores of steatosis(CAP > 300 dB/m) and fibrosis(F4: > 10KPa)) were analyzed.

Results: Of the 237 patients who performed Fibroscan®, 103 underwent total colonoscopy. The prevalence of colorectal polyps was 28.2% (n=29): 19.4% (20.0% vs 17.0%) adenoma and 4.8% (5.1%) advanced adenoma/adenocarcinoma. The mean age was 58.32 ± 5.51 years (vs70.9 ± 10.53; p = 0.009, with men predominant (51.7% vs 63.5%; p = 0.272), mostly located in the left colon (55.2% vs 44.8%; p = 0.314) and number and mean size of 1.46 ± 0.88 and 6.98 ± 6.56 mm, respectively. After multivariate analysis, colorectal polyps were associated with F4 liver fibrosis (34.5% vs 14.9%; p = 0.026; OR = 3.01) and obesity (BMI > 30 kg/m²; 55.2% vs 29.7%; p = 0.016; OR = 2.91); hyperplastic polyps were associated with liver fibrosis for a cut-off value of 6.9KPa (AUROC 0.689; p = 0.008; S = 85.7%; 10.0% vs 16.0%; p = 0.042; OR = 3.08) and obesity (BMI > 30 kg/m²: 55.2% vs 29.7%; p = 0.043; OR = 2.91). Inflammatory disease (9.5% vs 12.2%; p = 0.024; OR = 3.51) and diabetes (9.5% vs 3.24% vs 8.5%; p = 0.02; OR = 3.51) and obesity (58.5% vs 32.6%; p = 0.024; OR = 2.96) was associated with liver steatosis (88.2% vs 83.7%; p = 0.024; OR = 3.50). F4 liver fibrosis (41.2% vs 18.2%; p = 0.004; OR = 2.96) was associated with liver steatosis (88.2% vs 83.7%; p = 0.024; OR = 3.50). F4 liver fibrosis (41.2% vs 18.2%; p = 0.004; OR = 2.96) was associated with liver steatosis (88.2% vs 83.7%; p = 0.024; OR = 3.50). F4 liver fibrosis (41.2% vs 18.2%; p = 0.004; OR = 2.96) was associated with liver steatosis (88.2% vs 83.7%; p = 0.024; OR = 3.50).

Conclusion: More than 1/4 of the patients with NAFLD have colorectal polyps, being 16.5% adenoma and 4.8% advanced adenoma/adenocarcinoma. Obesity and liver steatosis are independent risk factors for colorectal adenoma. Liver fibrosis, especially F4 is an independent risk factor for all types of colorectal polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1319 "SUBTRACTED ADULTHOOD MASS INDEX" (SAMI) - A NEW INDEX TO PREDICT NAFLD RISK IN NON-OBESE INDIVIDUALS
A. Kiyak1, S. Elböl1, M. Sarıcı2, O. Saygli2, N. Tözün3

3School Of Medicine, Acibadem University, Istanbul/Turkey
Contact E-mail Address: atakiyak@gmail.com

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a common clinico-pathological bicon of the liver. It's often associated with metabolic syndrome and obesity. NAFLD may progress to cirrhosis and hepatocellular carcinoma (HCC). Obesity is accepted as the main risk factor for NAFLD, non-obese individuals are often diagnosed with NAFLD suggesting that high BMI may not be a sine qua non for the presence of NAFLD. Recent studies suggested that there might be a correlation between weight gain and metabolic diseases.

Aims & Methods: In our research; the relationship between NAFLD in non-obese individuals and the amount of weight gain during adulthood was investigated and a new index that is different from BMI was proposed. 362 individuals were included in the survey. The subjects were selected among patients who had abdominal ultrasonography(USG) in our clinic, during the last 6 months. A 5% increase in echogenicity detected in the USG was defined as the diagnostic
limit for hepatosteatosis. The beginning of adulthood was taken as 20 years old. Patients reported they had gained significant amount of weight during their adulthood. This information led us to create a new index named “Subtracted Adulthood Mass Index” (SAMI) to estimate the risk of NAFLD development in non-obese individuals. SAMI is calculated by dividing the difference between the subject’s current weight and his/her weight at the age of 20 years to his/her height squared (kg/m2). SAMI values for non-obese attendants were calculated. When the cut-off value was set as SAMI 4 kg/m2, sensitivity was 76.3%, specificity was 79.1, positive predictive value (PPV) was 84.3% and negative predictive value (NPV) was 69.4%. At a cut-off of SAMI 3 kg/m2 sensitivity was 85.2%, specificity was 66.9%, PPV was 79.1%, NPV was 75.4%. Inclusion: In this pilot study, we found that weight gain in adulthood is an important predictor of NAFLD development in non-obese individuals. The new index named SAMI can correctly identify non-obese people under the risk of developing NAFLD. Cut-off value of SAMI has been set as 3.5 kg/m2. We also observed that NAFLD prevalence increases as SAMI value goes up. We propose that SAMI is appropriate for clinical use to estimate the risk of NAFLD in obese individuals.Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cisplatin-treated cancer patients often face therapy failure caused by cisplatin resistance. Development of resistance was previously associated with modulation of transporters mediating cellular copper metabolism. Overexpression of the Wilson disease protein ATP7B, a TGN copper transporter, was proposed to increase cellular cp efflux.

Aims & Methods: The human hepatoma cell line HepG2 was compared with a HepG2-variant lacking functional ATP7B expression (KO) in regard to cp sensitivity. Hepatoma cell lines were generated that displayed cp resistance by stepwise increasing cp concentrations. Cells were examined via growth, cell viability assay (MTT) and analysed for apoptosis (Annexin V staining). Inductively coupled plasma mass spectrometry was used to determine intracellular cp level. Gene expression analysis (RT-qPCR) was carried out to determine the impact of various transporters. Overexpression of individual transporter genes and siRNA treatment were used for confirmation of the data.

Results: Treatment of HepG2 and KO cells with various cp concentrations revealed no significant differences in cell viability and intracellular cp accumulation. To examine how KO cells that lack ATP7B can adapt to high cp levels, a cp resistant subline (CPR) was generated. Cp resistance was confirmed by viability assay and intracellular cp load. Gene expression analysis of more than 16 transporters demonstrated an upregulation of metallothionein 1 (MTT: 8.91 ± 4.4) and a downregulation of organic cation transporter 3 (OCT3: –5.17 ± 2) compared to control cell lines. Weaning and regrowth of the CpR cell line in the presence of cp revealed a stable phenotype of resistance in the cells. Downregulation of OCT3 was identified to be permanent while MT1 upregulation was transient and rapidly induced by cp. Overexpression of OCT3 in CpR cells resulted in loss of cp resistance to a level of untreated cells indicating that downregulation of OCT3 is responsible for acquired cp resistance.

Conclusion: We suggest that ATP7B does not seem to be involved in cp resistance, at least in hepatic cells. OCT3 represents a novel marker of cp resistance. OCT3 expression could be a valuable tool for improved prognosis of cisplatin therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Recent studies have shown that the single nucleotide polymorphism (SNP) rs738409 in the PNPLA3 gene is strongly associated with severity of nonalcoholic fatty liver disease (NAFLD). However, the traditional direct sequencing (DS) method is time-consuming and labor-intensive. The i-densy (ARKRAY, Inc.), which is based on the quenching probe (QP) method, automatically detects target genes in blood samples by fluorescence quenching within 90 min.

Aims & Methods: The current study compared the QP and DS methods for detecting SNPs in the PNPLA3 gene, and established the impact of the genotype on prognosis of NAFLD. We enrolled 107 patients with fatty liver irrespective of etiology. We used the i-densy fully automated genotyping system with QP. The requisite number of tips, reaction tubes, reagent packs and blood samples were set in their designated places. The forward and reverse polymerase chain reaction (PCR) primers and guanine QP were 5’-cttctcctctgttccgtaa-g-3’, 5’-gtgtgagca-tgcctcctttacag-3’, 5’-ggtagaaggagatacacatc-3’, respectively. PCR consisted of initial denaturation for 1 min at 95°C, and 60 cycles of denaturation at 95°C for 1 s and annealing at 61°C for 30 s. After completion of the PCR, we analyzed melting temperatures. The SNP genotypes were determined by monitoring the change in fluorescence intensity with increasing temperature. The results obtained with the QP method were compared with those obtained with the conventional DS method. Then, we analysed 73 patients with NAFLD according to PNPLA3 genotype in terms of alanine aminotransferase (ALT), aspartate aminotransferase to platelet ratio index (APRI), Fibroscan value, and cumulative hepatocellular carcinoma (HCC) development rate.

Results: The genotypes obtained with the QP method were identical to those obtained with the conventional DS method. In 73 patients with NAFLD, the frequency of the PNPLA3 genotypes CC, CG and GG was 21 (28.8%), 24 (32.9%) and 28 (38.4%), respectively. Serum ALT, APRI and Fibroscan value according to PNPLA3 genotypes CC, CG and GG were 26 (14–59), 33 (11–113) and 46 (17–175) U/L, 0.3 (0.1–1.0), 0.5 (0.2–6.8) and 0.7 (0.2–3.1), respectively.

Conclusion: The i-densy using the QP method can automatically, quickly and easily identify PNPLA3 genotypes in real-world clinical settings. These findings indicate the feasibility of personalized medicine for NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.
**Introduction:** Orlistat is an effective pharmacologic weight loss treatment by inhibiting intestinal lipase to reduce dietary fat absorption. Previous studies have suggested that it lowers liver fat by ultrasound or semi quantitative histological scoring in nonalcoholic fatty liver disease (NAFLD).

**Methods:** We aimed to examine the efficacy of orlistat versus placebo in reducing liver fat content by the magnetic resonance imaging (MRI) based on chemical shift imaging. A total of 51 NAFLD patients diagnosed by MRI were randomly assigned to receive trice-daily 120mg oral Orlistat or placebo for 6 months, among them 30 (14 in the Orlistat group and 16 in the placebo group) were included in the interim analysis. Both groups received clinical parameters, laboratory tests and imaging tests at baseline and 6 months including body mass index (BMI), waist hip ratio (WHR), liver enzymes, haemoglobin A1c, total cholesterol (CHOL), serum triglycerides (TG), fasting plasma insulin (FINS), homeostasis model assessment IR (HOMA-IR). The primary outcome was a change in liver fat quantified by MRI which was however transient and dependent on Cu exposure.

Two genes involved in Cu homeostasis displayed an altered expression pattern was noticed. Once Cu resistance was established, the termination of Cu exposure was associated to gain resistance (CuR). Characterization of CuR cells revealed increased survival by FACS and Western Blot. Additional measurements of CTR1 expression was performed by qPCR was performed to quantify the expression of genes related to Cu homeostasis genes. Functional analysis of candidate genes was assessed via siRNA transfection. Notably, cell viability and expression (2.5 and 4.4) which was however transient and dependent on Cu exposure.

**Results:** FLI significantly predicts the presence of liver fibrosis with a sensitivity and 96.43% specificity with AUROC of 0.74. Liver fat fraction and the proportion of hypertension, hyperlipidemia, diabetes mellitus type 2, and obesity were similar. Compared to baseline, end-of-treatment liver fat content was significantly lower in the Orlistat arm (19.38% ± 9.52% to 11.56% ± 7.49%, change was 7.72 ± 6.39%, P < 0.001) but not in the placebo (16.05% ± 8.7% to 14.17% ± 5.98%, change was 1.43 ± 9.54%, P = 0.640) arm. Change of BMI was the only independent factors correlated with reduction of liver fat content (β = 0.522, p = 0.006).

**Conclusions:** Orlistat did significantly decreased liver fat in NAFLD patients via its effect of lowering weight.

**Discussion of Interest:** All authors have declared no conflicts of interest.

**Reference:**

Conclusion: We conclude that FibroScan® represents an eligible tool to diagnose liver diseases in Austrian bank employees. Compared to the previous work of Bedogni et al FLI predicts fatty liver at a lower cut-off level, at least for the examined population. This difference might be due to the fact that FibroScan®CAP is more sensitive than ultrasound.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Nonalcoholic fatty liver disease (NAFLD) is an affection with increasingly prevalence worldwide, having an important impact on morbidity and mortality, especially when it associated severe fibrosis.

Aims & Methods: We aimed to assess the metabolites that are associated with fibrosis stages in NAFLD, using metabolic method. A total of 40 patients were included in the study, 30 diagnosed with nonalcoholic fatty liver disease (NAFLD) and 10 controls. Steatosis and fibrosis were assessed using Fibromax elaborated by Biopredictive (R) (Paris, France). New metabolomic techniques (high performance liquid chromatography coupled with mass spectrometry (HPLC-MS) and principal component analysis (PCA)) were used to identify final products of various metabolic pathways correlated with liver fibrosis.

Results: Of the 30 patients with NAFLD included in the study, 6 patients (20%) had severe fibrosis. The metabolic profile identified four metabolites that are associated with severe fibrosis: 1.25(OH)2Vitamin D, (p = 0.03), isosropoadhatidyl-

 lipidolamine LPE 0:22:6 (p = 0.05), Lyso phosphatidylcholine LPC 18.2 (p = 0.003), and high levels of butenyl carnitine (p = 0.044). Of these, LPE was the strongest predictor of severe fibrosis (AUROC=0.795, Sensitivity (Se)= 88.33%, specificity (Sp) = 78.79%).

Conclusion: This metabolomics, we can identify patients with fatty liver and severe fibrosis who are significantly exposed to a progressive disease and a higher mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1327 CHRONIC RENAL FAILURE IS ASSOCIATED WITH THE DEVELOPMENT OF NAFLD/NASH
S. Gehring1, P. Di Fazio2, T.M. Gress3, T.T. Wisniewski1
1Gastroenterology, Philipps University, Marburg/Germany
2Department Of Visceral Thoracic And Vascular Surgery, Philipps University Marburg, Marburg/Germany

Contact E-mail Address: sonjagehring@gmx.de

Introduction: Chronic renal failure (CRF) is frequently associated bone metabo-

lism and osteoporosis with lowered levels of Vitamin D and/or hyperparathyry-

eodism particular in case of hemodialysis. Younger studies suggest an association of low vitamin D levels with non-alcoholic fatty liver disease (NAFLD) and non-

alcoholic steatohepatitis (NASH), as well as metabolic syndrome, and diabetes mellitus. Unfortunately, a causality could not yet be proven.

Aims & Methods: Our aim was to identify patients on higher risk to develop NAFLD/NASH in a selected patient cohort being admitted for renal disorders.

176 patients, admitted to the department of nephrology of the University Hospital Marburg for renal disorders whose plasma vitamin D concentration, phosphate and parathormone levels and liver enzyme levels had been quantified beforehand, were enrolled and a retrospective investigation of laboratory param-

eters (including electrolytes, hormones, and vitamins) and pre-existing medical conditions (including high blood pressure, diabetes, hyperlipoproteinaemia, and more) followed. Appropriate statistical test were used to characterise the cohort (ANOVA; MANN-Whitney-U; FISHER-EXACT) using SPSS TM. Other hepato-

pathies were excluded. Steatosis was assessed by ultrasonography.

Results: Patients were divided into 4 groups according to plasma vitamin D levels (normal >25 ng/ml; low <25 ng/ml) and transaminase levels (AST/ALT>=GT >30 U/l; normal: AST/ALT>=GT <30 U/l). Low 1,25-hydroxivitamin D levels correlated significantly with high creatinine, urea, and LDL levels, while low 25-hydroxivitamin D levels correlated with high cholesterol and triglyceride levels, suggesting a relationship between low vitamin D levels and fat metabolism disorders. Interestingly end stage renal failure (chronic hemodialysis) was signifi-

cantly correlated with the development of NAFLD/NASH with significantly higher levels of AST/ALT and gGT, hyperparathyreodism and hyperphosphate-

mia Transaminases were significantly lower if Vitamin D was supplemented

Conclusion: Vitamin D deficiency is often present in patients with kidney diseases such as chronic renal failure. Vitamin D levels are correlated to age and sex of the patient. Patients suffering from renal failure are on high risk developing NAFLD/NASH if diminished vitamin D levels are present. Supplement of Vitamin D saves from NAFLD/NASH. The correlation of hyperparathyreodism and NAFLD/NASH has to be further investigated in larger patient groups.

Introduction: Usually for the determination of nonalcoholic fatty liver disease (NAFLD) there are instrumental and laboratory techniques, including ultra-

sound diagnosis, determination of aminotransferases, steatotest, 13C-methacetin breath test (13C-MBT). These methods in the diagnosis of NAFLD clinical forms is not specific and do not allow make difference between steatosis and steatohepatitis. The determination of NAFLD clinical forms is a priority in the prediction of further disease and choice of treatment. Steatohepatitis is the active form of NAFLD and progresses to fibrosis oftenly with subsequent liver par-

enchyma degeneration into cirrhosis. Simultaneously, steatosis could be possibly treated in the early stages of disease.

Aims & Methods: The study involved 65 patients with type 2 diabetes and cor-

onary heart disease with metabolic syndrome, aged 37 to 82 years (mean age 53.82 ± 3.46), 29 men, 36 women. According to the ultrasound, the stage of fatty infiltration were differentiated by such criteria for steatosis as diffuse liver par-

enchyma echogenicity intensification against the background of a slight increase in its size (liver echogenicity was significantly higher than normal kidney or lumbar muscle echogenicity); for steatohepatitis - hyperechogenicity of liver par-

enchyma and expansion of portal vein (13 mm or more in diameter).

Results: For steatosis and steatohepatitis determination the ALT monitoring was used, where the level exceeding 0.68 mmol/l signed to steatohepatitis, and below 0.68 mmol/l to steatosis. Portal vein diameter size above 13 mm subscribed to steatohepatitis, and below 13 - steatosis. The study found that indicators of ALT and portal vein diameter negatively correlated with cumulative dose 13C2O2 for 120 minute in case of steatohepatitis. Thus, reduction cumulative dose 13C2O2 on 120 minute from 15% to 10% was accompanied by ALT level increasing (more than 0.68 mmol/l) and portal vein diameter enlargement (over 13 mm).

Conclusion: Differentiation between steatosis and steatohepatitis should be per-

formed by the cumulative dose 13C2O2 on 120 minute evaluation and ALT levels and portal vein diameter assessment.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Non-alcoholic fatty liver disease (NAFLD) is usually considered as the hepatic counterpart of the metabolic syndrome in close relation to obesity and encompasses a disease spectrum spanning simple steatosis through nonalcoholic steatohepatitis (NASH) with or without cirrhosis, and hepatic neoplasms [1]. Clearly, not all obese subjects develop NAFLD and NAFLD can also be found in non-obese patients. Globally, the reported prevalence of non-obese NAFLD varies widely, ranging from 3% to 30% [2]. Today remains unclear how patients without obesity develop NAFLD, therefore it is important to understand the clinical and pathological conditions of non-obese NAFLD.

Aims & Methods: In this study, we investigated the liver stiffness and liver fat content in addition to other clinical and metabolic parameters in type 2 diabetes patient with non-obese and obese NAFLD detected on ultrasonography (US). In this cross-sectional study, 245 T2D patients with age of 40–80 years from the Kyiv City Clinical Endocrinology Center were selected. Inclusion criteria were: age over 18 years, presence of T2D in association with fatty liver disease. The diagnosis of fatty liver was based on the results of abdominal ultrasonography, which was done by trained technicians with Ultima PA (Radmir Co., Kharkiv, Ukraine). Of 4 known criteria (hepatorenal echo contrast, liver brightness, deep intestinal endoscopy within 12 months, with a diagnosis of compensated chronic liver disease). We choose this specific liver stiffness cut-off value in order to reasonably rule-in all patients with advanced fibrosis and cirrhosis, based on the recently proposed Baveno VI criteria which recommends a liver stiffness value measured by ElastPQ and/or laboratory parameters that could help identify those patients who can safely avoid screening endoscopy, similarly to the early diagnosis and management of precancerous colorectal polyps. Our other hand, patient with obese NAFLD are characterized with more pronounced liver fat content and elevation of markers of chronic systemic inflammatory state.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Aims: The purpose of our study was to identify a liver stiffness cut-off value measured by ElastPQ and/or laboratory parameters that could help identify patients who can safely avoid screening endoscopy, similarly to the recently proposed Baveno VI criteria which recommends a liver stiffness value <20kPa measured by transient elastography in combination to a platelet count >150,000/µl. Data were collected on 1385 patients who underwent ElastPQ measurement from January 2013 to January 2016 in our Department. Inclusion criteria were a liver stiffness value of ≥7 kPa and an upper gastrointestinal endoscopy within 12 months, with a diagnosis of compensated chronic liver disease. We choose this specific liver stiffness cut-off value in order to reasonably rule-in all patients with advanced fibrosis and/or cirrhosis, based on the limited literature available on this specific elastographic technique. Exclusion criteria were history of decompensated liver disease, evidence of porto-spleno-mesenteric vein thrombosis and non-cirrhotic portal hypertension. Varices were graded as low risk (grade <2) or high risk (grade ≥2).

Results: The study included 184 patients (114 [62%] hepatitis C, and 160 [87%] Child-Pugh A). Varices were present in 36% cases, with 10% prevalence of high-risk varices. According to ROC curve analysis liver stiffness measurement and

Odd Odds Ratio (OR) 95% Confidence Interval (CI) P-Value
BMI 1.27 1.106–1.459 0.001
Waist circumference 1.078 1.047–1.112 <0.001
ALT 1.018 1.004–1.033 0.015
Cholesterol 1.008 1.003–1.013 0.003
FPG 1.010 1.003–1.017 0.004

Conclusion: Lean NAFLD was prevalent in our study population and was associated with metabolic risk factors. BMI and waist circumference can be used for preterm risk stratification. NAFLD is a common condition with significant impact on patients’ quality of life. Given the rapid increase in the prevalence of NAFLD, it is essential to better understand the disease, identify risk factors, and improve the diagnostic and therapeutic strategies.
platelet count were evaluated as predictors of high-risk varices. Overall 74/184 (40%) met the new “BAVElastPQ” criteria (that is, liver stiffness <12 kPa and platelet count >150,000/µl). Within this group 11/63 (17%) had any grade of varices and only 1/73 (1%) had high-risk varices. The BAVElastPQ criteria gave sensitivity of 0.95, specificity of 0.44, a positive predictive value of 0.216, and a negative predictive value of 0.98. The AUROC for liver stiffness and platelet count was 0.81 and 0.76, respectively.

Conclusion: The BAVElastPQ criteria correctly identified 99% of patients with high-risk varices. By applying such criteria we could have potentially avoided 40% surveillance endoscopies in our cohort. To our knowledge this is the first study that evaluated the potential role of a new p-SWE technique such as ElasPQ in the non-invasive assessment of clinically significant portal hypertension, similarly proposed Baveno VI criteria though using ElasPQ as an alternative to transient elastography.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1332 PROTON PUMP INHIBITORS INTAKE NOT ASSOCIATED WITH HEPATIC ENCEPHALOPATHY IN CIRRHOTIC PATIENTS

Introduction: Inhibitors (PPIs) are commonly prescribed and predispose to small bowel bacterial overgrowth. Hepatic encephalopathy is a frequent complication of cirrhosis and is associated with intestinal dysbiosis.

Aims & Methods: This study aimed to identify a possible association between PPI intake and hepatic encephalopathy development in cirrhotic patients. Retrospective analysis of consecutive cirrhotic patients hospitalized in two Gastroenterology Departments over 3.5 years. Collection of clinical data, PPI intake and hepatic encephalopathy development in cirrhotic patients.

Results: 386 patients, 321 males (83.2%), mean age 60.3 ± 12.1 years. Main etiologies of cirrhosis were alcohol (67.4%), alcohol plus hepatitis C (16.3%) and hepatitis B virus (5.2%). Hepatic encephalopathy was present in 222 (57.5%) of the patients and 26.9% had PPI intake. In univariate analysis hepatic encephalopathy was associated with infection (p < 0.001), gastrointestinal bleeding (p < 0.001) and Model for End-Stage Liver Disease (MELD) (p < 0.001). There was no association between hepatic encephalopathy and PPI intake (p = 0.057), gender (p = 0.228) or age (p = 0.352). In multivariate analysis, hepatic encephalopathy maintained association with infection (p < 0.001), gastrointestinal bleeding (p < 0.001) and MELD score (p = 0.001).

Conclusion: In our series, PPI intake was not associated with hepatic encephalopathy development in cirrhotic patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The incidence of bacterial infections in cirrhotic patients is significantly higher than that observed in general population, being one of the most important causes of decompensation. In theory, the final result of an infectious disease depends of three major factors: the antibiotic resistance of the bacteria or MDR bacteria regarding the 30 (p = 0.001) and 90-day mortality ratio. In the multivariate analysis, elevated BUN and bilirubin, presence of bacterial infection and lower albumin, sodium and SpO2 were independently associated with 30 and 90-day mortality. Higher INR and age were independently associated with 90-day mortality.

Conclusion: The presence of bacterial infection, independently of the antibiotic profile, was associated with a worse prognosis in cirrhosis. In patients with documented infections, no difference was noticed between non-MDI, non-MDR bacteria or MDR bacteria regarding the 30 (p = 0.801) and the 90-day (p = 0.525) mortality rate. In the multivariate analysis, elevated BUN and bilirubin, presence of bacterial infection and lower albumin, sodium and SpO2 were independently associated with 30 and 90-day mortality. Higher INR and age were independently associated with 90-day mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The place of non-invasive techniques for the prediction of presence of portal hypertension in patients with liver cirrhosis is one of the current research aims.

Aims & Methods: The aim of this study was to evaluate the applicability of the Baveno VI criteria in a cohort of known compensated HCV liver cirrhosis patients, to see how often we misclassify the presence of esophageal varices (EV).

Material and method: We did a prospective multicentre study, from September 2015 to October 2016, which included all patients with perfectly compensated HCV liver cirrhosis, diagnosed by means of elastography, ultrasound, endoscopic and biological criteria prior to interferon-free treatment. All patients were evaluated by upper gastrointestinal endoscopy, transient elastography, and laboratory tests. By using this method we classified the patients in: probably without EV (lower stiffness: LS <20kPa and thrombocytes >150.000/mm3), probably with EV (LS>25kPa) and the “gray zone” in between these criteria.

Results: Out of 403 patients, 127 (30.7%) had LS <20kPa, 89 (22%) had LS between 20–25kPa, 190 (47.3%) had LS >25kPa, 120 (29.7%) had thrombocytes >150.000/mm3, while 283 (70.3%) had thrombocytes <150.000/mm3. For the subgroup probably with EV, the Baveno VI criteria had PPV = 84.6% (Se = 40.7%, Sp = 74.6%, NPV = 26.8%) for predicting the presence of esophageal varices, while for the subgroup probably without EV had PPV = 80.3% (Se = 50.2%, Sp = 58.6%, NPV = 75.6%). The subgroup that had LS <20kPa and thrombocytes >150.000/mm3, was compound of 60 patients. Using these criteria we classified the patients in: probably without EV (lower stiffness: LS <20kPa and thrombocytes >150.000/mm3), probably with EV (LS>25kPa) and the “gray zone” in between these criteria.

Conclusion: By using the Baveno VI criteria in patients with liver cirrhosis for the prediction of presence of esophageal varices, we can misclassify only 20% of patients.

Disclosure of Interest: S.A. Popescu: I hereby confirm that I have received financial support (cognitive impairment from any other cause, colour-blindness or dyslexia. Baseline demographics, level of education and medical history were obtained, and a Child-Pugh score was calculated where relevant. Each patient performed the PHES test and the Stroop test. Outcomes included the time taken to perform each PHES test as well as the total PHES, the Stroop on-off time and time taken to complete 5 correct runs on the Stroop App. Results were analysed using exact Pearson’s chi-squared test, or Fisher’s exact test for predicting cut-off of 187 s. All tests were performed with a significance level of 0.05.

P1336 COMBINED RADIOLOGIC-BLOOD PARAMETERS AND BLOOD DERIVED NON-INVASIVE FIBROSIS SCORES IN PREDICTING OUTCOMES IN CHRONIC HEPATITIS C
R.B. Thandassery1, H. Wani1, S. Al Kaabi1, M. Khanna2
1Gastroenterology, Hamad General Hospital, Doha/Qatar
2Radiodiagnosis, Hamad General Hospital, Doha/Qatar

Contact E-mail Address: doc.raghes@gmail.com

Introduction: Non-invasive fibrosis scores (NIFS) are increasingly replacing liver biopsy (LB) for estimation of liver fibrosis. Only limited studies have evaluated the utility of combined use of radiological and blood derived NIFS in predicting cirrhosis and liver decompensation in cirrhotic patients. Similarly there are limited studies evaluating combination of radiologic and blood parameters in predicting fibrosis and outcomes of cirrhosis.

Aims & Methods: We aimed to compare combined radiologic-blood parameters (CRBP) and blood derived non-invasive fibrosis scores (NIF) for predicting pre treatment cirrhosis, development of esophageal varices (EV) and liver decompensation post antiviral treatment (AVT). 1605 patients (Jan 2002 to June 2013) with CHC underwent liver biopsy (LB) and received AVT with pegylated interferon and ribavirin. Three CRBPs (platelet count-bisphenolic diameter index [PSI], platelet count-bisphenidopemidentorial port vein index [PSVIP]), platelet count-bisphenidomnitrogenal port vein index [PSML]) and nineteen blood derived NIFS were calculated from routine blood tests and abdominal ultrasound done prior to starting AVT. AUROCs were calculated for each of these parameters predicting cirrhosis, development of LB and development of EV and decompensation on follow-up after AVT.

Results: Mean age was 41.9 ± 9.7 years (85% males), predominantly genotypes 4 (65%) and 1 (11%). Pretreatment LB (Scheuer criteria) showed stage-0 fibrosis in 190 (12%), stage-1 in 32.9%, stage-2 in 39.9%, stage-3 in 6.8% and stage-4 (cirrhosis) in 6.6% of the patients. After AVT, there were 1,089 (67.8%) responders, 482 (30%) nonresponders and 42 (2.1%) relapers. After median follow-up of 6580.5 patient-years post AVT, 39 (2.4%) developed EV (2 patients had both esophageal and gastric varices and one had only gastric varices) and 52 (3.2%) had decompensation (bleed-9, ascites-39, jaundice-22, hepatic encephalopathy-7, hepatorenal syndrome). CRBPs had higher accuracy for prediction of cirrhosis and EV, while NIFs had higher accuracy for predicting decompensation (Table 1). The highest AUROCs were seen for predicting cirrhosis (AUROC = 0.908) and EV (AUROC = 0.885) and with FIB-4 score for decompensation (AUROC = 0.854). At a cut of 1200 PSI had sensitivity of 87.2% and specificity of 73% for predicting cirrhosis and at a cut of 1100 PSI had sensitivity of 89% and specificity of 85% for predicting EV. A cut-off of 2.5, FIB-4 had a sensitivity of 82.5% and specificity of 80.1% in predicting decompensation.

Conclusion: CRBPs predict cirrhosis and development of esophageal varices with high accuracy. Some of the blood derived NIFS have high accuracy in predicting decompensation post antiviral treatment. Application of these simple scores may help in non-invasive screening of patients at high risk for development of esophageal varices and decompensation after antiviral treatment.

2Trinity College, Dublin/Ireland
3Gastroenterology Trinity Academic Gastroenterology Group (TAGG), AMNCH, Tallaght, Dublin/Ireland

Contact E-mail Address: tatiana.nuzum@amnch.ie

Introduction: Minimal Hepatic Encephalopathy (MHE) is present in more than 30% of patients with chronic liver disease (CLD), and is associated with a poorer prognosis including a higher incidence of falls, RTAs and overall mortality. Detection of MHE is often difficult due to time constraints associated with the current gold standard, the psychometric hepatic encephalopathy score (PHES), which is labor intensive. A smartphone application (EncephalApp Stroop Test) has been suggested as a viable alternative.

Aims & Methods: We aimed to validate the use of the EncephalApp Stroop Test as a screening tool for MHE in an Irish population. CLD patients and healthy controls were recruited from outpatients. CLD patients were identified based on clinical and radiological evidence. Written consent was obtained. Exclusion criteria: cognitive impairment from any other cause, colour-blindness or dyslexia. Baseline demographics, level of education and medical history were obtained, and a Child-Pugh score was calculated where relevant. Each participant performed the PHES test and the Stroop test. Outcomes included the time taken to perform each PHES test as well as the total PHES, the Stroop on-off time and time taken to complete 5 correct runs on the Stroop App. Results were analysed using exact Pearson’s chi-squared test, or Fisher’s exact test for predicting cut-off of 187 s. Both tests were compared and correlation coefficients calculated. Results were compared amongst patient groups using a student t-test, where p < 0.05 was considered significant. ROC analysis was used to establish a standard local cut-off for a positive Stroop Test.

Results: A total of 96 patients (51 males) were recruited. Overall, the mean age was 51.7 ± 16.6 years; mean years spent in education 13.8 ± 4.2. In all there were 35 CLD and 61 healthy controls. While there was no difference in age or years spent in education, there were more men in the CLD group compared to the controls, 23/35 (66%) vs. 28/61 (46%), p = 0.06. Within the CLD cohort, 30 (86%) patients were Child-Pugh class A, 4 (11%) were class B and 1 (3%) was class C. As expected, more CLD patients had a positive PHES, 4/35 (11%) vs. 3/61 (7%). Overall, correlation between the two tests was poor, 7 (7%) participants had a positive PHES, while 47 (49%) had a positive Stroop test (z = 0.1516). Among controls, 27 (44%) had a positive Stroop test, while 3 (5%) had a positive PHES. ROC analysis was performed to establish cut-off of 187 s. AUROCs were 0.885) and with FIB-4 score for decompensation (AUROC = 0.854). At a cut of 1100 PSI had sensitivity of 89% and specificity of 85% for predicting EV. A cut-off of 2.5, FIB-4 had a sensitivity of 82.5% and specificity of 80.1% in predicting decompensation.

Conclusion: CRBPs predict cirrhosis and development of esophageal varices with high accuracy. Some of the blood derived NIFS have high accuracy in predicting decompensation post antiviral treatment. Application of these simple scores may help in non-invasive screening of patients at high risk for development of esophageal varices and decompensation after antiviral treatment.

Introduction: Cirrhosis is accompanied by significant changes of the intestinal microbiome including the overgrowth of the intestine with potential pathogens that can translocate through a weakened gut barrier and cause severe infections. We hypothesized that probiotic bacteria repress intestinal pathogen growth and strengthen the gut barrier.

Aims & Methods: Therefore, we conducted a randomized, double-blind, placebo-controlled study to test the effects of the multispecies probiotic Ecologic Barrier (Winclove, Amsterdam, The Netherlands)/Omnibiotic Hetox (Allergosan, Graz, Austria) on microbiome composition, predicted metagenome functions, and tight junction function in cirrhosis patients. A once daily dose of the probiotic mixture (1.5×10^10 CFU) or placebo was administered to 58 patients with Child’s A cirrhosis. We analysed the stool microbiome prior, immediately after the intervention and six months following end of treatment. Hypervariable region 1–2 of the bacterial 16S rDNA was sequenced and predictive communities were identified using Ada Boost Classifier. Functional predictions were analysed by Phylogetnic Investigations of Communities by Reconstruction of unobserved States (PICRUSi). Zonulin and calprotectin were assessed in stool as markers for gut permeability and intestinal inflammation, respectively.

Conclusion: This is the first study investigating the efficacy of the Stroop test in Ireland. It was quicker and easier to perform compared to PHES test. Age and years in education had a greater impact on the Stroop test, which may affect its application and interpretation. While our ROC analysis suggests a similar cut off to previously published values, there is significant variability and local validation is likely to be required. Overall the comparison with the gold standard PHES was poor. However, there were no false negative Stroop tests suggesting it may be a convenient filter test for MHE.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: A community of 37 operational taxonomic units (OTUs) was sufficient to pinpoint characteristic features of the microbiome before and after the intervention. Within this predictive community, three OTUs were found to be differentially abundant: Lactobacillus brevis and Lactococcus lactis increased significantly and Enterococcus durans decreased significantly in the probiotic group. Zonulin normalized in 20% of patients in the probiotic group. Predicted metagenome functions (assessed by PICRUSi) and calprotectin did not show any differences during intervention.

Conclusion: In conclusion, a six months intervention with a multispecies probiotic enriched the microbiome of cirrhotic patients with probiotic bacteria. Additionally, the abundance of Enterococcus durans was reduced and the gut barrier was strengthened.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1339 THE IMPACT OF DIABETES MELLITUS ON SHORT-TERM AND LONG-TERM OUTCOMES AFTER LIVER TRANSPLANTATION

A. Eshraghian1, S. Nikeghbalian2, M.R. Fattahi2, S. Ali Malek-Hosseini2

Gastroenterology Research Center, Shiraz University of Medical Sciences, Shiraz/Iran

Transplant Research Center, Shiraz/Iran

Endoscopy Ward, Namazi Hospital, Fars-Shiraz/Iran

Introduction: Diabetes mellitus (DM) is a growing disease worldwide. Some previous studies have reported negative impact of DM in patients with chronic liver disease. Aims & Methods: This study aimed to investigate the prevalence of DM in patients with liver cirrhosis and its impact on post-liver transplant short-term and long-term outcomes. In a cross-sectional study patients with liver cirrhosis on liver transplant waiting list who had undergone liver transplantation between March 2012 and March 2015 at Shiraz Transplant Center, Shiraz, Iran were included. Clinical and laboratory data of patients were recorded and patients were followed during post-liver transplant period. DM was diagnosed if the patient had fasting plasma glucose (FPG) ≥126 mg/dL or random plasma glucose ≥200 mg/dL in 2 different checkings or receiving anti-diabetic medications. The impact of DM on post-transplant outcomes was investigated using student t-test and chi-square test. Multivariate logistic regression was used for analysis of independent risk factors of mortality after liver transplantation. Kaplan-Meier method was used for analysis of survival.

Results: 1014 patients were included in the study. 259 patients (25.5%) found to have DM. Prevalence of DM was significantly higher among patients with cirrhosis on liver transplant waiting list who had undergone liver transplantation between March 2012 and March 2015 at Shiraz Transplant Center, Shiraz, Iran were included. Clinical and laboratory data of patients were recorded and patients were followed during post-liver transplant period. DM was diagnosed if the patient had fasting plasma glucose (FPG) ≥126 mg/dL or random plasma glucose ≥200 mg/dL in 2 different checkings or receiving anti-diabetic medications. The impact of DM on post-transplant outcomes was investigated using student t-test and chi-square test. Multivariate logistic regression was used for analysis of independent risk factors of mortality after liver transplantation. Kaplan-Meier method was used for analysis of survival.

Introduction: Cirrhotic patients very often need to be hospitalized and it is known that they have a higher mortality rate. The study was retrospective, and we included all hospitalized patients with a final diagnosis of liver cirrhosis a period of 7 years. We divided them in two cohorts, an initial group, which was analysed; and a control group, in which we validated the score. We performed univariate and multivariate analysis in order to determine a prediction model for mortality.

Results: A total of 1163 cirrhotic patients were included. In-hospital mortality rate was 10%. The initial cohort included 899 patients. Regarding cirrhosis etiology: 384/899 (42%) had hepatitis C, 158/899 (17.5%) had hepatitis B, 293/899 (32.5%) were alcoholic, 6/899 (0.6%) were autoimmune, 7/899 (0.7%) were cardiac, 13/899 (1.4%) were premalignant liver cirrhosis and in 5% of cases the etiology was unknown. In univariate analysis, hypotension (p < 0.0001), hyperpotassemia (p < 0.0001), hypopulbunimemia (p < 0.0001), high values of bilirubin (p < 0.0001), high values of creatinine (p < 0.0001) were strongly associated with in hospital mortality. In multivariate analysis, the model including albumin, sodium, potassium, creatinine and bilirubin (all p-values < 0.05) had an AUROC of 0.78, C (0.75–0.81), p < 0.0001. Using this factors as predictors, by multiple regression analysis we obtained in the initial group the following score: ABCPS score = 0.04 + 0.03*Albumin + 0.05 + 0.02*Creatinine + 0.04 + 0.04*Bilirubin + 0.05 + 0.28*Sodium. 

Conclusion: Prevention and prompt treatment of kidney injury, hypotension, hyperpotassemia, can improve survival. ABCPS score can be an useful score to rule out patients with high mortality rate.

Introduction: The Baveno VI guidelines propose that cirrhotic patients with a liver stiffness measurement (LS) <20 kPa and a platelet count >150000/µL can avoid screening endoscopy as their combination is highly specific for excluding clinically significant varices.

Aims & Methods: The aim of the study was to validate the Baveno VI criteria. We did a retrospective study, from 2009–2014. We took all the patients with transtent elastography data. Inclusion criteria were a LS >12 kPa and an upper gastrointestinal endoscopy within 12 months, with a diagnosis of chronic liver disease. Varices were graded as low risk (grade <2) or high risk (grade ≥2).

Results: The study included 774 patients (hepatitis C virus 40.5%, hepatitis B virus 16.1%, 31.6% etiologies, 11.8% other etiology, and 47.5% were Child Pugh A). Varices were present in 561/774 (2.4%) patients. The diagnosis of ALI (acute liver injury) was mortality in the two cohorts and independent socio-demographic and medical risk factors for mortality in each cohort. Variables tested include age, gender, race, income, Charlson criteria, hospital factors and medical comorbidities including Malnutrition, HTN, Anemia, CKD, Diabetes, CHF, Coagulopathy, Alcoholism, HBV and HCV. Univariate and multivariate logistic regression analyses were performed to identify independent predictors.

Discussion: During the study period, a total of 437,390 patients were diagnosed with acute liver injury and were included in the study, of which 3,799 had previously undergone bariatric surgery. In the post-bariatric cohort, mean age was 58.7 years and 77% were women. The prevalence of acute liver injury in all inpatient admissions for that time period was higher in patients with history of bariatric surgery (0.88%) than in non-bariatric patients (0.75%), p < 0.01. Patients with history of bariatric surgery displayed odds ratio of 1.52 of developing ALI when compared to patients with no history of bariatric surgery (95%CI: 1.43–1.61, p < 0.01). The rate of overall inpatient mortality was higher in non-bariatric cohort (15.9% versus 9.3%). Post-bariatric patients admitted for ALI were more likely to be younger, female, Caucasian and residing in more affluent areas. Post-bariatric patients were also more likely to have higher rates of malnutrition, anemia, alcoholism, and significantly lower prevalence of hepatitis B and C; CHF, diabetes and kidney disease. In a multivariate regression model the presence of CHF and coagulopathy increased mortality risk, and diagnosis of alcoholism was associated with lower mortality risk from ALI in patients with prior history of bariatric surgery (Table).
P1344 LONGITUDINAL MONITORING OF LIVER STIFFNESS BY ACOUSTIC RADIATION FORCE IMPULSE IMAGING IN PATIENTS WITH CHRONIC HEPATITIS B RECEIVING ENTECAVIR

S. Wu, H. Ding, L. Liu, X. Xu, W. Jiang

Introduction: Acoustic radiation force impulse (ARFI) measures liver stiffness (LS), which significantly correlates with the stage of liver fibrosis in treatment-naïve patients with chronic hepatitis B (CHB). So far, the use of ARFI elastography to monitor change in liver fibrosis has not been properly evaluated during antiviral therapy in CHB patients.

Aims & Methods: We aimed to prospectively assess the clinical usefulness of ARFI during long-term antiviral therapy in CHB patients. Seventy-one CHB patients were consecutively recruited and received antiviral therapy with entecavir. Paired liver biopsies were performed in 27 patients at baseline and week 78 of entecavir therapy. LS was assessed by ARFI at multiple follow-up sessions.

Results: LS significantly decreased with treatment and continued to decrease after normalization of alanine aminotransaminase. Overall, 97.2% patients achieved improvement of LS, whereas 19.7% patients had more than 30% reduction in LS values between baseline and week 104. Multivariate linear regression analysis showed that the degree of LS reduction significantly correlated with the change in LS values between baseline and week 104. The presence of elevated triglycerides (239.9 ± 49.3 dB/m vs 284.1 ± 28.1 dB/m, p = 0.001) and obesity (240.4 ± 46.7 dB/m vs 290.7 ± 46.6 dB/m, p = 0.01) were associated with a higher degree of LS reduction.

Conclusion: Bariatric surgery increases the risk of subsequent acute liver injury. Post-bariatric surgery patients admitted for ALI are more likely to have anemia, malnutrition, and alcoholism, supporting the hypothesis that baseline nutritional status may predispose to drug-induced ALI. Addressing these potentially modifiable risk factors may decrease the significant morbidity and mortality of ALI.

Contact E-mail Address: smxaviera@gmail.com

Introduction: In chronic Hepatitis B virus (HBV) hepatitic steatosis is mainly attributable to metabolic risk factors, rather than virologic factors. We aimed to assess the presence of hepatic steatosis in chronic HBV inactive carriers using non-invasive methods, namely controlled attenuation parameter (CAP) measurement with fibroscan. We also aimed to identify the impact of hepatic steatosis and their impact in the values of fibrosis determined with fibroscan.

Aims & Methods: Fibroscan was performed in chronic HBV inactive carriers. Assessment of hepatic transient elastography and CAP, with simultaneous assessment of anthropometric, clinical and analytical parameters.CAP values of 248.268 and 280 dB/m defined cut-offs of steatosis grade I, II and III, respectively.

Results: Included 49 patients with a mean transient elastography of 5.1 ± 1.5 Kpa and a mean CAP of 248.9 ± 93.2 dB/m. A significant association was found between the value of CAP and the presence of steatosis in the last ultrasound (237.3 ± 49.3 dB/m vs p < 0.01). In the presence of elevated triglycerides (239.9 ± 49.3 dB/m vs 284.1 ± 28.1 dB/m, p = 0.001) and obesity (240.4 ± 46.7 dB/m vs 290.7 ± 46.6 dB/m, p = 0.01), the presence of elevated triglycerides and obesity were associated with a higher degree of LS reduction.

Conclusion: Different components of MS seem to contribute both to fibrosis and steatosis in chronic HBV inactive carriers. In this subset of patients, the interplay between fibrosus and fibrosus fibrosis should be made with caution since it may be influenced by metabolic parameters.

Disclosure of Interest: All authors have declared no conflicts of interest.

A total of 95 HBsAg-positive, HBeAg-negative patients (M/F: 73/22, median age 50 yrs, 34% cirrhotic) with stable viral suppression by NUCs, were treated with NUC antiviral therapy with stable viral suppression (HBV-DNA ≤10⁹ copies/mL) for >1 year before the seroconversion, and NUC therapy was successfully stopped, without reoccurrence of hepatitis B virus. There was no significant difference in age, gender, body mass index (BMI), HBsAg levels, alanine aminotransferase (ALT), or aspartate aminotransferase (AST) between the two groups at baseline. At week 24, HBsAg levels in peg-IFN-α-naa add-on therapy group were significantly lower than the baseline (2.96 ± 0.14 vs 2.90 ± 0.82 c/mL, p = 0.009), but there was no obvious change in NA monotherapy group (3.43 ± 0.46 vs 3.44 ± 0.44 c/mL, p = 0.843). The HBsAg loss in peg-IFN-α-naa add-on therapy group was significant higher than in NA monotherapy group at week 24 (0.87 ± 0.76 vs −0.01 ± 0.10 c/mL, p = 0.008). Among those patients who completed 96 weeks of follow-up, two patients in peg-IFN-α-naa add-on therapy group (22.2%) achieved HBsAg seroconversion, but none in NA monotherapy group (0%).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1347 QUANTIFICATION OF SERUM HBsAG IS A HELPFUL MARKER TO OPTIMIZE THE MANAGEMENT OF ANTIVIRAL NUC THERAPY IN CHRONIC HBeAG-NEGATIVE HEPATITIS B

M. Guarino1, M. Masarone2, G. Portella3, A. Sessa3, R. Bonavolta3, N. Caporoso1, F. Morisco1

2Internal Medicine and Hepatology Unit, San Giovanni e RuggiD’Aragona, University of Salerno, Salerno, Italy
3Department of Translational Medical Science, University of Naples “Federico II”, Napoli, Italy

Contact E-mail Address: asessa1990@gmail.com

Introduction: Serum HBsAg loss is the recommended stopping rule in nucleos(t)-analogues (NUC) responders, even if this event occurs rarely.

Aims & Methods: We aimed to investigate in patients with chronic HBV+ hepatitis the relationship of HBsAg levels during the NUC therapy to evaluate the predictive parameters of HBsAg seroclearance. Patients with CHB, receiving NUC antiviral therapy with stable viral suppression (HBV-DNA <2000 UI/ml), were recruited at the Gastroenterology Unit of the University of Naples “Federico II”. Serum samples from these patients were tested for HBsAg quantification with the Elecsys HBsAg II Quant immunoassay (Roche Diagnostics, Indianapolis, USA). HBsAg levels were determined before starting NUC treatment and on-treatment every 12 months.

Results: A total of 95 HBsAg-positive, HBeAg-negative patients (M/F: 73/22, median age 50 yrs, 34% cirrhotic) with stable viral suppression by NUCs were enrolled. Precisely 56 patients underwent to Tenofovir, 22 Entecavir and 17 Lamivudine. The median treatment duration was 111 months, range 25–183 months. There was a significant decrease of the HBsAg levels during NUC therapy from 3471 UI/ml at the baseline to 1758 UI/ml at the last determination (p < 0.001). The statistically significant HBsAg decrease was also maintained when the patients were clustered according to antiviral therapy, severity of liver disease and previous interferon treatment. HBsAg seroclearance occurred in 18/95 patients (19%).

Conclusion: The results of this study suggest a role of on-treatment HBsAg quantification in the management of NUC-treated patients. HBsAg measurement would be a useful parameter to optimize antiviral treatment schedule.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1348 IMPROVEMENTS IN CHRONIC HEPATITIS B PATIENTS AND THE ALTERATION IN GUT MICROBIOTA AFTER FECAL MICROBIOTA TRANSPLANTATION

C. Xiao, B. Zhang, J. Ren
Zhongshan Hospital Affiliated To Xiamen University, Department of Gastroenterology, Xiamen, China

Contact E-mail Address: xiaoxc@xmu.edu.cn

Introduction: Chronic hepatitis B (CHB) is a common liver disease worldwide, and can be progressed to liver cirrhosis and hepatocellular carcinoma. Unfortunately, only a minority of CHB patients could achieve the clearance or seroconversion of hepatitis B virus e-antigen (HBsAg), the end point of treatment, even after multiple years of antiviral therapy. Therefore, it is urgent to develop new and effective strategy for treatment of CHB and examine the mechanisms.

Aims & Methods: In this study, we performed 60 times of fecal microbiota transplantation (FMT) by nasointestinal tube for 20 CHB patients who continued IFN-α-2a add-on therapy during previous antiviral treatment, and accordingly measured the HBsAg level four weeks after each FMT. Fecal samples of CHB patients before (Baseline) and after FMT as well as donors were collected for analyses of gut microbiota by sequencing 16S V3-V4 regions on Illumina MiSeq using PE 250 reagents.

Results: Results showed that HBsAg of 13 patients (65%) was cleared or reduced after one to seven times of FMT. Based on OTUs at cutoff of 3% dissimilarity, there were significant (PERMANOVA, P = 0.001) differences in overall gut bacterial communities among CHB-Baseline, CHB-FMT, and donors forming three major clusters in PCA ordination. Whereas, no significant differences (ANOSIM, P > 0.05) were detected in α-diversity indexes among the three groups, including observed OTU numbers, Shannon index, Simpson index, and Pielou evenness. This implies that it is the taxonomic relative abundance, not taxon number, that contributed to the bacterial community differences. Overall, gut bacteria were mainly composed of Fimbicutes (Lachnospiraceae, Ruminococcaceae, Veillonellaceae), Bacteroidetes (S24-7, bacteroidaceae, Proteobacterales, and Proteobacteria (Alcaligenaceae, Enterobacteriaceae). More specifically, Actinomyces was significantly higher in CHB patients (CHB-Baseline) than FMT-treated patients (CHB-FMT) and donors, and was identified as the biomarker of CHB using LEfSe analysis. Conversely, Prevotella and Eubacterium were significantly decreased in CHB-Baseline after FMT to almost equal to the abundances in donors, and were also identified as biomarkers.

Conclusion: In summary, along with the clearance or remission of HBsAg, the gut bacterial communities of chronic hepatitis B patients were remarkably altered after fecal microbiota transplantation, with some taxa abundances changed accordingly, which suggested their potential application as targets for clinical diagnosis and treatments in future.

Disclosure of Interest: All authors have declared no conflicts of interest.
P1350 HEPATITIS C IN LEBANON: BURDEN OF THE DISEASE AND VALUE OF COMPREHENSIVE SCREENING AND TREATMENT
A. Abou Rachid1, S. Abi Kheir2, J. Sabe1, S. Assaf2, G. Kassar2, Y.S. Gonzales3, O. Ethgen4
1Lebanese University, Beirut/Libanon

3Abbvie Biopharmaceuticals GmbH, chicago/United States of America
4SERFAN Innovation, Liege/Belgium

Contact E-mail Address: abourachedantoine@gmail.com

Introduction: As few reliable data on the burden of hepatitis C virus (HCV) are available from the Middle East, we analyzed HCV burden in the Lebanese population and the value of comprehensive screening and treatment at different age groups and fibrosis stages.

Aims & Methods: A multi-cohort, health-state-transition model was developed to project the number of HCV patients achieving a sustained virologic response (SVR12) or progressing to compensated cirrhosis (CC), decompensated cirrhosis (DCC), hepatocellular carcinoma (HCC), and liver-related death (LrD) from 2016 to 2036. Epidemiology and mortality data were extracted from the Ministry of Health bulletin while costs were collected from insurance claims. The proportion of patients screened for HCV was projected to increase to 60%–85% (90% low/medium/high screening scenarios) in 2026, with a new cohort of patients being diagnosed each year. SVR12 rates were estimated from clinical trials. Separate models were used for 18–39 and 40–80 age groups to account for different prevalence and screening rates.

Results: Low, medium, and high HCV screening scenarios showed that 3838, 5865, and 7669 individuals would be diagnosed with HCV infection from 2016 to 2036, 40% aged 18–39 and 60% aged 40–80. In the absence of treatment, the projected number of patients with CC, DCC, HCC and LrD in 2036 was 899, 147, and 147 respectively for the 18–39 age groups. In the 40–80 age groups, these projections were substantially greater: 2828 CC, 736 DCC, 665 HCC and 958 LrD. The overall economic burden of these liver complications would reach 150 million € by 2036. Adopting direct-acting antivirals (DAAs) for F0-F4 patients would increase by 43% and 62% the proportion of remaining life-years (LYs) spent in SVR12, compared to DAAs given to F2-F4 or to F3-F4 only, respectively. Although DAAs for F0-F4 increase the cost of HCV treatment, they also provide the greatest population health benefit and lowest cost per LY gained in SVR12. Compared to no treatment and screening, adopting the high screening variant and DAAs access to F0-F4 would cost an additional 1.957 € for every LY gained in SVR12 for patients aged 18–39 and 168 € for the 40–80 age group.

Conclusion: An enhanced screening policy coupled with broader access to DAAs will diminish the future clinical and economic burden of HCV in the Lebanese population and provide the greatest health benefits per amount invested, among middle-aged and elderly adults with a big difference in additional costs between the 2 groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1351 HEPATITIS C TREATMENT IN HEMODIALYSIS PATIENTS: THE EFFICACY AND SAFETY OF DIRECT-ACTING ANTIVIRALS IN THE REAL LIFE
L. Carvalho, J. Rodrigues, M.A. Túlio, T. Bana, E Costa, L. Lebre, C. Chagas Gastroenterology, Centro Hospitalar de Lisboa Ocidental, Lisboa/Portugal

Contact E-mail Address: lilipcarvalhov@gmail.com

Introduction: Hepatitis C virus (HCV) infection in renal transplant patients pre-disposes to graft failure and progression of renal disease, increasing mortality. Due to immunosuppression and oscillating glomerular filtration rate (eGFR) in the evolution of virological response and clinical outcomes (kidney function, anemia and other adverse effects), HCV-infected and renal transplanted patients treated with DAAs between April 2015 and February 2017 were analyzed.

Results: Including 19 patients, 10 males (53%) and 9 females (47%) with a mean age of 57 years (40–70 years). The majority of these patients (89%) were treatment-naïve. Genotype distribution was the following: genotype 1–74% (14/19), genotype 3–16% (3/19) and genotype 4–10% (2/19). Distribution according to liver stiffness was as follows: F 2–63% (12/19), F3–21% (4/19) and F4–16% (3/19). Twenty-five patients (85%) were treated with sofosbuvir/ledipasvir, 2 (10%) with sofosbuvir/dacabasvir and 1 (5%) with sofosbuvir. Concomitant ribavirin was given in 4 patients. The treatment duration was 12 weeks for 16 patients (84%) and 24 weeks for others (20%). One patient realized only 21 weeks of treatment, needing to suspend it due to severe anemia. Regarding treatment response rates, 74% (14/19) of patients had Rapid Virological Response (RVR) and 100% (19/19) of patients had End of Treatment Response (ETR). The global sustained virologic response (SVR) rate was 100%.

Conclusion: In our sample of HCV-infected with kidney transplant, DAA are effective and well tolerated, even in the more advanced stages of fibrosis, maintaining the integrity and viability of the graft, without interfering with the efficacy of immunosuppressant.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Liver stiffness (LS) measurements by Transient Elastography (TE) has been widely accepted as a tool for fibrosis assessment. Aims & Methods: The aim of this study was to assess LS dynamics in a group of patients with HCV liver cirrhosis after DAA treatment. This birentic clinical
trial included 276 patients with compensated HCV cirrhosis (all genotype 1b), with a mean age of 57 years. All patients were evaluated by means of TE at the beginning and at the end of treatment (EOT), and one subgroup (180 patients) also 12 weeks after EOT, all of them with sustained viral response (SVR 12), and another subgroup (55 patients) also at 24 weeks after EOT (SVR 24). Liver stiffness measurements (LSM) values were defined as median value of 10 valid LSM, with IQR < 30% and SR ≥ 60%. Both M and XL probes were used. For diagnosing cirrhosis we used a cut-off value of 12 kPa as proposed by the Tschatschis meta-analysis. We considered a decrease or increase of more than 10% in LSM as being significant.

**Results:** Out of 276 subjects, reliable measurements were obtained in 92.7%, so that the final analysis included 256 patients. The mean LS values decreased significantly after DAA: 25.1±11.7 kPa vs. 22.5±12 kPa (p<0.009). Most patients (57.7% (152/256)) presented more than 10% decrease in LSM values. 23% (59/256) had stable LSM values, while in 17.3% (45/256) the LS values increased. In the subgroup of 180 patients where LSM were also performed 12 weeks after EOT (SVR 12), the mean LS values were significantly lower at EOT as compared to baseline: 20.3±10.8 kPa vs. 25.5±11.4 kPa (p<0.001) and also compared to EOT: 20.3±10.8 kPa vs. 22.8±12.2 kPa, (p<0.04). In the subgroup of 55 patients where LSM were also performed 24 weeks after EOT (SVR 24), the mean LS values were significantly lower at SVR 12 and SVR 24 as compared to EOT (18.7±8.2 kPa vs. 21.6±7.7 kPa and 18.5±6.6 kPa vs. 21.6±7.7 kPa, p<0.01).

**Conclusion:** In our group mean liver stiffness values evaluated by TE significantly decreased after antiviral treatment at SVR 12 and SVR 24, as compared to EOT. Overall, in our study almost 60% of patients had EOT liver stiffness values lower than at baseline, at SVR 12 almost 75% of patients had liver stiffness values lower than at baseline and at SVR 24 almost 77% of patients had liver stiffness values lower than at baseline.

**Disclosure of Interest:** I. Sporea: I hereby confirm that I have received financial support (congress travel grant or speaker fee) from Philips, Siemens, General Electric, Abbvie, Zenitiva, Bristol Meyers Squibb.

P1354 ACHIEVING SVR AFTER DAA THERAPY FOR HCV DECREASES THE ACCURACY OF THE BAVENO VI CRITERIA CLASSIFICATION OF HIGH-RISK VARIANTS IN CIRRHOTIC PATIENTS

**1** Hepatology, Regional Institute of Gastroenterology and Hepatology, Cluj-Napoca, **2** Hepatology, Cluj-Napoca University of Medicine and Pharmacy, **3** Medical Clinic, Hepatology and Medical Imaging, D, Cluj-Napoca, **4** Regional Institute of Gastroenterology and Hepatology, **5** Clinic of Gastroenterology, Chiuji Napoca, Romania

**Contact E-mail Address:** rotaruci.magda@gmail.com

**Introduction:** Baveno VI criteria suggest that cirrhotic patients with platelet count (PLT) <150,000/μl and liver stiffness measure values (LSM) <20 kPa bare a low risk for the development of esophageal varices (EV). Liver fibrosis was scored mild (F1), significant (F2) and advanced fibrosis (F3) in 2 cases and classmates (METAVIR). Compensated liver cirrhosis (F4) was diagnosed in 3 patients with liver biopsy or endoscopic screening for esophageal varices. Liver biopsy was done in 19 and histology showed fatty liver in 8 patients. Fatty liver was present in 17 of all patients on antiviral treatment, surgery laboratory panel included complete blood count, liver tests, HOMA-IR and serum lipid levels. Seventeen patients received treatment (standard of care peg-interferon alpha, ribavirin and/or direct-acting antivirals). Sustained virologic response (SVR) was attained by 12 and non-virologic response (NVR) by 5 patients. Serum probes were obtained before treatment and after response evaluation. Statistical analysis included Spearman’s ρ, Mann-Whitney U test, Wilcoxon’s test and Student’s paired t-test.

**Results:** M-C patients with BMI (r=0.522, p=0.015). M-C correlation between overweight and obese patients were higher than in those with normal weight (p=0.020). Patients with F3-F4 had higher BMI (p=0.010) and HOMA-IR (p=0.042). An increase in serum M-C was found in patients after SVR (p=0.018), while no significant variation from baseline values was found in NVR patients. The result remained significant in subgroup analysis of SVR patients with F1-F2 (p=0.028) and in those with fatty liver (p=0.017). M-C in serum did not show any association with assessment of liver fibrosis, fatty liver, insulin resistance and serum lipid levels.

**Aims & Methods:** The aim of the study was to explore the associations between serum M-C, liver fibrosis, fatty liver and metabolic factors in CHC patients before, and after antiviral treatment. We included 21 patients in the study (11 men, 10 women, age 42±7.9) with chronic hepatitis C virus (HCV) infection–17 with genotype 1 and 4 with genotype 3. Liver biopsy was done in 19 and histology showed fatty liver in 8 patients. Fatty liver was present in 17 of all patients on antiviral treatment, surgery laboratory panel included complete blood count, liver tests, HOMA-IR and serum lipid levels. Seventeen patients received treatment (standard of care peg-interferon alpha, ribavirin and/or direct-acting antivirals). Sustained virologic response (SVR) was attained by 12 and non-virologic response (NVR) by 5 patients. Serum probes were obtained before treatment and after response evaluation. Statistical analysis included Spearman’s ρ, Mann-Whitney U test, Wilcoxon’s test and Student’s paired t-test.

**Results:** M-C in serum correlated with BMI (r=0.522, p=0.015). M-C correlation between overweight and obese patients were higher than in those with normal weight (p=0.020). Patients with F3-F4 had higher BMI (p=0.010) and HOMA-IR (p=0.042). An increase in serum M-C was found in patients after SVR (p=0.018), while no significant variation from baseline values was found in NVR patients. The result remained significant in subgroup analysis of SVR patients with F1-F2 (p=0.028) and in those with fatty liver (p=0.017). M-C in serum did not show any association with assessment of liver fibrosis, fatty liver, insulin resistance and serum lipid levels.
Conclusion: MCP-1 concentrations in serum depend on overweight in patients with CHC. Overweight and insulin resistance are associated with progression of CHC. Serum levels of MCP-1 increase after HCV clearance. Fluctuation of the MCP-1 concentration in serum could reflect an antiinflammatory activation of MPS and a gradient dependent dynamic replacement of the profibrotic cell subsets in the liver with resolution ones after SVR. Fatty liver plays a role for inflammatory responses in CHC patients after SVR.

Introduction: HCV interferes with the host lipid metabolism leading to insulin resistance and hepatic steatosis. Although it is usually mild in genotype 4, metabolic syndrome in patients with CHC; the potential to progress to fibrosis, cirrhosis and subsequent hepatocellular carcinoma. Many heritable host factors with observed inter-ethnic variation in the prevalence of steatosis are documented, and in many cases hepatic steatosis may be detected in absence of all these risk factors; so a role for host genetic factors in development of hepatic steatosis in chronic HCV patients may be suggested.

Aims & Methods: In this study, we aim to evaluate the association of HLA class A-B alleles and presence of steatosis in chronic HCV genotype 4 infected patients.

Study: A total of 200 Egyptian patients with non-diabetic chronic HCV patients with normal lipid profile, 98 of them had biopsy proven steatosis. Serological testing of HLA class I antigens (HLA-A, and HLA-B alleles) were performed with a standard complement-dependent micro-lymphocytotoxicity assay.

Results: The frequency of A02, A03, B15 and B17 alleles were significantly higher in chronic HCV patients with steatosis (OR = 1.77, 2.64, 4.44, 5.68) and 95% CI = 0.96–3.27, 1.02–7.04, 0.84–31.17, 1.12–36.65 with P = 0.034, 0.022, 0.044, 0.015 respectively. On the other hand, the frequency of A01 and B12 alleles were significantly higher in patients without steatosis (OR = 0.56, 0.41) and 95% CI were 0.30–1.05, 0.20–0.83 and P = 0.015 and 0.005. On logistic regression analysis, patients who carry HLA-A02, A03 and HLA-B15 alleles may have 2.2, 3.9 and 11.18 fold risk to have hepatic steatosis (B coefficient: 0.78, 1.37; 2.41) with 95% CI = 1.09–4.42, 1.04–11.05, 2.15–58.13; P = 0.027, 0.009, 0.004) while carrying HLA-A01 alleles may be protected from having HCV associated hepatic steatosis; (OR = 0.34,95% CI = 0.16–0.72; P = 0.005) with constant 94.7 and overall accuracy of 69%.

Conclusion: In chronic HCV genotype 4 patients, carrying HLA-A02, HLA-A03 and HLA-B15 alleles may have a risk of presence for hepatic steatosis while presence of HLA-A01 alleles may have a protective role.

Introduction: Chronic liver diseases are quite frequently encountered in daily practice and are due mostly to chronic viral infections (B or C viruses) and to other conditions such as alcoholic steatohepatitis - (ASH) and to non-alcoholic fatty liver disease (NAFLD). While liver biopsy remains the gold standard method for fibrosis assessment, stage classification and also for necro-inflammation grading, in the last years, non-invasive assessment methods (biological tests and elastographic methods) were developed and they are being used more and more, to the detriment of liver biopsy.

Aims & Methods: The aim of this study was to evaluate the performance of the 2D shear wave elastography technique from General Electrics (2D-SWE.GE), for the evaluation of liver fibrosis in patients with HCV compensated chronic hepatopathies, using Transient Elastography (TE) as the reference method. The study included 145 consecutive subjects with HCV compensated chronic hepatopathies, in whom liver stiffness was evaluated in the same session by means of 2 elastographic measurements: TE (FibroScan, EchoSens) and 2D-SWE.GE (LOGIQ E9, GE Healthcare). Reliable LS measurements were defined as follows: for TE—the median value of 10 measurements with a success rate of >60% and an interquartile range< 30% and for 2D-SWE.GE - the median value of 10 measurements acquired in a homogeneous area and an interquartile range (IQR) < 30%. To discriminate between various stages of fibrosis by TE we used the following cut-offs: F0 = 2.7 kPa, F3 ≥ 9.5 kPa, and F4 = 12.5 kPa [1].

Results: Reliable LS measurements were obtained in 138/145 (95.1%) subjects by 2D-SWE.GE and in 139/145 (95.4%) subjects by TE. Final analysis was performed on 134 subjects with valid measurements by both methods. We found a good positive correlation between the LS values obtained by the 2 methods: r= 0.79, p = 0.0001. Based on TE cut-off values [1] we divided our cohort into 4 groups: F0-F1: 36/134 (26.6%), F2: 23/134 (17.2%), F3: 23/134 (17.2%) and F4: 52/134 (38.8%). The areas under the receiver operating characteristic curve (AUROC) were 0.909 for significant fibrosis (F2 ≥), 0.954 for severe fibrosis (F3 ≥) and 0.942 for cirrhosis (F4 ≥). The best cut-off values for F2 ≥ was 7 kPa (Sensitivity 85.7, Specificity 80.5), for F3 ≥ it was 9.2 kPa (Sensitivity 85.3, Specificity 91.5) and for F4 it was 10.7 kPa (Sensitivity 84.6, Specificity 91.4).

Conclusion: 2D-SWE.GE seems a reliable method for liver fibrosis staging in patients with HCV compensated chronic hepatopathies. The best 2D-SWE.GE cut-off values for F2 ≥, F3 ≥ and F4 ≥ in HCV chronic hepatopathies were 7, 9.2 and 10.7 kPa.

Introduction: The risk of developing de novo hepatocellular carcinoma (HCC) persists after reaching sustained virological response (SVR) in patients infected with hepatitis virus C. It has been suggested that risk is increased in patients treated with the new direct antiviral agents (DAA). In this prospective study we present our results of incidence and prevalence of novo HCC in cirrhotic patients treated with DAA and SVR, and also, the risk factors involved in its development.

Aims & Methods: We included all cirrhotic patients due to HCV infection without previous HCC who reached SVR after DAA treatment in our hospital from February 2014 until December 2016 (n = 197, median of follow-up of 17 months). We evaluated with chi square test the following qualitative variables: age, Child-Pugh stage, alcohol consumption pre-treatment, tobacco consumption pre-treatment, diabetes mellitus (DM) pre-treatment, genotype, radiological and endoscopic portal hypertension features pre-treatment. The quantitative variables were evaluated with student t test; age, no. of platelets pre-treatment, fibrosis stage pre-treatment.

Results: During follow-up 11 patients were diagnosed of HCC (5.6% prevalence, 3.9% annual incidence). Among all variables evaluated being in a Child- Pugh B stage vs. an A stage (p = 0.007), pre-treatment DM (p = 0.002) and presence of radiation portal hypertension (p = 0.001) were associated with developing novo HCC. Among the quantitative variables, we evidenced statistically significant differences in the mean value of platelets (p = 0.015).

Conclusion: In our group of patients, a worse hepatic function evaluated with the Child-Pugh classification and indirect markers of portal hypertension (platelets and radiological features) and also DM are associated statistically significant with the development of novo HCC. The incidence (≥1.5%) of novo HCC justifies the screening of HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.
more patients above Clavien IIa were in the observation group, there was no statistically significant difference in the peroperative mortality between the two groups. Besides, preoperative TACE could effectively reduce complications caused by immune reaction ($P = 0.048$). In terms of postoperative index of liver function, TBIL, ALT, AST all had a transient rise during the first 3 days after liver transplantation, but recovered gradually over time. There’s no remarkable difference in the liver function recovery level between two groups ($P = 0.495$; $P = 0.141$; $P = 0.101$).

Conclusion: Preoperative TACE won’t affect liver function recovery and perioperative safety after liver transplantation. For some patients, it could also reduce complications caused by immune reaction.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** Primary sclerosing cholangitis (PSC) is associated with an increased risk of cholangiocarcinoma, colorectal cancer (CRC) and gallbladder cancer. Orthotopic liver transplantation (OLT) patients are at increased risk of developing de novo malignancies, however limited and conflicting data exists regarding cancer risk post OLT for PSC.

**Aims & Methods:** To examine all recorded malignancies over 2 decades in OLT PSC pts and compare to our non-transplanted PSC cohort. To analyse factors associated with development of malignancies post OLT. We retrospectively studied PSC patients attending the Irish National Liver Unit (INLU) and the Centre for Colorectal Disease (CCD) at St. Vincent's University Hospital from 1/1/1994 to 30/9/16. We integrated this database with the National Cancer Registry in Ireland. This enabled accurate determination of the no. of malignancies recorded in the PSC cohort. Analysed data included age of recipient at OLT, gender, primary OLT indication, immunosuppressive regime, de novo malignancy post OLT, time from OLT to diagnosis of malignancy or death. Statistical analysis was primarily descriptive. Cox Proportional Hazard Model was used to analyse factors associated with mortality in the PSC OLT cohort.

**Results:** 107 of 173 patients had undergone transplant for PSC. 27/107 pts were transplanted for cholangiocarcinoma. 12 post-transplant de novo cancers and 12 HCC/SCC carcinomas were found in 107 patients during 737.8 person years of follow-up. Median time to cancer diagnosis post OLT was 5 years (IQR 2.8–5.9). Recurrence of PSC was observed in 21 patients (19.6%). Post-transplant lymphoproliferative disease (PTLD) remains a major complication after OLT. Previous studies have reported rates of 1–3% in adult OLT pts. 5 pts were diagnosed with lymphoma post OLT representing 4.7% of cohort. Median time to diagnosis was 5.3 yrs [IQR 2.8–10.2]. Regarding CRC, 2 patients developed CRC post OLT. 4 patients who developed colon dysplasia: 3/4 underwent colectomy. All those who developed colonic dysplasia/CRC post OLT had co-existing IBD. All 5 coloectomy specimens for dysplasia/CRC showed significant co-existing inflammation. One patient post OLT underwent a completion proctectomy for rectal cancer. As expected, cholangiocarcinoma as indication for OLT (p = 0.005, RR 2.573, 95%(CI 1.3–4.95) and an older age at transplant (p = 0.05, RR 1.027, 95% CI 1.0–1.054) were associated with higher mortality.

</tbody>
</table>

**Conclusion:** These findings represent national cancer figures in our PSC OLT cohort. The rate of cancer is more than three times higher in this population than the general population. The rates of PTLD are >30 times higher than those in the normal population, and slightly higher than previously reported in unselected liver transplant groups. We could not find any association between the development of PTLD and aggressive immunosuppressive regimes for co-existing IBD post OLT. The study highlights that IBD/PSC patients remain at significant risk of colonic neoplasia after OLT and require intensive surveillance.

2Department Of Immunogenetics, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
3Transplantcentre, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: drastich@hotmail.com

**Introduction:** Primary sclerosing cholangitis (PSC) is a chronic liver disorder of unknown etiology, characterized by inflammation, fibrosis and stenoses of both extra- and intrahepatic bile ducts. For those who develop end-stage liver disease, orthotopic liver transplantation (OLT) remains the only effective treatment currently available. PSC is accompanied with concomitant ulcerative colitis (UC) in a significant proportion of patients. Benefits of routine HLA typing in donor and recipient prior to OLT were proved in the past.

**Aims & Methods:** The aim of this study was to assess the impact of HLA-DR mismatch on acute cellular rejection (ACR), PSC recurrence (rPSC) and course of UC after OLT. time from OLT to diagnosis of malignancy or death. Statistical analysis was primarily descriptive. Cox Proportional Hazard Model was used to analyse factors associated with mortality in the PSC OLT cohort.

**Results:** Of 57 patients, 27 (47.4%) had single mismatch (“M1” group) and 30 (52.6%) had double mismatches (“M2” group) in HLA-DR. No patient had full mismatch. 33/57 (57.9%) patients had ACR: 15/27 (55.6%) of M1 and 18/30 (60%) of M2 (p = 0.94). 4/27 (14.8%) of M1 and 2/30 (6.3%) of M2 had corticosteroid ACR (p = 0.57). Multiple–episodes of ACR occurred in 11/57 (19.3%) patients: 6/27 (22.2%) of M1 and 5/25 (20%) of M2 (p = 0.74). 12/27 (21.1%) had de-novo UC after OLT: 7/27 (25.9%) of M1 and 5/30 (16.7%) of M2 (p = 0.60). In 37 (68.5%) patients, UC was diagnosed prior to OLT. 9/16 (56.3%) patients with M1 and 6/21 (28.6%) patients with M2 had more severe course of UC as compared to course prior to OLT (p = 0.17). 38 patients were evaluated for rPSC, which was diagnosed in 17 (44.7%) individuals. 6/19 patients with M1 and 11/19 with M2 had rPSC (p = 0.19).

**Conclusion:** Patients with single mismatch in HLA-DR have slight tendency towards development of rPSC and worsening of UC after OLT as compared to patients with double mismatch. Analysis of combined mismatch in HLA-DR and HLA-DQ could demonstrate more substantial linkages in respective clinical variables. Therefore, these data have to be considered as preliminary as typing for HLA-DQ from frozen blood samples is currently underway. Contact E-mail Address: es18497@gmail.com

**Introduction:** Liver biopsy remains the gold standard in the diagnosis of graft dysfunction in post-liver transplantation (GDPLT). Liver transient elastography is a valid non-invasive method for liver fibrosis evaluation, with a good correlation in chronic liver diseases. The progression of fibrosis represents a major problem in the post-liver transplantation.

**Aims & Methods:** We aimed to evaluate the predictive role of liver transient elastography in the evaluation of GDPLT and to determine the predictive factors of liver transplantation fibrosis. This was a retrospective analysis of the cohort study of total of 49 patients with post-liver transplantation status who underwent liver transient elastography by Fibroscan®. Selected patients who underwent percutaneous/transjugular liver biopsy. In case of more than one liver biopsy, it was selected the biopsy closer to Fibroscan®. The fibrosis and steatosis evaluated by Fibroscan® were compared with those obtained by liver biopsy. Significant fibrosis was considered if ≥2F. Demographic, analytical and associated variables were evaluated for their impact on liver fibrosis.

**Results:** A total of 32 patients underwent Fibroscan® and liver biopsy. Mean age of 48.53 ± 11.20 years and male gender in 68.8% (n = 22). The mean time between Fibroscan® and liver biopsy was 29.77 ± 36.90 months. The mean elastastography score was 13.45 ± 8.31KPa with IQR/median of 17.11 ± 8.66%. Mean CAP score was 207.12 ± 57.35 dB/m. Regarding liver biopsy, 34.4% (n = 11) had significant fibrosis and 25.0% (n = 8) presented steatosis. Comparing two methods, there was no concordance for steatosis (kappa = 0.273; p = 0.117) or inflammation (Kappa = 0.063; p = 0.710). On the contrary, a moderate agreement for significant fibrosis (kappa = 0.431; p = 0.003) was verified. The mean elastastography score showed an accuracy of 79.7% in predicting histological fibrosis (AUROC = 0.797; p = 0.0007) to a cut-off value of 11.6 KPa (S = 81.8%; Sp = 76.2%). In relation to analytical parameters, only serum albumin was predictive of histological fibrosis (OR = 2.79; p = 0.043).

**Conclusion:** Liver transient elastography represents a non-invasive and valid alternative procedure to liver biopsy in the evaluation of post-liver transplantation fibrosis but not steatosis or inflammation. Liver transient elastography scoring ≥11.6KPa and low values of serum albumin are predictors of post-liver transplantation fibrosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P1365 NEW-ONSET DIABETES AFTER TRANSPLANT (NODAT): INCIDENCE, RISK ANALYSIS AND IMPACT ON SURVIVAL

Y. Abbas1, K. Nawaz2, M. Salih3, N. Ullah4, S. Saada5
1Gastroenterology, Hepatology And Liver Transplant, Shifa International Hospital, Islamabad/Pakistan
2Gastroenterology And Hepatology, Shifa international hospital, Islamabad, Islamabad/Pakistan

Contact E-mail Address: dryasirab@gmail.com

Introduction: Orthotopic liver transplant has become the standard of care for end-stage liver disease and hepatocellular cancer. Better immunosuppressant paved way for improved survival rates post-transplant. But with this longevity comes a higher prevalence of chronic diseases such as New Onset Diabetes After Transplant (NODAT), Hypertension, metabolic syndrome etc. which have a negative impact on function and patient survival.

Aims & Methods: Primary: To determine the incidence of New Onset Diabetes After Transplant (NODAT), Impaired Fasting Glaucemia (IFG) and post-transplant hyperglycemia in living-donor liver transplant recipients. Secondary: To determine the risk factors associated with NODAT and IFG. To determine impact of NODAT on survival and mortality. It was a retrospective cohort study of 283 living donor liver transplant recipients from 29/4/2011 till 26/4/2016. Data was collected from records. Simple means and standard deviation was calculated for continuous variables while frequency statistics were calculated for categorical ones. Risk factors were assessed using binary logistic regression analysis.

Results: A total of 130 post liver transplant patients were analyzed after exclusion. NODAT was present in 41/130 (31.5%) patients, while 19/130 (14.6%) patients had impaired fasting glycemia. Acute cellular rejection, Post-transplant Hyperglycemia and Pre-transplant prediabetes showed increased odds of acquiring NODAT post-transplant. NODAT had significant association with mortality and decreased survival (p = 0.05).

Conclusion: This cohort showed that NODAT is an important post-transplant entity with significant impact on mortality and survival. Early identification of at-risk patients is suggested.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1367 OUTCOMES OF LIVER TRANSPLANTATION IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

A. Eshraghian1, S. Nikheghbi2, S. Ali Malek-Hosseini3, B. Geramizadeh2
1Gastroenterology And Hepatology, Shiraz University of Medical Sciences, Shiraz/ Iran
2Transplant Research Center, Shiraz/Iran

Contact E-mail Address: eshraghiana@yahoo.com

Introduction: Hepatocellular carcinoma (HCC) is the second leading cause of cancer-related mortality worldwide. Patients with viral hepatitis and those with non-alcoholic fatty liver disease (NAFLD), the prevalence of HCC is estimated to be increased in next years. Liver transplantation is now considered as a modality of treatment for patients with HCC.

Aims & Methods: This study aimed to investigate outcomes of liver transplantation in patients with HCC compared to other causes of liver transplantation. In a cross-sectional study patients who had undergone liver transplantation between March 2012 and March 2015 at Shiraz Transplant Center, Shiraz, Iran were included. Patients' characteristics including age, gender, model for end stage liver disease (MELD) score, rejection episodes, laboratory data and information included. Patients' characteristics including age, gender, model for end stage liver disease (MELD) score, rejection episodes, laboratory data and information included. Patients' characteristics including age, gender, model for end stage liver disease (MELD) score, rejection episodes, laboratory data and information included. Patients' characteristics including age, gender, model for end stage liver disease (MELD) score, rejection episodes, laboratory data and information included. Patients' characteristics including age, gender, model for end stage liver disease (MELD) score, rejection episodes, laboratory data and information included. Patients' characteristics including age, gender, model for end stage liver disease (MELD) score, rejection episodes, laboratory data and information included. Patients' characteristics including age, gender, model for end stage liver disease (MELD) score, rejection episodes, laboratory data and information included. Patients' characteristics including age, gender, model for end stage liver disease (MELD) score, rejection episodes, laboratory data and information included.

Results: Totally 1014 liver transplant patients were included. 94 patients with HCC underwent liver transplantation. There was no statistically significant difference between those with and without HCC in terms of gender, portal vein thrombosis (PVT), diabetes mellitus (DM), hepatic encephalopathy and hospitalization before liver transplantation (P > 0.05). HCC was significantly more prevalent in cirrhosis due to viral hepatitis (P < 0.001). Acute rejection episodes were not different in patients with and without HCC in early post-transplant period (OR = 0.563; 95% CI: 0.27-1.14, P = 0.098). In regression analysis, presence of post-transplant DM (OR = 3.89; 95% CI: 1.36-11.11, P = 0.011) and acute kidney injury within 30 days after liver transplant (OR =4.38; 95% CI: 1.44-1327, P =0.009) were independent predictors of post-transplant mortality. Mean post-liver transplant survival in HCC patients within Milan criteria was 40.48±3.69 months compared to 36.80±6.28 months in those beyond Milan criteria (P =0.82). Mean post-transplant survival in patients with HCC + DM was 32.79±4.7 months compared to 48.51±2.6 months in HCC patients without DM (P =0.009).

Conclusion: Liver transplantation can be used for patients with HCC, however, post-transplant survival seems to be lower. Diabetes mellitus and acute kidney injury were predictors of mortality among our patients with HCC after liver transplantation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1368 THE ASSESSMENT OF THE ADC PREDICTIVE VALUE IN SURVIVAL OUTCOMES OF PATIENTS UNDERGOING RADIONUCLIDE ABLATION FOR METASTATIC COLORECTAL CANCER LIVER TUMORS

O. Kozak1, T. Nowicki, J.M. Pienkowski2, E. Izryka-Swięszewska2, Z. Zadrozny2, E. Szarowska1, 2
1Department Of Radiology, Medical University of Gdańsk, Gdańsk, Poland

Clinic Of Oncologic And Liver Surgery, University Warmia and Mazury, Olsztyn, Poland

Introduction: Liver is one of the most common metastatic sites of colorectal cancer, nearly 50% patients develop hepatic metastases during the course of their disease. Metastatic spread influences survival rate of those patients. The diffusion weighted imaging (DWI) is MRI sequence designed to detect random movement of water protons in extracellular compartment. Biophysical parameter expressed ADC (apparent diffusion coefficient) is for their system. ADC values for b parameter lower than 300 s/mm² are influenced by perfusion whereas ADC values for b greater than 300 s/mm² depend mainly on diffusion. Aggressive malignant process often develops necrotic areas within neoplastic lesion. Necrotic changes are characterized by high ADC values. We suppose that low ADC values correlate with presence of necrosis in highly malignant lesions effecting in lower survival rate.

Aims & Methods: This is a post hoc analysis of prospective study to assess the predictive value of the ADC in survival outcomes of patients undergoing radiofrequency ablation due to metastatic colorectal cancer lesions in the liver. We analyzed the MRI studies of 52 patients (18 F, 34 M, aged 43±8) performed on 1.5 T scanner one day before the percutaneous RFA treatment. The total number of analyzed lesions was 110 (15 per patient), 83 of them were completely ablated 27 incompletely, what was assessed in follow-up CT studies. The standard protocol of the liver MRI was applied including DWI sequence in b values of 0, 15 and 300 s/mm². ADC maps were calculated for b values of 0.15 and 0.500 s/mm². The mean ADC value was obtained by threefold marking ROI covering the whole metastatic lesion. In cases of multiple foci only the lesion with the highest ADC value was included into analysis. On basis of ROC analysis the cut-off values of ADC were established: 2.49 mm²/s for b value of 0.15 s/mm² and 1.43 mm²/s for b value of 0.500 s/mm². The survival outcomes were assessed by mean of Kaplan-Meier estimator. The p value lower than 0.05 was considered significant.

Results: The statistical analysis included Kaplan-Meier estimator for 52 patients with 39 censored cases (77%). In ADC maps for b value of 0.500 s/mm², the ADC value ≥1.43 mm²/s correlated with longer survival time, whereas ADC value <1.43 mm²/s correlated with shorter survival time. Statistically significant differences were identified by log rank test = 2.6986, p = 0.007. Such a correlation was not observed for ADC values in ADC maps for b value of 0.15 s/mm² (p = 0.058).

Conclusion: The study showed significant differences in survival rate depending on diffusion influenced ADC values of metastatic lesions.

Disclosure of Interest: All authors declared no conflicts of interest.

Contact E-mail Address: isporaer@umf1.ro

Introduction: Type II diabetes and nonalcoholic fatty liver disease (NAFLD) are frequently associated. NAFLD being considered the hepatic expression of the metabolic syndrome.

Aims & Methods: The aim of the present study was to assess the severity of liver fibrosis and steatosis in a cohort of type 2 diabetic patients, using non-invasive methods: Transient Elastography (TE) and Controlled Attenuation Parameter (CAP). The study included 354 type 2 diabetic patients, who were prospectively randomized (every first 6 patients who were referred to the Metabolic Disease Outpatient Clinic on a consultation day), evaluated in the same session by means of TE and CAP (FibroScan EchoSens) to assess both liver fibrosis and steatosis. Each patient was evaluated for the presence of viral hepatitis (B, C) and an AUDIT-C score was performed to exclude alcohol abuse. Reliabiler liver stiffness measurements (LSM) were defined as the median value of 10 LSM with an IQR/median <30%. For TE and CAP, M and XL probes were used. A cut-off value of 8.2kPa [1] was used to define severe fibrosis (F≥3). For differentiation between stages of steatosis we used the following cut-off values [2]: S2(moderate) > 235 db/m, S3(severe) > 290 db/m.

Results: Out of 354 diabetic patients, we included those with associated viral hepatitis, those with an AUDIT-C score ≥8 and those with unrelatable LSM. The final analysis included 239 subjects (59.4% women, 40.6% men, mean age 64.9±9.3; BMI = 31.8±6.1 kg/m²) with reliable LSM. Accordingly to BMI, 10.8% had normal weight, 26.4% were overweight and 62.8% were obese (35.6% obesity grade I, 17.2% obesity grade II and 10% obesity grade III). Moderate and severe steatosis by means of CAP was found in 18.4% and 69.5% cases respectively. Severe fibrosis was defined by means of TE (LSM ≥ 8.2 kPa) in 29.3% (70/239) of subjects.

Conclusion: In our group, 87.9% of diabetic patients had moderate or severe steatosis by CAP and 29.3% of them had severe fibrosis (TE ≥ 8.2 kPa), suggesting that low ADC values correlate with presence of necrosis in highly malignant lesions effecting in lower survival rate.

Introduction: Nowadays liver fibrosis can be assessed using non-invasive elastographic techniques. ElastIPQ is a quite novel point share wave elastography integration in an ultrasound system.

Aims & Methods: The aim of our study was to evaluate the learning curve of obtaining reliable liver stiffness measurements (LSM), using ElastIPQ. LSM of a trainee were compared to LSM of an expert (with an experience of more than 900 examinations). Our study group included 50 subjects (mean age: 52.7 years, 66.6% men, mean BMI = 25.6 kg/m²). Both the trainee and the expert obtained LSM for each subject, using ElastIPQ (EPIQ 7, Philips Healthcare, Bothell, WA, USA). Reliable LSM were defined as the median value of the measurements of the LSM in a homogeneous area avoiding major blood vessels and with an IQR/median <30%. The learning curve was evaluated using the Receiver Operating Curve analysis using the expert’s results as reference.

Results: The trainee’s performance in obtaining reliable LSM was good (AUC: 0.735, 95% CI (0.557–0.913), p = 0.01). The trainee started to have similar results with the expert after the 30th subject. When looking at the IQRs, they became significantly lower after the 30th subject (2.6 ± 2.1 kPa vs 6.5 ± 2.1 kPa, p = 0.03).

Conclusion: Obtaining reliable LSM using ElastIPQ can be easily achieved after 30 LS examinations.

Disclosure of Interest: R. Mare: I hereby confirm that I have received financial support (congress travel grant) from Philips.

I. Sporea: I hereby confirm that I have received financial support (congress travel grant or speaker fee) from Philips, Siemens, General Electric, Abbvie, Zentiva, Bristol Meyers Squibb

PI371 ENHANCEMENT PATTERN OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH CHRONIC LIVER DISEASE

M. Danila1, I. Sporea1, R. Sirli2, A. Popescu2, T.V. Mogă2, A. Stănășan1
1Department Of Gastroenterology And Hepatology, Victor Babes University of Medicine and Pharmacy Timisoara, Timisoara/Romania
2Gastroenterology, Pediatrics, University of Medicine and Pharmacy ‘Victor Babes’ Timisoara, Romania

Introduction: In patients with liver cirrhosis, hepatocellular carcinoma (HCC) can be diagnosed by noninvasive imaging methods (contrast-enhanced ultrasound CEUS, contrast CT/MRI).

Aims & Methods: The aim of this study was to evaluate which is the most common enhancement pattern of HCC on CEUS in all three phases (arterial, portal and late phase). We performed a retrospective study that included patients with a final diagnosis of HCC established by an imaging method (contrast-enhanced CT or MRI) or biopsy. A total of 249 patients with HCC were examined (180 men, 69 women, mean age 64 ± 10 years); 181 patients had liver cirrhosis and 68 patients chronic hepatopathy with severe fibrosis. All 249 HCCs were evaluated by CEUS using low mechanical index ultrasound, following an intravenous bolus of 2.4 ml SonoVue. CEUS was considered conclusive for HCC if a typical pattern was present following contrast examination (hyperenhancement in the arterial phase accompanied by portal and/or late phases washout). The nodules were classified according to their size in ≤3 cm and >3 cm. We re-evaluated all 249 HCCs CEUS studies using the ACR CEUS LI-RADSv 2016 algorithm.

Results: After CEUS examination a conclusive diagnosis of HCC was obtained in 190/249 cases (76.3%). Arterial phase hyperenhancement pattern was present in 249/249 cases, arterial washout in the arterial phase was observed in 17/249 cases (6.8%) and hypoenhancement in 5/249 cases (2%). In the portal phase washout was observed in 111/249 cases (44.6%); in 121/249 (48.6%) patients the nodules were isoenhancing and in 17/249 (6.8%) the arterial hyperenhancement pattern was maintained. In the late phase washout was observed in 197/249 (79.1%) cases. The nodules ≤3 cm were diagnostic conclusive on CEUS in 63.7% (72/113), while nodules >3 cm had a conclusive result in 86% of cases (117/136), P < 0.001. CEUS examination was conclusive for HCC in 76.3% of the cases (190/249), while using the ACR CEUS LI-RADSv 2016 algorithm in 72.2% of all HCCs (180/249), P = 0.35.

Conclusion: In our study, CEUS arterial hyperenhancement is the most common pattern observed in HCC(91.2% of cases), followed by washout in the late phase (79.1% of cases). The size of the nodule modifies CEUS sensitivity for the diagnosis of HCC: P < 0.001.

PI372 DIAGNOSTIC ACCURACY OF CONTRAST-ENHANCED ULTRASOUND ALGORITHM (ACR CEUS LI-RADSv 2016) FOR THE DIAGNOSIS OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH CHRONIC LIVER DISEASE

A. Stănășan1, M. Danila1, R. Sirli1, S.A. Popescu2, T.V. Mogă2, C. S. Ivascu1
1Gastroenterology, University of Medicine and Pharmacy ‘Victor Babes’ Timisoara, Romania
2Gastroenterology And Hepatology, County Hospital Timisoara, Timisoara/Romania

Contact E-mail Address: stepan_ana@yahoo.com

Introduction: Contrast-Enhanced Ultrasound (CEUS) is an imaging method that can be used to discriminate between hepatocellular carcinoma (HCC) and other focal liver lesions (FLLs).

Aims & Methods: This study aimed to test the latest approved version of a contrast-enhanced ultrasound algorithm (ACR CEUS LI-RADSv 2016) for detecting hepatocellular carcinoma (HCC), in a real-life cohort of high-risk patients. In the CEUS study, we evaluated 249 liver lesions in patients at high-risk for HCC (liver cirrhosis of any etiology, chronic hepatitis B or C, with severe fibrosis, current or prior HCC) using the ACR CEUS LI-RADSv 2016 algorithm. CEUS LI-RADS categories used for the diagnosis of HCC were: CEUS LR-S (definitely HCC), CEUS LR-S-V (HCC with macrovascular invasion), CEUS LR-Tr (treated HCC). Contrast-enhanced CT, contrast-enhanced MRI or histology were used as reference methods to evaluate the CEUS LI-RADS classification of the 298 lesions.

Results: According to reference method, the 298 lesions were classified as follows: 216 HCC, 60 non-HCC-nodular lesions (fatty infiltration, hemangiomata, simple cysts, regenerative nodules) and 27 non-HCC malignant lesions (liver metastases, cholangiocarcinoma, indeterminate). The diagnostic accuracy of ACR CEUS LI-RADSv 2016 for the diagnosis of hepatocellular carcinoma was 74.4%, specificity, positive predictive value (PPV) and negative predictive value (NPV) were 65.4%, 96.5%, 97.8% and 53.5%, respectively. When we used CEUS alone, a conclusive diagnosis of HCC was obtained in 69.6% of the cases (147/211), while using the algorithm in 65.4% of all HCCs (138/211), P = 0.35.

Conclusion: In our study 65.4% of all HCCs (138/211) were correctly diagnosed using ACR CEUS LI-RADSv 2016 algorithm, showing good sensitivity, excellent specificity and PPV for the diagnosis of HCC.

PI373 DICKKOPF-1 AS A SERUM BIOMARKER FOR PREDICTION OF HEPATOCELLULAR CARCINOMA TREATMENT RESPONSE

A. L. Sharaf1, E. G. El-Badrawy1, N. A. Khalifa2
1Tropical Medicine Department, Zagazig University, Zagazig/Egypt
2Clinical Pathology Department, Zagazig University, Zagazig/Egypt

Contact E-mail Address: drahmed_lobty@hotmail.com

Introduction: Hepatocellular carcinoma (HCC) is the 5th most common cancer worldwide and the 3rd leading cause of cancer-related mortality. In Egypt, HCC is the 2nd most common cancer in men and the 6th most common cancer in women. Egypt has the highest prevalence of HCC worldwide and has rising rate of HCC. HCC is a disease with fast infiltrating growth and poor prognosis. This bad prognosis is due to the lack of an effective method for early diagnosis. So, it is necessary to find a specific & sensitive marker for early diagnosis of HCC and for monitoring of treatment response.

Aims & Methods: The aim of this work is to assess prognostic value of serum DKK1 in predicting treatment response, complication and survival in HCC patients. This study included 60 Patients divided into two groups. Group A: consisted of 30 patients with liver cirrhosis. Group B: consisted of 30 patients with HCC. Group B patients underwent either radiofrequency ablation or ethanol injection. Clinical assessment, routine laboratory evaluation, CT studies and measurement of serum alpha-fetoprotein (AFP) and DKK1 were performed to all patients and repeated to group B patients 1 and 3 months after treatment.

Results: DKK1 significantly can be used for HCC diagnosis even in HCC with inconclusive AFP. The optimum cut off value of DKK1 for diagnosis of HCC was 4.3 ng/ml (AUC 0.89, sensitivity 66.7% and specificity 96.6%) (P < 0.001). Serum DKK1 level significantly decreased after HCC treatment with either radiofrequency ablation or ethanol injection (P < 0.001).

Conclusion: DKK1 has a promising prognostic value and can be used for follow-up of HCC patients before and after treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI374 EFFECT OF FIBROBLAST GROWTH FACTOR-2 AND ITS RECEPTOR GENE POLYMORPHISMS ON SURVIVAL IN PATIENTS WITH HEPATITIS B VIRUS-ASSOCIATED HEPATOCELLULAR CARCINOMA

J. Cheong
Gastroenterology, Ajou University Hospital, Suwon/Korea, Republic of

Contact E-mail Address: jaeoyoun62@gmail.com

Introduction: Fibroblast growth factor (FGF), vascular endothelial growth factor, and hepatocyte growth factor play a critical role in the pathogenesis of hepatocellular carcinoma (HCC). We determined the association of single nucleotide polymorphisms (SNPs) in growth factor signaling–related genes in 245 HCC patients and 483 chronic HBV carriers. The FGF2 rs308447 A allele was significantly associated with small tumor size, early tumor stage, and less vascular invasion. The Flt-1 (FGFR1)-2, Flt-1, and c-MET genes in 245 HCC patients and 483 chronic HBV carriers without HCC.

Results: None of the SNPs was associated with the risk of HCC development in chronic HBV carriers. The FGF2 rs308379 A allele was significantly associated with small tumor size, early tumor stage, and less vascular invasion. The Flt-1 rs4772129 C allele was associated with low alpha-fetoprotein levels. Kaplan-Meier analysis showed that the patients with the FGF2 rs308447 TT genotype had lower survival rates than the patients with the CC or CT genotype (P = 0.016) and that the FGF2 rs308379 A allele carriers had shorter survival rates than those of patients with the TT genotype (P = 0.020). The FGF2 rs1219648 CC genotype was significantly associated with increased survival rates (P = 0.047). Multivariate Cox proportional analysis revealed that the FGF2 rs308379 A allele (hazard ratio = 1.663, P = 0.004) and advanced stage (hazard ratio = 3.430, P < 0.001) were independent prognostic factors for overall survival rates in patients with HCC.
Conclusion: These observations suggest that the SNPs of the FGFR2 and FGF18 genes can be potential prognostic indicators in patients with HBV-associated HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1375 EXTRAHEPATIC HEPATOCELLULAR CARCINOMA METASTASIS: IMPORTANCE OF AN EARLY DIAGNOSIS AND TARGETED THERAPY
1Gastroenterology, Centro Hospitalar São João, Porto/Portugal
2Centro Hospitalar São João, Porto Medical School, Porto/Portugal

Contact E-mail Address: ruirmorais20@gmail.com

Introduction: Extrahepatic HCC metastasis are associated with a poor prognosis. Nevertheless there are some effective therapies available.

Aims & Methods: The aim of this study was to assess the main sites of extrahepatic metastasis in hepatocellular carcinoma (HCC) patients and to evaluate the clinical evolution and treatment. This was a retrospective single-center study in which patients with HCC confirmed extrahepatic metastasis between January 2010 and December 2016 were evaluated.

Results: We evaluated 51 consecutive patients, 80% male, with a mean age of 64 ± 11 years at the time of metastasis. In 41% of the patients the metastases were present at the time of HCC diagnosis. In patients with subsequent metastases, the median time until its development was 9 months (IQR 5–16). The diagnosis of metastasis was incidental in 51% of the patients. Computed tomography (CT) was the main diagnostic method (86%) and in 18% of the cases histological confirmation was obtained. Nineteen patients underwent thoracic CT and five performed bone scintigraphy prior to metastasis. A total of 70 metastatic sites were identified, the more frequent were lung (33%) and bone (14%).

Conclusion: A systematic HCC staging, with thoracic CT and bone scintigraphic studies, may provide an earlier metastasis detection and enable a targeted treatment with increased survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1376 MANAGEMENT OF INTERMEDIATE STAGE HEPATOCELLULAR CARCINOMA
A. Deguchi
Division Of Gastroenterology, Kagawa Rosai Hospital, Marugame-shi, Kagawa/ Japan

Contact E-mail Address: akihm41@me.com

Introduction: According to the Barcelona Clinic Liver Cancer (BCLC) staging system, intermediate stage contains very heterogeneous hepatocellular carcinoma (HCC) patients. Recently, subclassification of intermediate stage on the basis of Milan criteria and up to 7 criteria is proposed. In this study, the effectiveness of delivering bead-transarterial chemoembolization (DEB-TACE) in intermediate stage was investigated.

Aims & Methods: 120 patients (M: F = 90:30; median age = 76; Child A: B: C = 72:4:4; BCLC stage A: B: C: D = 6:85:23:6) with unresectable HCC who received DEB TACE in our hospital were studied. The objective radiological response was classified according to the modified Response Evaluation Criteria in Solid Tumors (mRECIST) v.1.1 by using dynamic CT at one or two months after therapy. Adverse events were evaluated using NCI CTCAE v.4.03.

According to Bolondi’s subclassification, the patients of BCLC B stage were divided into four groups (B1: 31, B2: 19, B3: 19, B4: 10). The response rate and tumor factor associated response in these patients group were examined.

Results: The overall response rate and disease control rate in intermediate stage were 36% and 89%, respectively. Considering the subclassification, the response rate in B1 group (61%) was significantly higher than that of B2 + B3 group (29%). Although B2 + B3 group was constituted by the patients who did not satisfy the up to 7 criteria, only in the patients with less than 7 tumors, the response rate (60%) was similar to that of B1 group. Tumor factors associated response and found to be significant on univariate analysis were simple gross classification (classification based on tumor number) and number of tumor. Tumor diameter was not associated with the response.

Conclusion: For the treatment of intermediate stage of HCC, although DEB-TACE is considered to be most effective in B1 group, it is suggested that DEB-TACE is also effective in the patients with less than 7 tumors in B2 + B3 group. In cases with more than 7 tumors, as the response rate is considered to be extremely low, sorafenib and arterial infusion therapy are recommended in B2 + B3 group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1377 HEPATOCELLULAR CARCINOMA RECURRENCE RATE IN INFECTED PATIENTS TREATED WITH DIRECT ANTIVIRAL AGENTS. A SINGLE-CENTER EXPERIENCE
Hepatology Unit, Cardarelli Hospital, Naples/Italy

Contact E-mail Address: raffaellatorrata@live.com

Introduction: In the last few years many HCV patients with previous diagnosis of hepatocellular carcinoma (HCC) have been treated with direct antiviral agents (DAAs) for HCV infection. However there are conflicting data on HCC recurrence rate after DAAs therapy.

Aims & Methods: Aim of this study was to prospectively evaluate the rate of HCC recurrence following sustained virological response (SVR) by DAAs. From April 2015 to September 2016 we consecutively enrolled HCV infected patients previously treated for HCC at Liver Unit of Cardarelli Hospital. All patients had a free-disease survival from HCC of at least 6 months before starting antiviral therapy. The efficacy of HCC therapy was evaluated according to mRECIST criteria at CT or MRI. Radiological evaluation was carried out within 30 days from the start of therapy. All patients underwent DAAs therapy, selected on an individual basis according to the recommendation issued by the Italian association of the study of the liver.

Results: A total of 71 patients were enrolled. Among them, 42 patients had available data on SVR status and were considered for the analysis. There were 21 males (58.3%) and 15 females. The median age of the patients was 73 years (range 48–83). The median time of treatment was 12 months after the beginning of therapy (range: 6–18 months). Genotype distribution was as follows: 36 patients infected with genotype 1 (85.7%), 5 with genotype 2 and 1 patients with genotype 3, SVR was achieved in 38/42 patients (90.5%). HCC recurrence was observed in 11/38 patients with SVR (28.9%). The median time for recurrence was 9 months from the start of therapy with a range of 1–13 months; with 2 patients who showed recurrence during therapy. Among the patients who did not achieve SVR, 1/4 showed HCC recurrence after 10 months from end of treatment.

Conclusion: Treatment with DAAs are highly effective with a SVR of about 90% even in patients with advanced liver disease. Nonetheless, in patients with previous history of HCC, the eradication of HCV did not reduce the risk of short and medium-term recurrence.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Primary liver cancer is the sixth most common cancer in the world, after cancers of the lung, breast, colorectal, prostate and gastroesophageal. However, the extremely poor prognosis for primary liver cancer makes it the second leading cause of cancer-related death globally (745,000 deaths, 9.1% of the total death)[2]. Histologically, the majority of primary liver cancer is either
hepatoceleular carcinoma (HCC) or intrahepatic cholangiocarcinoma (ICC), which combined hepatoceleular carcinoma and cholangiocarcinoma is less common[3]. Though these treatments have shown modest improvement in overall survival in early stage disease, the 5-year relative survival for distant metastasis patients is still low (3.1%). As we all know, primary liver cancer preferentially metastasis to the portal vein and extrahepatic metastasis with or without extrahepatic spread, and AFP > 200 as post-treatment factors and DC as post-treatment variable were associated with survival. Multivariable cox regression revealed that the only independent predictors of mortality were AFP > 200 (HR 2.2, 95%CI 1.27–3.8, p = 0.004) and DC (HR < 0.50; p < 0.05). However, the influence of these factors was not homogeneous during time. Indeed, in the early and intermediate period AFP > 200 was an independent predictor of worse outcome (at 6 mo: HR 16.602, 95%CI 1.97–139.5, p = 0.009; at 1 yr: HR 3.069, 95%CI 1.07–8.76, p = 0.036). As illustrated in the multivariable post-treatment prognostic model DC was associated with a better mid- and long-term survival (at 1 yr: HR 0.245, 95%CI 0.06–0.87, p = 0.030; at 2 yrs: HR 0.356, 95%CI 0.12–1.03; p = 0.05; at 3 yrs: HR 0.904, 95%CI 0.62–0.29; p = 0.00001).

Conclusion: In patients with BCLC-C HCC, AFP > 200 mg/mL is a strong prognostic factor in the early and intermediate period, while DC is associated with long-term patients’ survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Portal vein thrombosis (PVT) is defined as a partial or complete occlusion of portal vein and/or its tributaries by a thrombus. It exposes to portal hypertension (PHT) by infrarenal occlusion and consequently to upper digestive hemorrhage, usually due to rupture of gastro esophageal varices.

Aims & Methods: The aim of this study is to specify the evolution of esophageal varices and thus risk of rebleeding in patients with PHT by PVT unrelated to cirrhosis. It is a retrospective study from January 2010 to February 2017, including 101 patients followed for PHT by PVT without liver disease in the department of hepatogastroenterology (medicine C) at Ibn Sina University hospital of Morocco. PVT was diagnosed by abdominal doppler ultrasonography in all patients.

Results: The mean age of patients was 36 ± 15 years with extremes ranging from 11 years to 70 years. The sex ratio M/F was 0.42. Five percent of patients had a splenectomy for undocumented reasons before the diagnosis of PHT. Concerning the etiology, 10.9% (n = 11) were hospitalized for melena, 60.4% (n = 61) for hematemeisis and melana and 28.7% (n = 29) for non-specific abdominal pain. Clinical examination was normal in 10.9% (n = 11), showed an asities in 11.9% (n = 12), and signs of PHT such as splenomegaly and collatellar abdication in 30.7% (n = 32). Endo-scopic examination revealed in 95.1% (n = 100) a complete blood count showed that 16.8% (n = 17) had thrombocyteopenia, 12.9% (n = 13) had bictryopenia, and 42.6% (n = 43) had pancytopenia. In all patients, upper GI endoscopy was performed. Hypertensive gastropathy was found in 50.7% (n = 31), grade I esophagogastric varices (EGV) in 5.9% (n = 6), grade II in 30.7% (n = 32), grade III in 48.5% (n = 49) and gastric varices were found in 13.9% (n = 14). These varices were with red spots in 18.8% (n = 19). All patients had abdominal doppler ultrasoundography showing a PVT in 60.3% (n = 61), was partial in 33.6% (n = 34), complete in 13.9% (n = 14). This was attributed to the splenic vein in 19.9% (n = 15). Portal vein thrombus was found in 39.6% (n = 40). All patients performed an etiologic assessment of thrombosis, myeloproliferative syndrome was found in 8.9% (n = 9), deficiency in inhibitors of coagulation in 31.7% (n = 32), celiac disease in 4.9% (n = 5), neoplastic lesions in 2.9% (n = 3), no etiology was found in 51.4% (n = 52). Endoscopic variceal Ligation (EVL) was performed in 70.3% (n = 71), the mean number of ligation sessions was 3 and eradication of oesophageal varices was noted in 69.3% (n = 70). All patients received anticoagulant therapy except those having portal cavernoma with no obvious cause and 23% of patients (n = 43) received beta-blockers for secondary prophylaxis. During follow up, 5.9% (n = 6) of patients have not been seen at consultation and no rebleeding was noted in 89.1% (n = 90). Concerning portal thrombus, it dissolved in 49.5% (n = 50) and stabilized in 10.8% (n = 11).

Conclusion: The evolution of esophageal varices in non-cirrhotic portal hypertension due to PVT seems to be better than in cirrhotic portal hypertension. Indeed 89.3% of patients in this study didn’t rebleed after eradication of esophageal varices.

P3185 LONG-TERM OUTCOMES OF PATIENTS WITH ACUTE CALCULOUS CHOLECYSTITIS AFTER SUCCESSFUL REMOVAL OF GALLBLADDER STONES WITH PERCUTANEOUS TRANSPANIC THEPATIC CHOLANGIOSCOPY: A DECADE EXPERIENCE AT A SINGLE TERTIARY CENTER

S. Dong, C.H. Oh, J.R. Moon
Department of Internal Medicine, Kyeong Hee University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: gidong201@hamil.net

Introduction: Percutaneous cholecystostomy (PCT) has been an alternative treatment for acute calculous cholecystitis (ACC) for the patients unsuitable for early cholecystectomy. Lithotomy with percutaneous transhepatic cholangioscopy (PTCS) after PCT track maturation is particularly considered for those patients with gallbladder (GB) stones who are poor surgical candidate. We examined the long-term outcomes of 171 patients with ACC treated by PTCS.

Aims & Methods: This study was a retrospective observational study of 171 consecutive patients who treated with PTCS for ACC in the period from 1 Jan 2005 to 31 Dec 2015. Outcome measures included the success rates, adverse events, recurrence rate and mortality. All data were collected from patients’ medical records.

Results: PTCS achieved complete clearance of GB stones in 157 patients (91.8%). The complication rate of PTCS was 3.5% (6/171). The adverse events included GB perforation (n = 3; 1.8%), hemorrhage (n = 2; 1.2%), disruption of the percutaneous transhepatic biliary drainage fistula (n = 1, 0.6%), and all of which resolved with conservative treatment. The overall recurrence rate of gallstone diseases was 11.5% during the follow up period. The incidence of recurrent gallstone diseases was significantly higher in those with completely removing GB stones than in those without complete clearance (10.2%, 16/157 vs 21.4%, 3/14; p<0.05). The frequency of recurrence of gallstone disease in patients with contrast passage to the duodenum on cholangiography after PTCS was lower than that in patients without contrast passage.

Conclusion: Gallbladder stone removal with PTCS would be recommended as an effective and safe treatment modality for the patients with acute cholecystitis who are unsuitable for surgery.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) with sphincterotomy is a well-established standard method for treating bile duct stones (BDS). After cannulation of the common bile duct (CBD), a guidewire is placed into the CBD and a sphincterotomy is performed. Subsequently, stone extraction using a balloon or basket catheter is performed. Because of this multistep process, endoscopic treatment for BDS always comes with a risk of losing CBD cannulation. A combination catheter that combines a sphincterotomy and a retrieval balloon in a single instrument can eliminate one step in the procedure.

Aims & Methods: We aimed to evaluate the feasibility and safety of POC to confirm CBD complete clearance after endoscopic treatment of difficult bile duct stones. From 1st June 2016 to 30 March 2017 all consecutive patients treated with Dilated assisted stone extraction (DASE) for difficult bile duct stones at our institution, underwent POC to verify CBD stones complete clearance. Ultrasonic (5.9 mm diameter) or Slim (8.5 mm diameter) endoscopes (Fujifilm EG 530NW or EG 530FP) or standard gastroscope (9.9 mm diameter) ( Olympus GIF-HQ190), under CO2 insufflation, were used by the peroral route for intubating all accessible bile ducts. Technical success rate, procedural time, outcome and side-effects of POC were assessed. All adverse events were recorded.

Results: POC was performed in 26 patients (17F/9M mean age 74.6 years ± 11.9) under propofol sedation (25 patients) or deep sedation (3 patients). Mean CBD size was 15 mm ± 3.65; mean stone diameter (13.5 mm ± 1.70); mean balloon dilation (13.5 mm ± 2.12). Intubation of the papilla and distal biliary duct was successful in 26 (100%) cases (guide-wire assistance in 17 cases, 65.4%). Hepatic hilm was reached in 13/26 (50%) patients with a complete CBD evaluation. Mean investigation time was 6.3 ± 1.5 min (range of 5–9 minutes). POC showed partial or persistent large amount of stones in 91.5% (sludge in 2.7% cases), complete success in the endoscope, and stones in 4 (15.4%) cases with subsequent endoscopic stones removal. In the remaining patients, POC confirmed complete duct clearance. No adverse events occurred.

Conclusion: POC for CBD complete clearance confirmation using POC is a feasible, quick and safe procedure that can help on clinical decision making (for example obviating the need for possible plastic stent or naso-biliary drainage placement) without substantial increase of time or costs. Our experience, however, is preliminary and should be followed up to evaluate the feasibility of the procedure, which could represent the first step for the development of a possible new indication in the setting of difficult biliary stone management.

Disclosure of Interest: All authors have declared no conflicts of interest.

American Society for Gastrointestinal Endoscopy (ASGE) emitted, in 2010, guidelines for the clinical orientation of patients with suspected choledocholithiasis (CL), suggesting the direct referral to endoscopic retrograde cholangiography (ERC) in certain groups. However, the ERC is an invasive exam and some studies demonstrated that a significant amount of patients classified with very strong risk of CL did not have alterations in ERC.

Aims & Methods: The aim of this work was to assess the accuracy of the ASGE guidelines in portuguese population. This is a retrospective study included that 212 patients (52.8% female sex; 47.2% male sex; mean age 73.9 (+14.6 years) admitted to the hospital from 2014 to 2016.

Results: Of the 212 patients, 28 (13.2%) had intermediate risk of CL and 184 (86.8%) had high risk, according to the ASGE criteria. These patients were submitted to the following exams/interventions: ERC (154 patients); magnetic resonance cholangiography (50 patients) and endoscopic ultrasound (8 patients). In patients initially classified with high risk of CL, this was confirmed in 119 (64.7%). The same was seen in 10 (35.7%) of the patients with intermediate risk. The ASGE criteria, when applied to this population, demonstrated an accuracy of 64.3% (21.7% sensitivity; 92.3% specificity) in the high-risk group, and an accuracy of 35.5% (78.3% sensitivity; 7.8% specificity) in the intermediate-risk group. Of the patients with intermediate probability, 12 (42.8%) underwent ERC and CL was found only in 4 of these patients. The presence of cholangitis, a common bile duct > 6 mm, a common bile duct stone visualized on transabdominal US and a total bilirubin >4 mg/dL were strong predictors of CL. The overall ERC complication rate was 13% (20 patients), of whom 8 had no complication. The ASGE guidelines showed a limited diagnostic accuracy in the identification of patients who actually require ERC, conditioning a significant number of unnecessary procedures with subsequent complications associated with it. If the orientation of these patients, with greater use of less invasive diagnostic techniques such as magnetic resonance cholangiography and endoscopic ultrasonography.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1388 DOES FIBRIN GLUE APPLIED ON THE CHOLANGIOTOMY IN LAPAROSCOPY IN COMMON BILE DUCT EXPLORATION REDUCE THE RISK OF BILE LEAKAGE? A RANDOMIZED STUDY

B. Darkahi1, G. Sandblom1, T. Nörden1

1Surgery Department, Enköping/Sweden
2Surgery Department, Uppsala/Sweden

Contact E-mail Address: bahman.darkahi@gmail.com

Introduction: Laparoscopic choledochotomy as a method of extracting common bile duct stones is a technique with many advantages. One problem, however, is bile leakage around the T-tube. To some extent, the leakage may be reduced if the incision is sutured around the T-tube, but this technique has some disadvantages. The aim of this study was to investigate whether application of fibrin glue around the tube results in less leakage than suturing.

Aims & Methods: Between 2012 and 2016 a total of 1347 cholecystectomies were performed in Enköping Hospital. From this group, 42 patients were included in the study and randomized to suturing or fibrin glue for closing the cholangiotomy around the T-tube. Postoperative cholangiography was performed after 7–10 days after surgery. The amount of flow in the abdominal drain and the level of bilirubin was measured daily. In case the flow ceased, the abdominal drain was extracted three days after surgery.

Results: No significant difference between the groups was seen regarding the flow of the abdominal drain or the T-drain for the first three days or operation time

Conclusion: Discussion Fibin glue may be an option to seal cholangiotomy around the T-tube, but studies with greater statistical power are needed to confirm this.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1389 THE IMPACT OF BARIATRIC SURGERY ON ACUTE CHOLANGITIS MORTALITY AND OTHER OUTCOMES: A NATIONWIDE ANALYSIS

Introduction: Rapid weight loss after bariatric surgery (BS) has been associated with the formation of gallstones, and subsequent acute cholecystitis and cholangitis (AC). However, the complex post-surgical anatomy limits the possibility of performing an ERC as part of AC treatment. Therefore, the aim of this study was to assess the impact of bariatric surgery on mortality and resource utilization among patients with AC using a national database.

Aims & Methods: This was a case-control study using the National Inpatient Sample 2013, the largest publically available inpatient database in the United States. All patients with an ICD-9 CM code for a principal diagnosis of AC were included. There were no exclusion criteria. Patients with a past history of BS were identified using the appropriate ICD-9-SCM codes. The primary outcome was all cause mortality. The secondary outcome was resource utilization: use of ERC, cholecystectomy, length of hospital stay (LOS), total hospitalization charges and costs. Multivariate regression analyses were used to adjust for the following confounders: Age, sex, race, income in patients’ zip code, Charlson Comorbidity Index, hospital region, location, size and teaching status.

Results: A total of 274,775 patients with AC were included in the study, of which 4,240 (1.7%) had undergone BS. The mean patient age was 51 years and 48% were female. After adjusting for confounders, patients with and without history of bariatric surgery had similar adjusted odds of mortality (adjusted Odds Ratio (aOR): 1.37, 95% CI: 0.51–3.65, p = 0.52). As far as resource utilization, patients with bariatric surgery had lower adjusted odds of ERC (aOR: 0.28, 95% CI: 0.09–0.83, p = 0.02), but higher odds of cholecystectomy (aOR: 3.18, 95% CI: 1.00–10.05, p = 0.04). Both patient groups had similar adjusted length of stay (adjusted mean difference: 1.19 days, 95% CI: 0.09–0.83, p = 0.16) total hospitalization charges (adjusted mean difference: $2237, 95% CI: $2308 – $6782, p = 0.49), and total hospitalization charges (adjusted mean difference: $7477, 95% CI: -$8955–$24549, p = 0.39).

Conclusion: Bariatric surgery has no impact on inpatient all-cause mortality among patients who develop acute cholangitis, despite its association gallstone acute pancreatitis and limited ERC performance. In addition, bariatric surgery does not affect resource utilization in this patient population as measured by length of stay and total hospitalization costs.

Introduction: Prevalence of gallbladder polyps in the Netherlands is 943 per 100,000 cholecystectomies. Histopathologically these gallbladder polyps can be divided into neoplastic and non-neoplastic polyps (without malignant potential). Although cholecystectomy is only indicated for neoplastic polyps, 47% of polyps after cholecystectomy are nonneoplastic polyps. Data of the Dutch Pathology Registry was used. In this search 2081 histopathologically proven gallbladder polyps (or focal) wall thickening > 5mm were identified in patients of >18 years undergoing primary cholecystectomy between 2003 and 2013. Of these
polyps 56.3% was neoplastic (adenoma, dysplasia, carcinoma or other malignancies) and 43.7% was nonneoplastic (all abdominal symptoms of polyp). Age and sex of the patient, number of polyps, size of the polyp, coincidence with gallstones and presentation as protruding polyp or wall thickening were extracted from the excerpts. Additional clinical and radiological information was collected from patients’ medical records at three hospital in the Netherlands (n = 178). The following clinical and radiological predictors were considered: age, gender, ethnicity, BMI, medical history (PSC, Hepatitis, metabolic syndrome, gallbladder disease, Salmonella typhi or Helicobacter pylori infection), family history of gallbladder disease, and presence or absence of abdominal symptoms and radiological features (size, number, shape, surface and echogenicity of the polyp). Associations between possible predictors and gallbladder polyps were assessed using univariate and multivariate logistic regression analysis.

Results: Patients with nonneoplastic polyps were found to be significantly older than patients with nonneoplastic polyps (mean age 65.0 vs 54.2 years, p < 0.001). Neoplastic polyps were significantly larger (mean size 18.1 mm (SD 17.9) vs 7.5 mm (SD 5.9), p < 0.001), more frequently presented as wall thickening (29.2% vs 15.6%, p < 0.001) or as a single polyp (88.3% vs 68.0%, p < 0.001). Gallstones were more frequently found in gallbladders with neoplastic polyps (50.1% vs 40.4%, p 0.001). No preoperative clinical features were predictive for neoplastic or nonneoplastic polyps. Presence of a single polyp on ultrasound was a predictor for neoplastic polyps (OR 6.00 (95%CI 1.32-27.31)). Size and type of polyp were often not mentioned in ultrasound report, or different from histopathological confirmation.

Conclusion: Except for age, no clinical characteristics for neoplastic polyps were identified in this cohort. Although pathological characteristics of neoplastic and nonneoplastic polyps are confirmed, identification of these characteristics on preoperative radiological investigations is poor.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1392 METFORMIN INDUCES APOPTOSIS AND MODULATES PROLIFERATION IN THE BILE DUCT CANCER CELLS

Gastroenterology; Hallym University Dongsan Sacred Hospital, Gyeonggi-Do/Korea, Republic of

Contact E-mail Address: jinlee@hallym.or.kr

Introduction: Metformin has evidence of antineoplastic activity in some cancer cells.

Aims & Methods: This study was performed to demonstrate in the bile duct cancer cells whether metformin inhibits the proliferation of cancer cells by inducing apoptosis and affects the expression of gene-related proteins involved in cancer growth, and to identify how metformin affect molecular mechanisms involved in the inhibition of cancer cell growth. Human extrahepatic bile duct cancer cells were cultured. 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assays were performed to determine the effect of metformin on cell proliferation. Apoptosis was measured by a cell death enzyme detection kit linked immunosorbent assay and caspase-3 activity assay. Various protein expressions with or without specific siRNA transfection were measured by Western blot, and migratory activity of the cancer cells was evaluated by wound healing assay.

Results: 1) Metformin suppressed cell proliferation in bile duct cancer cells by inducing apoptosis. 2) Metformin inhibited mammalian target of rapamycin (mTOR) by activation of pAMPKThr172 - tuberous sclerosis complex 2 (TSC2) pathway, and hyperglycemia impaired metformin-induced AMPKThr172 activation and enhanced phosphorylation of AMPKser485. 3) Metformin inhibited expression of key genes of the BER short and long patch pathway. The data also suggests a noticeable enhancement of both short and long patch pathway, was down-regulated in majority of the GBC, CL and CS cases compared to controls; and in GBC compared to CL and CS cases. The mRNA expression of hOGG1 and XRCC1 gene, which harbors the highest number of cases globally, and to ethnically distinct NEI population; Whole blood and surgically resected tissue samples were collected from clinically and histopathologically confirmed cases of GBC (adenocarcinomas, N = 49) along with non-neoplastic control sections, histopathology (CL, N = 78) and cholecystitis (CS, N = 56); along with blood from voluntary controls (N = 122) with informed consent. The pathway genes polymorphisms were screened by PCR-RFLP using DNA samples from the enrolled cases and controls. Differential mRNA expression profile of SHR short and patch pathway genes was studied by RT-PCR. Difference in protein expression was studied by immunofluorescence microscopy. Estimation of oxidative stress in DNA was done using 8-OH-dG EIA kit. The difference in percentage promoter methylation of BER pathway genes was analyzed using RT-PCR.

Results: The genetic alterations in hOGG1 and XRCC1 gene were highly prevalent in both controls and gall bladder disease cases in NEI population, and was associated with susceptibility and severity of gall bladder anomalies compared to controls.XRCC1 was significantly highest in GBC cases DNA compared to controls [OR = 1.986, p = 0.047]. Differential mRNA expression profile clearly showed a sharp down-regulation in hOGG1, APE1, p38, and PARP1 expression in GBC, CL and CS cases compared to controls; and in GBC compared to CL and CS cases. The mRNA expression of XRCC1 in percentage promoter methylation of both short and long patch pathway, was down-regulated in majority of the GBC, CL and CS cases compared to controls; and in GBC cases compared to CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in both short and long patch pathway. The oxidative stress marker 8-OH-dG estimation showed significantly increased levels in CL, CS and GBC cases DNA compared to controls, the highest being in GBC cases. The higher 8-OH-dG levels in GBC correlated significantly with the variant hOGG1 genotype (p < 0.001). The percent methylation of both XRCC1 and hOGG1 in cases and controls was between 0-30%. Hyper-methylation of XRCC1 and hOGG1 promoter was noticeable in GBC cases compared to controls.

Conclusion: The data indicates an important role of oxidative stress in the pathogenesis of gall bladder diseases and progression to GBC in NEI population, which is due to genetic, expression and epigenetic deregulations in the key genes of the BER short and long patch pathway. The data also suggests the prognostic significance of BER pathway parameters, as well as potential therapeutic targets for the disease, and hence holds clinical relevance. The genetic alterations in hOGG1 and XRCC1 gene were highly prevalent in both controls and gall bladder disease cases in NEI population, and was associated with susceptibility and severity of gall bladder anomalies compared to controls. XRCC1 was significantly highest in GBC cases DNA compared to controls [OR = 1.986, p = 0.047]. Differential mRNA expression profile clearly showed a sharp down-regulation in hOGG1, APE1, p38, and PARP1 expression in GBC, CL and CS cases compared to controls; and in GBC compared to CL and CS cases.

Introduction: Gallbladder cancer (GBCa) is often diagnosed at advanced stage because of the absence of any symptoms and the tissue cannot be obtained easily with anatomical reason.

Disclosure of Interest: Thirty patients with GBCa were enrolled in this study. Bile juice obtained from 24 of 30 patients was analyzed for mutations of 50 oncogenes (Cancer panel; Haloplex, Agilent Technology) by next generation sequencing (NGS; Illumina, San Diego, CA, USA). Tumor tissues from 20 of 30 patients were analyzed as well as bile juice. Each sample was obtained prior to the
1. Zacharoulis D, Lazoura O, Sioka E, et al. Habib EndoHPB: a novel endoablation depth was superficial. Further studies are needed to validate the optimal ablation injury was found in even short ablation time in which microscopic divided into three groups according to RFA time variation (60, 90 and 120 catheter (ELRAb)).

2. Intraductal radiofrequency ablation (RFA) is a new endoscopic approach to the treatment of bile duct lesions. It is particularly useful in the treatment of hilar cholangiocarcinoma and bile duct stenosis. RFA is a minimally invasive procedure that uses radiofrequency energy to heat and destroy tissue. The procedure is typically performed under fluoroscopic guidance and may be used as a standalone treatment or in combination with other procedures such as stenting and palliative chemotherapy.

3. The aim of this study was to evaluate the efficacy and safety of intraductal RFA using a novel RFA catheter in the treatment of unresectable bile duct lesions.

4. Results: A total of 26 patients were enrolled in the study, with 13 patients in each arm. The median depth of microscopic ablation was significantly different between the three groups (60, 90, and 120 seconds). In addition, focal ablation injuries of bile duct lesions were not detected in any group. A histological analysis of the bile duct lesions showed no microscopic ablation injuries in any group.

5. Conclusion: Intraductal RFA using a novel RFA catheter successfully ablated bile duct lesions in the majority of cases. The procedure was associated with minimal morbidity and was well tolerated by the patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction

In perihilar cholangiocarcinoma (ICC) multi-organ inflammatory disease of unknown cause, IAC may present with jaundice, abdominal pain and weight loss; immunosuppression is the preferred treatment. Since the disease presentation may closely mimic that of malignancies of the pancreatobiliary tract and accurate diagnostic tests have only recently been developed, misdiagnosis and unnecessary surgery are common. In many cases, ICC has been misdiagnosed as intrahepatic cholangitis, which has severe consequences. Before the introduction of digital cholangioscopy, the diagnosis of ICC was challenging. The presence of bile duct strictures in patients with high levels of serum levels of IgG4 may be suggestive of IgG4-related disease. The aim of this study was to evaluate the diagnostic yield of new-generation d-SOC in diagnosis and treatment of perihilar cholangiocarcinoma.

Aims & Methods: Our aim is to assess the incidence of Immunoglobulin G4-associated cholangitis in ICC patients, and to evaluate the diagnostic yield of a new single-operator digital cholangioscope (d-SOC) in diagnosis and treatment of perihilar cholangiocarcinoma.

Results: Between 1984 and 2015, 321 patients underwent liver and bile duct resections at our institution. Of these 166 patients were included who had received immunosuppression. Patients’ age ranged from 25 to 89 years old. Of these 166 patients, 115 patients had received immunosuppression for at least 3 months. Out of these 115 patients, 36 patients had received renal transplantation. The disease remission was achieved in 22 patients (20%). The median duration of the disease remission was 24 months (range 7–120 months).

Conclusion: The incidence of IAC in patients with ICC is high, and the disease remission rate is low. New-generation d-SOC shows that it provides high diagnostic yield in diagnosis (1) diagnostic yield of d-SOC visual diagnosis and biopsies in patients with undetermined biliary strictures; (2) the efficacy of d-SOC directed treatment of difficult lithiasis and (3) to analyze adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

References:
water are also contaminated with heavy metals, which can in turn accumulate in humans and animals that feed on these contaminated foods. The serum cadmium levels of residents of Dakahlia Province are almost 10-fold higher than those of residents from cadmium-polluted areas in Cairo and 32 times higher than reference levels for healthy populations in the United States. Aims & Methods: We aimed to assess serum levels of heavy metals namely Zink (Zn), lead (Pb), Cobalt (Co), Cadmium (Cd), Chromium (Cr) and Iron (Fe) as a markers of exposure in cholangiocarcinoma patients and healthy control subjects from the same region in Egypt and its correlation with differentiation of cholangiocarcinoma and tumour marker CA 19-9. This study included 45 patients with cholangiocarcinoma (diagnosed after radiological &histopathological examination) and 20 healthy control subject attending Mansoura Surgical Gastroenterology centre. All patients and control were permanent residents of North Delta region and they were recruited before receiving chemotherapeutic or radiotherapy. There were no restrictions based on age, sex, or tumor stage. The serum samples were analyzed for concentrations of zinc, lead, cobalt, cadmium, iron and chromium by the acid digestion method followed by using atomic absorption spectrometry and ICP-MS. “Bud Scientific Accuas 214 atomic absorption spectrophotometer”. The results are reported in mg/L. in addition to CA 19-9 was assayed by IMMULITE® 2000 Xi immunoassay system supplied by Siemens Healthcare (GmbH Henkestr. Erlangen Germany) using its commercial kits.

Results: The serum levels of Zn, Pb, Co, Cd and Fe were significantly higher in patients having cholangiocarcinoma more than control subjects (P < 0.001). Preussive increase in the median values of serum levels of lead (Pb) was found in well differentiated to moderately differentiated to undifferentiated tumours. (P < 0.05). When correlation was made between the heavy metals and CA-19-9 and the survival of the patients, it was found that Cd only has a positive correlation with CA 19-9 and negative correlation with the survival of the patients (P < 0.5, P < 0.01) respectively.

Conclusion: The results from this study suggest that cholangiocarcinoma in the Nile Delta region is significantly associated with high serum levels of heavy metals especially Cadmium and lead.

P1403 SELF-EXPANDABLE METAL STENT ARE SUPERIOR TO PLASTIC STENT FOR PREOPERATIVE BILIARY DRAINAGE IN RESECTABLE MALIGNANT DISTAL BILIARY STRUCTURE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Introduction: Early surgery is the standard treatment in patients with resectable periampullary or pancreatic head cancer with jaundice. However, early surgery is not always feasible and it could be a necessary for patient with jaundice at diagnosis or for those undergoing neoadjuvant treatment. Most studies considered plastic stents for PBD, although SEMS are currently considered superior. A recent RCTS showed that fully covered SEMS are associated with better outcomes compared to plastic stents.

Aims & Methods: Aim compare the rate of endoscopic reintervention (Stent failure of PBD) before surgery and post operative outcome of metal vs plastic. We conducted a bibliographic search using PUBMED, EMBASE including randomized and non randomized trials. OR using the Mantl-Haenszel method was used for dichotomous variables. Weighted mean differences (WMD) were used as the summary statistic for quantitative analysis of continuous variables, Quantitative synthesis was performed using Review Manager version 5.0.
Primary outcome was the rate of endoscopic reintervention before surgery. Secondary outcomes were postoperative complications, hospital readmission, overall pancreatic fistula, overall biliary anastomotic leak, overall postoperative mortality. Clinical heterogeneity was assessed by I² value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity.

Results: Three RCTs and five non RCTs were selected including 909 patients. Of these, 303 patients (33%) were treated with SEMS and 606 (67%) with plastic stents. The rate of endoscopic reinterventions after PBD was significantly lower in the metal stent group in the plastic stent group (p < 0.001). The rate of post operative pancreatic fistula was significantly lower in the plastic stent group (I² = 0.44; 95% CI 0.20–0.96) (p < 0.001). The rate of overall postoperative surgical complications, hospital readmission, overall biliary anastomotic fistula and postoperative mortality did not differ between the two groups.

Conclusion: Metal stents are more effective than plastic and should be preferred for PBD in patients with resectable periampullary or pancreatic head tumor without early postoperative mortality. Clinical heterogeneity was assessed by I² value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity.

P1404 THE EFFICACY AND SAFETY OF PREOPERATIVE BILIARY DRAINAGE IN PATIENTS WITH OBSTRUCTIVE JAUNDICE: A SYSTEMATIC REVIEW AND META-ANALYSIS
A. Tringali1, M. Cintolo2, L. Cristoferi2, E. Forlì3, F. Pugliesi1, L. Diosacondi1, M. Mastignani1, A. Pisu2

Introduction: There is considerable controversy as to whether temporary relief of biliary obstruction prior to major definitive surgery (preoperative biliary drainage) is of any benefit to the patient. A Cochrane meta-analysis revealed a major morbidity with no difference in mortality in the group subjected to PBD. However, the clinical status of patients was heterogeneous between studies.

Aims & Methods: We aimed to investigate the benefits and harms of pre-operative biliary drainage versus no pre-operative biliary drainage (direct surgery) in patients with obstructive jaundice. A computerized medical literature search was performed by using MEDLINE, EMBASE, Cochrane Library, from 1980 to June 2016 aimed at identifying RCTs comparing PBD versus direct surgery. Data from RCTs related to safety and effectiveness of PBD versus no PBD were extracted. A dependent review of risk ratio or mean difference were calculated with 95% confidence intervals. Clinical heterogeneity was assessed by I² value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity.

Results: Nine trials including 734 patients with malignant or benign obstructive jaundice comparing PBD (375 patients) with no PBD (359) were included in this review. There was no significant difference in mortality (risk ratio 0.89; 95% CI 0.67 to 1.18; P = 0.42) between the two groups. Complications were higher in the PBD group (RR 1.41; 95% CI 1.09–1.81 = p < 0.008). Overall serious morbidity was higher in the PBD group than in the direct surgery group (RR 1.66 95% CI 1.28–2.16 = p < 0.0002). There was no significant difference in length of hospital stay between the two groups: mean difference 4.55 (95% CI: 1.31–10.61) days (P = 0.014).

Conclusion: There is currently not sufficient evidence to support or refute the routine use of biliary drainage for patients with obstructive jaundice. PBD in patients undergoing surgery for obstructive jaundice is associated with similar mortality but increased serious morbidity compared with no PBD. Therefore, PBD should not be used routinely. Further RCTs are needed.

Introduction: Dietary fat consumption affects the human body fat composition. It has been described that unsaturated fatty acids, enriched in human pancreatic exocrine secretions, worsen clinical outcomes and pancreatic head tumors when early surgery without PBD is not feasible. However, more RCTs are needed before a firm conclusion could be made.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: DM induction resulted in increased 1-deoxySL levels but also atrophy and fibrosis in pancreas. Reduction of 1-deoxySL by oral L-serine supplementationameliorated the damage of the exocrine pancreatic tissue, without restoring insulin production in beta cells. This suggests that elevated 1-deoxySLs rather than insulin deficiency contribute to the exocrine damage in DM. In vitro studies showed that treatment with 1-deoxyxypamine, one of the early products of 1-deoxySLs synthesis at low concentration reduced replication and promoted cytotoxicity in pancreatic acinar cells. In addition, this 1-deoxySL-mediated cytotoxicity was associated with mitochondrial dysfunction and increased endoplasmic reticulum stress.

Conclusion: Our work revealed that 1-deoxySLs are cytotoxic for exocrine pancreatic cells, suggesting a role for these lipids in the exocrine dysfunctions following DM. Oral L-serine supplementation could be a therapeutic treatment for ameliorating diabetic exocrine pancreatic diseases in diabetic patients.

Introduction: Splanchnic venous thrombosis (SVT) is a common vascular complication of acute pancreatitis (AP). There is paucity of data on its frequency, risk factors, outcome and natural history. Coagulation abnormality has been implicated but not proven as a cause of SVT in AP.

Aims & Methods: We aimed to prospectively study the frequency, risk factors and extent of SVT in patients with AP as well as role of thrombophilia in causation of SVT. Patients with AP presenting to our centre between January 2015 and June 2016 were prospectively evaluated with contrast enhanced computerized tomography (CECT) abdomen for presence of SVT. These patients were subjected to Doppler study done in 7 patients with SVT. On follow-up, Doppler study done in 7 patients with SVT, spontaneous resolution of SVT occurred in 5 (71.4%) within 1 year. None of the patients had varices on follow-up.

Conclusion: SVT is more common in patient with necrotizing pancreatitis and higher CT and MCTSI indices suggesting that local inflammation plays a major role in its causation. Thrombophilia in some form is seen in one third of the patients with AP but does not increase the risk of AP.

Introduction: Infected pancreatic necrosis (IPN) is associated to significant morbidity and mortality. Current management of IPN is based on a step-up approach, based on minimally invasive procedures. Our group has recently published a protocol of local infusion of antibiotics for the treatment of IPN (Pancreatology. 2016;16:719–25).

Aims & Methods: We aim at analysing the efficacy of this step-up approach for the treatment of IPN in clinical practice. This was a retrospective single-centre study of patients admitted with acute pancreatitis (AP) between January 2015 and December 2016. The cases with the diagnosis of pancreatic necrosis (NP) and IPN (defined by positive culture of necrosis and clinical, analytical, and/or radiological data of infection) were identified and evaluated. IPN was treated following a step-up approach defined by 1. intravenous antibiotic therapy, 2. Endoscopic ultrasound guided transmural drainage plus local antibiotic therapy, 3. endoscopic necrosectomy. Number of patients responding to each therapeutic step was assessed.

Results: 694 cases of AP were included (mean age 79.5 ± 18.3, 555 male). CT scan was performed only if clinically indicated. 67 patients (9.0%) had acute necrotizing pancreatitis (ANP) and 21 of them IPN (31% of ANP). IPN patients were treated with intravenous antibiotics (imipenem [n = 15] and meropenem [n = 6], with good response in 8 (38% of IPN). The remaining 13 cases underwent a EUS guided transmural drainage plus local antibiotic therapy, 3. endoscopic necrosectomy. Number of patients responding to each therapeutic step was assessed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1410 EVALUATION OF A PROTOCOL OF AN ENDOSCOPIC ULTRASONOGRAPHIC TRANSGASTRIC DRAINAGE WITH LUMEN-APPOISING METAL STENTS OR PLASTIC DOUBLE PIGTAIL STENTS: A MULTIFACTORIAL ANALYSIS

N. Ge, S. Sun
Dept. Of Endoscopy, Shengjing Hospital, Shenyang/China

Contact Email Address: ge_nan2013@163.com

Introduction: We aimed to compare the efficiency of plastic and metal stents for symptomatic pancreatic fluid collection drainage and analyze other main associated factors that affect the outcome of drainage therapy.

Aims & Methods: Rates of technical and clinical success, procedure-related side effects (hemorrhage, stent migration, and cyst rupture), re-interventions, and duration of hospital stay.

Results: There were 52 patients, 40 who underwent plastic stent placement and 12 who underwent lumen-approsing metal stent placement. The total rate of technical success was 100%. The total rate of clinical success was 100%. The total rate of adverse events was 7.7% (4/52). On multiple logistic regression analysis, the use of plastic stents (P < 0.05, Exp B = 12.168) and presence of a large cyst (P < 0.05, Exp B = 1.036) were shown to significantly increase the risk of re-intervention. On multivariate linear regression analysis, etiology of pseudocyst (P < 0.05, B = 8.427; -9.785; -5.514) was associated with prolonged hospital stent, while stent type was not shown to be a factor (P > 0.05).

Conclusion: Both plastic and lumen-approsing metal stents are proven to be highly efficient in pancreatic fluid collection drainage. The lumen-approsing metal stent is superior in preventing complications such as migration and cyst leakage and reducing the rate of re-intervention. Large cyst size is associated with an increased risk of re-intervention and prolonged hospital stay.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: The aim was to evaluate the efficacy of local instillation of antibiotics into walled-off pancreatic necrosis. Between 2012 and 2016 we evaluated all patients treated with endoscopic transmural drainage and necroscopy (EDTN) and concomitant local instillation of antibiotics. We added antibiotics (either gentamicin, vancomycin, or amphotericin B) to the irrigation fluid according to the microbiological findings. The antimicrobial efficacies of local and systemic antibiotics were evaluated using uni- and multivariate logistic regression analyses and Kruskal-Wallis test by stratification of the isolates in sensitive versus not sensitive/antibiotics not given.

Results: Ninety-one patients were included. At the first drainage 81 (86%) patients had infected and 10 sterile WON. A total of 139 isolates were found at the first drainage. Most patients were infected with enterococci (44%) or other gram-positive cocci. More than a quarter of the infected patients had fungal species cultured. The infected patients often had polymicrobial infections (56%). At the second culture 152 isolates were found. Neither local nor systemic antibiotics were associated with the eradication of microbes between first and second culture. Between second and third culture, the use of local antibiotics was associated with the eradication of microbes (OR = 2.54, P = 0.01), but not systemic antibiotics (P = 0.33) (Table). Between first and second culture 12 patients with fungal infections were treated with local amphotericin B. In all 12 patients the fungus was eradicated. After second culture 20 patients were treated local amphotericine B and in 17 (85%) patients the fungus was eliminated at the third culture.

Conclusion: Our data suggest a better efficacy of local antibiotics in the treatment of infected WON compared to systemic antibiotics. The local instillation of antibiotics may be a promising alternative or supplement to systemic administration. Particularly the use of local instillation of amphotericin B appears to be promising in the treatment of local cutaneous fungal infections.

Introduction: Pancreatitis is a disease of protein manifestations. In its more severe form, involvement of any organ is possible. Cardiovascular and respiratory failure are possible and feared complications.

Aims & Methods: The aim of this study was to evaluate the effect of chronic ischemic heart disease and chronic obstructive pulmonary disease (COPD) in the outcome of acute pancreatitis (AP), in our population. Retrospective cohort study that included all patients admitted with AP from January 2003 to December 2016, in a tertiary referral center. Demographic and clinical variables were analyzed by logistic regression (SPSS v23). Clinical outcomes included organ failure (OF), persistent OF (>48 h), intensive care unit (ICU) admission and mortality.

Results: A total of 553 patients with AP were included, 58.4% male, median age 60 (18–98) years. Most common etiologies included gallstones (38.9%) and alcohol (27.3%). Twenty-three percent (n = 129) developed OF (in 43% persistent) and 26.8% (n = 148) were admitted to ICU. Mortality rate was 5.6% (n = 31). Fifty-six patients (10.1%) had previous history of coronary disease and 5.1% (n = 28) had been diagnosed with COPD. The presence of coronary disease and COPD were not associated with higher Rasmon’s score (≥3), p = 0.076 and p = 0.959, respectively. No association was found between previous history of coronary disease and the development of OF (p = 0.525), persistent OF (p = 0.287), need for ICU admission (p = 0.115) and mortality (p = 0.262). There was no association between the development of OF and the development of OF (p = 0.803), persistent OF (p = 0.588), need for ICU admission (p = 0.514) and mortality (p = 0.720). At multivariate analysis (correcting for age and gender) coronary disease and COPD were not independent predictors of worse outcome.

Conclusion: In our population, previous history of coronary disease and COPD were not predictors of worse outcome in AP.

Disclosure of Interest: All authors have declared no conflicts of interest.
P1415 WORSE OUTCOMES IN ACUTE PANCREATITIS IN PATIENTS WITH TYPE-2 DIABETES MELLITUS

Introduction: Predicting severe pancreatitis is important for early aggressive management of patients with acute pancreatitis (AP). Despite the established role of type-2 diabetes mellitus (DM) in the risk of AP, the impact of DM on the clinical outcome in AP has not been fully elucidated.

Aims & Methods: Retrospective study including hospital admissions between January 2003 and December 2016 in a single tertiary referral center. Clinical outcomes included organ failure (OF), persistent OF (>48 h) admission to intensive care unit (ICU) and mortality. Variables were analysed by logistical regression (SPSS v23.0). The objective of this study was to assess the risk of mortality and severity in AP among patients with type-2 DM.

Results: A total of 555 patients (58.4% male) with AP were included, median age 80 (18-98) years. Most common etiologies included gallstones (38.9%) and alcohol (27.3%). Twenty three percent developed OF (in 43% persistent) and 5.6% (n = 31) died. There were 127 AP patients (23.0%) with type-2 DM. Type-2 DM were not associated with higher Ranson's score. There was an association between DM and development of OF (OR 3.17, CI95% 1.88-5.37, p < 0.001), persistence (OR 45.1, CI95% 18.7-108.9, p < 0.001), ICU admission (OR 12.3, CI95% 2.8-54.9, p < 0.001) and mortality (17.1, CI95% 6.8-42.8,4, p < 0.001). At multivariate analysis DM was an independent predictor of OF development and ICU admission.

Conclusion: In our population, Type-2 DM was associated with severity and increased mortality in patients with AP. Our findings provide evidence of the potential role of DM in the management of severe AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

3Transplantcentre, Institute For Clinical And Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: peter.macinga@iikem.cz

Introduction: Acute pancreatitis (AP) is an uncommon but potentially devastating condition that may occur in patients with organ transplantation. Reported incidence ranges from 1.5 to 8% in patients undergoing liver transplantation with significant mortality.

Aims & Methods: The aim of our study was to assess the incidence, potential risk factors and outcome of AP following liver transplantation in our center. We performed a retrospective analysis of medical records of all adult patients who underwent liver transplantation in our center between September 1996 and November 2014. The diagnosis of AP was defined by combination of clinical manifestation, finding on imaging methods (CT, USG) and elevation of serum amylase and lipase.

Results: Nine hundred and sixty-seven orthotopic liver transplantations were performed in 578 males and 389 females (mean age 51 years, range 18-74). AP occurred in 18 patients (1.9%, 16 males, 2 females) and resulted in death in 5 patients (28%). According to timing of AP we recognized two clinical presentation—early AP (<1 month after liver transplantation) and late (>1 month). Four patients (22%) developed early AP, which was severe necrotizing with MODS in all cases and resulted in death in 3 of them (75%). Two of them were transplanted for fulminant hepatic failure, one for end-stage liver disease due to alcoholic hepatitis B infection and one for polycystic liver disease. Two patients were treated by surgical necrectomy and died, the third deceased patient was treated conservatively. In the only surviving patient, a successful EUS-guided drainage of walled of pancreatic necrosis and repeated endoscopic retroperitoneal drainage were performed, and patient was able to identify. The fourth patient was responsible for development of AP. Late AP occurred in 14 patients (78%) with a median delay of 31 months after liver transplant (range 2-176). In 12 patients AP was mild with no mortality and the following etiologies were represented: 4 post-ERCP, 2 alcoholic, 1 biliary (CBD stones), 1 drug-induced (necrotizing, 1 obstructive (pancreatic cancer); in 3 patients the etiology was unknown. One patient developed a pseudocyst. Two patients with late acute pancreatitis had a severe necrotizing form and both died. One patient with cirsrhosis of the liver grade 4 and chronic rejection following ERCP pancreatitis which was complicated by retroperitoneal hemorrhage and graft failure. The other patient with necrotizing pancreatitis of unknown etiology developed MODS and eventually died. Male patients (p=0.01) and patients transplanted for end stage liver disease resulting from chronic hepatitis B are more likely to develop post-liver transplantation pancreatitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Biliary sludge (BS) may be one of the factors, related to development of chronic pancreatitis (CP) via sphincter of Oddi dysfunction. As it was demonstrated by Okazaki K et al. in 1988, patients with biliary sludge have higher sphincter of Oddi (SO) pressure and contraction frequency vs. controls.

Aims & Methods: To assess the frequency of CP signs in patients with BS and to investigate the state of major duodenal papilla (MDP) in patients with idiopathic CP with BS by endoscopic ultrasound (EUS), to evaluate whether antispasmodics can be effective in pain relief at CP, that developed on the background of biliary sludge. Protocols of computer tomography, endoscopic and transabdominal ultrasound studies of over 6000 patients of gastroenterological tertiary clinic were examined. Those who had signs of BS were selected to evaluate the presence of CP and, at least "mild CP" was sufficient to start BS removal. Modified Cambridge classification. Exclusion criteria were: established etiology of CP and signs of pancreatic neoplasm. Patients, who received ursodeoxycholic acid and drugs that affect smooth muscle contractility for less then 3 month prior to the study were excluded. Thirty consecutive patients (15m, 15 f, mean age ± SD: 52.8 ± 15.3), who had both BS and CP were summoned for physical examination, quality of life assessment, US-cholecystography and endoscopic pancreaticbiliary ultrasound — elastography calculation of Max SMDP (=max x SMDP)2.12.7 and state of MDP before and after 3 weeks of hymecromone monotherapy 400 mg tid.

Results: Signs of CP were revealed in 6.3% of BS cases. CP was most common in those who had ointment-like bile (33.3%) vs patients with heterogeneous bile with clots – 7.7% and hypocholic particles –1.7% (chi-square 38.21, p < 0.0001). Mean SMDP was 14.9 ± 5.2 mm2 (95%CI 10.9 –18.9), SMDP was below the normal range (20-25 mm2) in 78% of patients. SMDP had positive correlation to the volume of evacuated bile according to US-cholecystography (p = 0.042) and gallbladder contractility coefficient (r = 0.817, p = 0.007). All patients with higher density of MDP at US-cholecystography had SMDP lower than the normal range and were attributed to “fibrosis” group. Only 38% of patients with CP and BS had normal MDP at EUS. Periapillary diverticula were found in 13% of the cases, papillary edema — in 38%, fibrosis in 13%. MDP changes were associated with higher AP level and larger MDP diameter. Hymecromone monotherapy resulted in significant improvement in abdominal pain (rp = 7.92, p = 0.000) and "bodily pain" score of SF-36 questionnaire (rp = 7.579, p = 0.001). Dynamics of “bodily pain” index per SF36—demonstrated significant negative correlation to the post-treatment level of abdominal pain (rp = -0.395, p = 0.037) Post-treatment pain level had significant negative correlation to the SMDP size (rp = -0.067, p = 0.002), though no correlation of pre-treatment pain level to MDP features was found, i.e. patients with less MDP size (most of them had decreased elasticity of papilla of Vater, that was considered as indirect marker of fibrosis) had lower hymecromone efficacy.

Conclusion: BS may cause MDP changes, resulting in development of obstructive CP. Intensity of pain in biliary CP may be related to sphincter of Oddi dysfunction. Efficacy of antispasmodic therapy in these patients could be predicted by the features of MDP at pancreaticbiliary EUS.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic exocrine insufficiency is a late complication of chronic pancreatitis; its clinical onset is characterized by steatorrhea and weight loss, borborygmi, flatulence, abdominal pain and malnutrition. Exocrine and endocrine pancreatic function decreases differently in various diseases (autoimmune, paroduodenal, genetic, idiopathic). It has been observed that there has been a recovery of exocrine pancreatic function in autoimmune pancreatitis. In the literature there are no studies analysing the exocrine pancreatic function over time.

The fecal elastase test is a good test procedure to evaluate the exocrine pancreatic function

Aims & Methods: The objective of the retrospective study was to re-evaluate a series of patients with chronic pancreatitis with the aim to evaluate the pancreatic exocrine function over time, in particular, by comparing the exocrine pancreatic function in subgroups of patients with different types chronic pancreatitis. Pancreatic exocrine function was estimated through fecal elastase in 143 patients with at least 2 values each (classified into normal, mild and severe exocrine pancreatic insufficiency), the first one taken at the diagnosis of chronic pancreatitis. Patients undergoing surgical pancreatic resection before the second value of fecal elastase were excluded. Etiology was classified in: biliary pancreatitis/sequela of necrotizing pancreatitis (15), autoimmune (69), paroduodenal (15), genetic (17) and idiopathic (27).

Results: The results show a high frequency of severe exocrine pancreatic insufficiency in the moment of diagnosis of chronic pancreatitis (38%) and it appears stable over the first five years. Autoimmune and paroduodenal chronic pancreatitis are correlated with severe exocrine pancreatic insufficiency at diagnosis in a high percentage of cases (51% and 40%), biliary/outcomes of necrotizing pancreatitis and idiopathic pancreatitis in an intermediate (33% and 26%), while genetic in a low percentage (12%).

Conclusion: The exocrine pancreatic function in patients with autoimmune pancreatitis improved in the first five years of the disease, probably due to the efficacy of steroid/immunosuppressive therapy. Pancreatic exocrine function was less compromised at diagnosis, but showed a progressive deterioration in the first five years. Endocrine and exocrine insufficiency were strictly correlated.

Introduction: The term “painless” chronic pancreatitis (CP) represents a specific subset of CP characterized by the lack of pancreatic pain. So far, scarcity of data has been reported in the literature about this matter and what differentiates this group of patients from those with chronic pancreatitis associated with pancreatic pain.

Aims & Methods: The aim of the present study is to characterize “painless” CP from the epidemiological, clinical, radiological, functional, and follow-up standpoint, through a comparison with other forms of chronic pancreatitis presenting with pancreatic pain. The Institutional Database of the Gastroenterology Unit of the Verona University was queried, and all chronic pancreatitis cases were retrieved. Patients were clustered based on the presence of “pancreatic-specific pain” into “painless” and “pain-associated” CP. A retrospective case-control analysis was carried out.

Results: Of 678 patients included from March 2006 to March 2016, 436 were considered eligible for the present study. Of these, 368 (84%) were affected by pain-associated CP, while 68 (16%) had “painless” CP. “Painless” patients were older (median age of 58.5±10.8 y/o vs. 42.5±15.3 y/o; p < 0.001), less frequently presenting with a history of alcohol consumption (35% vs. 55%; p < 0.001), more frequently diabetics (18% vs. 1%; p < 0.001), presenting with steatorrhea (16% vs. 2%; p < 0.001), and asymptomatic (63% vs. 2%; p < 0.001) compared to pain-associated controls. From the radiological standpoint, less cases were revealed presenting with mediastinal adenopathies than controls (90% vs. 68%; p < 0.001). Moreover, in most of painless cases, the CP cause remained unknown (56%). After a median follow-up of 2.6±2.3 years, the incidence of diabetes was higher in the painless cases than in controls (48% vs. 30%; p = 0.006).

Conclusion: The present study represents the first definition of "painless" CP so far reported in the literature. The "painless" CP is a distinct entity from the epidemiologic, clinical, and radiological standpoint when compared to other forms of CP characterized by chronic pain.

Introduction: Recently, EUS-guided pancreatic duct drainage with transmural stent (EUS-PD) has been used for patients with painful obstructive pancreatitis in whom endoscopic retrograde pancreatography (ERP) has failed. Although the feasibility and safety of EUS-PD with a fully covered self-expandable metal stent (FCSEMS) has been assessed, little is known about the long-term outcomes of EUS-PD with a fully covered self-expandable metal stent (FCSEMS). Removability of an FCSEMS in long-term use and higher cost are the main concerns of EUS-PD with an FCSEMS compared with EUS-PD with a plastic stent.

Aims & Methods: The aim of this study is to evaluate the procedural and long-term outcomes of EUS-PD with an FCSEMS for patients with painful obstructive pancreatitis who failed ERP. Forty-one consecutive patients with painful obstructive pancreatitis underwent EUS-PD with an FCSEMS after failed ERP. Seventy-eight interventions without scheduled stent exchange were considered in malignant MPD strictures or complete MPD obstruction in benign pancreatic stricture. Technical and clinical success, adverse events, and stent patency were assessed. An endoscopic examination and CT scan was performed every 6 months to assess stent patency in benign structure.

Results: 15 patients had malignant MPD obstruction and 26 patients had benign stricture. EUS-PD was successful in all 41 patients (technical success rate, 100%), and symptoms improved in all patients (clinical success rate, 100%). EUS-guided pancreaticogastrostomy (n = 39) and pancreatogastrojejunostomy (n = 2) were performed. Pain scores improved significantly after FCSEMS placement (P < .01). Early mild-grade adverse events occurred in 5 patients (12.2%) with self-limited abdominal pain, which resolved with conservative treatment. Late adverse events developed in eight patients (22.2%), including distal stent fracture (n = 6), stent occlusion (n = 2). These patients were successfully treated endoscopically. No other adverse events related to FCSEMS, including stent migration, pancreatic sepsis, and stent-induced ductal stricture were observed during follow-up periods.
Overall mean stable mean parity duration was 412 days (range 14–1081) during mean follow-up of 1.4 years). Median stent duration for malignant patients was 95 days (range 14–297). Mean stent duration in benign strictures was 525 days (range 14–1081). No patients with malignant strictures required FCSEMS revision or exchange during follow-up periods. FCSEMS removal and exchange could be successful in patients with benign strictures until 3-year placement of an FCSEMS. Prospective randomized trial comparing EUS-PD with FCSEMSs and plastic stents may be warranted for painful obstructive pancreatic fistulae after failed ERP.

Introduction: Fundamental aspects in the treatment of pancreatic exocrine insufficiency (PEI) include pancreatic enzyme replacement therapy (PERT). Monitoring the symptoms of malabsorption as well as the nutritional markers is essential.

Aims & Methods: To follow-up patients with PEI receiving PERT and to provide normal nutritional status by optimizing the suboptimal PERT if necessary. Study enrolled 142 patients (88 males, mean age 52 years): 82 patients had chronic pancreatitis, 26 patients had oncological disease, and 34 patients were newly diagnosed. Study succeeded in 78 patients. In 32 patients we observed suboptimal PERT with nutritional deficiencies despite an essential.

Conclusion: Proper follow-up and correction of suboptimal PERT as well as optimization of the risk of severe malnutrition complications and associated morbidity and mortality by ensuring optimal therapeutic results and better quality of life.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1420 HU RID MEDICATED POST-TRANSCRIPTIONAL REGULATION OF HO-1 AND INHIBITORS OF APOPTOSIS PROTEINS IS ASSOCIATED WITH THE POOR CLINICAL OUTCOMES AMONG PATIENTS WITH Pancreatic ADenocarcinoma

Z. Dambrauskas, A. Gulbinas, A. Jakstaitė, A. Urboniene
Institute For Digestive Research, Lithuanian University of Health Sciences, Kaunas/Lithuania

Contact E-mail Address: zilvinas.dambrauskas@gmail.com

Introduction: The mRNA binding protein HuR is involved in the post-transcriptional regulation of cytoprotective molecules, such as COX-2, HO-1 and inhibitors of apoptosis proteins (IAP, IAP2, XIAP, SURVIVIN), and might be related to poor prognosis in numerous cancer types. However, the association of HuR, COX-2, HO-1 and IAPs family, and their impact on chemotherapy and carcinogenesis in PDAC still remain unclear.

Aims & Methods: The aim of our study was to assess the relevance and correlation of the IAP regulation by mRNA stabilizing protein HuR and COX-2 and/or COX-2 signaling pathway, and to determine the association with clinicopathological parameters and prognosis of PDAC. Data of 32 patients after pancreateodudodenectomy (PD) between 2011–2016 were analyzed. Patient’s mRNA expression levels of HuR, COX-2, HO-1, IAP1, IAP2, Survivin and XIAP, as well as their respective correlations with clinicopathological parameters were analyzed. The Kaplan-Meier method and log-rank tests were used for univariate analysis. Cox proportional hazard model was applied to identify prognostic factors that were independently associated with survival.

Results: HO-1, COX-2, HuR, IAP1, IAP2 mRNA expression were accordingly 3-fold, 8.8-fold, 1.5-fold, 4.8-fold and 5-fold higher, while XIAP and Survivin mRNA expression were 3.8-fold and 3.4-fold lower when compared to normal pancreatic tissue. Expression of HuR was positively associated with COX-2, HO-1, IAP1, IAP2, XIAP, Survivin and XIAP, as well as their respective correlations with clinicopathological parameters were analyzed. The Kaplan-Meier method and log-rank tests were used for univariate analysis. Cox proportional hazard model was applied to identify prognostic factors that were independently associated with survival.

Conclusion: Our results suggested that upregulation of HuR in PDAC patients were significantly related with poor outcome. Even though, significant correlation with IAP proteins in PDAC was noticed, more data is needed to analyze the mechanism underlying HuR and IAP interaction.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1421 HYPOXIA INDUCED HIF1A-MEDIATED DIFFERENTIAL O- GLYCOSYLATION REGULATES SIGNALING PATHWAYS IN PANCREATIC CANCER

Department Of General, Visceral And Thoracic Surgery, University Medical Center Hamburg-Eppendorf, Hamburg/Germany

Contact E-mail Address: ge.wolters@uke.de

Introduction: Hypoxia-induced reprogramming of cell energy metabolism and changes in glycosylation are hallmarks of cancer promoting the induction of an invasive and treatment-resistant phenotype, triggering metastases at an early stage of tumor development.1 We examined the impact of hypoxia on O-GalNAc glycosylation in human HEK293, PDAC cell lines and clinical specimens from cancer patients.

Aims & Methods: We profiled the expression of 88 glycosylation related genes by qPCR in HEK293 cells subjected to hypoxia either induced by 1% O2 or 200mM CoCl2 identifying key O-GalNAc glycosyltransferases downregulated. Functional assays and glycoprotein analysis displayed a pronounced rate of O-GalNAc modified cysteolic proteins derived from hypoxia-treated cells and PDAC specimens. Glycosidase assays could validate specificity of detection method used. aberrant glycolyte could be induced by HIF pathway activator
ML 228 and inhibited using Echinomycin. PTK and STK analysis of cell lysates displayed correlation between phosphorylation and O-glycosylation in hypoxic samples.

**Results:** Mechanistically we could show, that hypoxia-induced decreased levels of C1GALT1C1 results in reduced T-Synthase activity as evidenced by engineered COSMC-deficient cells, displaying O-GalNAc moieties in addition to O-GlcNAc in cytosolic protein fractions. Further, we could show PI3K/AKT/ MAPK signalling is depending on the state of cellular O-glycosylation providing a new rationale for the correlation of PDAC Tn antigen glyctype and cancer cell properties.  

**Conclusion:** Our findings point to a novel crosstalk of O-GalNAc and O-GlcNAc under hypoxia extending the knowledge base of differential O-GlcNAc expression in pancreatic cancer.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: The dismal prognosis of pancreatic ductal adenocarcinoma (PDAC) is mainly due to chemoresistance linked to the tumor microenvironment. Recent data supported ultrasonic (US) targeting to nephron US signal-regulated US-induced cavitation could help overcome chemoresistance by breaking microenvironmental barriers and increase cytotoxic drug availability. Three-dimensional (3D) culture in the form of spheroids is a useful model for reproducing multicellular resistance and analyzing the effects of cavitation.

Aims & Methods: The objective of this work was to study the effects of acoustic cavitation on a model of PDAC spheroids and to investigate possible potentiality of chemotherapy by US. CAPAN-2 PDAC cell line-derived spheroids were cultured as previously described by Iwasa et al. Four conditions, i.e., control, 400 nM-gemcitabine-based chemotherapy (CT) alone, US alone, CT-US combination (n = 12 spheroids per condition), were studied. Experiments were carried out to optimize US settings, in order to observe the occurrence of controlled acoustic cavitation. Comparisons between groups were based on proliferation and growth. Proliferation was evaluated 24 hours after treatment(s) by Uptiblue. Growth was assessed by diameter measurement on light microscopy at day 7 and day 10.

Results: Correlated to the control group, cell proliferation was decreased in spheroids treated with CT (p < 0.0001), but not with US alone. Proliferation was also further impaired in spheroids treated with CT-US combination compared to those treated with CT alone (p < 0.0001), but this synergistic effect of US and CT did not improve spheroid growth, meaning that spheroid diameter did not decrease after US-CT compared to CT alone.

Conclusion: This study shows the feasibility of applying an ultrasonic treatment (acoustic cavitation) in a three-dimensional culture model of PDAC. The combination of CT and ultrasonic cavitation synergistically reduced cell proliferation. Further analysis of the cytotoxic effects of acoustic cavitation on PDAC spheroids is in progress.

Introduction: Because of the progression of systemic chemotherapies (CT) for locally-advanced pancreas cancer (LA-PC), chemoradiotherapy(CRT) was selected for limited cases. However, very long survival cases were reported in CRT and detection of prognostic factors were warranted. In this analysis, we analyzed the LA-PC cases received CRT compared with CT.

Aims & Methods: Gemcitabine (GEM) and S-1 combination chemoradiotherapy was performed according to our previous Phase 1 trial (Journal of Japan Pancreas Society 2010). Till March 2016, 30 LA-PC cases received GS-CRT, and the selection criteria were LA-PC with 1) pathological diagnosis, 2) large vessels (CA, SMA, CHA, PV, SMV) invasion, 3) allochronic and concurrent, 4) unexecuted antitumor therapy. The chemotherapy in CRT administration of GEM (200mg/m2) once a week for 6 weeks, administration of S-1 (80 mg/m2) for 2 weeks a week withdrawal was done twice. Radiation was performed 18 Gy in power of 10 MeV in a week 5-day period for 5.5 weeks, and total dose was 50.4 Gy (Total 28 times). As after treatment, GEM 1000mg/m2 was continued until PD. The patients of CT group were also recruited by the same criteria. One of the regimens among GEM alone, S-1 alone and GEM + S-1 was selected for the primary treatment, and total 26 cases were implemented in more than 2 courses.

Results: Baseline characteristics in CRT and CT group were median age (62, 72.5: p = 0.004), male (20, 12: ns) and tumor location Ph/Pb (17/13, 16/10; ns), respectively. There were significant differences in progression free survival (PFS) (8 months, 6 months: p = 0.002) and overall survival (OS) (13M, 9M: p = 0.0165), respectively. The cases who survived for 18 months and longer were significantly (p = 0.0495) more in CRT (43.3%) than CT group (19.2%). Grade 3/4 adverse events in CRT group were 13 cases of neutropenia (G4-3 cases) and one case of gastrointestinal symptom, and those in CT group, neutropenia was 11 cases (G4-4 case), interstitial pneumonia (IP) aggravation was one case.

Conclusion: For LA-PC, GS-CRT showed better local tumor control and longer survival, and was considered as good candidate of neo-adjuvant therapy. More analysis will be other basis. The LA-PC voice should think about good selection criteria of CRT and improve the survival of LA-PC.

Disclosure of Interest: All authors have declared no conflicts of interest.

PDAC as defined by the new upcoming TNM 8th edition and to establish the alone and in combination, in establishing the T stage of surgically resected system to evaluate the preoperative staging defined by CT and EUS.

geneous results and often dated machines, and no study adopted the new TNM could be preferred in tumors being efficaciously compared to previous editions. In this context, an efficient employed in the neoadjuvant setting, the correct evaluation of the T stage of Chemoradiotherapy in the Management of Locally Advanced Pancreatic Carcinoma: A Qualitative Systematic Review. Florence Huguet, Nicolas Girard, Clotilde Sélain-El Guerche et al.

disease was 62.3 age was 62.3

HIFU device used is FEP-BY02 (Yuande Bio-Medical Engineering Co.LTD., China). The subjects were 140 PC patients, i.e. 69 cases in stage III, 71 cases in stage IV. Performance status (PS) was PS0; 79, PS1; 38, and PS2; 3 cases. Mean age was 67.8 years. The details of the T stage (overlap) was chemo-radiotherapy in 4, arterial infusion chemotherapy in 8, operation in 17, and BSC in 7 cases. Results: All tumors were visualized by HI U monitor system. Tumor location was head in 38, uncus in 19, body in 59, body + tail in 6, tail in 2, and others (recurrence) in 16 cases. Treatment data was followed; mean tumor size before and after therapy was 33.5 ± 10.7 and 33.7 ± 11.5 mm, mean treatment sessions: 2.3 ± 0.7 times, mean total treatment time: 105 ± 65.6 min, mean total number of HI U shots: 967.8 ± 1106 shots. The effects of HI U therapy were as follows: the rate of complete tumor ablation was 87.9%, the rate of symptom relief effect was 64.9%, the effectiveness of primary lesion was CR,0, PR,21, SD,35, PD,34 cases, primary disease control rate (DCR) more than SD was 75.7%. The therapy and HI U treatment was operation in 8, chemotherapy in 116, chemotherapies in 4, and best supportive care (BSC) in 14 cases. MST after diagnosis in HI U with chemotherapy and chemotherapy alone (38 patients in our hospital) was 1028.3 ± 366.6 days, respectively (p = 0.001). MST after HI U therapy was 669.4 ± 156.6 days, the therapeutic index of HI U therapy with chemotherapy was better result than common chemotherapy alone.

Conclusion: This study suggested that HI U has the potential of new combination therapy for PC.

Disclose of Interest: All authors have declared no conflicts of interest.
P1431 PREVALENCE STRATIFICATION OF MALIGNANCY IN RESECTED INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS INVOLVING MAIN DUCT: IS THE 10 MM WURSING DIAMETER AN ADEQUATE CUTOFF?

T. Cúrdia 

Introduction: According to the 2012 International guidelines on the management of intraductal papillary mucinous neoplasms (IPMN), main-duct IPMN patients with a maximum diameter of the main pancreatic duct (MPD) diameter of ≥10mm should have surgical resection, whereas surgery is not always mandatory in those with MPD diameter between 5 and 9mm.

Aims & Methods: The aim of the study was to analyze the prevalence of malignancy (high-grade dysplasia or invasive carcinoma) in resected IPMN with MPD diameter between 5 and 9mm and to identify predictive factors of malignancy.

Retrospective analysis of patients with surgically resected IPMN between 2001 and 2016. Demographics, clinical presentation, imaging and histological features were compared between patients with preoperative evidence of MPD diameter between 5–9mm (Group A) and >10mm (Group B). Malignancy was defined as high-grade dysplasia or invasive carcinoma.

Results: From 122 patients with IPMN submitted to surgery, 66 with MD- or Main Duct IPMN entered the final analysis. Mean age was 66 ± 12 years and 48 (72.7%) patients were men. Group A comprised 47 patients and Group B 19. Abdominal pain was present in 23 (34.3%) patients, jaundice in 19 (28.8%), diabetes in 18 (27.3%), pancreatitis in 15 (22.7%) and weight loss in 12 (18%). There were no statistical differences between study groups. The most common location of the MPD-IPMN was the head of pancreas (60.6%), and it was multifocal in 34.8% of the patients. The prevalence of no dysplasia, low-grade dysplasia, mixed-IPMN was 18.2%, 42.6% and 38.3% in Group A and 10.5%, 21.1% and 57.9% in Group B. No significant difference was found between the two groups. The median survival time of the patients who were receiving chemotherapies was 197.0 days in group A and 291.0 days in group B. No significant differences were also found between the two groups. The median survival time of the patients who underwent chemotherapy in group A (332.0 days) was significantly longer than that of patients who underwent BSC (71.0 days).

Conclusion: Chemotherapy could be safe and effective for patients older than 75 years who have unresectable pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1432 CLINICAL SIGNIFICANCE OF CHEMOTHERAPY FOR ELDERLY UNRESECTABLE Pancreatic CANCER PATIENTS

S. Kaino 

Introduction: Pancreatic cancer has poor prognosis despite of improvements in multimodal treatments. As aging of the population advances, it is expected that elderly pancreatic cancer patients increase.

Aims & Methods: The aim of this study was to investigate the clinical significance of chemotherapy for patients with unresectable pancreatic cancer. At our hospital, 96 patients were diagnosed as having unresectable pancreatic cancer between January 2010 and December 2016. In this study, we defined elderly patients as those older than 75 years. We retrospectively examined the safety and efficacy of chemotherapy in patients with unresectable pancreatic cancer. We analyzed and compared the survival outcomes of chemotherapy and aged patients.

Results: Twenty-seven patients were older than 75 years (group A), and 59 were younger than 74 years (group B). We treated 6/10/0/2/5/4 patients in group A with GEM/S-1/modified FOLFIRINOX (mFOLFIRINOX)/GEM + nabPTX/ first-line supportive, respectively. On the other hand, we treated 12/14/11/5/13 patients in group B with GEM/S-1/mFOLFIRINOX/ GEM + nabPTX/BSC/other/chemotherapies, respectively. Severe adverse events (more severe than grade 3 according to CTCAE v4.0) occurred in 18.2% of the patients in group A and in 33.3% of the patients in group B. No significant difference was found between the two groups. The median survival time of the patients who were receiving chemotherapies was 197.0 days in group A and 291.0 days in group B. No significant differences were also found between the two groups. The median survival time of the patients who underwent chemotherapy in group A (332.0 days) was significantly longer than that of patients who underwent BSC (71.0 days).

Conclusion: Chemotherapy could be safe and effective for patients older than 75 years who have unresectable pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.
In the surgery group, methylation of the GNAS complex locus was found in 1/2 ADC, 1/3 IPMNs (the malignant IPMN has GNAS mutation and no methylation of the GNAS complex), 1/3 MCNs, 0/2 SCA and 0/1 retention cyst.

Conclusion: Sanger sequencing of KRAS and GNAS genes is highly specific for the diagnosis of mucinous neoplastic cysts of the pancreas and may be useful in selected patients. The specificity of Sanger sequencing of KRAS and GNAS genes for the diagnosis of malignant cystic lesions decreases but is higher than CEA/cytology analysis. Methylation in GNAS complex locus was found in malignant cystic lesions and may need further evaluation. More fluid markers are needed to improve pancreatic cyst classification. All other authors have declared no conflicts of interest.

Disclose of Interest: S. Faias: This Work was Financed by a Research Grant of Clube Portugues Do Pancreas.

Introduction: EUS FNA is accepted as the primary modality for tissue diagnosis of solid pancreatic lesions. The presence of on-site cytopathology for immediate evaluation is mandatory and need on-site guided fine needle aspiration (EUS-FNA) has previously been shown to improve performance characteristics. Due to service pressures EUS FNA is also undertaken in the absence of in-room cytopathology assistance. This is a review of current practice.

Aims & Methods: We retrospectively assessed 700 consecutive EUS-FNA procedures from January 2011 to January 2016. 459 (65.5%) solid pancreatic lesions were included in the final analysis after excluding 230 for biliary strictures, hepatic lesions, lymph nodes, gastric, oesophageal lesions, pancreatic cysts and 11 for insufficient information.

Results: In 399 (86.9%) cases on-site cytopathology support was available, while the remaining was unsupported. There were 228 males (57.1%) in the supported and 29 (48.5%) in the unsupported group. Mean age was 64.6 (SD: 11.4) and 64.1 (SD: 11.9) respectively. The mean number of passes in the two groups were 2.8 (SD: 1.12) and 1.9 (SD: 1.0) (P <0.001). A conclusive diagnosis (malignant, benign, NET, GIST) was made in 384 (48.6%), 104 (21.8%), 23 (5%) of the supported group and in 38% (23%, 10%, 3%, 2%) of the unsupported (P <0.001). The mean survival of patients diagnosed with malignancy was 10.9 months (SD: 8.7). Overall performance characteristics of EUS FNA were Sensitivity: 90.8% Specificity: 69.6% PPV: 91.8% NPV: 85.4%

Conclusion: This review confirms high performance characteristics of EUS FNA. The presence of on-site cytopathologist significantly increases the diagnostic yield.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1435  CLINICAL IMPACT OF GNAS AND KRAS MOLECULAR ALTERATIONS ADDED TO CEA AND CYTOLOGY IN Pancreatic CYSTIC FLUID OBTAINED BY EUS-FNA

S. Faias1, M. Duarte2, C. Albuquerque2, R. Roque1, J. Pereira Du Silva1, R. Fonseca1, A. Dias Pereira1

Introduction: Pancreatic cystic lesions are a common finding in clinical practice. Classification of cysts as mucinous or non-mucinous cysts, using EUS-FNA with cyst fluid analysis for cytology and CEA became widely used in clinical work-up of patients with suspicious pancreatic cysts. Molecular analysis (KRAS and GNAS) is not yet recommended in clinical practice.

Aims & Methods: We aimed to determine if mutation in GNAS and KRAS in addition to CEA level and cystic fluid cytology of cyst fluid obtained by EUS-FNA can help in pancreatic cyst classification and decision making. Evaluation of methylation of the GNAS complex locus was performed for cyst classification.

Between 2008–14, 266 EUS were performed for pancreatic cyst evaluation in a patient who died because of alcoholic delirium and the last one was indicated for surgical drainage. This is a review of current practice.

Results: Among 147 patients with pancreatic masses, 118x were diagnosed as cancer, 26x chronic pancreatitis, 3x neuroendocrine tumor. In total 147 native aspirates, 118 cytological smears and 94 plasma samples were examined. The test sensitivity of KRAS mutation was 100% (92/92 samples), but only 34% (31/92 samples) of patients with malignant cystic lesions were confirmed in the course of the disease as a cancer, one patient died because of alcoholic delirium and the last one was indicated for surgery recently.

Conclusion: Examination of KRAS mutations can be performed in all patients undergoing EUS-FNA, with the cytology being the most reliable type of sample for genetic tests. KRAS examination would be reasonable to introduce into routine clinical practice in a group of patients with unclear differential diagnosis of chronic pancreatitis, especially in those with suspicion of cancer in inflammatory terrain. Financial support by The Ministry of Defence and Armed Forces of the Czech Republic MO 1012.

P1437 DO BILARY STENTS REDUCE THE DIAGNOSTIC PERFORMANCE OF EUS BIPSY IN PATIENTS WITH A MASS IN THE HEAD OF THE Pancreas?

Introduction: Self-expanding metal stents (SEMS) are increasingly preferred to plastic stents (PS) for postoperative drainage and palliation of biliary obstruction secondary to a stricture in the head of pancreas (HOP). Their use has increased over the last 5-6 years. Endoscopic ultrasound (EUS) with fine needle aspiration or biopsy (FNA or FNB) is commonly utilised to make a tissue diagnosis and to aid in staging in those with borderline resectable tumours. Stents may reduce diagnostic performance of FNA/FNB by reducing the visible mass to puncture. There have been 2 studies that assessed the impact of stenting on EUS-FNA/FNB performance, one found no difference in yield and sensitivity among patients with or without stents and between SEMS and plastic. Whilst a more recent study found accuracy was significantly reduced by the presence of a stent.

Aims & Methods: The aim was to assess whether stents (SEMS or PS) impair diagnostic performance of EUS tissue acquisition, in a retrospective study of all patients with HOP mass undergoing EUS biopsy between January 2010 and June 2016. Stenting information was obtained from the EUS report and images. Biopsies reported as malignant were considered as such, all other reports were considered benign. A definitive diagnosis of cancer was based on positive pathology, stable imaging and symptoms for a year or more. Patients with cystic lesions were excluded.

Results: A total of 1861 patients had EUS FNA/FNB of which 731 were for HOP lesions. Mean age of patients was 37±15y, 53% were females. Distribution was mostly HP mass (21/36, 59%), but also corporeal in 25% (9/36), caudal in 25% (9/36), inhom in 11% (4/36) and in uncus in 5% (2/36). Mean tumor size measured on EUS was 40±22 mm. Needle used was a 25G in 3% (1/37), 2G in 76% (28/37), 2G in 8% (3/37) and 19G in 13.5% (5/37). The diagnostic accuracy of EUS-FNA/FNB was performed in 56% (24/43) and trans-gastric in 44% (19/43). Mean number of needle passes was 2.2±0.7. EUS-FNA allowed certain preoperative diagnosis of SPN in 74% of cases (35/47), probable diagnosis in 6% (3/47), negative in 4% (2/47) and wrong in 6% (3/47). No acute complication of EUS-FNA was reported. With a mean follow-up of 36±3 months, only one local recurrence was noted. In this 74 years old man case, a 19G needle was used (2 trans-gastric passes), and recurrence occurred after 84 months.

Conclusion: In this large multicenter retrospective series, a systematic preoperative EUS-FNA did not seem to modify the SPN recurrence rate. Therefore this study allows to validate this attitude as a possible alternative. The data for the series are incomplete at the date of submission of the abstract. The final data will be completed on the day of presentation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic neuroendocrine tumours (PNETs) are relatively rare, i.e., 1, per 100,000 individuals per annum, and account for only 1–2% of all pancreatic tumours. They are separated into 2 major categories: 1) well-differentiated (WD-NETs) which have round to oval nuclei, coarse stippled chromatin and finely granular cytoplasm and 2) poorly-differentiated (PD-NETs) which have a diffuse architecture with an irregular nucleus and less cytoplasmic granularity. WD-NETs tend to have an indolent course, but ~50% have metastasised at the time of diagnosis. PD-NETs are high-grade cancers with an aggressive course resembling NETs arising in lung. WD-NETs contain neurosecretory granules which stain for synaptophysin and/or chromogranin. Endoscopic ultrasonography guided fine-needle aspiration biopsy (EUS-FNA) can provide a non-operative cytological diagnosis of PNETs when the pathologist is provided with a good specimen such as the pellet of cells obtained through SurePath (SP).

Aims & Methods: EUS-FNA samples of pancreatic tumours were collected into a SurePath vial and slides prepared from the cellular pellet. The slides were stained for synaptophysin and KIt67 by immunohistochemistry (IHC) and examined by 2 independent senior cytologists.

Results: Sixteen (16) patients with a mean age 65 years (male) were identified by EUS with a suspected PNET. The mean tumour size was 16.2 mm+/−4.2 mm. All had the morphology of a PNET and stained positive for synaptophysin. Immunohistochemical staining of the tumor of our large multicenter study was to assess the short- and long-term safety of preoperative EUS-FNA in SP.

Aims & Methods: This study is a multicenter retrospective register of all SPN diagnosed in the last decade in 14 European expert centers (GROPE task force). Inclusion criterion was realization of preoperative EUS-FNA followed by surgical resection. Patient and tumor characteristics were collected, as the EUS-FNA technique (number of passes, needle size, trans-gastric or trans-duodenal access). Immediate or late complications of EUS-FNA and recurrence of SPN were then recorded.

Results: During the period study, 49 patients (41 women/8 men) with preoperative EUS-FNA for SPN were recorded. Mean age of patients was 37±15y, 53% were females. Distribution was mostly HP mass (21/36, 59%), but also corporeal in 25% (9/36), caudal in 25% (9/36), inhom in 11% (4/36) and in uncus in 5% (2/36). Mean tumor size measured on EUS was 40±22 mm. Needle used was a 25G in 3% (1/37), 2G in 76% (28/37), 2G in 8% (3/37) and 19G in 13.5% (5/37). The diagnostic accuracy of EUS-FNA was performed in 56% (24/43) and trans-gastric in 44% (19/43). Mean number of needle passes was 2.2±0.7. EUS-FNA allowed certain preoperative diagnosis of SPN in 74% of cases (35/47), probable diagnosis in 6% (3/47), negative in 4% (2/47) and wrong in 6% (3/47). No acute complication of EUS-FNA was reported. With a mean follow-up of 36±3 months, only one local recurrence was noted. In this 74 years old man case, a 19G needle was used (2 trans-gastric passes), and recurrence occurred after 84 months.

Conclusion: In this large multicenter retrospective series, a systematic preoperative EUS-FNA did not seem to modify the SPN recurrence rate. Therefore this study allows to validate this attitude as a possible alternative. The data for the series are incomplete at the date of submission of the abstract. The final data will be completed on the day of presentation.

Disclosure of Interest: All authors have declared no conflicts of interest.
mitotic index derived from Ki67 staining helps identify WD-NETs which can be monitored and PD-NETs which need aggressive treatment.

Introduction: Pancreatic neuroendocrine neoplasms (PNE) are highly angiogenic tumors which despite of various targeted options including mTOR and VEGF inhibition frequently develop secondary drug resistance. IGF2BPs (IGF2 mRNA-binding proteins) represent a family of canonical RNA-binding proteins (RBP) comprised of three members (IGF2BP-1–3) which have been described to promote stem and/or progenitor cell maintenance with reported expression and oncogenic roles in aggressive cancers. IGF2BPs show a differential expression pattern in various solid tumors including pancreatic neuroendocrine tumors.

Aims & Methods: We aimed to characterize the role of IGF2BPs in progression and resistance of pancreatic neuroendocrine neoplasms. We used three different siRNA-pools (IGF2BPs) to inhibit the different IGF2BP isoforms in pancreatic neuroendocrine BON1 tumor cells. Cellular effects where investigated by Western blot analyses, flow cytometry, clonogenic survival, cell viability and migration assays.

Results: In the pancreatic neuroendocrine tumor cell line BON1, knock-down of IGF2BP1 resulted in a significant reduction of cell viability. Cell cycle analysis by FACS showed a decreased S phase progression parallelled by a reduction in the proliferation marker PCNA and a markedly reduced MEK/ERK activation. In contrast, Akt signaling was unaffected. Moreover, knock-down of IGF2BP1 significantly reduced clonogenic growth as assessed by colony formation assays and led to decreased cell migration as determined by scratch assays. Interestingly, knock-down of IGF2BP1 was insufficient to induce apoptosis, as assessed by PARP cleavage and the 3′-end of DNA as assessed by annexin-V and PI staining. Rather, si-IGF2BP1 increased the expression of both the anti-apoptotic and pro-survival factor BCL-2 and the cell cycle inhibitor CDK1, in contrast to IGF2BP1 knock-down of IGF2BP3 rather induced cell viability, whereas IGF2BP2 modulation had no impact on cell viability and cell cycle progression indicating opposing effects of the three IGF2BPs on PNE progression. These in vitro findings were paralleled by distinct expression patterns of IGF2BPs in human and murine PNE tumors. Elicudation of IGF2BP-modulated RNAs in PNE cells is ongoing.

Conclusion: In summary, our data suggest that IGF2BP1 promotes tumor progression by enhancing cell cycle progression and clonogenic growth, whereas IGF2BP2 and -3 exert no tumor-promoting role in PNE.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The chemopreventive effect of aspirin (ASA) and other NSAIDs have been observed in the setting of colorectal cancer, showing a reduction in the incidence and mortality. However, the impact of aspirin use on clinical outcome of patients with gastro-entero- pancreatic neuroendocrine tumors (GEP NEN) has not yet been evaluated.

Aims & Methods: Aim of the study was to retrospectively evaluate the clinical outcome of GEP NEN patients treated with ASA at three different European referral Centres for NENs. All the GEP NEN patients followed up in three European Centres (Fondazione IRCCS Ca Granda Ospedale Policlinico Milano, Italy; Fondazione IRCCS Istituto Tumori Milano, Italy; Mater Misericordiae University Hospital, Dublin, Ireland), from January 2005 and September 2016, were retrospectively enrolled. The possible association between ASA and disease grading, staging, primary site, overall OS and PFS were evaluated. At the time of enrolment, clinical data and biochemical parameters were collected for every patient. Chromogranin A (CgA) and specific circulating peptides were evaluated. Morphological and functional imaging (computed tomography, magnetic resonance and Gallium 68PET) were performed to follow up the patients at each Centre.

Results: In the 253 patients included (121 M, median age 64 yrs), the primary neuroendocrine tumor was located at the stomach (n=35), pancreas (n=82), small bowel (n=80), appendix (n=37), colon (n=9) or unknown (n=7). Grading was G1 in 154 patients, G2 in 64, G3 in 5 and not available in 28. TNM staging was I in 99 patients, II in 16, III in 32 and IV in 86. No clear impact on OS or PFS was observed in patients taking ASA compared to those not taking it. Interestingly, in pNEN an inverse relation was observed between Ki67 and ASA assumption (r = -0.35, p = 0.008). In small bowel NEN an inverse relation was observed between positive lymphnodes at surgery and ASA assumptions (r = -0.3, p = 0.02). As expected, the intake of ASA was related with the older age of the patients.

Conclusion: According to present data, ASA therapy seems not to have a direct clinical impact on disease progression or survival of NENs, even if it is associated with lower Ki67 values and less node involvement. Further studies are needed to confirm this observation.

Introduction: Von Hippel-Lindau disease (VHL) is a rare heritable genetic syndrome that may affect different systems and organs: pancreatic manifestations of the disease are frequent during lifetime of the patients. The key feature is the presence of simple cysts, but serous cystadenomas (SCAs) or neuroendocrine tumors (NETs) can be frequently found as well. The aim of this study is to describe pancreatic manifestations in patients with VHL, considering the peculiarity and rarity of this disease.

Aims & Methods: All patients who referred to the established multi-disciplinary team in our center (Molinette Hospital - Turin) for management and follow-up of VHL were included in the study. We considered the ones with pancreatic involvement (simple cysts, SCAs or pNETs). We collected data about the patients (demographics and medical history), about the lesions (imaging features, pathologic and cytopathological analysis) and about the management.

Results: In total 24 patients, 18 of which (75%) had a pancreatic involvement. Multiple simple pancreatic cysts were found in 13 patients, SCAs were found in 2 patients and NETs in 7 patients. The mean age of the patients with pancreatic lesions was 42 (min 25 - max 75), 11 were males and 7 females (1.6:1 M:F). Simple cysts were found in 15 patients, 11 were multiple (ranging from 12 to 80 mm) mostly in the head. 3 patients underwent surgery for symptomatic disease. All pNETs were well differentiated (G1, Ki67 <2%), 7 were located in the head and 2 in the tail (2 patients had multiple tumors). 5 out of the 7 pNET patients underwent surgery. The two SCAs were multiple (max 65 mm), mostly affecting the head and the tail in the other. No surgery was performed.

Conclusion: 75% of our VHL patients showed pancreatic involvement, mostly in males compared to females. 72% of patients with pancreatic lesions suffered from multiple cysts, 39% from NETs and 11% from SCAs. To note that all NETs were G1 and behaved in a benign fashion. Surgery was performed only in patients with NETs in the pancreatic head and in patients with symptomatic cystic disease. The mean age of incidence of VHL-related pancreatic lesions was lower than in previous studies, thus confirming literature data. Although all lesions in our patients were benign or stable, constant monitoring is needed.

Introduction: Neuroendocrine tumours (NETs) consist of a diverse group of neoplasms that derive from diffuse neuroendocrine cells throughout the body. Commonly found in gastrointestinal (GI) duct and lung, they (GI) also arise in the pancreas. The relationship between tumour size and metastasis rate is poorly recognized in patients with pancreatic neuroendocrine tumours (PNETs). The impact of tumour size on prognosis was controversial in previous investigations.

Aims & Methods: The aim of this study is to evaluate the prognostic impact of tumour size on survival outcomes and its correlation with risk of metastasis in a large PNETs cohort, including all stages. Methods: PNETs cases diagnosed from 1988 to 2013 were retrieved from the Surveillance, Epidemiology, and End Results (SEER) database. Clinicopathologic features were retrospectively analyzed. Survival was calculated by the Kaplan-Meier method. Multivariable Cox regression models with hazard ratios (HRs) were constructed to analyze survival outcomes and risk factors. Cubic spline analysis was used to assess relationship between tumour size and probability of metastasis.

Results: A total of 5,424 patients were identified. There were 1,226 patients (22.6%) with tumour size of 2 cm or less. The probability of metastasis increased in a non-linear fashion with increasing tumours size. Univariate analysis showed that tumour size was significantly correlated with survival (P<0.001), no matter surgery was performed or not. However, subgroup analysis suggested this association to be linear for patients with localized and regional tumours (P<0.001), but stochastic in patients with distant stages (P=0.703). On multivariate analysis, tumour size was an indicator for metastasis (HR = 1.010, 95% CI: 1.008–1.012, P=0.001 and size <2 cm vs >2 cm: HR=0.703). No surgery was an independent prognostic factor for good survival (HR = 1.211, 95% CI: 1.048–1.399, P=0.009 for size <21 mm; HR = 1.282, 95% CI: 1.161-1.474, P<0.001 for size >20 mm). For tumours ≤20 mm, surgical treatment was associated with significantly improved survival compared with those patients who did not undergo operation (P<0.001).

Conclusion: Tumour size affects the probability of metastasis. Its prognostic impact on survival is restricted to patients with localized and regional disease. For tumours with tumour size ≥20 mm, surgical treatment should be considered preferably.

P1445 THE LARGEST FAMILY IN TURKEY WITH MULTIPLE ENDOCRINE NEOPLASIA-TYPE 1 AND A NOVEL MUTATION
A. Çetin1, D. G. Duman2
1Internal Medicine, Marmara University School of Medicine, Istanbul/Turkey
2Gastroenterology, Marmara University Hospital, Istanbul/Turkey
Contact E-mail Address: alicetcindr@gmail.com

Introduction: Multiple Endocrine Neoplasia type-1 (MEN-1) occurs usually sporadically but because it is an autosomal dominant disorder it may affect other family members too. The combination of parathyroid tumors, pancreatic islet cell tumors, and anterior pituitary tumors is characteristic of MEN-1 although it may be accompanied by a substantial number of non-endocrine tumors. The mutations in MEN-1 result in the inactivation of one of the MEN1 gene product, a serine/threonine protein kinase encoded by this gene and is responsible for tumor-suppression under normal circumstances. Herein we present the largest MEN-1 family in Turkey to the best of our knowledge and a newly discovered mutation in MEN-1 that affects this family.

Aims & Methods: The family inherited the specific MEN-1 mutation is originally 5' einkaharihas, Giresun and most of the members have moved to Istanbul and Yalova. Consanguineous marriages have been practiced within the family. From a young age, eleven patients underwent biochemical, radiologic and if necessary endoscopic evaluation along with the genetic testing. Additionally, we learnt that 2 members of the family had died of pancreatic malignancy. Diagnostic criteria for familial MEN-1 include 1- the presence of at least one MEN-1 associated tumor that are from parathyroid, pituitary, or GEP tract origins, 2- at least one first-degree relative with one or more of these endocrine tumors and/or 3- positive genetic testing for abnormal MEN-1 mutation. For our index case, DNA sequencing of the MEN1 gene performed using Sanger sequencing technique at ABI 3500 sytem. For the other family members only the targeted mutation analysis is performed.

Results: Among the family members we had peripheral blood DNA from 9 and we found presence of tumour tissue DNA from 1 patient. MEND1 gene was analyzed by Sanger sequencing. Our index case was ZK who had hypophysis adenoma, parathyroidectomy and pancreatic neuroendocrine tumor and had whipple operation. A three nucleotide deletion p. ser560delg*3c.1680_1683 del TGA (MEN-1) mutation was detected. Seven out of ten who were analyzed and tested positive for the mutation. Genetic counseling and information about pre-implantation genetic diagnosis (PGD) was given to all patients who are tested positive for the mutation. All 7 patients had p. ser560delg*3c.1680_1683 del TGA) three nucleotide deletion same with that of index case. Out of 15 patients, MEN-1 diagnosis was confirmed in 11. Tumours detected at patients with MEN-1 diagnosis were: nonfunctional pancreatic neuroendocrine tumour at three, parathyroid adenoma/hyperplasia at 6 patients and hypophysis adenoma
P1446 PROGNOSTIC VALUE OF THE DIFFERENT PRE-TREATMENT BIOMARKERS FOR PATIENTS WITH NEUROENDOCRINE TUMORS

Introduction: Several inflammatory response materials could be used for predic- tion of prognosis in cancer patients. The neutrophil lymphocyte ratio (NLR), platelet lymphocyte ratio (PLR), thrombocytosis (the platelets number >400*103/mm3) have been introduced for prognostic scoring system in various cancers.

Aims & Methods: The objective of this study was to determine whether the NLR, the PLR or thrombocytosis could predict the clinical outcomes in G1-G2 neuroendocrine tumors. We performed a retrospective review of 31 patients with neuroendocrine tumors with ki 67 below 20% diagnosed in Fundi Clinical Institute between 2011-2017. Data about site of the primary tumor, presence of metastasis, NLR, PLR, thrombocytosis (platelet count >400) and survival were collected and analysed.

Results: The patients characteristics were: primary tumor location was: 61.29% pancreas, 22.58% gastrointestinal tract, 16.13% unknown, 61.29% had hepatic metastasis, 6.45% had locally advanced tumor. The primary tumor was resected in 35.48% patients. The overall 2-year survival rate was 77.42%. The Ki 67 index (p < 0.04), PLR (cut off >300) p < 0.01 have statistical significant impact on survival. Univariate analysis and on multivariate analysis (P < 0.03). Other factors like ki 67 index, metastatic disease, thrombocytosis and NLR have an impact on survival statistical significant on multivariate analysis.

Conclusion: This study demonstrates the prognostic role of different variables like Ki 67 index, PLR and PLT value, thrombocytosis and metastasis. This factors may be integrated in different scoring systems for prognosis that could guide clinicians for a better management in patients with neuroendocrine tumors.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Neuroendocrine pancreatic tumors represent the second prevalent entity of malignant tumors of the pancreas and show an overall mortality of about 60%. At the moment surgical resection is the only option of potentially curative therapy, as with the currently available chemotherapies and radiotherapies. Approaches inhibit tumor growth but no regression of the tumor can be achieved. Therefore for about 80% of pNET patients no curative therapy can be offered. To obtain the identification of novel potential target genes for the development of new therapeutic strategies, primary tissues from pNET patients were analyzed. Amongst others Plac8 (Placenta-specific 8) was identified, which

is a small protein of unknown function, showing different forms of cellular localization depending on the cell type analyzed, indicating at its ability to fulfill a variety of physiological functions.

Aims & Methods: In the course of this study, the function of Plac8 in neuroendo- crine pancreatic tumors is to be unveiled to evaluate its value as a potential target for pNET therapy. Therefore primary tumor tissue of about 100 pNET patients were analyzed for Plac8 expression by quantitative real-time PCR and immunohistochemistry. Furthermore established pNET cell lines from human origin where transfected with siRNAs against Plac8 and there proliferative activity and differentiation where analyzed by proliferation- and MTT assay. Changes in these impor-
tant characteristics of tumor cells were further examined by westernblot analyzes of key regulators of apoptosis and cell growth.

Results: Plac8 is highly expressed in primary human pNET tissue on RNA- as well on protein level. Functional in vitro analyses show that the siRNA-mediated knockdown of Plac8 not only in human but also in rat cell lines leads to significantly reduced proliferative activity and reduced cell growth. These effects come along with indicative changes in the expression of central regulatory cell cycle pathways seen in the siRNA- treated cells.

Conclusion: Overexpression of Plac8 in neuroendocrine tumors of the pancreas promotes the proliferative phenotype of the tumor cells while the inhibition of Plac8 inhibits cell growth and metabolism. Therefore in the future Plac8 could represent a very interesting target molecule for the treatment of pNETs.

Introduction: Since the majority of laryngopharyngeal carcinomas are detected at an advanced stage, most cases are treated with concurrent chemotherapy and radiation therapy. The key to improving the prognosis and quality of life is early detection of the primary cancer and treatment using minimal invasive surgery. We previously reported the good oncologic outcomes with ELPS (Endoscopic laryngopharyngeal surgery) for superficial laryngo-pharyngeal carcinoma. However there is no clinical evidence for an additional treatment nor prognosis about the cases conducted endoscopic resection which were diagnosed to be superficial carcinoma with lympho-vascular invasion histopathologically.

Aims & Methods: This study aimed to investigate the optimal additional treat-
ment and clinical course for the suralxing laryngo-pharyngeal carcinoma with lympho-vascular invasion. We analyzed clinicopathological data in 9 patients showed Lympho-vascular invasion receiving ELPS between 2007 and 2014.

Results: Positive lympho-vascular invasion was found in 9 cases. Detected the tumor depth was SEP in 7 lesions and MP in 2 lesions. Mean alcohol consumption is 9.9 abw units. Average smoking history is 38.9 pack years. 5 cases are low activity ALDH2 heterozygotes and have alcohol flushing reaction. 7 cases show positive ALDH2 enzymology findings with lympho-vascular invasion(ly0, v1), 2 cases with vascular invasion(ly0, v1), and 2 cases with lympho-vascular inva-
sion.(ly1, v1). Two patients underwent an additional chemoradiotherapy without recurrence. Four patients had a cervical lymph node or local recurrence, two of them were salvage ELPS cases after chemoradiotherapy. One other salvage cases also had distant metastasis and was given palliative treatment, and finally died. The other one underwent surgical salvage and remained alive. One case with lymphatic and vascular invasion had no adjuvant therapy and remained recurrence-free. And the other 2 cases had no recurrence but died of other cause.

Conclusion: Lympho-vascular invasion is a risk factor for cervical lymph node metastasis, which has a possibility to a very aggressive disease. In those cases, chemoradiotherapy as an additional treatment is recommended as far as possible. If patients already had prior radiotherapy, close follow-up is essential to detect recurrence early. In those cases, chemotherapy or additional surgical resection are also considerable if the general conditions are satisfactory.

Introduction: Bleeding control is one of the most important factors to success in endoscopic submucosal dissection (ESD). We investigated the deference of hemostatic ability between S method and F1-10 method in clinical procedures and surgical trainees.

Aims & Methods: We investigated the deference of hemostatic ability between S method and F1-10 method in clinical study and ex vivo study. In clinical study we analyzed retrospectively their hemostatic ability by consecutive six gastric ESD cases in each groups excluded some cases, which have the risk of affecting data. The median frequency of hemostatic ability of the large vessel in case 2 mm was defined for the prevention of bleeding when relatively large vessels penetrating between muscle layers are dissected. However, we have thought that S method is insufficient especially for large vessels such as more than 2 mm, we have to use hemostatic forceps for preventing hemorrhage despite treated vessel more than 2 mm. We have found that F1-10 method with low-high frequency power setting (F1-10 method) can exhibit precoagulation function without bursting vessels. It is suggested that F1-10 method is useful for large vessel precoagulation.

Aims & Methods: We investigated the deference of hemostatic ability between S method and F1-10 method in clinical study and ex vivo study. In clinical study we analyzed retrospectively their hemostatic ability by consecutive six gastric ESD cases in each groups excluded some cases, which have the risk of affecting data. The median frequency of hemostatic ability of the large vessel in case 2 mm was defined for the prevention of bleeding when relatively large vessels penetrating between muscle layers are dissected. However, we have thought that S method is insufficient especially for large vessels such as more than 2 mm, we have to use hemostatic forceps for preventing hemorrhage despite treated vessel more than 2 mm. We have found that F1-10 method with low-high frequency power setting (F1-10 method) can exhibit precoagulation function without bursting vessels. It is suggested that F1-10 method is useful for large vessel precoagulation.

Methods: The bleeding rate after vessel processing was 18.4% (8/49) and 4.8% (3/63) in the S and F1-10 methods, respectively. The median frequency of the compressed vessel was twice in both methods. The bleeding frequency after vessel processing was 4.8% (3/63) and 4.8% (6/126) in the S and F1-10 methods, respectively. No significant difference was found between the two methods, at 100%, 97.4% respectively. In close surveillance periods, 12 patients were confirmed to local recurrence by follow-up biopsy, then delayed re-treatment was performed (7 patients in re-do ESD). 5 patients in surveillance were treated with re-ESD, and 17 patients were treated with additional surgery. Among these two groups, there were no significant difference in recurrence rates (8.3% vs. 0%) and five-year survival rates (both 100%).

Conclusion: Training on endotherapy prior to certification is limited. The current GI certification process does not guarantee competency in endotherapy for UGIB. In response, JAG QA team have recently released new DOPS forms specific to UGIB, and are consulting on introducing formal certification in endotherapy for UGIB.

Disclosure of Interest: All authors have declared no conflicts of interest.

1. GMC National Training Survey Results 2016, Gastroenterology.
March and September of 2016. All patients underwent EC with iScan. The esophagus was inspected with a ECM capable endoscope (EG-2990-Zi) and deliberate biopsies were taken from tissue identified by ECM that suggested BE. All biopsies were confirmed by a GI pathologist. Primary endpoint was the correlation between visual inspection diagnosis of dysplastic BE by ECM versus pathologic diagnosis of BE as the gold standard.

</tbody>
</table>

Results: In our cohort 41% were male, with mean age of 47.7 years. Endoscopic diagnoses by ECM were divided into nonsyndypastic BE (96/100) and suspected dysplastic BE (4/100). On pathology nonsyndypastic BE was found in 94/100 patients, BE with low-grade dysplasia was found in 4/100 patients. Benign gastric mucosa with no alterations (1/100), and ulcerated esophagitis (1/100). The overall accuracy of endoscopic diagnoses using ECM against pathology diagnosis was of 98%, with sensitivity of 100% [95% CI (96%–100%)], and positive predictive value of 98% [95% CI (93%–99.7%)].

Conclusion: Endoscopic diagnosis of BE by directed biopsies of esophageal tissue with use of ECM is highly accurate. Future prospective studies are needed to validate our preliminary findings and assess inter-observer variability.

Introduction: Endoscopic full-thickness resection (EFTR) for sub-epithelial lesions (SEFs) of GI tract is less frequently described; possibly due to technical challenges involved in dissection and need for resultant defect closure. Current study describes single-center experience of EFTR for treatment of SETs.

Aims & Methods: Prospective database of patients undergoing EFTR for SETs over 6-years (2011–2017) was abstracted. Patient selection for EFTR-endoscopy, endoscopic ultrasound (EUS) and CECT. Inclusion criteria: encapulated lesions, predominantly endophytic component and absence of features of invasive malignancy. Exclusion criteria: patients unfit for general anesthesia or major invasive procedure, unacceptable coagulopathy or high risk features for malignancy. All procedures performed under general anesthesia with endotracheal intubation. High-definition endoscope (GIF-HQ-190 or CF-HQ-190, Olympus Corp., Japan) with distal transparent hood and carbon dioxide insufflation used in all. Alter submucosal (SM) elevation by Gelofuscin, mucosal incision and SM dissection performed to expose SET. Encapsulated SET enucleated maintaining intact capsule. Adherent and attached muscularis propria (MP) layer fibers divided. IT or Dual-knife™️ used for dissection and coag-grasper for hemostasis. Resultant MP layer defect closed endoscopically.

Results: Total N = 18(M:F–11:7), mean age-53.6 (Range-28–78). Presentation—GI bleed (73%), abdominal pain (42%), non uker dyspepsia-1, rectal mass-1 and asymptomatic, incidentally diagnosed (63%). Layer of origin—MP layer in all. Location—stomach-15(72%), duodenum-2, rectum-2, proximal jejenum-1. Mean size of SET-3.3 cm (range 1–7). Mean procedure time-182 mins (60–345), and mean hospital stay was 4 days. Adverse events-two (11%)–esophageal laceration during specimen retrieval–1 (closed using endoclips), failure–1 (due to undetected large exophytic component–surgical resection). Histopathology with

</table>

Admitting Diagnosis (AD) Group 1 BO without DYS/OAC (n = 82): BO patients with DYS/OAC but no visible lesions (Group 2, n = 33): BO patients with DYS/OAC and visible lesions (Group 3, n = 4). All patients underwent an endoscopy under deep sedation at IOV with HD magnification endoscopes + NBI + acetic acid chromoendoscopy. Target biopsies and/or EMR were obtained in case of endoscopically visible lesions; 4-quadratic biopsies 2-cm were obtained otherwise. All the specimens were diagnosed by two expert GI pathologists, who reached a final diagnosis (FD). In Group 2 patients where FD was BO without DYS/OAC, previous history was reviewed by two expert pathologist.

Results: Results are summarized in Table 1. Group 1 (n = 82): FD of DYS/OAC with visible lesion was reached in 2 out of 82 patients (2.4%), both treated by EMR + RFA. No one had a FD of DYS/OAC without visible lesions. Group 2 (n = 33): FD of DYS/OAC with visible lesions was revealed in 13 out of 33 patients (39.4%: 11 were treated by EMR + RFA, 1 by surgery and 1 chemotherapy.

Conclusion: When upper endoscopy is performed in a BO reference center where specific facilities and expertises are available (i.e. deep sedation, HD magnification endoscopes, chromoendoscopy, expert endoscopist and pathologist) “invisible” DYS is a very rare diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1455 PROPHYLAXIS OF VARICEAL BLEEDING IN CIRRHOTIC PATIENTS: EFFICACY AND SAFETY OF ENDOSCOPIC VARICEAL LIGATION - A TERTIARY CENTRE
E. Soares1, M. GravitoSoares1, A. Henrique1, N. Almeida1, L. Tomé1
1Gastroenterology, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal, Coimbra/Portugal
Contact E-mail Address: es18497@gmail.com
Introduction: In the natural history of chronic liver disease, variceal bleeding represents a life-threatening complication of portal hypertension, with high risk of recurrence and mortality.
Aims & Methods: We aimed to evaluate the efficacy of EVL therapy in both primary prophylaxis of variceal bleeding in cirrhosis and to establish the patient’s clinical outcome. This was a retrospective observational cohort study of a total of 444 EVL procedures performed in 250 cirrhotic patients, who were admitted in a gastroenterology department of a tertiary centre, between 2010 and 2016, as prophylaxis of gastrointestinal bleeding. All EVL procedures were repeated every two to three weeks in order to achieve variceal eradication. The clinical outcome included the recurrence of bleeding (primary endpoint), the eradication success rate of oesophageal varices, EVL-related complications and overall and bleeding-related mortality.
Results: The mean follow-up period for all 250 cirrhotic patients enrolled in the study was 73.2±40.0 months, with a mean age of 63.9±8.8 years and a predominance of male gender (80.4%;n=201). At initial endoscopy, 237 (52.1%) patients had oesophageal varices and severe in 168 (37.8%). EVL was performed as primary prophylaxis in 50.9%(n=226) and secondary prophylaxis in 49.1%(n=218). Varices were obliterated in 209 (83.6%) patients with mean number of EVL procedures necessary to eradicate varices of 1.8±0.95 and a maximum of procedures of 6. Recurrent bleeding occurred in 11.2%(n=28) of cases with a mean time to rebleeding occurrence of 8.1±14.2 months. Major and significant complications were verified in 8.1%(n=36) of patients. The main complications were bleeding related to post-banding ulceration (75.0%(n=27)) and infection (22.2%(n=8)), with mean time between EVL and complication occurrence of 11.1±11.9 days (minimum:0;maximum:43). Intra-procedure complications occurred in 11.2(5) patients with no death, despite of two cases of SengstakenBlakemore tube telescoping and one case of bleeding. The overall mortality was 3.4%(n=24), being 0.4%(n=2) related to varical bleeding.
Conclusion: EVL seems to be an efficient, safe and relatively simple therapeutic modality both in primary and secondary prophylaxis of variceal bleeding in cirrhotic patients. Since the main complications occurs over 1 week after EVL procedure, the majority of patients can be safely treated in an ambulatory setting.

P1456 THE VALUE OF ENDOCOPIC FULL-THICKNESS ERECTION FOR GASTRIC AND DUODENAL SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULIUS PROPRIA LAYER
M. Xu1, C. Zhang1, Q. Li1
1Endoscopy Center, Zhongshan Hospital, Shanghai/China
Contact E-mail Address: whiteilly.chen@aliyun.com
Introduction: Given diminishment of quality life caused by surgery in the stomach and duodenum, a minimally invasive treatment is desirable for gastric and duodenal submucosal tumors (SMTs).
Aims & Methods: We aimed to assess the value of endoscopic full-thickness resection (EFTR) technique for gastric and duodenal submucosal tumors (SMTs) originating from the muscular propria (MP) layer. A total of 276 patients with single gastric SMTs originating from the MP layer were performed EFTR between January, 2010 and February, 2014. The light adhesion of the tumor to gastric or duodenal serosal layer could be seen in every case from endoscopic ultrasound (EUS) before the procedure. The SMTs oriented endoscopically were performed EFTR using a standard ESD technique without laparoscopic assistance under direct endoscopic view. The defect of gastric and duodenal wall was closed after resection.
Results: A total of 276 patients included 94 males and 182 females. Their median age was 57.8 years (range, 30-81 years). Among all the 276 SMTs in our study, 165 located in gastric fundus, 96 located in gastric body, 8 located in the antrum, 1 located in pylorus, 7 located in duodenal bulb, 1 located in duodenal cap, 1 located in duodenum and 1 located in duodenal postbulbar. The size of lesions was 1.7 cm (range 0.7-6.0 cm). The success rate of EFTR was 98.9% (273/276). EFTR was failed in 3 cases: one case was out of control because of bleeding into enterocoelea, two cases required conversion into laparoscopic surgery because of torrent lobulations of the tumor outside the cavity. The median operation time was 65 min (range, 14-210 min). In bled resection rate was 98.1% (268/273), piecemeal resection rate was 1.9% (5/273). The median length of hospital stays was 4.4 days (range, 1-23 days). Pathological outcomes revealed that the primary tumors were 137 (49.2%) well-differentiated adenocarcinomas, 174 (31.7%) adenomas, 9 (2.5%) glomus tumors, 5 (1.8%) displaced pancreas, and 3 (1.1%) fibromatoses. The procedure-related complications were as follows. Different degrees of postgastric pain occurred in 168 (60.9%) cases, among which 24 (8.7%) cases required analgesics. Pneumoperitoneum occurred in all the patients and was treated successfully with peritoneocoelea decompression. Seroperitoneum occurred in 15 (5.4%) cases. localized peritonitis occurred in 3 (1.1%) cases, and digestive tract leakage occurred in 1 (0.4%) case. All the cases with above complications recovered spontaneously or after conservative treatments. No massive bleeding or abdominal abscess was found after EFTR. None of the 273 cases developed procedure-related death. No tumor residual or recurrence was found during the follow-up period ranging 3-55 months.
Conclusion: EFTR without laparoscopic assistance is minimally invasive, safe, and effective for treating gastric and duodenal SMTs, which originate from the MP layer and adhere tightly to the serosa. High end bleed resection rate could be achieved. However, a larger number of the cases and long-term outcome deserve further research.

P1457 BLUE LIGHT IMAGING AND LINKED COLOR IMAGING FOR DETECTION AND CHARACTERISATION OF CHRONIC GASTRITIS
J. Weigt1, A. Link1, A. Canbay1, P. Malfertheiner1
1Gastroenterology, Hepatology & Infectious Diseases, Medizin. Universität Magdeburg Gastroenterologie und Hepatologie, Magdeburg/Germany
Contact E-mail Address: jochenweigt@gmx.de
Introduction: Current standard in the characterization of gastric mucosal changes is the use of virtual chromoendoscopy with magnification to visualize the pit pattern and vascular changes. The most recent development in light emitting technology is the so called Multi Light Illumination, that composes light output of 4 coloured LED. Blue Light Imaging (BLI) is composed of a continuous spectrum with peaks at 410 and 430 nm to enhance surface and vascular structures. Linked Color Imaging (LCI) uses BLI light together with post processing that realocates colour tones resulting in a high contrast of different red tones. Until now only few data exist about the use of BLI and LCI in chronic gastritis (CG).
Aims & Methods: We aimed to analyse the use of LCI and BLI in detecting and characterizing of chronic gastritis and premalignant conditions of the stomach. All authors have declared no conflicts. All patients were included.
Results: We investigated 24 patients (15 female, 9 male, age 65 yrs (25-87yrs)). H. pylori was detected by histology or urease test in 7 patients. 3 patients showed normal gastric mucosa, 13 patients presented IM or AG either in the antrum or the corpus. According to MAPS criteria 7 patients had extensive disease with premalignant condition in both, antrum and corpus. The concordance of endoscopic classification and histology was 79.1% (19/24) in the antrum and corpus each. Despite the inconcordance of histology and endoscopic diagnosis in 5 cases the intervals for surveillance according to MAPS guidelines would have been correctly respected with the use of endoscopic assessment in all cases.
Conclusion: LCI and BLI are accurate in detection and characterization of visible focal lesions. Endoscopy a prediction of histology was made by the endoscopist.
Results: We investigated 24 patients (15 female, 9 male, age 65 yrs (25-87yrs)). P1458  LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION(ESD) FOR RELATIVE INDICATION GROUP OF EARLY ESOPHAGEAL SQUAMOUS CARCINOMA (EESCC) IN AGED PATIENTS
Z. Qi1, Y. Zhong1, P. Zhou1
1Endoscopy Center, Zhongshan Hospital Fudan University, Shanghai/China

Contact E-mail Address: poet001@qq.com

Introduction: According to the Japanese Esophageal Society Guidelines, Early Esophageal Squamous Cell Carcinoma (EESCC) involving the muscularis mucosa or <200um invasion of the submucosa, and circumferential extent of >2/3 were relative indications (RI) for ESD. Additional treatment (AT, including esophagectomy or chemoradiotherapy) may be needed after ESD. But in aged RI patients, most will refuse AT due to higher rates of debilitating symptom in China.

Aims & Methods: The aim of this study was conducted to evaluate the long-term outcomes of aged RI patients without AT after ESD.

Between January 2008 and December 2013, a total of 158 aged EESCC patients were included in the present retrospective study. Prognosis outcomes were analyzed.

Results: 89 patients included in absolute indication (AI) group and 69 in RI group. The baseline characteristics were balanced between two groups. During the follow-up time (median 56 (1-108) months), short-term adverse events (4.3% vs 1.1%, p = 0.319) and postoperative stricture rate (31.8% vs 21.3%, p = 0.134) were higher in RI group than in AI group. 5-year recurrence-free survival rate (85.8% vs 67.2%, p = 0.561), metastasis-free survival rate (100% vs 96.6%, p = 0.437), overall survival rate (96.6% vs 90.0%, p = 0.613) and cause-specific survival rate (98.9% vs 98.5%, p = 0.264) for AI group and RI group were comparable.

Conclusion: Aged EESCC patients without AT(esophagectomy or chemoradiotherapy) showed comparable prognosis outcomes with AI group after ESD. So follow up may be recommended, substituted for AT in aged RI group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1459  RETROSPECTIVE ANALYSIS ON SUSPICTION OF FOREIGN BODY INGESTION AND FOOD IMPACTION ON GASTROENTEROLOGY EMERGENCIES
J. T. Correia De Sousa1, D. Libanio1, P. Lago1, R. Marcos-Pinto1, I. Pedroto1
1Gastroenterology, Centro Hospitalar do Porto, Porto/Portugal

Contact E-mail Address: joao.correia.de.sousa@gmail.com

Introduction: Suspicion of foreign body (FB) and food impaction (FI) are one of the most common motives for endoscopic emergency. This retrospective study reviewed 288 cases of suspicion on FB/FI, by the frequency of endoscopic alterations.

Aims & Methods: Uni-centric retrospective cohort study of endoscopies performed during one year of gastroenterology emergency setting.

Results: In 2015, 286 endoscopies were performed on suspicion of FB/FI (22% of total endoscopies, n = 1,309, of them 69.1% (n= 199) were performed during the night. Patients’ median age was 58 years, and 52.8% were women. The presence of FB/FI was confirmed in 71.2% (n= 205); of them 61.5% (n= 126) were FB. The most frequently found foreign bodies were meat bones 18% (n= 37) and fish bones 14.6% (n= 30). Most FB/FI were found on the proximal esophagus (56.1%, n = 115). Endoscopic removal was performed on 129 cases (63.4%), endoscopic mobilization in 54 (26.3%), and in 22 endoscopic closure. In surgery group, complications occurred in 6 patients (1 leakage, 1 stricture, 1 hernia and bowel obstruction, 1 wound infection and 2 worsened fibrotic lesions, regardless of size and location, all took a very long time, more than 100 minutes.

Conclusion: It needs accumulate experience with the help of a professional expert up to 30 cases, and to the more advanced level, about 90 procedures are needed. And, the location of the lesion is the important factor in determining the difficulty of the procedure. Therefore, it is best to avoid the upper third lesion as far as possible until experience 90 cases or at least 30 procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1460  LEARNING CURVE FOR ENDOSCOPIC SUBMUCOSAL DISSECTION OF GASTRIC NEOPLASMS; LOW-VOLUME SINGLE-CENTER EXPERIENCE
S.T. Kim1, T.H. Kim, S. Na
1Internal Medicine, Jeju National University Hospital, Jeju/Korea, Republic of

Contact E-mail Address: panzervor@paran.com

Introduction: Endoscopic submucosal dissection (ESD) has become a standard therapy for early gastric neoplasia. There is no consensus yet about the number of experiences required for performing ESD alone.

Aims & Methods: We aimed to investigate the learning curve of ESD performed by a single beginner endoscopist focusing on developing the performance of dissection, shortening the procedure time, and preventing complications.

Methods: Records of 120 consecutive ESD procedures performed by a single beginner endoscopist with an ESD knife from March 2012 to February 2016 were collected. For analysis of the learning curve, total procedures were divided into four periods, each comprising 30 sequential ESD. The parameters assessed were the en-bloc resection rate, complete resection rate, procedure time, and related complications.

Results: In the procedure time according to the number of experiences, the procedure time decreased from 54 experience. However, there was no statistical difference from the first (45.4±24.0) to the second quarter (44.1±23.1, p = 0.19), to the third quarter (40.7±27.3, p = 0.08), and to the fourth quarter (40.8±23.1, p = 0.09). There was no procedure that exceeded 100 minutes from the third quarter. There were a total of seven perforations, four of which were in the first quarter, two in the second, and one in the third. In the procedure time according to the location of the lesions, upper third lesion (92.4±43.7) showed longer procedure time than middle (46.6±40.2, p < 0.01) and lower third (39.5±27.5, p < 0.01) with statistically significant difference. In addition, in the fibrotic lesions, regardless of size and location, all took a very long time, more than 100 minutes.

Conclusion: ESD can be one of good options for the resection of gastric submucosal gastric epithelial neoplasms. 2006;38:991-5.
P1462 CAP ASSISTED UPPER ENDOSCOPY VERSUS SIDE-VIEWING ENDOSCOPE FOR EXAMINATION OF THE MAJOR DUODENAL PAPILLA: A RANDOMIZED, BLINDED, CONTROLLED, NON-INFERIORITY CROSSOVER STUDY (CAPPAR-II STUDY)
M. Abdelhafez1, V. Phillip1, A. Hapflemeier2, M. Elsayougy3, M. Dollhopf4, A. Elshagid Kassen5, P. Käre1, M. Bajhoud1, R.M. Schmid6, S. Delius1, F. Eckel Florian1

4Kasr Alami Hospital, Cairo University, Cairo/Egypt
5Innen Abteilung, RoMed Klinik Bad Aibling, Bad Aibling/Germany
Contact E-mail Address: dr.mhafez@hotmail.com
Introduction: Examination of major duodenal papilla (MDP) by standard forward-viewing is limited and the use of side-viewing endoscope (SVE) is mandatory. Cap assisted esophagogastroduodenoscopy (CA-EGD) utilizes a cap fitted to the tip of the endoscope that can depress the mucosal folds and thus might improve visualization of MDP. The aim of this study was to compare CA-EGD to SVE for complete examination of the MDP.
Aims & Methods: Prospective, randomized, blinded, controlled, non-inferiority crossover study. Subjects scheduled for elective EGD were randomized to undergo CA-EGD (group A) or SVE (group B) before undergoing second examination by the alternate method. Imaging of the MDP was evaluated, after image processing, by three blinded multicenter-experts. Our primary outcome measure was complete examination of the papilla. Secondary outcome measures were image quality of mucosal pattern, ability to obtain an overview of the papilla and overall satisfaction of the evaluators. For secondary outcomes, a score was given from 1 to 10 (1=poor, 10=excellent).
Results: A total of 62 patients were randomized and completed the study. Complete examination of MDP was achieved in 59 patients using CA-EGD compared to 60 patients using SVE (95 vs. 97%, p=0.10). CA-EGD had mean scores of 8.7±1.3, 7.1±0.86 and 7.9±1 regarding mucosal pattern, overview and overall satisfaction, respectively, versus 5.3±1.6 (p<0.001), 8.3±0.9 (p<0.001) and 7.6±0.6 with SVE (p=0.01).
Conclusion: CA-EGD is non-inferior to SVE for complete examination of MDP. CA-EGD had significantly higher scores than SVE regarding the image quality and overall satisfaction, while SVE had a better overview. CA-EGD is a safe and effective method for examination of MDP and can replace the SVE for diagnostic indications.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1463 INACCURACY OF CAMBRIDGE PROTOCOL FOR PATIENTS HARBOURING CDH1 MUTATION: A CONSECUTIVE SERIES
R. Castro, D. Libânio Monteiro, T. Pinto-Pais, M. Dinis-Ribeiro, C. Brandão
Department Of Gastroenterology, Instituto Português de Oncologia, Porto, Porto/Portugal
Contact E-mail Address: rut.arrais.castro@gmail.com
Introduction: Hereditary diffuse gastric cancer (HDGC) accounts for 1 to 3% of all gastric cancer and can be caused by a mutation of the gene CDH1. Life time risk for gastric cancer is 80% with a mean age at diagnosis of 40 years. Affected individuals generally present multiple foci of signet ring cell carcinoma (SRCC) scattered throughout the gastric mucosa, difficulty detected by endoscopy.
Aims & Methods: The aim of this study was to access the validity of Cambridge protocol with a high resolution endoscope in patients with proven pathological germline mutation of the gene CDH1. A prospective cohort study was performed between September 2016 and March 2017 in 11 patients with CDH1 mutation. They perform a base line high-resolution endoscopy (Olympus-GIF-HQ190) with random biopsies according Cambridge protocol and additional targeted biopsies of different signs. The total number of biopsies and the total number and localization of SRCC foci was registered. For those patients submitted to prophylactic gastrectomy, data was compared with surgical specimen histology. To access the validity of Cambridge protocol with a high resolution endoscopy in patients with proven pathological germline mutation of the gene CDH1.
Results: During the 11 endoscopies a total of 353 biopsies (329 random biopsies and 24 targeted biopsies; mean of 32.1 biopsies per patient) were performed. Two patients presented 1 SRCC foci in random biopsies, being that one of them presented in the esophagus. The total number of biopsies and the total number and localization of SRCC foci was registered. For those patients submitted to prophylactic gastrectomy, data was compared with surgical specimen histology. To assess the accuracy of the Cambridge protocol with a high resolution endoscopy in patients with proven pathological germline mutation of the gene CDH1.
Conclusion: Despite the use of high-resolution endoscopes and the high number of random biopsies, endoscopic evaluation presents many limitations for the diagnosis of HDGC. According to literature, prophylactic total gastrectomy remains the gold-standard patients carrying CDH1 mutation.

Introduction: Endoscopic clips are used in a variety of clinical situations in GI endoscopy—for arrest of bleeding or for closure of bowel perforations or chronic fistulae. Conventional through-the-scope clips often cannot provide optimum results; and therefore full-thickness (FT) over-the-scope (OTS) clips have been devised.
Aims & Methods: Current study describes the clinical experience of use of a recently developed FT OTS clip (Padlock™, Aponos Medical, USA). Data from a prospectively maintained database of all patients undergoing the new fusion clip were abstracted, blind, and prospective. Primary outcome was to assess the success of previous endotherapy, endoscopic procedure, indications for FT OTS clip usage, technical and clinical success and early and delayed adverse events were recorded. The clip–clip is available in two different sizes for use in upper and lower endoscopy. It is supplied preloaded on a cartridge that fits on the distal end of the endoscope. The trip-wires travel alongside the endoscope, enabling additional instruments to be passed through the endoscope channel, and special double-channel endoscope is not required for its application. Technique of clip application—the clip was loaded on the distal end of the endoscope and endoscope advanced to site of interest. Bowel wall defect or bleeding point was positioned within the clip and strong suction was applied. Clip was fired by closing the handle on the delivery system. Suction was slowly released and site was inspected. Results: Total 21 clips used in 19 patients. M:F=12:7, mean age–57.9 years (range –24-94 years). Indications for FT OTS clip use—severe GI bleeding–7 (36.8%) (duodenal ulcer bleed–5, rectal ulcer–1, bleed during ESD for rectal lateral spreading tumor–1); for closure of bowel perforation during endoscopic resection–7 (36.8%) (gastric–3, duodenum–2, rectum–2); and closure of chronic bowel fistulae–5 (26.3%) (esophagus–3, duodenum–1, rectum–1). Previous h/o endotherapy–3/7 of bleeding patients, primary therapy using OTS clip in remaining 16. Technical success was 100%. Two patients needed two clips each due to large size of defect. Clinical success–bleeding arrested in 7/7 (100%); bowel perforation sealed–7/7 (100%); fistula closure successful–4/5 (80%). In one patient of chronic duodenal fistula, fistula reopened 12 weeks after initial sealing of fistula and required surgery. Follow up at 4 weeks revealed no delayed adverse events in any patient.
Conclusion: The new OTS Clip (Padlock™, Aponos) is safe and effective for treatment of severe bleeding and for closure of post ER full-thickness defects and chronic fistulae. Further studies with larger sample size are recommended.

Contact E-mail Address: bmiutescu@yahoo.com
Introduction: Endoscopic resection of ampullary adenomas has increased in the last decade due to the high morbidity with a high mortality in patients undergoing surgical procedures.3
Aims & Methods: This study aims to evaluate the outcome of endoscopic ampullectomy (EA) in a tertiary endoscopy department. We included in the study patients that underwent EA between January 2014 - April 2017 at the Regional Institute of Gastroenterology and Hepatology Cluj-Napoca, Romania. All patients had a benign pathological result prior to the EA. Post-procedural complications such as bleeding, perforation, cholangitis, pancreatitis and mortality were analyzed. Data about resection type, post EA histology and 1 year follow-up was also processed.
References
Results: 19 patients underwent EA, with a mean age of 63.5 ± 17.7 years and a successful resection of the tumor of 17.4 ± 7.8 mm. The male to female ratio is 0.7. "En bloc" resection was done in most cases 15/19 (78.9%). Bleeding occurred in 6 cases (31.6%) and two patients (10.5%) developed acute pancreatitis. One patient died due to severe bleeding. The average days of hospitalization after endoscopic ampullectomy were 5.7 with a range from 2 to 25 days. Adenocarcinoma was described in the final histopathological result in 4/19 cases (21.1%). One year follow-up noted a recurrence rate of 15.8% (3/19 cases).

Conclusion: In conclusion, endoscopic ampullectomy is a difficult procedure with an increased risk of complications but performed by experienced endoscopists is safe and surgical interventions can be avoided.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: This is the largest UK case series of POEM for achalasia including the first successful UK POEM procedure for DES. At our institute, POEM was performed successfully in a potentially more challenging cohort where 52.9% had prior endoscopic/surgical treatment with intervention. Our results are line with international consortia and ASGE findings that POEM is a safe and efficacious procedure for the treatment of achalasia and oesophageal spastic disorders for both short term and sustained symptomatic benefit.

P1467 NEW CHALLENGE FOR SAFER ENDOSCOPIC SUBMUCOUS DISSECTION USING CO2 LASER

V. Morita, R. Aiyoshi
Gastroenterology, Kobe University, Kobe/Japan

Introduction: Endoscopic submucosal dissection (ESD) is increasingly accepted as a minimally invasive treatment for the patients with early gastrointestinal cancers. However, ESD demands high maneuverability technique, and the success of the operation is dependent on each operator’s skill. We have developed a novel laser surgery system for ESD to overcome such difficulties of ESD, which is composed of a CO2 laser source and a disposable flexible hollow fiber probe. Compared to conventional ESD (C-ESD) using electric surgical knives, ESD using CO2 laser (L-ESD) method has an advantage of less risk of perforation and massive thermal damage, because the CO2 laser is strongly absorbed by water such as saline or sodium hyaluronate. Further more, the cutting point can be precisely recognized by another visible guide laser. Due to non-contact laser irradiation and adequate visualization of treatment area, the laser system facilitates more precise and safer treatment and provides high quality and stable dissection. We hypothesized that performing ESD using CO2 laser with a submucosal laser absorber could be a safer and simpler ESD technique.

Aims & Methods: The aim of this study was to evaluate the feasibility of L-ESD and the quality of the resected specimen obtained by L-ESD in living porcine compared with C-ESD. We performed ESD for a total of 14 hypothetical lesions in three porcine stomachs (L-ESD, 7 lesions; C-ESD 7 lesions) under general anesthesia. En-bloc resection rate, procedure time, adverse events, and the quality of the resected specimen were evaluated. To evaluate the smoothness of the cutting surface in the resected specimens, we compared the length of the resected side of the submucosa (LRS) with the length of the muscularis mucosa (LMM).

Results: The en-bloc resection rate was 100% in both groups. Although the mean L-ESD procedure time was 23.3 ± 10.8 minutes, and was significantly longer than that of the C-ESD group (9.4 ± 6.6 minutes; p < 0.05), there was no uncontrollable bleeding or perforation in either group. The mean ratio of LRS to LMM was 107.3 ± 3.3% in the L-ESD group, and was significantly lower than that of the C-ESD group (138 ± 28%); (P < 0.005).

Conclusion: ESD using CO2 laser might be a feasible and effective method for the treatment of early gastrointestinal cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1468 LONG-TERM OUTCOME OF ACUTE CORROSIVE INGESTION: A PROSPECTIVE SINGLE-CENTER STUDY

S. Dhar Chowdhury, B. Kumar, R. T. Kurien, S. K. Ghatak, D. Sreekar
Gastroenterology, Christian Medical College, Vellore, Vellore, India

Introduction: Acute corrosive ingestion (ACI) is a common and serious medical problem accounting for a number of hospital admissions. ACI causes significant mortality and morbidity. These patients are at risk of developing luminal strictures of the upper gastrointestinal tract in the long term. This is more in patients with high-grade injury.

Aims & Methods: The present study aimed at assessing the long-term outcomes of high-grade (Zargar’s grade ≥ Grade 2A) corrosive-induced injury of upper gastrointestinal tract (1). This was a prospective study conducted in the Department of Gastroenterology at Christian Medical College, Vellore. The study period was between January 2008 to December 2014. All patients were managed by a standard protocol which included doing a gastroscopy within 24 hours of ACI. In this study we included patients ≥ 15 years with high-grade (Zargar’s grade ≥...
Grade 2A) corrosive-induced injury of upper gastrointestinal tract. Patients in whom not done or who did not return for another hospital were excluded from the study. The study was approved by the Institutional Ethics committee and was funded by a fluid research grant received from Institutional Review Board at Christian Medical College, Vellore, India. The data was analyzed using SPSS version 17. T-test was used to determine if the paired samples were different. Continuous variables were expressed as mean ± SD and the non parametric continuous variables were expressed as median. Comparison between groups was done using Fisher’s exact test.

Results: During the study period a total of 112 patients presented with ACI. In all 82 patients were included in the study. Amongst them, 53% of the patients were females and the mean age was 36.5 ± 15.5 years. The intent of corrosive ingestion was suicidal in 70% and accidental in 30%. In majority (50%) of patients the nature of corrosive ingested was not known. Nasojejunal tube placement was done in 50%, nasojugal tube placement was done in 32% and 8% no tube was placed. Surgery as needed in 19% (tracheostomy or feeding jejunostomy or a definitive surgery). Amongst the 82 patients who were included in the study, 11 were lost to follow up during the first 31 months (range 2 m-72 m) during which 12 (16.9%) patients expired (73% related to ACI). Amongst the 59 patients, that were alive 16(27%) were symptomatic, 12(20%) had dysphagia, 5(6%) had regurgitation, 4(5%) had chest pain, 67% had weight loss and 111(18%) patients required nil per os nutrition. In all, 43(73%) patients underwent barium study during follow up and strictures were noted in 21(36%). The site of stricture was esophageal in 11(53%), stomach in 8(38%) and connected esophagogastric and stomach in 20%). Esophageal stricture was seen in all patients with Grade III B esophageal stricture, 27% (6/22) with Grade III A injury and 19% (5/27) with Grade II B injury. None of the patients with Grade II A injury developed stricture. Stricture in stomach developed in 27% (22/80) with Grade III B injury and 13% (4/31) with Grade III A injury, 10%(1/10) with II B injury and 20% (1/5) with I A injury.

Conclusion: Acute corrosive ingestion is associated with significant morbidity and mortality. There needs to be stringent control on sale, use and storage of such chemicals.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1469 PROBE-BASED CONFOCAL LASER ENDOMICROSCOPY (pCLE) FOR IN VIVO DIAGNOSIS OF ESOPHAGEAL AND GASTRIC LESIONS - RESULTS OF A PROSPECTIVE, CONTROLLED, CROSS-OVER STUDY

M. Kollar1, J. Krajcova2, J. Maluskova1, M. Kment1, Z. Vackova1, J. Spicak1, J. Martink1

1Clinical And Transplant Pathology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
2Department of Pathology and Transplantology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: marek.kollar1@seznam.cz

Introduction: Probe-based confocal laser endomicroscopy (pCLE) provides real-time microscopic visualization with 1000-fold magnification, allowing endoscopic access to the histological evaluation of gastrointestinal lesions. pCLE may thereby be helpful in guidance of endoscopic therapy. However, histopathological assessment still remains a gold standard for histological diagnosis so far, while pCLE-based diagnosis has not been generally accepted yet. Therefore, more studies assessing diagnostic accuracy of pCLE are warranted.

Aims & Methods: The aim of the study consisted in the analysis of the accuracy of three risk scoring systems used in non-variceal upper digestive bleeding for assessing patient’s prognosis, previously estimated to be predictive for re-bleeding/death after gastrointestinal bleeding. We assessed prospectively a batch of 1872 patients admitted in the Gastroenterology Department of Emergency County Hospital Timisoara in a 12-year period, in which we calculated 3 risk scoring systems, Rockall, Cedars-Sinai and Baylor, based on clinical and endoscopic data. We compared their accuracy for assessing patient’s prognosis, expressed as the need of blood transfusions, number of hospitalization days, re-bleeding, surgery and death. Discriminatory ability was assessed using the area under the receiver operating characteristic curve (AUROC).

Results: The batch included 1134 (60.6%) male and 738 (39.4%) female, mean age 62.7±8.4 years. Regarding the need of blood transfusions, the predictive ability of the scores is as follows: Rockall AUROC 0.59 (CI 0.55–0.62), sensitivity(Se)=81.7%, specificity(Sp)=35.5%, positive predictive value(PPV)=28.4%, negative predictive value(NPV)=86.1% (p<0.0001); Cedars-Sinai AUROC 0.59 (CI 0.55–0.63), Se=72.4%, Sp=41.3%, PPV=28.5%, NPV=82.3% (p<0.0001); Baylor AUROC 0.56 (CI 0.49–0.63), Se=41.9%, Sp=75.5%, PPV=40.6%, NPV=76.5%. Number of hospitalization days: Rockall AUROC 0.66 (CI 0.55–0.77), Se=61.5%, Sp=65.2%, PPV=90%, NPV=25% (p=0.003); Cedars-Sinai AUROC 0.63 (CI 0.50–0.75), Se=53.1%, Sp=73.9%, PPV=89.5%, NPV=27.4%; Baylor AUROC 0.52 (CI 0.51–0.73), Se=47.06%, Sp=66.6%, PPV=84.2%, NPV=25%. Re-bleeding: Rockall AUROC 0.67 (CI 0.66–0.73), Se=65.4%, Sp=76.5%, PPV=14.2%, NPV=92.8% (p<0.0001); Cedars-Sinai AUROC 0.73 (CI 0.69–0.77), Se=84.4%, Sp=49.02%, PPV=13.7%, NPV=97%; Baylor AUROC 0.54 (CI 0.45–0.65), Se=35.1%, Sp=81.2%, PPV=16.2%, NPV=94.2%. Surgery: Rockall AUROC 0.67 (CI 0.61–0.73), Se=71.7%, Sp=59%, PPV=16%, NPV=98.1%; Cedars-Sinai AUROC 0.72 (CI 0.66–0.78), Se=58%, Sp=77.4%, PPV=9.3%, NPV=97.9%; Baylor AUROC 0.55 (CI 0.41–0.66), Se=50%, Sp=66.2%, PPV=5.1%, NPV=94%. Death: Rockall AUROC 0.85 (CI 0.82–0.88), Se=84.2%, Sp=76.2%, PPV=18.2%, NPV=99.5% (p<0.0001); Cedars-Sinai AUROC 0.71 (CI 0.66–0.76), Se=83.1%, Sp=48.1%, PPV=10.2%, NPV=97.6%; Baylor AUROC 0.75 (CI 0.67–0.83), Se=76.89%, Sp=72.3%, PPV=19.2%, NPV=97.2%. There were no statistically significant differences encountered in predicting the need of blood transfusions and surgery between the scores (p>0.05). Baylor score was superior to Rockall in estimating the hospitalization period (p=0.04) and Rockall and Cedars-Sinai proved to be superior to Baylor score in predicting re-bleeding (p=0.002) and to Rockall score in predicting death (p=0.006).

Conclusion: On our cohort of patients, Cedars-Sinai score proved to be the best in predicting the re-bleeding and death in patients with NV-UBD in comparison to Rockall and Baylor scores.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1471 PERCUTANEOUS ENDOSCOPIC GASTROSTOMY: A SAFE PROCEDURE EVEN IN CANCER PATIENTS

J. Pinho1, J. Lage2, D. Libanio2, S. Ferraz2, N. Silva2, M. Dinis-Ribeiro2, C. Brandão3

1Gastroenterology, Centro Hospitalar Tondela/Viseu, Viseu/Portugal

Contact E-mail Address: julianapinho18@gmail.com

Introduction: Dysphagia and malnutrition is a common feature in up to 64% of patients with upper gastrointestinal cancer, and the need of radiotherapy or chemotherapy often worsens this symptoms. Percutaneous endoscopic gastrostomy (PEG) is the preferred route of feeding and nutritional support in these patients. Although generally considered to be a safe procedure, it has been reported that PEG tube placement complications in cancer patients may be superior when compared to non-cancer patients.

Aims & Methods: The aim of this study was to evaluate the complications rate after PEG tube placement in cancer patients. We did a single-centre prospective database including all patients with PEG tube insertion between March 2014 and June 2016, evaluating the complications during 6 months follow-up.

Results: A total of 265 patients (83% men, mean age 59 years) underwent PEG tube insertion. 224 patients (84.5%) had head and neck cancers and 33 patients supported by a grant from Ministry of Health of the Czech Republic, No. 16–

Disclosure of Interest: All authors have declared no conflicts of interest.
P1472 A PROSPECTIVE, SINGLE-CENTER, CROSS-OVER CONTROLLED TRIAL OF CONFOCAL LASER ENDOMICROSCOPY ASSESSMENT OF PERSISTENT OR RECURRENT INTESTINAL METAPLASIA AND RECURRENT OF NEOPLASIA AFTER ENDOSCOPIC TREATMENT OF BARRETT’S ESOPHAGUS-RELATED NEOPLASIA (BORN) 

J. Krajíčová1, M. Kollar2, J. Malušková3, M. Kment2, Z. Vucková1, J. Spíčak1, J. Martinek1

Contact E-mail Address: kraji@ikem.cz

Introduction: Probe-based confocal laser endomicroscopy (pCLE) has been developed to overcome limitations of the current endoscopic sampling techniques. pCLE allows detailed examination of cellular structures and may examine areas that are not accessible for standard biopsies.

Aims & Methods: The aim of this prospective study was to evaluate the efficacy of pCLE (vs. standard biopsies) in detection of persistent/recurrent IM/neoplasia in patients after endoscopic treatment of BORN. A single-center, prospective, controlled and pathologist-blinded (still ongoing) study in patients undergoing surveillance following endoscopic treatment of BORN. pCLE images were obtained from the neo-Z-line (a few cases including macroscopically visible tongues), the cardia and the esophagus. Thereafter, standard biopsies were taken and sent for histopathological analysis (4 biopsies from macroscopically normal neo-Z-line, 2 biopsies from the cardia and the esophagus and targeted biopsies from visible abnormalities, if present).

Results: We examined 29 patients, from these 14 patients (48%) had the initial diagnosis of intestinal metaplasia or neoplasia (IM or neoplasia (N)).

Disclosure of Interest: All authors have declared no conflicts of interest.

Regression analysis showed that the presence of cases of persistent/recurrent IM after endoscopic treatment of BORN. Nevertheless, these results need to be confirmed in a larger cohort of patients. Supported by a grant from Ministry of Health of the Czech Republic. No. 16-2748/A.

P1473 FLEXIBLE ENDOSCOPIC SEPTUM DIVISION (FESD) OF ZENKER’S DIVERTICULAR OUTCOMES: A FLEXIBLE TERTIARY CENTER USING A NEW SYMPTOMS SCORE 

1Humanitas Research Hospital, Rozzano/Italy
2Clinic of Gastroenterology and Digestive Endoscopy, Humanitas Research Hospital, Rozzano, Italy

Contact E-mail Address: roberta.maselli@humanitas.it

Introduction: Symptomatic Zenker’s diverticulum (ZD) can be treated by flexible endoscopic septum division (FESD) as a minimally invasive alternative to surgery or to rigid endoscopic procedure. There is still a lack of standardization of the FESD as well as data on late outcome are scarcely reported. Moreover, a specific outcomes are currently rare reported in available literature and no specific scores have been yet validated.

Aims & Methods: We aim to report the outcome of all ZD treated by FESD in our institution by using a new symptoms score. We retrospectively reviewed consecutive patients with ZD treated by FESD in a single tertiary-care academic medical center between April 2014 and Feb 2017. All patients were included in a prospectively maintained database. A dedicated new score was created to obtain reliable and objective evaluation of outcome of our patients. This score (Milano-Zenker score, MZ-score) is based on the three main ZD symptoms: dysphagia, regurgitation and weight loss.

Results: 100 patients underwent FESD, with a mean age of 70.3 ±11.2 years (range 39-95) and prevalence of male gender (66%). Twenty-nine (29%) of treated ZD were re-intervention: 20 (69%) after previous FESD; 8 (27.6%) after previous surgery and MZ. Mean initial MZ score was 4.5 ± 1.8 (range 1-8). Intraprocedural bleeding was observed in 5 patients (5%), with all of successfully treated by clips. No postprocedural/late bleedings were recorded. One perforation was observed and treated conservatively.

Conclusion: FESD represents a safe and effective treatment for symptomatic patients with Zenker’s diverticulum. The score should be used in all patients after FESD in order to be able to compare results. The score could represent a useful tool to monitoring post-procedural symptoms and guide subsequent management.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1474 HOW ACCURATE ARE THE SYMPTOMS IN PATIENTS WITH FOOD IMPACTION AND FOREIGN BODIES INGESTION? 

A. Laranjo1, J. Mocanu2, M. M. Carvalho1, S. Pires4, N. Veloso1, L. Gonçalves5, R. Godinho1, I. Medeiros1
1Gastroenterology Department, Hospital Espirito Santo de Évora, Évora/Portugal
2Hospital Espirito Santo, Évora/Portugal

Contact E-mail Address: anamllaranjo@gmail.com

Introduction: Food impaction (FI) and foreign body ingestion (FBI) remain the most frequent indications for emergency esophagogastroduodenoscopy. The symptoms in these patients are often nonspecific and their location is not always related to the endoscopic findings.

Aims & Methods: The aim of this study was to characterize the symptomatology of the patients with suspected FI and FBI, to correlate the clinical symptoms with the endoscopic findings and to assess its management and complications. This was a retrospective uncenter cohort study including patients with suspected FI and FBI during three years (2013-2016). Statistic analysis were performed using IBM SPSS Statistics 22 with p < 0.05 deemed to be statistically significant.

Results: 198 patients were included (90 patients with FI, 70 patients with FBI, 38 patients without endoscopy finding of FI or FBI). 59.1% men, with a mean age of 60.10 ± 19 years. Patients with FI were predominantly men and were significantly older when compared with FBI patients (p < 0.05). Dysphagia was the most frequent symptom in FI patients, while foreign body perception and odynophagia were more common in FBI. The symptoms in FI group were localized more frequent in the esophagus (83.3%) and FI was identified by esophagogastroduodenoscopy in the distal esophagus in 58.9% of those patients. In comparison, the symptoms in patients with FBI were predominantly localized in oropharynx (65.5%) and FBI was identified in proximal esophagus in 55.7% of those patients. There was more correlation between the location of the symptoms and the endoscopic findings in patients with FI compared with the patients with FBI (FI 65.6% VS 47.1%; p < 0.05). In FI patients, the most frequent symptoms were odynophagia and foreign body sensation (96.8% and 96.6%). Although it seems to be a need for proposing a ZD score could represent a useful tool to monitoring post-procedural symptoms and guide subsequent management.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

(12.5%) had esophageal cancer; 207 patients (78.1%) had stage IV disease. At the time of treatment, 138 patients (52%) had grade 3 dysphagia and the mean body mass index (BMI) was 20.9 Kg/m2. All the patients underwent antibiotic prophylaxis previous to the procedure. There was an increase on BMI to 23.8 Kg/m2 at 6 months follow up. Eight patients (3.8%) had immediate complications after the procedure (bleeding from the PEG tract; 6; anesthetic complications - 2). The overall complication rate at the first month of follow up was 14.4%, at the third month 20.5% and at the sixth month 11.7%. The overall peri-PEG infection rate was 14%, and was the main complication at the first month of follow up. Development of hyper-granulation tissue was the most frequent complication at the third month of follow-up. Buried bumper syndrome occurred in 10 patients (3.7%). None of the patients had tumor seeding at the gastrostomy site. Overall mortality was 26.4%, none of the deaths attributable to PEG tube insertion.

Conclusion: PEG placement is a safe and effective technique in cancer patients. The rate of major complications and tube site infection were similar to the results found in literature for non-cancer patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1475 GASTROINTESTINAL ENDOSCOPY UNDER SEDATION IS ASSOCIATED WITH PNEUMONIA IN OLDER INPATIENTS—RESULTS OF A RETROSPECTIVE CASE-CONTROL STUDY
C. M. Kollmann, W. Schmiegel, T. Brechmann
Department Of Gastroenterology And Hepatology, Berufsgenossenschaftliches University Hospital Bergmannsheil GmbH, Bochum/Germany
Contact E-mail Address: christopher.kollmann@rub.de
Introduction: Apparent aspiration is a notable adverse event during gastrointestinal endoscopy under sedation (GIES) [1, 2], but little is known about the incidence and the role of inappropriate aspiration is scarce. Furthermore, patients undergoing endoscopies experience respiratory symptoms such as coughing, shortness of breathing, fever and other respiratory adverse events within 24 hours relatively often in more than 5% [3]. Since coughing during endoscopy has been attributed to an increased risk of aspiration-related postprocedural infection [4] respiratory infections might be underreported. Additionally, patients in advanced age are not only determined as a high-risk group for GI adverse events following colonoscopies [5], but are also more likely to develop hospital-acquired pneumonia [2]. Therefore, the aim of the study was to determine the risk of pneumonia, lower respiratory infection (LRI) and systemic inflammatory activation after GIES.
Methods: A total of 250 consecutive inpatients who had undergone GIES during a hospital stay of at least three days were included in a retrospective cohort study. Age-, gender- and length of hospital stay-matched controls (ratio 1:1) who had not undergone any invasive procedure or sedation served as controls. Living conditions of GIES- and controls patients had to be available before and three and/or seven days after endoscopy. Primary objective was the occurrence of pneumonia in general and older patients (≧65 years). Secondary objectives were the development of LRI, elevation of inflammatory markers (CRP and WBC), initiation of antibiotic treatment, pathogen detection and pulmonary infiltration. Statistics included $\chi^2$ test, paired t-test, ANOVA, multiple linear regression analysis.
Results: No significant differences for the occurrence of pneumonia (1.6%, GIES group vs. 0.4%, control group, $p = 0.178$, $\chi^2$ test) and LRI (4.8% vs. 2.0%, $p = 0.084$) in general, but in the older age group (2.6% vs. 0.0%, $p = 0.041$, and 7.8% vs. 2.5%, $p = 0.034$, respectively) were detected. Infectious parameters were significantly increased after GIES, particularly on day three. GIES patients received antibiotic treatment more frequent while pulmonary infiltration did not differ.
Conclusion: This data confirms a higher risk of pneumonia due to GIES in the advanced aged population. In general, patients are more likely to develop inflammation and to receive antibiotic treatment suggesting an increased risk of radiologically non-visible inflammation due to micro-aspiration.

P1476 SYMPTOMATIC RESPONSE OF PYLORIC PNEUMATIC DILATATION, BOTOKX INJECTION OR COMBINATION THERAPY IN PATIENTS WITH GASTROPARESIS OR DELAYED GASTRIC DILATION—ENDOSCOPIC POST-PROCEDURE TRANSIENT PERFORATION
A. Gupta, M. A. Everson, R. Haidry, M. Banks, S. Bown, D. Graham, R. Ganatra, A. Ramasubramoni, L. Lovat, R. Sweis
Department Of Gastroenterology, University College London Hospital, London/United Kingdom
Contact E-mail Address: abs.gupta@aol.com
Introduction: Therapeutic options for gastroparesis or delayed emptying following oesophagectomy with gastric transposition are limited. Although commonly performed [1], partial or good response, both of which had combination therapy. Partial or good response was observed in 93% (13/14); treatment with Botox alone or as part of combination therapy led to a good or partial response in 86% (24/28) compared to 33% (1/3) who had PD alone (p=0.03). 14 procedures were performed in the post-surgical group with a mean post-procedure follow-up of 10 weeks. Overall, a partial or good response was observed in 93% (13/14); treatment with Botox alone or as part of combination therapy led to a good or partial response in 100% (10/10) compared to 75% (3/4) who had dilatation alone (p=0.1). 6 therapies were performed without a defined indication, 2 patients (33%) had a partial or good response, both of which had combination therapy.
Conclusion: Pyloric intervention with Botox, PD or combination therapy are safe and effective treatment options for patients with gastroparesis or delayed gastric emptying following gastric transposition. Subjective treatment without a clear indication shows little improvement.
Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: 33 patients (13 male; mean age 45, range 17–80) underwent a total of 60 endoscopic procedures over 2 years. Treatments were either 100 IU units of Botox injected into 4 quadrants of the pylorus or pneumatic dilatation (PD) incrementally up to 16–20 mm (Hercules; Cook Medical). Patients with gastric malignancy, previous pyloric surgery or no documented follow-up were excluded. Most-therapeutic response was assessed at first follow-up post-procedure and graded as ‘good’, ‘partial’ or ‘none/poor’. Patients were grouped according to type of therapy and indication.
Results: There were no immediate or late complications observed, 31 procedures were performed for gastroparesis with a mean post-procedure follow-up of 11 weeks. Overall, a partial or good response was observed in 81% (25/31). Specific treatment with Botox alone (18 procedures) or as part of combination therapy (10 procedures) led to a good or partial response in 86% (24/28) compared to 33% (1/3) who had PD alone (p=0.03). 14 procedures were performed in the post-surgical group with a mean post-procedure follow-up of 10 weeks. Overall, a partial or good response was observed in 93% (13/14); treatment with Botox alone or as part of combination therapy led to a good or partial response in 100% (10/10) compared to 75% (3/4) who had dilatation alone (p=0.1). 6 therapies were performed without a defined indication, 2 patients (33%) had a partial or good response, both of which had combination therapy.
Conclusion: Pyloric intervention with Botox, PD or combination therapy are safe and effective treatment options for patients with gastroparesis or delayed gastric emptying following gastric transposition. Subjective treatment without a clear indication shows little improvement.
Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We aimed to identify the type and site of lesions being treated in a Western setting as well as the rate, timing and predictors of complications in order to evaluate current admission practice. An electronic database of all ESD procedures performed in our academic institution from 2012–2017 was analysed. Parameters were the number, type, onset and management of complications following ESD. Significant complications (bleeding and perforation) necessitating hospital admission were categorised as early (within 24 hours) and delayed (24 hours to 2 days) post procedure.
Results: A total of 410 ESDs were performed within the time period (225 colorectal, 117 oesophageal, 52 gastric and 16 duodenal). There were 21 complications; ESD for gastric and duodenal lesions had a higher complication rate (11.5% and 12.5% respectively). The table below stratifies the complications according to type, location and onset.

<table>
<thead>
<tr>
<th>Site</th>
<th>Early (within 24 hours)</th>
<th>Delayed (2 days–1 month)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Colorectal</td>
<td>3/225</td>
<td>6/225</td>
</tr>
<tr>
<td>Oesophageal</td>
<td>1/117</td>
<td>4/225</td>
</tr>
<tr>
<td>Gastric</td>
<td>0/52</td>
<td>2/225 (3.9%)</td>
</tr>
<tr>
<td>Duodenal</td>
<td>0/16</td>
<td>1/225 (0.6%)</td>
</tr>
</tbody>
</table>

Conclusion: ESD in this Western setting was more commonly performed for colorectal and oesophageal lesions rather than gastric as seen in Japan. The complication rate is modest and almost all were managed successfully with an endoscopic approach. They occurred more commonly in gastric and duodenal sites. This may be related to the technical difficulties of resection or low volume of procedures performed at these locations. The use of anticoagulants is a risk
factor for delayed bleeding. Given that the majority of delayed complications occurred than 5 post procedure, a standardised 5 day inpatient stay would prove futile in our cohort.

P1478 PREDICTIVE FACTORS AND MANAGEMENT OF REFRACTORY BENIGN OESOPHAGEAL STRICTURES

M. Moura, C. Simões, C. Noronha Ferreira, P. Santos, J.P. Freire, J. Lopes, L. Carrilho Ribeiro, J. Velosa
Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, EPE, Lisboa, Portugal

Contact E-Mail Address: cmiguelmour@gmail.com

Introduction: The optimal management and the predictive factors of response to endoscopic dilation of refractory benign oesophageal strictures remains controversial.

Aims & Methods: To evaluate the prevalence and factors predicting response to treatment of benign refractory oesophageal strictures with scheduled endoscopic dilatations

Retrospective analysis of 75 patients submitted to scheduled endoscopic dilation of benign oesophageal strictures between October 2010 and November 2016. Strictures were classified as refractory when ≥5 endoscopic dilations were needed with at least one dilation achieving ≥15 mm of diameter during the course of management of the oesophageal strictures.

Results: The study sample included 42 (56%) male patients and the mean age was 57 ± 17 years. Dysphagia score at baseline was 30 (17–33) semi-solids (2–23) (30.7%), liquids (3–23) (30.7%) and complete (4–12) (16%). Body mass index (BMI) at baseline was 22 ± 5 Kg/m². The aetiology of the benign strictures was: surgical – 31 (41.3%), peptic–15 (20%), caustic–10 (13.3%), radiotherapy–10 (13.3%) and others – 9 (12%). The location of the oesophageal strictures was as follows: proximal third–34 (45.3%), middle third–12 (16%), distal third–27 (36%) and multiple locations–2 (2.7%). Stricture type: simple–44 (58.7%), complex–31 (41.3%). Patients underwent a median of 4 (1–26) endoscopic dilatation over a median period of 19 weeks (1–229). Dilations were done with Savary-Gillard dilators–35 (46.7%), TTS-balloons–24 (32%) or both–16 (21.3%). The mean diameter of dilation achieved was 15.7 ± 2.2 and a dilation diameter of ≥15 mm was achieved in 56 (74.6%) patients. Local injection of corticosteroids during endoscopic dilatations performed at least once in 39 (52%) patients and in ≥25% of dilations in 39 (52%) patients. From the study sample, 25 (33.3%) patients fulfilled criteria of refractory strictures. In this subgroup, there was a significant association with post-surgical aetiology (p = 0.042), higher rate of local injection of corticosteroids (p < 0.001) and higher dilation diameter (p < 0.001). Refractory strictures were significantly associated with the need for local curettage (OR 9.76, 95% CI 0.03–0.46, p = 0.02) by binary logistic regression analysis. However, none of the other factors were found to be independent predictors of response to therapy.

Conclusion: Surgical aetiology was significantly associated with refractory benign oesophageal strictures and these patients were significantly more likely to require local curettage during subsequent dilatations.

P1490 TRENDS IN CERTIFICATION FOR GASTROINTESTINAL ENDOSCOPY AND VARIATIONS BETWEEN TRAINEE SPECIALTIES: RESULTS FROM THE UK TRAINEE ENDOSCOPY DATABASE

*JAG Working Group For The Quality Assurance Of Training, Joint Advisory Group, London/United Kingdom

Contact E-Mail Address: keith@siau.org

Introduction: In the UK, endoscopy certification is overseen by the Joint Advisory Group (JAG). Since 2011, certification has been awarded for upper and lower GI endoscopy online via the JAG Electronic Training System (JETS). We aim to analyse trends in endoscopy e-certification, and assess for differences between trainees in gastroenterology (GI), surgical (GS) and non-medical specialties (NME).

Aims & Methods: We prospectively identified trainees awarded certification for gastroscopy, flexible sigmoidoscopy (FS) and colonoscopy from the JETS database. For each specialty, we collected data on lifetime procedural counts, formal assessments, and key performance indicators (KPIs) at the time of certification. Comparisons between specialties were analysed using a combination of chi², Mann-Whitney and median tests.

Results: Between June 2011-Dec 2016, 2857 applications were awarded certification. Numbers of gastroscopy and provisional colonoscopy awarded have been in steady state since 2013, whilst numbers for sigmoidoscopy and full colonoscopy continue to increase. Trainees awarded certification comprised mainly of GI (53.2%), GS (28.5%) and NME (15.8%) trainees. With the exception of FS, most certifications were awarded to GI trainees (Figure 2). Median procedural numbers (p < 0.001) and formatative DOPS counts (p < 0.001) pre-certification varied for each modality in the order of NME > GI > GS. Caecal intubation rates (CIR) at full certification were similar between GI (95.6%) and GS (95.6%, p = 0.81), but lower in NME (93.6%, p = 0.02 vs. GS, p = 0.006 vs. GI), despite no differences at provisional certification (median CIR 95.6%, p = 0.32). Rates of D2 intubation (median 98.7%) varied across groups (GS > GI > NME, p = 0.002). Certification awarded at first attempt were similar across specialties (mean 89.4%, p = 0.19), but varied for gastroscopy (NME 95.5%, GS 90.1%, GI 89.7%, p = 0.01).

Conclusion: Despite variations amongst trainee specialties, endoscopy certification is a transparent and robust benchmark for assessing competency, as evidenced by trainee KPIs. Further studies are required to study the impact of recent changes to certification, and if variations in KPIs exist following certification.

P1481 EFFICIENCY AND SAFETY OF ENDOSCOPIC PAPILLECTOMY FOR TREATMENT OF DUODENAL PAPILLA TUMORS

Y. Chu¹, M. Xu¹, P. Zhou¹, C. Zhang¹
¹Endoscopy Center And Endoscopy Research Institute, Fudan University Zhongshan Hospital, Shanghai/China

Contact E-Mail Address: xu.meidong@zs-hospital.sh.cn

Introduction: A duodenal papilla tumor is an uncommon neoplasm in the upper gastrointestinal tract. In the early stage, patients often have no complaints and the tumors are usually occasional found during gastroduodenoscopy examination. Endoscopic papillectomy can be achieved with curative resection for benign adenoma and some early papillary carcinoma. However, some complications are accompanied with the procedure, like pancreatitis and bleeding. This retrospective study is to evaluate therapeutic effect and safety of endoscopic papillectomy on duodenal papilla tumors.

Aims & Methods: From June 2009 to November 2016, the information of patients who received endoscopic papillectomy was recorded, which included basic characteristics and clinical outcomes, such as recurrence rate, bleeding, pancreatitis. Clinical outcomes (totally 40 cases) received endoscopic papillectomy. The procedure was completed with gastroscope in 32 cases and duodenoscope in 8 case. Endoscopic mucosal resection (EMR), endoscopic piecemeal mucosal resection (EPMR) and endoscopic submucosal dissection (ESD) was performed in 21, 17 and 2 cases respectively. None of the lesions invaded the submucosal layer.
Pancreatic stents and biliary stents were inserted in 9 and 12 patients respectively. In general, 5% (2/40) and 12.5% (5/40) cases had intraoperative and postoperative bleeding respectively. 20% (8/40) cases suffered from pancreatitis, of which mild, moderate and severe happened in 3, 4 and 1 cases. Six patients had tumor recurrence. And 3 patients received repeat endoscopic papillotomy, two received pancreatic-cystoduodenectomy and one received no other treatments with close follow-up. Two patients died from failures of treatments for papillary tumors and one patient died due to other unrelated cause.

Conclusion: Endoscopic papillary is proved to be efficient in treating papilla tumors without submucosal invasion. However, adverse events like pancreatitis and bleeding should be taken seriously and managed properly.

**P1482** CHANGES IN SCORING OF DIRECT OBSERVATION OF PROCEDURAL SKILLS (DOPS) FORMS IN ENDOSCOPY TRAINING AND THEIR IMPACT ON COMPETENCE ASSESSMENT

K. Siau, 1 P. Dunckley, 1 A. Nevill, 1 J. Anderson, 1 I. Beales, 1 R. Broughton, 1 M. Feeney, 1 A. Haycock, 1 N. Hawkes, 1 B. Mckai, 2 B. Gibson, 2 R. Valori, 1 C. Wells, 1 G. Johnson, 2

1JAG Working Group For The Quality Assurance Of Training, Joint Advisory Group, London/United Kingdom
2Faculty Of Education, Health And Wellbeing, University of Wolverhampton, Walsall/United Kingdom

Contact E-mail Address: keith@siau.org

Introduction: DOPS are validated tools for assessing competence in endoscopy. Previously, DOPS were scored on a 4-point competence-based scale, with scores of 3 and 4 signifying competence. In July 2016, the DOPS rating scale changed to a supervision-based scale that has been shown to be more reliable, with 4 ratings from maximal supervision, up to competent without supervision. We aimed to assess whether changes to the rating scale have affected distribution of scores and hence demonstrate validity.

Aims & Methods: We used the UK trainee endoscopy database (JETS) to collect DOPS scores for gastroscopy (n = 1934), sigmoidoscopy (n = 517), colonoscopy (n = 2296) and polypectomy (n = 370) in the 6-months before July 2016 (old DOPS) and after (new DOPS). Trainees at early stages of training (total procedures ≤ 100). To allow analysis, the new DOPS rating scale was aligned to a 4-point scale, hence a score of 4 on new DOPS = Scores 3 or 4 on old DOPS, and scores on the new and old DOPS compared using the Mann-Whitney U-test. Results: 5117 DOPS (77.7% new and 22.3% old) were included for analysis. Overall, there were variations in distributions of all scores (p < 0.001) between forms (Figure 1). Compared to new DOPS, scores of 1 were underutilised on old DOPS (0.6% vs. 3.0%, p < 0.001). Frequencies of low scores (pooled scores of 1-4) were similar for gastroscopy (p = 0.53) and sigmoidoscopy (p = 0.34), but not for colonoscopy (11.9% vs. 13.9%, p < 0.001) and polypectomy (6.8% vs. 19.9%, p < 0.001). Trainees on old DOPS were more likely to be rated as competent (score 3 or 4) compared to new DOPS (86.4% vs. 85.5%, p < 0.001). On subgroup analysis, this was evident for gastroscopy (86.3% vs. 49.1%, p < 0.001), colonoscopy (86.1% vs. 58.2%, p < 0.001), sigmoidoscopy (90.6% vs. 62.0%, p < 0.001), but not polypectomy (80.1% vs. 67.9%, p = 0.12).

Conclusion: Endoscopy assessors are applying a greater range of scores using a new DOPS rating scale based on degree of supervision, in two cohorts of trainees matched for experience. This indicates better construct validity with the new rating scale. Further work is underway to determine the reliability of the new DOPS to inform summative assessment and certification for UK endoscopy trainees.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1484** PROTECTIVE VACUUM SPONGE IMPLANTATION AND CONTINUOUS EVACUATION OF BILE AND PANCREATIC JUICE FOR PREVENTION OF SECONDARY PERFORATION AFTER PRIMARY SUCCESSFUL ENDOSECOPIC RESECTION OF WIDESPREAD D2/D3 DUODENAL AND PAPILLARY ADENOMATA

J. Hochberger, 1 J. Jung, 2 E. Weid, 1 M. Hofmeyr 3

1Gastroenterology, Vivantes Klinikum Friedrichshain, Berlin/Germany
2Visceral Surgery, Vivantes Klinikum Friedrichshain, Berlin/Germany
3Anesthesiology, Vivantes Klinikum Friedrichshain, Berlin/Germany

Contact E-mail Address: juhochbercher@mac.com

Introduction: Endoscopic resection of duodenal adenomata carries an increased risk of perforation compared to other locations in the upper or lower GI tract. 1,2 Additionally in endoscopic resection of widespread adenomata (Spigelman III/IV) at the level of D2/D3 there is an increased risk of secondary perforation due to auto-digestion of the denuded duodenal wall by pancreatic enzymes and bile independent of the primary endoscopic resection method. We recently reported of the successful implantation of a mini-vacuum sponge with extended length of the suction tube and reduced in volume compared to a standard esophageal vacuum sponge.3

Aims & Methods: From September 9th, 2015 to March 20th, 2017 endoscopic resection of widespread duodenal adenomata >2 cm in D2/D3 was performed in five patients. There was a surgical indication for Whipple’s resection as primary intervention or in case of failure in all patients. All patients agreed and gave their informed consent to the procedure.

Results: Five patients with widespread duodenal adenomata were included (2x papilla, 3x D2/D3 extrapapillary adenomata; 1x tubular; 3x HGIN, 2x LGIN). The macroscopic mean maximum diameter and perpendicular diameter of the lesions were 4 x 2.8 cm (largest 7.5 x 3.7 cm; smallest 2.2 x 1.8 cm). In all cases the implantation of mini-vacuum sponge (ActiVAC) reduced in volume to 1.2 x 1.5 cm (dia, length) with extended suction tube; Braun Corp., Melsungen). Continuous suction was applied over several days (~125 mm Hg; ActiVAC, KCI Medical, Wiesbaden) depending on the size of the resection area and healing status (n = 10 days, 4–14 days). An endoscopic/radiocative vacuum sponge exchange was performed every 3–5 days. In 4 cases additional atraumatic over-the-scope-clips (OTSC, Ovesco Tuebingen) were placed during the procedure and in 5/5 cases additional hemoclips were applied to secure the wall and for hemostasis. In 5/5 cases (100%) an excellent healing could be observed during follow-up. No patient had to be operated during or following the intervention (FU 2-14 mo.). In all cases the resection was curative with ‘en bloc’ resection, though in one case the specimen ruptured during retrieval into three parts (4x HGIN, 1x LGD; 4x R0, 1x Rx). In one case 10 days after resection an acute bleeding occurred with the need of endoscopic clipping and prophylactic radiologic coiling of the gastroduodenal artery with uneventful course. In a second case a minor bleeding occurred without necessity of transfusion during ablation of an OTSC three mo after the primary intervention. All patients were asymptomatic during follow-up.

Conclusion: The endoscopic resection of large duodenal adenomata in D2/D3 is feasible and was safe in our collective using the application of a duodenal mini-sponge as local drainage of bile and pancreatic juice as alternative to Whipple’s resection. The results in this first small collective should be reproduced in a prospective multicentric trial.

P1405 ENDOSCOPIC CLOSURE OF ACUTE PERFORATIONS OF THE GASTROINTESTINAL TRACT IN ANIMAL MODELS: A SYSTEMATIC REVIEW AND META-ANALYSIS
A. Gabr1, N. Ammar2, M. El Houssine2, M. Rutter3

2Public Health Department, Ain Shams University, Cairo/Egypt
3Gastroenterology, University Hospital of North Tees, Stockton on Tees/United Kingdom
Contact E-mail Address: ahmedgabr@hotmail.co.uk
Introduction: Acute perforations are one of the recognized complications of both diagnostic and therapeutic gastrointestinal endoscopy. For decades, surgical treatment has been the standard of care, but endoscopic closure has become a more popular approach, due to feasibility and the reduction of the burden of surgery, combined with the availability of various endoscopic closure devices.
Aims & Methods: We aimed to assess the technical and clinical success and safety of endoscopic closure, in total, and for each endoscopic device used in closing acute perforations in animal models. Medical literature (Cochrane library, PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) were looked into. A total of 214 endoscopic closures were randomised controlled trials, met our inclusion criteria (acute, less than 24 hours). A systematic review and meta-analysis were performed on studies reporting technical and clinical success, and low complication rate. Further confirmation from prospective studies in human is needed.
Disclosure of Interest: All authors have declared no conflicts of interest.
Results: 46 studies on animal models were identified. 15 studies, including 4 randomized controlled trials, met our inclusion criteria (acute, less than 4 hours, iatrogenic, no fistulas or leaks, clear documentation of the method of closure, and technical and clinical success). In 5 cases or more of endoscopic closure per study, were analysed. A total of 214 endoscopic closures were attempted in these studies. The overall technical success rate was 94.8% (n = 201/214, 95% CI: 92.9%-96.7%), clinical success was 92.3% (n = 199/214, 95% CI: 88.5%-95.8%), and complication rate was 4.2% (n = 6/214, 95% CI: 1.6%-8.2%). Technical success for endoclamp closure was 84.9% (95% CI: 71.4%-93.6%), and clinical success was 83.2% (95% CI: 69.5%-92.5%), and complication rate was 2.7% (95% CI: 90.1%-99.8%). For OTSC (Over the scope clip device), technical success was 97% (95% CI: 88%-99.7%), clinical success was 97% (95% CI: 88%-99.7%), and complication rate was 1.8% (95% CI: 91.2%-98.8%). The technical success for endostitching (endoscopic suturing device) was 92.7% (95% CI: 82%-98%), clinical success was 87% (95% CI: 74.9%-94.8%), complication rate was 1.9% (95% CI: 91.1%-98.9%).
Conclusion: Our study suggests that endoscopic closure is a suitable treatment option for acute iatrogenic gastrointestinal perforations with a reasonable technical and clinical success rate. Further confirmation from prospective studies in human is needed.
Disclosure of Interest: All authors have declared no conflicts of interest.

5. Of the 1862 patients, prevalence of colorectal polyps and adenomatous polyps were 13.1% and 7.8%, respectively. Multivariate analysis revealed that metabolic syndrome (OR, 1.89, 95% CI, 1.13–3.17, P = 0.015) was independent predictor for colorectal polyps. Age over 80 years old (OR, 1.48, CI, 1.4-1.84) was independent predictor for adenomatous polyps.
Conclusion: Metabolic syndrome is risk factor of colorectal polyps in young adults aged >50 years. Age over 40 years old is additional risk factor of adenomatous polyps.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1407 COMPARISON BETWEEN AN ASYMMETRIC (SMALL DOSE IN THE MORNING) AND A SYMMETRIC SPLIT-DOSE REGIMEN OF POLYETHYLENE GLYCOL PLUS BISACODYL FOR BOWEL PREPARATION FOR SCREENING COLONOSCOPY: A RANDOMIZED NON-INFERIORITY CLINICAL TRIAL

Introduction: Bowel cleansing has a critical role to increase the quality and effectiveness of colonoscopy. International guidelines recommend the use of split-dose regimens of PEG solutions. However, the adoption of split dose regimens in clinical practice remains sub-optimal, in particular in early morning. Aims & Methods: We aimed to compare the efficacy of bowel preparation using an asymmetric split-dose regimen (approximately 25% of the dose is given on the day of the procedure and 75% of the dose is given on the day before) with the standard split-dose regimen in patients undergoing screening colonoscopy. We prospectively enrolled consecutive outpatients undergoing screening colonoscopy. All subjects received a split-dose preparation with a 2L PEG-citrate-simethicone plus Bisacodyl. Patients were randomly assigned to: group A, asymmetric split-dose regimen (1.5 L of PEG + bisacodyl the day before and 0.5 L 3 hours before colonoscopy); group B, symmetric split dose regimen (1 L of PEG + bisacodyl the day before and 1 L 4 hours before colonoscopy). Bowel preparation was evaluated using the Boston Bowel Preparation Scale (BBPS) score. The primary endpoints were the proportion of adequate bowel cleansing (BBPS ≥3) and the overall score of patient satisfaction. Moreover, all patients filled in a nurse-administered questionnaire assessing compliance, tolerability and safety of bowel preparation. The threshold for statistical significance in this study was p<0.05 and a 10% margin was used to demonstrate non-inferiority of asymmetric vs. symmetric split-dose regimen.
Results: 179 patients were enrolled (mean age 60 ± 8 years, males 56%; 88 in group A and 91 in group B. Split-dose was taken by 76/88 and by 77/91 patients in group A and B, respectively (85.2% vs. 88.5%, p=0.831). Failure of cecal intubation occurred in 1 patients for each group. In the ITT analysis, adenoma detection rate [32/76 (42.1%) vs 17/77 (45.4%); p = 0.745] and scores of each colon segment. The full amount of product and adjunctive fluids were taken by 68/76 (89.4) and 71/77 (92.2%) (p = 0.158) in group A and B, respectively. Tolerability and occurrence of adverse events were similar in the two groups.
Conclusion: An asymmetric (low morning-dose) split-dose preparation with a low volume formulation with additional Bisacodyl is not inferior to the standard split-dose regimen in achieving an adequate bowel cleansing in patients undergoing screening colonoscopy. A lower amount of preparation in the morning allow to the patients to wake up later; this regimen could be thus preferred by patients undergoing colonoscopy early in the morning. Further study are needed to determine the efficacy and tolerability of the asymmetric preparation for colonoscopy scheduled in early morning.

Introduction: Colorectal endoscopic submucosal dissection (ESD) is a technique with remarkably greater difficulty than upper gastrointestinal ESD because of unstable maneuvers and inherited anatomic variability in the colon. Thus, aiming at reducing these restrictions, we have used single balloon (SB) overtube to assist colorectal ESD in cases considered to have difficult operability. In this study, to evaluate the usefulness of a single balloon overtube to assist colorectal ESD.
Aims & Methods: The study included 35 patients with 39 colorectal lesions who underwent ESD (group SB) or ESD without SB (group NSB). The background of the patients in group NSB were corrected by using the propensity score matching method. The application of the combined use of SB was determined when the circumferential access to the lesion was difficult, and paradoxical movement was observed. Results: The characteristics of the lesions in group SB were as follows: proximal, 28 lesions; distal, 9; mean size of tumors, 37.6 ± 9.8 mm; gross findings of laterally spreading tumor of granular type (LST-G), 11 lesions; non-granular type (NG) tumors, 28; adenomas, 11; mucosal cancers, 22; and submucosal cancers, 6. The mean procedure time was significantly shorter in group SB (129.3 ± 30.7 min vs 106.0 ± 24.5 min; p < 0.05). No significant differences were found in en bloc resection, complete resection, postoperative bleeding, and perforation rates. No accidental symptom associated with balloon endoscopy was observed. Conclusion: Using a balloon overtube can be expected to improve not only access to the lesion but also facilitate scope manipulation for colorectal ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.
domains—Communication (COMM), Situational Awareness (SITA), Leadership (LEAD) and Decision-making (D&M). Each MARS domain was represented by 10 items and is assessed on a 7-point scoring scale—endoscopists should score >90 in each domain (80–90 = need for improvement, <80 = suboptimal performance). CIR and PDR measures are routinely calculated for all colonoscopists using the HICCS Electronic Reporting System with manual validation of these data. Feedback is presented on a quarterly basis to practitioners—endoscopists are expected to achieve 90% CIR and 20% PDR. Correlation of these factors with practitioners ENTS scores were measured using the Pearson test.

Results: 9 endoscopists with known variability in standard colonoscopy KPIs consented to an assessment of ENTS using the MARS tool. Their ENTS scores were correlated with existing KPIs for each colonoscopist (Oct 2016-Mar 2017), with an overall positive correlation between ENTS domains and CIR (COMM 0.58, SITA 0.66, LEAD 0.66; D&M 0.75) and PDR (COMM 0.49, SITA 0.55; LEAD 0.50; D&M 0.60). Three endoscopists were identified as having sub-optimal scores in all of the ENTS domains (operators 5, 7, 9). Taking into account important KPI thresholds 2 out of (33%) of these endoscopists identified were not meeting CIR targets (c.f. 66% of ENTS competent group) and one (33%) did not meet PDR targets (c.f. 0% in ENTS competent group).

Colonoscopy: The MARS is a practical way to measure of ENTS performance designed as a 360-degree feedback and identifies areas for development within independently practitioners that are not currently highlighted by standard colonoscopy KPI measures. There is some correlation with current KPI feedback panels but utilizing a specific validated ENTS assessment tool allows better current assessment panels. Both CIR and PDR primarily depend on the colonoscopists' individual skills rather than the team elements required by polypectomy or EMR and these more complex tasks may show stronger correlation with MARS ENTS evaluation.

P1492 EARLY ECONOMIC MODELLING OF EMI-137 TO IMPROVE THE DETECTION RATE OF POLYPS IN PATIENTS WITH INCREASED COLON CANCER RISK

B. Shinkins1, A. Smith1, N. King1, A. Davies2, I. Wilson2
1Test Evaluation Group, Academic Unit Of Health Economics, University of Leeds, Leeds/United Kingdom
2Edinburgh Molecular Imaging, Edinburgh/United Kingdom

Contact E-mail Address: b.shinkins@leeds.ac.uk

Introduction: Safety and diagnostic accuracy of colonoscopy depend on the quality of bowel cleansing. Several factors have been reported to affect the quality of bowel cleansing, one of them being hospitalization.

Aims & Methods: We performed a prospective, randomised endoscopist blinded clinical trial between February 2016 and January 2017 included. Our aim was to evaluate the potential impact that the use of EMI-137, a novel bowel preparation, would have on colorectal polyps detected at colonoscopy.

Results: Of the 42 patients included in the study, 21 patients were randomized to a bowel preparation in which EMI-137 was used (b.i.d., 4L polyethylene glycol solution) and in the remaining 21 patients only standard polyethylene glycol was used (control). The addition of EMI-137 fluorescent agent to standard WL colonoscopy results in a lifetime per-patient average additional NHS cost of £426 and an additional 0.04 QALYs, giving an incremental cost-effectiveness ratio (ICER) of £11,245 per additional QALY. The cost-effectiveness of EMI-137 was sensitive to the proportion of polyps that are dysplastic at the time of colonoscopy. The results of this modelling exercise have since been used to inform the design of Phase II/III clinical studies.

Conclusion: The results of this early economic modelling exercise demonstrated that EMI-137 has the potential to be cost-effective for patients participating in the UK National Bowel Cancer Screening Programme. The value of information analyses have highlighted the key parameters for which further evidence is required, and this will be used to inform the design of future clinical studies.

**Conclusion:** The use of a visual educational booklet for the preparation of colonoscopies does not provide a significant improvement in hospitalized patients in our health area. Heart disease and/or colon cancer were predictors of poor preparation for colonoscopy. An optimized preparation should be considered for this type of patients.

**P1494 STUDY OF ULCERATIVE COLITIS COMPPLICATED BY PRIMARY SCLEROSING CHOLANGITIS**

S. Murasugi, A. Ito, H. Kambayashi, M. Yonezawa, T. Ohnori, K. Tokushige Institute of Gastroenterology, Tokyo Women’s Medical University, Tokyo, Japan

**Contact E-mail Address:** murashun0305@yahoo.co.jp

**Introduction:** Primary sclerosing cholangitis (PSC) is often associated with autoimmune diseases, and approximately 70% of PSC patients in Europe/United States and 32% in Japan also have ulcerative colitis (UC). The while the complication of PSC is confirmed in about 5% of UC patients, the clinical features of UC associated with PSC differ from those of UC without PSC.

**Aims & Methods:** We investigated the clinical and colonoscopic features of colitis associated with PSC. We retrospectively examined the clinical features, including the clinical course and colonoscopic findings, of 25 colitis patients with PSC attending our hospital between 2000 and 2010.

**Results:** The male-to-female ratio was 12:13 and the age at diagnosis of PSC was 49 ± 15 years. PSC was the initial diagnosis in 12 patients (48%), while colitis was the first to be diagnosed in 4 patients (16%), and both diseases were found concurrently in 9 patients (36%). Among the 21 patients with the diagnosis of PSC, 15 were operated (62%) before the diagnosis of PSC and the latter was recognized by screening. There were 12 patients with UC (52%) and 11 patients with nonspecific colitis (48%). Among the 24 patients in whom the disease extent was assessed, 22 had pancolitis, 1 had left-sided colonitis, and 1 had proctitis. Inflammation predominately affected the right colon in 20/22 patients with pancolitis and also involved the terminal ileum in 9 patients (48%). The Mayo score for colonoscopic evaluation of UC was 1 in 16 patients (64%), 2 in 8 patients (32%), and 3 in 1 patient (4%). There were no rectal lesions in 10 patients (40%). Liver biopsy was performed in 17 patients, and Ludwig’s stage was Stage I in 1 patient (6%), Stage II in 12 patients (71%), Stage III in 3 patients (18%), Stage IV in 1 patient (6%). Ludwig’s stage did not correlate with the Mayo score. All patients with PSC and enterocolitis received oral ursodeoxycholic acid (UDCA), including 13 patients with UDCA only (52%), 2 patients with combination of sulphasalazine (SASP) (8%), 5 patients in combination with 5-aminosaliclyic acid (5-ASA) (20%), 2 patients in combination with prednisolone (PSL) (8%), 1 patient with the combination of SASP+PSL (4%), and 2 patients with 5-ASA+PSL (8%). The UDCA dose was 300 mg in 2 patients (8%), 600 mg in 15 (60%), and 900 mg in 8 (32%).

**Conclusion:** In colitis patients with PSC, there was no clear association between colonoscopic disease activity and the severity of PSC. There was no sex difference and the age at diagnosis of PSC showed a bimodal distribution (30 s and 60 s). Pancolitis was very frequent and predominantly affected the right colon, but disease activity was low. Rectal lesions were mild or absent. About half of the patients had inflammation of the terminal ileum.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Primary sclerosing cholangitis (PSC) is often associated with autoimmune diseases, and approximately 70% of PSC patients in Europe/United States and 32% in Japan also have ulcerative colitis (UC). While the complication of PSC is confirmed in about 5% of UC patients, the clinical features of UC associated with PSC differ from those of UC without PSC. Since July 2016, electronic assessment forms (DOPS) for UK trainee endoscopists have been updated to include ENTERS as an assessable domain. We aimed to assess the uptake and distribution of ENTERS scoring in DOPS and their correlation with other endoscopic skills, across all assessable endoscopic modalities.

**Aims & Methods:** We identified all DOPS submitted between July 2016 and Feb 2017 from the UK endoscopy trainee database (JETS) and acquired data on trainees, procedures and scores. We collated scores for each of the 4 assessable domains (pre-procedural, procedural, post-procedural and ENTERS) into overall outcomes of “not competent” (if any domain items required supervision) or “competent”, and compared this to the overall competence rating. Statistical analysis was performed using chi2 and regression modelling.

**Results:** 860 DOPS were prospectively collected, with ENTERS assessed in 99.3%. Competency rates of individual ENTERS items are summarised in Table 1. Rates of overall ENTERS competency (defined as all items scoring competent) varied across procedures (p<0.001): ERCP 39.8%, EUS 44.1%, gastroscopy 59.6%, colonoscopy 62.3%, PEG 71.1%, sigmoidoscopy 72.4%, and polypectomy 73.2%. Scores by individual ENTERS components are displayed in Table 1. Of DOPS awarded overall competency, 5.9% (240/4077) lacked full competence in ENTERS (p=0.10 across modalities). Across trainee specialties and endoscopic modalities, competency was greater for “communication and teamwork” (77.1% overall), but least with ‘judgement and decision making’ (68.3%). Competency in ENTERS increased with lifetime procedural count (OR 1.008 per increase in procedure, p<0.001), and correlated strongly with other assessable domains, including overall score (p<0.001). After adjusting for procedural count, factors predictive of ENTERS competence included trainee seniority (OR for ST5 level: 1.96, p<0.001), surgical trainees (OR 1.21, p=0.014), trainees performing polypectomy (OR 2.02, p<0.001), and higher DOPS count (OR 1.03 per increase in DOPS, p<0.001).

**Conclusion**: ENTERS is an assessable domain within endoscopy training, with scores that correlate with other procedure-related skills, demonstrating construct validity and convergent and discriminant validity. Competency of ENTERS develops with procedural count, and vary with trainee seniority and specialty. Longer term data are required to assess the impact of ENTERS on certification.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Table 1: Unadjusted ENTERS scores by endoscopic modality.**
Introduction: The development of Endoscopic Non-Technical Skills (ENTS) is associated with expert performance and high quality endoscopic outcomes. Whilst ENTS domains have been incorporated into Joint Advisory Group (JAG) Direct Observation of Procedural Skills (DOPS) forms, used as training tools, knowledge of ENTS domains amongst independent practitioners varies. To improve performance in this area of practice requires validated measurement tools and specific feedback against which improvement can be measured. We have previously developed a validated 360-degree multi-assessor rating scale (MARS tool) based on experienced endoscopy assistant ratings for ENTS processes and outcomes of ENTS comprising 10 related but independent practice points. Providing an optimised feedback format for this data is likely to maximise the potential benefits of measuring ENTS performance.

Aims & Methods: We aimed to provide an optimised format for performance enhancing feedback in the ENTS domains and basis for specific auditable outcomes and performance indicators. Local colonoscopists gave consent to application of the ENTS questionnaire. The validated MARS tool assesses 4 ENTS domains - Communication (COMM), Situational Awareness (SITA), Leadership (LEAD) and Judgement & Decision-making (J&DM). Each MARS domain in the administered questionnaire was represented by 10 items and is assessed on a 7-point scoring scale. We sought to develop 1) a format to illustrate an individual’s overall performance in each of the 4 main ENTS domains in comparison to other operators and 2) a detailed domain breakdown highlighting areas of underperformance 3) Collate feedback on the presentation formats.

Results: 9 endoscopists consented to an assessment of ENTS using the MARS tool. The MARS questionnaires were administered during January 2017–relating to the prior 3 months clinical practice. Acceptable performance thresholds were set as ≥90% good-excellent ratings in each domain. Need for improvement was defined as 80–90% good-excellent ratings (i.e. 10–20% average or poor ratings) and sub-optimal performance as ≤80% or less good-excellent ratings (i.e. >20% average-poor ratings). Good intra- and inter-rater reliability was demonstrated for these cut-off values during validation of the MARS tool. Scatter plots were used to present the overall domain ratings for COMM, SITA, LEAD and J&DM domains allowing comparison with other endoscopists. To provide more detailed domain-specific feedback to endoscopists an individual report is generated of 4 domain tables summarising the question items and using a ‘traffic-light’ display to help operators quickly identify those specific skills that require areas for improvement. The consensus reported regarding the MARS feedback helpful and indicated that it was ‘likely’ or ‘very likely’ to prompt an alteration in practice. A suggestion to add an additional column to the summary table indicated where performance level has changed in subsequent audit rounds is being considered.

Conclusion: The MARS tool is a practical way to measure ENTS performance allowing the observer to generate an audit of a robust quality assurance system. The benefits of providing overall comparative data has been established previously in sharing more established key performance indicators. The feedback format for data derived from the MARS tool has additionally provided detailed domain-specific ENTS performance ratings that brings to attention areas for improvement in a clear and understandable way that can be re-tested as part of an integrated audit cycle.

Disclosure of Interest: All authors have declared no conflicts of interest.
and O2 have relatively dark xenon light sources and maximum optical magnifi-
cation at 110 times, respectively. Therefore, the differences in visualization of mucosal blood flow in the small and large bowel among the
groups were considered to be attributable to differences in instrument efficiency.

Conclusion: Our results show that magnifying observation with BLI is superior to
that with ODI regarding the observation of mucosal blood flow in the small and
large bowel. We are planning to conduct a study on the clinical application of
magnifying observation with BLI for visualization of mucosal blood flow in the
small and large bowel.

P1499 MULTIPLE COLORECTAL ADENOMAS WITHOUT APC OR MUTYH GERMINE MUTATION: A HETEROGENEOUS SUBGROUP OF PATIENTS

L. Sanchez Mete, E. Mannisi, A. Martayan, M. Varanese, V. Sigligna
Gastroenterology And Digestive Endoscopy, Regina Elena National Cancer
Institute, Rome/Italy

Introduction: Multiple colorectal adenomas (MCRA) can be defined as an endedo-
sic feature of ≥ 10 colorectal adenomas in patients (pts) without APC or MUTYH germine mutation. At present its clinical features, management and the presence of extracolonic cancer are not well studied.

Aims & Methods: The aim of the present study is to better define the clinical characteristics at diagnosis and during follow-up of MCRA affected patients. Focally submucosal fibrosis on endoscopic examination or submucosal fibrosis on endoscopic submu-
cosal dissection of colorectal LSTs and excluded lesions of the depressive or ulcerative type. Each data is

Results: The mean age at MCRA diagnosis was 50.1 ± 14.6 years (range, 19 to 79
years) and 20 pts (41.6%) had at least a first degree relative affected with color-
ecal neoplasia. Clinical features at diagnosis: the number of polyps ranged
between 10 and 20 in 43.7% of the cases; 21 and 50 in 27.1%; > 50 in 29.2%;
22.9% of pts had one or more adenocarcinomas (ADC); 16.6% had a previously
diagnosed extracolonic cancer (breast, endometrial, thyroid, lung, bladder, brain, larynx). Twenty-five pts (52%) needed surgery, ten underwent a subtotal cotie-
obteny and fifteen a total colectomy. During follow-up twenty-two (55%) pts
developed recurrent adenomas and two (5%) had one or more ADC in the retai-
ned colorectum; 12.5% of pts developed duodenal adenomas, one had a dia-
ral adenoma; we recorded one case of abdominal wall desmoid.

Conclusion: MCRA patients in the present study had similar clinical character-
istics to MUTYH associated Polyposis (MAP) affected patients. They were
generally diagnosed at a mean age of > 50 years, they had more than 20 polyps
(56.3%) at diagnosis, associated with ADC in 22.9% of the cases and required
surgery in the majority of cases (52%). During follow-up, pts also developed
recurrent adenomas. Clinical characteristics and family history in these patients
support the hypothesis that pathogenic alterations in yet unknown genes may be involved. The promising technology aimed at this purpose.

However, these patients should undergo a close surveillance than those with sporadic adenomas.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A degree of fibrosis on targeted lesion is one of the widely known
factors which affects the results of Endoscopic mucosal resection (EMR) and
Endoscopic submucosal dissection (ESD). Severe fibrosis is associated with com-
lications such as perforation, post-coagulation syndrome and bleeding.

P1501 ADVANCED NEOPLASIA YIELD IN PATIENTS UNDERGOING COLONOSCOPY AFTER SCREENING FLEXIBLE SIGMOIDOSCOPY: DOES THE DISTAL COLON PATHOLOGY PREDICTS THE YIELD IN PROXIMAL COLON?

R. Ramreshshanker, F. Purcharoni, A. Cruedel, A. Rajendran, I. Stasinos, A.
Wilson, S. Thomas-Gibson, A. Haycock, A. Humphries, N. Suzuki, B.P. Saunders
Wolfson Endoscopy Unit, St Mark’s Hospital, Harrow, London/United Kingdom

Contact E-mail Address: r.ramreshshanker@nhs.net

Introduction: Currently patients undergoing a screening flexible sigmoidoscopy
(Bowel Scope screening) examination at the age of 55 are referred for colono-
scopy if the following polyp criteria are met: polyp > 1 cm, villous histology, high
grade dysplasia, 3 or more adenomas or > 20 hyperplastic polyps (HP)

Aims & Methods: Objective is to assess the proportion of patients who had an
advanced adenoma (size > 3 cm, villous or high grade dysplasia on histology) in the
proximal colon when referred for a colonoscopy after a screening flexible
sigmoidoscopy. A retrospective cross-sectional study of patients who underwent
Bowel Scope screening between July 2013 - July 2016 at St Mark’s Bowel
Cancer Screening (BCS) Centre was performed. Epidemiological, procedural and polyp
data were retrieved from the endoscopy and Bowel Cancer screening database.

Results: 9960 patients had a screening flexible sigmoidoscopy in the time period.
Descending colon was reached in 82% of patients. Advanced adenomas were
detected in 351 (3.2%) patients. 520 (5.2%) patients had a colonoscopy following
screening flexible sigmoidoscopy as per the BCS protocol. Median age at was 55
years (male: female ratio 2:1). Cœcal intubation was achieved in 98% (510/520)
cases.

</table>

Conclusion: Distal colonic advanced adenomas are a marker of synchronous proximal colonic adenomas and sessile serrated polyps. When colonscopies were performed for other indications (non-adenomatous poly >1 cm, multiple distal HP polyps) the yield in the proximal colon was significantly smaller. These "soft" indications for colonscopy accounted for a significant additional workload that appears unjustified.

P1502 LEARNING CURVE FOR OPTICAL DIAGNOSIS OF COLORECTAL POLYPS USING CUMULATIVE SUM ANALYSIS
R. Rameshshanker, A. Wilson, S. Thomas-Gibson, N. Kamperidis, N. O’Shea, B.P. Saunders
Wolfson Endoscopy Unit, St Mark’s Hospital, Harrow, London/United Kingdom
Contact E-mail Address: r.rameshshanker@nhs.net

Introduction: Optical diagnosis for diminutive and small colorectal polyps is an attractive option to reduce costs and streamline patient care. The American Society of Gastrointestinal Endoscopy Preservation and Incorporation of Valuable Endoscopic Innovations (PIVI) established a 90% diagnostic threshold for real time endoscopic assessment of the histology of diminutive colorectal polyps. For adoption of optical diagnosis in clinical practice, colonoscopists must be trained and show on-going competence. The learning curve for trainees to achieve the competency has not been fully explored.

Aims & Methods: Aim is to evaluate the minimum number of polyps to achieve and maintain the optical diagnostic thresholds per PIVI standards using an upward CUSUM plot. Four trainees without previous experience in optical diagnosis at our institution participated in this prospective study. Four weeks before the commencement of the study they were given a training module on optical diagnosis (OD). OD was based on NICE and WASP classification.1 During the study period (January 2016-August 2016), each trainee documented the optical diagnosis of polyps less than 10 mm in size. Confidence levels of OD were noted at the same time. Patient demographics and polyp details (site, size, Paris classification and histology) were collected prospectively. OD of each polyp was compared against the polyp histology. Polyps without the histological confirmation were excluded from the analysis. Every trainee had on-going feedback on their performance.

Results: A total of 708 polyp observations were performed by trainees during the study period. Total number of adenomas, hyperplastic polyps and sessile serrated adenomas/polyps (SSA/P) were 364, 214 and 52 respectively. Trainees OD performance was plotted on a upward CUSUM plot.

All 4 trainees achieved sustained accuracy (90% threshold) in OD within 12–58 observations. The number of polyps required to reach the plateau varied between 12 to 58. Every trainee’s confidence level improved over time (from 69% to 89%) and the effect was augmented by in- vivo feedback and revision of training module. Table 1 summarises the optical diagnostic performance of all 4 trainees. Negative predictive value for adenomas were above 90% for all trainees.

Conclusion: The CUSUM scores of all 4 trainees in the study reached the PIVI standards plateau by the 58th polyp observation. In- vivo feedback and continued training appears important to maintain the performance. Our preliminary findings could be used as a guide to plan the certification process for implementation of optical diagnosis.

P1503 THE CLINICAL VALUE OF ENDOSCOPIC FULL-THICKNESS RESECTION FOR COLORECTAL SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULARIS PROPRIA: A PROSPECTIVE SINGLE-CENTER STUDY
M. Xu, C. Zhang, Q. Li
Endoscopy Center, Zhongshan Hospital, Shanghai/China
Contact E-mail Address: xumeidong@aliyun.com

Introduction: Given diminishing quality of life caused by colectomy and resection, a minimally invasive treatment is desirable for colorectal submucosal tumors (SMTs).

Aims & Methods: The aim of the current study was to evaluate the clinical efficacy, safety and feasibility of endoscopic full-thickness resection (EFTR) for colorectal SMTs originating from the MP layer. A prospective study was carried out, including a consecutive cohort of 56 patients who underwent EFTR for colorectal SMTs originating from the MP layer between January 2008 and September 2014 in our center. Among these patients, 21 located in the colon, 9 located in the intraperitoneal rectum and 26 located in the extraperitoneal rectum. The tight adhesion of the lesion to the serosal layer was identified before EFTR in all cases. EFTR was performed using a standard ESD technique under direct endoscopic view. The defect of colorectal wall was closed after resection in all cases. Complete resection rate, complications and lesion recurrence were evaluated.

Results: Successful EFTR was performed in 54 (96.4%) patients. The other 2 patients were transferred to suffer laparoscopic right hemicolectomy and EFTR combining laparoscopic operation respectively, because the lesions involved the external organs and were too difficult to get an e block resection endoscopically. The endoscopic resection rate and complete resection rate were both 96.4% (54/56). Among 54 cases, 52 of these lesions were performed with EFTR without laparoscopic assistance, while 2 needed laparoscopic assistance to get the defect closed after resection. The median operation time was 45 min (range, 20–130 min). The median maximum diameter of resected tumors was 1.5 cm (range, 0.5–5.0 cm). Accurate histopathologic results were acquired from all the resected lesions, including 18 leiomyomas, 11 gastrointestinal stromal tumors (GISTS), 8 fibrous tumors, 3 schwannomas, 11 granulomas, 2 displaced endometrium, and 1 hamartoma. Three patients had local peritonitis and two patients developed postoperative bleeding. All of them recovered after receiving conservative treatments. No single case developed diffuse peritonitis. No lesion residual or recurrence was found during the follow-up period ranging 2–54 months.

Conclusion: EFTR appears to be a safe, feasible, and effective procedure for providing accurate histopathologic evaluations, as well as a curative treatment for colorectal SMTs originating from the MP layer. However, it should be performed by the very experienced endoscopists.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1504 COLONIC ESD BY UTILIZING SHORT DOUBLE BALLOON ENDSCOPE—HOW TO TREAT DIFFICULT CASES IN COLONIC ESD?
S. Katsuki, T. Fujita, K. Takamashi, E. Waga
Center Of Gastroenterology, Otaru Ekisaikai Hospital Center of Gastroenterology, Otaru/Japan
Contact E-mail Address: sinichi-katsuki@otaru-ekisaikai.jp

Introduction: Colon ESD has been a standard treatment in the world. However, sometimes it is hard to remove the colon tumor during ESD. When we find it difficult to detach the tumor from the muscularis propria, we need to consider the following three points: if we don’t have enough experience and skill, we should take the training more. If there are lots of vessels and fibrosis in the submucosal layer, it is necessary to choose adequate tools. And if patients have complicated colon, suitable endoscope need to be selected. In such cases we always use DBE.

Aims & Methods: We evaluated the outcomes of colon ESD by using DBE (DBE-ESD). Short DBE we used were EC450B5, EN530Bi and EI530BT (Olympus Co., Tokyo, Japan). We’ve performed DBE-ESD on 211 lesions in 184 patients. We analyzed the lesions located in the proximal colon, and the following items were examined: arrival time, procedure time, rate of negative margin, perforation rate, length of hospital stay and recurrence rate in the 5th year after the ESD.

Results: There were 159 lesions located in the proximal colons. The median arrival time to the lesion was 7.9 min, operation time 51.1 min, negative rate of horizontal margin 99.4%, vertical margin 99.4%, perforation rate 0%, median length of hospital stay 3.1 days, and recurrence rate in patients with more than 5 year follow-up 0%.

Conclusion: Because the balloons and the overtube retained the scope at stable position, we were able to get good working space. Therefore, DBE should be one option for difficult cases in ESD.

P1505 WITHDRAWAL TIME MONITORING AND FULL-SPECTRUM ENDOSCOPY IMPROVE ADENOMA DETECTION RATE

G. De Nucci1, P. Andreozzi2, C. Bezio3, R. Reati1, D. Morganti1, D. Redaelli1, E. Mandelli1, B. Omazzi3, I. Arena3, S. Saibeni3, G. Manes1

Aims & Methods: evaluation of the hidden areas of the colon. Colonoscopy. Monitoring withdrawal time (WT) and use of full-spectrum endoscope (SFVE) (n = 330) or with FUSE (n = 330) without a dedicated WT protocol. In this phase, colonoscopy WT were measured without the endoscopists’ knowledge of being monitored. In phase 2, endoscopists were informed of being monitored and performed further 660 colonoscopies either with SFVE (n = 330) or with FUSE (n = 330).

Results: No differences were observed among the four arms in terms of demographic, clinical features, and indications to colonoscopy. WT was lower in phase 1 arms compared to phase 2 arms (SFVE: 267 ± 96 vs. 387 ± 65, p = 0.001; FUSE: 293 ± 112 vs. 430 ± 93, p = 0.001). When endoscopists were aware of being monitored and used full-spectrum endoscope we observed a higher ADR [phase 1 SFVE 27.3% (90) phase 1 FUSE 33.0% (109) phase 2 SFVE 33.6% (111) phase 2 FUSE 41.8% (138); p = 0.001] and adenoma per colonoscopy (APC) [phase 1 SFVE 0.43 ± 0.85 phase 1 FUSE 0.56 ± 1.08 phase 2 SFVE 0.11 ± 0.24 phase 2 FUSE 0.71 ± 1.08; p = 0.004]. The detection rate of adenoma located proximally to the splenic flexure was higher in phase 2 arms (phase 1 SFVE 11.2% vs. phase SFVE 16.4%, p = 0.056; phase 1 FUSE 12.7% vs. phase 2 FUSE 18.9%, p = 0.033), whereas adenoma located distally to the splenic flexure was higher in the FUSE arms compared to SFVE arms, but these differences were not significant (Phase 1 SFVE 20.0% vs. Phase 1 FUSE 24.8%, p = 0.081; Phase 2 SFVE 21.8% vs. Phase 2 FUSE 27.0%, p = 0.147).

Conclusion: Unmonitored endoscopists have a sub-optimal WT, which increases with experience. Use of full-spectrum scopes combined with WT monitoring results in increase of adenoma detection rate. In particular, monitoring WT increases the detection of adenomas in proximal colon, whereas the use of FUSE seems to increase the detection of adenomas in distal colon.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1506 HIGH LEVELS OF “PRESUMED POLYP MISS RATE” AT 1 AND 3 YEARS FOLLOWING INDEX SCREENING COLONOSCOPY: NO ROOM FOR COMPLACENCY

Wolfson Endoscopy Unit, St Mark’s Hospital, Harrow, London/United Kingdom

Contact E-mail Address: r.rameshshanker@nhs.net

Introduction: Polyp detection rate remains as an imperfect tool and the adenoma miss rates vary between 6-27%.

Aims & Methods: Aim is to determine the presumed miss rate for adenomas and sessile serrated polyps (SSAs/SPs) after a complete screening colonoscopy. Methodology: A prospective observational study was performed at our bowel cancer screening centre over 12 months from July 2015. Patients who underwent a surveillance colonoscopy following an index colonoscopy were included (one and three-year surveillance). All colonoscopies were performed by 6 experienced, accredited bowel cancer screening endoscopists. Polyp characteristics and procedural data were prospectively recorded and collected. Polyp histology and epidemiology data were retrieved from our endoscopy database. A polyp was considered as “missed” if the index colonoscopy if at 1 year surveillance it was not adjacent to a scar (a recurrence) or at 3 years if >5 mm in size and not adjacent to a scar.

Results: 241 patients underwent a surveillance colonoscopy (male: female 2:1, median age 65 years). 90/241 (37.3%) patients had a one-year surveillance colonoscopy. There was no significant difference in the quality of bowel preparation, caecal intubation rate and total procedure time between index and surveillance procedures. Total number of polyps detected during index and surveillance colonoscopies were 815 and 469 respectively. The presumed miss rate of polyps, adenomas, SSAs/SPs and advanced adenomas were 37.8% (469/1241), 22.1% (167/768), 41.7% (2048) and 15.2% (36236) respectively. More adenomas were missed in the proximal colon when compared to distal colon (26.64% vs 18.04%, p = 0.01). Table 1 illustrates the distribution of missed adenomas in each segment of colon. Adenoma miss rates per size as follows: < 5 mm, 6-9 mm and >10 mm were 24.27 and 8% respectively. Higher number of polyps (>3 detected during index colonoscopy independently correlated with high miss rates (84.3% vs 72%, p = 0.04).

<td>0</td>
</tr>
</tbody>
</table>

Conclusion: Our study highlights that there is likely to be a significant miss rate for adenomas and SSAs/SPs even after careful index colonoscopy. Miss rate was higher when multiple polyps are seen at the index examination. This finding appears to justify the current BSOG (British Society of Gastroenterology) guidelines for a yearly surveillance colonoscopy when multiple polyps are seen. The presumed miss polyp rate at 1 & 3 years may be justified as a new quality metric within screening programmes.

4Quality Assurance Working Group, Austrian Society of Gastroenterology and Hepatology (OEGGH), Vienna/Austria

Contact E-mail Address: angelikadokladanska@meduniwien.ac.at

Introduction: Systemic diseases including several types of cancer have been associated with periodontitis, potentially owing to the constant systemic inflammatory state in those patients. Data on a potential association of periodontal disease and colorectal neoplasia is scarce and conflicting.

Aims & Methods: Data from 25,407 patients undergoing healthy check up assessment periodontal disease according to periodontosis-risk classes (PRC 0-healthy gingiva, PRC 1 - tatar or plaque, PRC 2 - redness or swelling) and screening colonoscopy between 2009 and 2012 in Austria were included. Colonoscopy outcomes were compared between patients with and without signs of periodontal disease using multivariate models adjusting for age, sex, smoking, alcohol consumption, diabetes and BMI.

Results: In multivariate adjusted models, patients with periodontal disease had similar odds for the detection of colorectal polyps as those without signs of periodontal disease [adjOR 1.07; 95% CI: 0.91; 1.247]. Regarding the prevalence of adenomas, patients with periodontal disease, likewise, had similar odds as those with healthy periodontal tissue [adjOR 1.01; 95% CI: 0.84; 1.213]. Similarly, those with periodontal disease had comparable odds for colorectal adenomas as those without signs of periodontal disease [1.05 (0.78; 1.418)].

In the table below the adenoma detection rate (ADR) and advanced adenoma detection rate (AADR) divided into the periodontosis-risk classes.

Table 1: ADR (adenoma detection rate) and AADR (advanced adenoma detection rate) according to the periodontosis-risk classes

</tr>
</tbody>
</table>

Conclusion: Periodontal disease has no impact on the adenoma and advanced adenoma detection rates in a large screening colonoscopy cohort.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: Adults with confirmed colitis (ulcerative colitis extending beyond the rectosigmoid junction and crohn’s colitis affecting at least the left colon) with lesions at least 20 mm in size within the colitis segment were included. Data including demographics, clinical history, lesion characteristics, method of resection and post-resection surveillance were collected prospectively in patients from January 2011 to November 2016. Resection techniques included endoscopic mucosal resection (EMR), endoscopic submucosal dissection (ESD) and hybrid ESD. Surveillance of resection site with magnification chromoendoscopy (mCE) was performed at 3 months with pan colonic mCE at 1-year post resection and annually thereafter.

Results: Thirty lesions satisfied the inclusion criteria in 13 patients. Patient demographics and clinical data are presented in table 1. Mean lesion size was 47.3 ± 22.4 (20–90) mm. All lesions were non-polyoid with distinct margins and no ulceration. High-frequency mini-probe ultrasound confirmed intramucosal lesions in 5 cases where pit/vascular pattern was distorted due to inflammation. In 6 cases, 69% lesions were deeply scarred of which 66% had experienced prior instrumentation. Resection of a single lesion was performed at the right colon, 9 at left-half colon and 31 at rectum. The mean diameter of the lesions was 3.26 ± 1.27 (0.8–12.0) cm. There were not intraoperative complications including serious bleeding and perforation. Delayed bleeding on the second post-ESD day was diagnosed in 1 (1.6%) patient who was cured by transfusion. 3(4.9%) patients suffered post-ESD electrocoagulation syndrome and perforation did not present in all cases. In this group with transanal tube discharge of the gas and liquid in the intestine. The efficacy of this method to reduce incidence of complications and to promote recovery of intestinal function have been verified by a number of studies. Based on this, we applied transanal tube to some patients with colorectal ESD, hoping to provide new ideas for the prevention and treatment of complications.

P1510 OUTCOMES FOLLOWING UNDERWATER ENDOCOSCOPIC MUCOSAL RESECTION (UEMR) OF > 10MM COLONIC POLYPS: A PROSPECTIVE DUAL-CENTRE STUDY

K. Sia1, A. Yusuf2, N. Suzuki3, S. Ishaq4
1 Royal College Of Physicians, AAG Clinical Fellow, London/United Kingdom
2 Gastroenterology, East Sussex Healthcare NHS Trust, Eastbourne/United Kingdom
3 Wolfson Endoscopy Unit, St Mark’s Hospital, Harrow, London/United Kingdom
4 Department Of Gastroenterology, Dudley Group Hospitals NHS Foundation Trust, Dudley/United Kingdom

Contact E-mail Address: keith@sia.org

Introduction: Underwater endoscopic mucosal resection (UEMR) is an alternative to thermal EMR for the resection of colonic polyps. With this technique, water insufflation is used in place of air or CO2, and submucosal lifting is usually not required, as water-immersed submucosal cushions itself from the muscularis propria. Theoretically, this reduces the risk of diathermy-induced injury, and allows for more complete resection margins.

Aims & Methods: In this prospective dual-centre study, we aim to evaluate the safety and efficacy of UEMR for clinically significant (>10 mm) colonic polyps. Studied outcomes included: completeness of UEMR, 2 intraprocedural and 30-day complication rates, 2 percentage requiring submucosal lift, and 4 rates and predictors of polyp recurrence. Procedures were performed by two screening endoscopists accepting tertiary referrals at St Mark’s Hospital, London, and Russell’s Hall Hospital, Dudley, UK. Recurrence was defined as the presence of any polyp tissue at the resection site. Endoscopy records were examined and correlated with histology. Uni-variate analyses were performed using Pearson’s chi² to identify predictors of measured outcomes.

Results: Between June 2014 and March 2017, and A total of 85 patients (median age 69.5 years, interquartile range [IQR] 11, 50.6%) underwent UEMR of 97 colonic polyps (median size 25 mm, IQR 25 mm, range 10–160 mm). 13 (13.4%) were recurrences following previous conventional EMR. Polyps were predominantly left sided (66%) with flat (63.5%) or sessile (35.4%) morphology. 43.8% of polyps were removed en bloc, whilst argon plasma coagulation (APC) was used in 17.3%. Histology comprised of: low-grade dysplasia (80.2%), high-grade dysplasia (12.5%), adenocarcinoma (3.1%) and non-adenomatous sessile serrated adenomas (4.2%). Overall, resection at index UEMR was deemed endoscopically complete in 97.9%. Submucosal lift was required in 27.8% and positively correlated with polyp size >30 mm (OR 3.58, 95% CI 1.37–9.38, p = 0.01), but not morphology (flat vs. sessile, p = 0.099). The 30-day complication rate was 4.1% (n = 4), comprising: bleeding (n = 2, average diameters: 35 mm) and delayed rebleeding (n = 2; average diameter: 57.5 mm), with haemos-tasis achieved for all cases. No cases of perforation or mortality were identified. Of the 60.8% (n = 59) who attended for repeat endoscopy post-UEMR, the rate of recurrence or residual polyp was 14.8% (9/63) at 4 months and 15.9% (22/140) within 1 year. Significant predictors of post-UEMR recurrence included: piece-meal vs. en bloc resection (OR 5.50, 95% CI 1.10–27.6, p = 0.03) and recurrent polyp (OR 4.17, 95% CI 1.02–17.05, p = 0.01), and allows for more complete resection margins.

Conclusion: UEMR is a safe alternative to conventional EMR for the management of clinically significant colonic polyps. However, our post-UEMR recurrence rate of 22.0% appears higher than other studies,[2] but may be skewed by the tertiary nature of referrals. Although randomised trials are awaited, we suggest that those performing UEMR should attempt en bloc resection where possible, and consider wider resection margins for recurrent polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1511 WATER-AIDED COLONOSCOPY - RESEARCH FOCUS IN THE PAST DECADE AND CURRENT CLINICAL PRACTICE

F. W. Leung
Medicine, Seguridada Ambulatory Care Center, VAGLAHS; David Geffen School of Medicine at UCLA, North Hills/United States of America/CA

Contact E-mail Address: felixleung@socalrr.com

Introduction: Water-aided techniques have forged a paradigm shift in endoscopic diagnosis and therapy. The inauguration (10/22/2014) of the International WATERS with memberships worldwide attested to participants’ commitment to advance clinical, educational and research missions. To aid planning of future work in each of these areas, a descriptive study of water-aided colonoscopy was performed.

Aims & Methods: The aims of this study were two-folds. Study 1: To assess the frequency of water-assisted colonoscopy in the past decade and current practice. To obtain a cross-sectional snapshot of current clinical practice. Study 1: Studies registered at Clinicaltrials.gov were searched for using the search term "water colonoscopy". Study 2: Members of International WATERS voluntarily participated in a survey. Data collection was carried out after obtaining the proportion of participants with different forms of seda-tion, respondents selected yes (1) or no (0) responses to each of 16 questions related to their practice of water-aided colonoscopy.

Results:
Study 1: In the past decade, 48 trials of water-aided colonoscopy were registered at Clinicaltrials.gov. They aimed at evaluation of insertion pain in unsedated, minimally sedated, or on demand sedation patients; assessment of efficacy in difficult colonoscopy; study of the impact on adenoma detection; and underwater mucosal resection or polypectomy. Study 2: Questionnaire responses are summarized in Table 1. Respondents: n = 23. Water-aided colonoscopy is used in patients sedated with propofol, minimal sedation on demand (3–16%), but more commonly in patients with moderate or no sedation (30–34%). During insertion 95.5% use infusion of water and only 36.4% leave the air/CO2 pump on. 42.9% and 33.3% record volumes infused and suctioned upon arrival to the cecum. 52.4% remove almost all infused water during inser-tion. 71.4% and 59.1% performed polypectomy (<20 mm and >20 mm, respec-tively) underwater during withdrawal.

</tbody>
</table>

Conclusion: The variable modes of application amongst responders who profess to use water-aided colonoscopy reflect the versatility and strength of the paradigm-changing approach, which is easily adaptable to meet the diverse needs of individual colonoscopists. Standardization based on results of randomized controlled trials appears to be prudent to permit further assessment of water-aided colonoscopy in clinical, educational and research settings.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) is a suitable technique used for the endoscopic management of selected early gastrointestinal neoplasms (EGN).

Aims & Methods: This is a prospective study of patients with EGN eligible for ESD in three tertiary hospitals. The main goal was to evaluate initial therapeutic results and learning curve of ESD. Initial Technical success rates, procedure speed, en-bloc & R0 resection, R0, speed and complications rates were prospectively evaluated. The results of the learning curve were analysed by chronological order of bles of 50 cases. Perforation was established as any disruption of the muscular layer, regardless of size or identification of perioperative fat. Time of procedure was considered from initial submucosal injection to final detachment of the specimen.

Results: ESD was attempted in 183 lesions from January 2012 to April 2017. Majority of procedures were performed at Puerta de Hierro University Hospital (160/87.4%). Mean age was 67 (SD 10.6) years, with male proportion 55.2%. Most common location was colorectal (77.8%), followed by gastric (12.8%) and esophageal (9.4%). Success was observed in 96.2% of patients with en-bloc and R0 resection of 93.9% and 92.3% respectively. Mean lesion size was 46.5 mm (range 8–130) with a mean speed of 9.01 min/cm2 (range 1–209). Perforation was
the main complication (48 (26.2%) events), requiring surgery in 5 (10.4%) cases. Perforation was also statistically significant in comparison to location (p = 0.05) and LST morphology (p = 0.05). Most frequent location of perforation was transverse colon (OR 88.3; SE 137), followed by descending colon (OR 13.5; SE 19.4) and splenic flexure (OR 6.3, SE 11.8). Perforation was more common in LST-NG lesions vs LST-G (OR 14.1; SE 19.3 vs 11.6 SE 15.0). Perforation rates were not statistically associated with the presence of severe submucosal fibrosis compared to absence of fibrosis (0.8 SE 0.6 vs 1 SE 1; p = 0.9). Post-ESD complications were observed in 15 (8.2%) patients (delayed perforation(7), bleeding(4), electrical burn injury syndrome(1), severe esophageal stricture(1), haemopterri- nome(1) and splenic rupture(1)). Six cases (40%) were managed with surgery. Results from the learning curve progression according to consecutive chronological blocks of 50 cases (33 last bloc) are summarized in table 1. Initial success increased from 94% to 100%; speed of ESD decreased after the first 50 cases (15.5 cm²/min), up to 6.7 and 6.5 cm²/min in the last 2 blocs. A high perforation rate in the first period (32%) was reduced to 18–30.3% the following periods. Endoscopic treatment was successful in most cases of perforation (89.6%). Surgery was required for severe complications, incomplete ESD and/or perforation (n, %) (16 cases, 8.7%).

Conclusion: On clinical ESD, high rates of success and en-bloc and R0 resection can be achieved along the learning curve. Perforation is the most common complication and is a still a challenge for Western countries. However, increasing experience reflects a high success in endoscopic management of perforation.

Introduction: Despite the advantages of endoscopic submucosal resection (ESD) demonstrated in large series from the far east, the procedure is not commonly practiced in the west and its role in standard practice is still debated. Although limited evidence of its efficacy in European practice is emerging, very few centres in the United Kingdom perform ESD regularly, if at all. We report the experience of a UK tertiary referral institution using ESD as part of a lesion specific, pragmatic approach to endoscopic resection in a complex patient cohort. Aims & Methods: Consecutive patients who underwent endoscopic submucosal resection of colorectal lesions ≥2 cm were included. Lesions were assessed with magnification chromoendoscopy supplemented by colonoscopic ultrasound in selected cases. A lesion specific approach was used to decide on resection technique, which included assessment of morphology, pit pattern, risk of submucosal invasion, and presence of submucosal fibrosis or scarring. ESD was used where en bloc resection was deemed essential, and was a preferred approach to assist snare resection was not included. Results: 116 lesions (mean size 58.8 mm) were resected using ESD (n = 58) and hybrid ESD (n = 58). 82 (70.7%) had been subjected to prior attempts at resection (n = 58) or extensive sampling. Only 11 lesions had no prior biopsies performed. En bloc resection was achieved in 93.1% where ESD was used alone, with a recurrence rate of 4.7% after a mean follow up of 19.7 months. There were 6 microporations treated with either endoscopic clips or antibiotics alone with no adverse sequelae, and one clinically significant perforation requiring surgery. However, the resected lesion in this case contained an invasive adenocarcinoma with deep submucosal invasion—there was no residual tumour in the surgical resection specimen. Post- procedure bleeding occurred in 6 patients, none of which needed further treatment. 91% of cases were successfully performed as day case procedures. 97% of patients without invasive cancer were free from recurrence and had avoided surgery at last follow-up.

Conclusion: Colorectal ESD can be used as part of a standard lesion specific approach to a western referral centre to deliver safe and effective organ conserving treatment to patients with large challenging lesions. Knowledge regarding lesion assessment and selection in western practice should be improved to reduce the incidence of prior heavy manipulation and guide appropriate referral.

P1514 RISK OF STENOSIS AND OUTCOMES FOLLOWING ENDOSCOPIC RESECTION OF LARGE COLORECTAL LESIONS INVOLVING MORE THAN 75% OF THE LUMINAL CIRCUMFERENCE
A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji
Endoscopy, King’s College Hospital, London/United Kingdom

Introduction: Little is known about the risk of stenosis and outcomes following endoscopic resection of lesions in the colorectum which leave extensive mucosal defects. A limited number of studies suggest significant stenosis rates, although reports on outcomes and suggested management are conflicting. We determined the risk of stenosis and outcomes of endoscopic resection of colorectal lesions leaving mucosal defects ≥75% of the circumference.

Aims & Methods: Patients who underwent endoscopic resection of colorectal lesions ≥2 cm were included. Resection technique included EMR, ESD and hybrid techniques involving ESD. Patients were grouped according to circumferential extent of the mucosal defect after resection. Surveillance colonoscopy was performed at 3 and 12 months. Clinicopathological characteristics and outcomes were compared between groups.

Results: 435 colorectal lesions ≥2 cm were resected using EMR (n = 342), ESD (n = 45) or hybrid techniques (n = 48). Circumferential extent of the resulting mucosal defect was ≥75% in 41 patients. 8 lesions were fully circumferential: 1 caecal lesion and the rest in the recto-sigmoid and rectum. 3 of these circumferential lesions contained deep invasive adenocarcinoma and 1 benign lesion ultimately required surgery. The 41 lesions with a mucosal defect ≥75% of the circumference had a mean size of 100.5 mm vs 49.0 mm for other lesions (p < 0.001). These patients had significantly more complications (16.7% vs 4.7%, p < 0.001), including a higher rate of perforation (8.3% vs 2.3%, p = 0.02), although none required surgery, and a significantly higher rate of recurrence (44.8% vs 9.2%, p < 0.001). 79% of patients without cancer were free from recurrence and had avoided surgery at last follow-up compared to 97% of patients with mucosal defects <75% (p < 0.001). Stenosis occurred in 7 patients: 4 lesions extensively involving the rectum and recto-sigmoid and 2 lesions involving the sigmoid colon extending to the rectosigmoid. 1 of these involved a mucosal defect of only 50% of the circumference and 3 were fully circumferential. 1 patient had a symptomatic anorectal stenosis requiring dilatation under anaesthesia, 1 patient was asymptomatic but underwent early dilatation after the first surveillance endoscopy at 3 months. The remaining patients were asymptomatic and managed expectantly. In all these latter cases spontaneous improvement in the stricture was noted at the subsequent surveillance endoscopy.

Conclusion: The majority of patients with these extensive complex lesions can successfully be treated with endoscopic resection and avoid surgery. However, these patients have a significantly greater risk of complications and recurrence and should be managed in a tertiary institution. Although there is a significant risk of stenosis, it appears that most cases are asymptomatic and spontaneously improve with expectant management.

Introduction: Although it is well recognised that the risk of invasive carcinoma in Appplanation neoplastic lesions differs according to morphology, the incidence of invasive cancer varies between studies and there is limited data from large western series to inform practice. The importance of appropriate resection techniques, including the use of ESD, is increasingly recognised in western practice. It is therefore imperative that the risk of submucosal invasion is assessed as accurately as possible to prevent inappropriate attempts at resection. We determined the risk of submucosal invasion and high-grade dysplasia (HGD) in different morphological sub-types of large colorectal lesions subjected to endoscopic resection.

Aims & Methods: Colorectal lesions ≥2 cm subjected to endoscopic resection were included. Lesions were assessed with magnification chromoendoscopy. Clinicopathological data recorded included morphological type according to Paris classification, sub-types of laterally spreading tumours (LST), degree of dysplasia, presence of submucosal invasion and outcomes following resection.

Results: 435 colorectal lesions ≥2 cm were resected. Mean lesion size was 55.2 mm (range 20 mm–160 mm). The frequency of and the incidence of high-grade dysplasia and invasive adenocarcinoma in the different morphological sub-types are shown in Table 1. The incidence of high-grade dysplasia (8.6%) and invasive adenocarcinoma (1.2%) was very low in LST granular homogenous lesions.

LST G H = LST granular homogenous LST G MN = LST granular mixed nodular LST NG = LST non-granular ESD or hybrid ESD was used to resect 97 lesions. 53% of lesions had been subjected to previous failed attempts at resection, >6 biopsies or had tattoo injected at their base prior to referral. Of 29 invasive adenocarcinomas, 9 were deemed incurable by endoscopic resection (superficial submucosal invasion with no adverse prognostic features). Of the remaining 20, 5 patients refused surgical resection, 5 were unfit for major surgery and 10 had had tumour in the surgical resection specimen, 5 had residual tumour in their resection cavity. Only 1 patient was initially benign lesions developed adenocarcinoma in subsequent lesions—all of these were early cancers with nodal metastases at surgical resection.

Conclusion: In one of the largest European series reporting the incidence of invasive carcinoma in different morphological sub-types of colorectal neoplastic lesions, we confirm that LST granular homogenous type lesions have a very low incidence of invasive carcinoma and that care should be taken in the choice of resection technique for other sub-types of LSTs which more frequently harbour malignancy. Appplanation neoplasms assessment and classification to aid metachronous lesion selection is essential to this process.

**P1517 OUTCOMES OF ENDOSCOPIC RESECTION OF RECURRENT COLORECTAL LESIONS TREATED AT A UK TERTIARY REFERRAL CENTRE**

A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji
Endoscopy, King’s College Hospital, London/United Kingdom

Contact E-mail Address: amemanuel@nhs.net

Introduction: Endoscopic resection of large colorectal lesions, especially by piecemeal resection (EMR), carries a significant risk of recurrence. Although several series examine the outcomes and risk of recurrence following endoscopic resection, few focus on the outcomes of patients being treated for recurrence after initial expert resection, and these mostly focus on one technique to deal with recurrence. We evaluated the outcomes after recurrence of colorectal lesions after apparent successful endoscopic resection in a specialised UK tertiary institution employing a range of resection techniques.

Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥2 cm were included. All lesions were assessed with magnification chromoendoscopy supplemented by colonoscopic ultrasound in selected cases. A lesion specific approach was used to decide on resection technique. Outcomes were evaluated for patients treated for recurrent lesions.

Results: Of 396 colorectal lesions ≥2 cm initially resected, recurrence occurred in 48 patients. 36% of these patients had already had a mean of 1.6 previous failed attempts at resection prior to referral to our institution, and 66% had had either a failed attempt at resection or extensive sampling involving >6 biopsies or tattoo placed under the lesion. 69% of patients were successfully treated with further endoscopic resection and avoided surgery. 27 recurrent lesions larger than 20 mm were treated with endoscopic resection, with a mean lesion size of 48.3 +/- 19.8 mm. Techniques used were EMR (n = 16), ESD (n = 2), Hybrid ESD and EMR (n = 9). The remaining lesions <2 cm were resected using EMR. A mean of 1.4 +/- 0.75 procedures were required to achieve successful endoscopic treatment of recurrence. Of 23 patients who were ultimately successfully treated with endoscopic resection, 15 required a single further endoscopic resection after recurrence, 8 patients required 2 or more further resections. 8 patients required surgery, 3 as a result of developing invasive adenocarcinoma with the recurrence. There were no perforations as a result of endoscopic resection of recurrent lesions.

Conclusion: These data demonstrate the challenges of an advanced endoscopic resection service in much of western practice where patients with recurrent lesions represent a particularly complex cohort, most of whom have already had extensive prior manipulation or attempts at resection. Familiarity with a range of resection techniques and appropriate equipment is essential to successfully treat recurrent lesions in this group with endoscopic resection, which can be achieved in the majority of patients without significant morbidity.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1518 THE EFFECTIVENESS OF NEW TECHNIQUE WITH SELF-EXPANDABLE METALLIC STENT INSERTION IN TREATING RIGHT-SIDED COLORECTAL OBSTRUCTION**

Introduction: Self-expandable metallic stent (SEMS) is widely used to treat malignant colonic obstruction. However, most reports about SEMS insertion have represented a particularly complex cohort, most of whom have already had extensive prior manipulation or attempts at resection. Cannulation time between straight and curved type guiding tube, technical and clinical success, complications, and technical difficulties were analyzed. We compared the results between SEMS insertion and decompression tube placement in right colons and the outcomes of SEMS insertion between right- and left-sided colonic obstructions.

Results: Cannulation time with a curved type guiding tube decreased of all cases (20mn vs 8.5mn). For ascending colons, the technical and clinical success rate of SEMS insertion with new technique significantly 100% (10/10). There was no...
P1519 ENDOSCOPIC FULL-THICKNESS RESECTION FOR COLONIC LESIONS. INITIAL EXPERIENCE IN 3 CENTERS OF CATALONIA

Introduction: Endoscopic full-thickness resection (EFTR) in the colon using the FTRD kit is a recent technique that allows en-bloc resection of colonic lesions that are poor candidates for resection by endoscopic mucosal resection (EMR). It does not require the injection of a solution into the submucosa and allows an en-bloc resection of colonic lesions up to approximately 30 mm. We present results of the initial experience in 3 centers of Catalonia.

Aims & Methods: We retrospectively analyzed the clinical, endoscopic and anatomicopathological data of all cases of EFTR performed in 3 centers in Catalonia using the FTRD kit (Ovesco Endoscopy, Tübingen, Germany) during the period between June 2015 and January 2017. All patients underwent the procedure under deep sedation with propofol, all patients were duly informed of the technique and potential complications derived from the procedure, obtaining written informed consent prior to the procedure. All EFTR resections in the colon were performed using the FTRD kit (Ovesco Endoscopy, Tübingen, Germany), grasping and pulling the lesion in the base of the polyp, deploying the OTSC and resecting the tissue over the OTSC with the preloaded snare. Clinical assessment was performed before and after procedures with a complete blood test before procedure. Blood test was not routinely used after procedures. Demographic, clinical, endoscopic and histologic data were collected from each patient, and analyzed with STATA software.

Results: 16 endoscopic full-thickness resections of the colon were performed. The mean age of the patients was 69 years (53–79), with men being 88%. The indications were recurrent/residual lesions with non lifting sign (75%) and unresected lesions with non lifting sign (25%). The locations were juxtavalvular (n = 3), transverse colon (n = 4), descending colon (n = 3), sigma, stub or anastomosis (n = 4) and location (right/left colon).

Conclusion: Endoscopic full-thickness resection is a safe and feasible technique for selected cases in colon.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic mucosal resection (EMR) has been shown to be useful in the removal of large colorectal adenomas. These lesions are often resected by using a piecemeal technique, which a risk of recurrence in 10% to 30% of cases. Recently, hot avulsion technique (HA) has shown promising results in the resection of residual fragments of large colorectal adenomas, with lower recurrence rate.

Aims & Methods: The aim of this study was to evaluate the efficacy and safety of HA at index EMR and at EMR local recurrence. We did a retrospective study based on all the HA performed between June 2015 and February 2017. The endoscopic characteristics, complications and recurrence rate after the initial HA were evaluated.

Results: 33 HA were performed among 29 patients (16 men and 13 women) with an average age of 69 years. The average follow up time was 11 months. HA was used to remove residual adenomatous tissue at 17 index EMR (mean size of the lesion (30 mm) and to remove recurrent fibrotic adenomatous tissue at EMR scar in 12 cases (mean size of recurrence tissue 14 mm). HA was successful in removing residual/recurrent adenomatous tissue in all patients. There were no immediate or long term adverse events. Comparing the two groups, local recurrence after initial HA occurred in one case at the index EMR group (1/17) and in 2 cases at the local EMR recurrence group (2/12). The overall recurrence rate in patients with a minimum 6 months follow up was 15% (3/20).

Conclusion: HA is a safe and effective technique to eradicate both residual tissue in large colorectal adenomas and recurrent fibrotic adenomatous tissue at EMR site, with low recurrence rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Quality of bowel preparation and adenoma detection rate (ADR)
are routinely assessed in screening colonoscopy. However, data on patient experi-
ence are scarce.
Aims & Methods: This prospective non-interventional study compared bowel
preparation quality according to the Harefield Scale, performance quality mea-
sures and patients satisfaction in screening colonoscopies performed within an
Austrian quality assurance program.
Results: Colonoscopies performed by 20 endoscopists were included in this
study. 50.3% of screened individuals were women. Because of the unequal patient count using CitraFlx® (CF, n = 261), Picoprep® (PP, n = 2678), Klean-Prep® (KP, n = 804) and Moviprep® (MP, n = 1252), PC and
CF were grouped as low volume (LV) purgatives. Age and gender adjusted
success rates and ADR per purgative were 97.0% and 23.3% for LV, 97.5%
and 32.5% for KP and 93.5% and 26.0% for MP. Women had higher success
rates than men (p = 0.007) and success rate decreased with patients’ age
(p = 0.008). The consequence regarding comparison of the entire volume was
best with LV (89.2%, KP 87.6%, MP 87.3%), which had a significant effect on
success rate p = 0.027. 93.5% of patients in the LV group would use the same
purgative again compared to 68.4% in the KP and 73.2% in the MP group.
Conclusion: All investigated purgatives met the required quality standards of
≥90% rate of adequate bowel preparation according to the current ESGE guide-
lines. Success rates were higher in women and younger patients. Although only
<90% of patients consumed the whole volume, the majority of patients would
use the same purgative again.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1524 DIFFERENCES IN QUALITY OF BOWEL PREPARATION AT SCREENING COLONOSCOPIES IN PRIVATE PRACTICES AND HOSPITALS

Introduction: Bowel preparation influences the adenoma detection rate and is
therefore an important quality parameter in screening colonoscopy. According
to ESGE guideline “Performance measures for lower gastrointestinal
endoscopy: a European Society of Gastrointestinal Endoscopy (ESGE) Quality
Improvement Initiative”, 90% of colonoscopies should have adequate bowel
preparation. The aim of this study was to investigate whether there is a difference
in quality between private practices and hospitals.
Aims & Methods: Data from screening colonoscopies performed within quality
certificate in Austria (2012 - 2017) provided by 245 endoscopists were evaluated.
The recording of the quality of the bowel preparation was described as one of the
EMR site.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1525 DIFFERENCES BETWEEN BOWEL PREPARATION QUALITY OF SURVEILLANCE AND SCREENING COLONOSCOPY
A. K. Hinterberger, D. Penz, E. Waldmann, B. Majcher, A. Dokladanska,
A. Szymanska, M. Trauner, M. Ferlitsch

Introduction: bowel preparation is necessary for a successful and com-
plete colonoscopy. Minimum of adequate rate (excellent + good + fair) should be
90% according the actual ESGE guidelines (Kaminski et al, Endoscopy 2017).
The aim of study was, to verify if there is a difference at quality of preparation
between screening and surveillance colonoscopy. It might be that there is an
improvement at surveillance colonoscopy due to better knowledge.
Aims & Methods: 107,614 examinations from 288 endoscopists were analysed
between 2012 and 2017 within the Austrian certificate of screening colonoscopy.
For bowel preparation different categories were used: excellent, good, fair,
unsatisfactory, poor only in the right colon. Data are shown as Mean and SD.
Results: ES78 surveillance colonoscopies (43.88% female, mean age 66.67) and
99271 screening colonoscopies (51.94% female, mean age was 62.31) were
included. Within screening colonoscopy 37.59% (SD = 31.50) were excel-
pres vs. 34.60% (SD = 33.98) within surveillance colonoscopy, good 47.43
(SD = 27.28) vs. 45.61% (SD = 31.28), fair 11.39% (SD = 11.58) vs. 14.39%
(SD = 21.69), poor 2.38% (SD = 3.06) vs. 3.68% (SD = 9.75), unsatisfactory
0.77% (SD = 1.20) vs. 0.89% (SD = 3.69), poor only in the right colon 0.69%
(SD = 1.81) vs. 0.39% (SD = 1.22). Calculations revealed no significant differ-
ces among screening and surveillance colonoscopies relating the following
categories: excellent (p = 0.4357), good (p = 0.5911), unsatisfactory (p = 0.6282)
and poor only in the right colon (p = 0.1672). Purgative preparation varies signi-
ficantly between screening and surveillance in groups of fair (p = 0.0454) and poor
(p = 0.0497). Bowel preparation influences the adenoma detection rate (ADR). Mean ADR in excellent preparation was 22.16% (SD = 16.36%), in good
25.41% (SD = 17.30%), in fair 24.63% (SD = 19.44), in poor 19.94%
(SD = 25.57), in unsatisfactory 12.08% (SD = 22.77) and in poor only in the
right colon 24.22% (SD = 30.89%). Adequate rate in screening colonoscopy
was 96.22% (SD = 3.98%) vs. 95.07% (SD = 10.45%) in surveillance
colonoscopy. Rates correspond to ESGE guidelines and do not differ signifi-
cantly (p = 0.058). Conclusion: Data showed distinctions between fair and poor, whereas there were more
fair and more poor prepared patients at the surveillance colonoscopy, than at
the screening colonoscopy. Age of patients at surveillance colonoscopy was
higher, hence D-H, Freed normalized improvement. ADR in excellent, good and
fair bowel preparation was adequate. In poor, unsatisfactory was low and ADR
at poor only in the right colon is high due to low count (N = 374).

P1525 RISK FACTORS FOR RESIDUAL NEOPLASIA AFTER ENDOSCOPIC MUCOSAL RESECTION OF LATERALLY SPREADING TUMORS
N. Brogyak1, T. Grega1, M. Voska1, O. Ngo2, O. Majek3, M. Zavoral1,
S. Suchanek3

Military University Hospital, Prague/Czech Republic
2Institute Of Biostatistics And Analyses, Masaryk University, Faculty of Medicine,
Brno/Czech Republic
Contact E-mail Address: Nadja.Brogyak@uvn.cz
Introduction: Laterally spreading tumors (LSTs) are important precursors of
colorectal carcinoma. They are usually removed by endoscopic mucosal resection
(EMR). However, local residual neoplasia (LRN) may occur during follow-up.
The aim of the study was to evaluate the occurrence of LRN and the risk factors
for its presence.
Aims & Methods: This retrospective study in a high-volume tertiary-referral
center examined patients who had undergone EMR between 2013 and 2015
and who had had at least 1 surveillance colonoscopy after the initial treatment.
LRN was defined histologically as the presence of neoplastic tissue in the post-
EMR site.
Results: 160 laterally spreading tumors were diagnosed in 138 patients (62% men,
mean age 67 years). Mean follow-up interval for surveillance colonoscopy was
6 months. Residual neoplasia at surveillance endoscopy was present following 21%
(35/160) EMRs. Single variate analysis showed occurrence of an increased risk of
residual neoplasia for LST ≥ 20 mm (p = 0.006), villous adenomas (p = 0.001),
piecemeal resection (p = 0.011) and G-type morphology (p = 0.003). In multi-
ariate analysis, only size of the lesion (p = 0.080) and villous component
(p = 0.043) were found to be a significant risk factor for LRN.
Conclusion: This retrospective study shows that the occurrence of LRN is fre-
cent. Careful colorectal surveillance after EMR and the use of new methods
to further reduce residual neoplasia are needed.
Disclosure of Interest: All authors have declared no conflicts of interest.
P1527 BOWEL PREPARATION FOR FLEXIBLE SIGMOIDOSCOPY: COMPARISON OF POLYETHYLENE GLYCOL ELECTROLYTE SOLUTION (PEG-ES) AND PHOSPHATE ENEMA IN 4,949 PATIENTS AT TWO UK HOSPITALS

A. Yusuf 1, S. Paranekhwa 1, A. Jevengan 1, P. Mayhead
Gastroenterology, East Sussex Healthcare NHS Trust, Eastbourne/United Kingdom

Contact E-mail Address: abdyus12@shts.net

Introduction: Flexible sigmoidoscopy is increasingly used to examine the left side of the bowel for diagnostic and surveillance purposes, and is now part of the UK bowel cancer screening programme. It is crucial to achieve adequate bowel cleansing in order to optimise the diagnostic yield of the test, and also to minimise the number of repeat procedures. However, the optimum bowel preparation for this procedure has consistently been debated.1,2,3

Aims & Methods: Both phosphate enema and (PEG-ES) are commonly used for bowel preparation in flexible sigmoidoscopy at both hospitals participating in this study. We therefore wanted to compare the outcomes for these two methods. We retrospectively reviewed all the patients who underwent flexible sigmoidoscopy from January 2014 to December 2016 using each hospital’s electronic database. This study included patients with large colonic lesions (LCLs, >20 mm) performed for surveillance or diagnostic purposes. The primary outcome was the adequacy of bowel preparation and the secondary outcomes were the number of patients who required repeat procedures.

Results: In total 6196 patients underwent flexible sigmoidoscopy during the study period (males 2885 (46.56%), mean age 62.80 years, range 16–101 years). 1247 (20.13%) patients were excluded from further analysis for the following reasons: N=297 patients were not enrolled at procedure-time (n=284) or at 15 days for adverse events and follow-up (n=13) because they only had phosphate enema. The results are summarised in the table below.

EFFECTIVE BUT INTERVALS CAN BE WIDENED

P1528 MANAGEMENT OF RESECTION OF LARGE COLONIC LESIONS IN A REAL-LIFE SETTING: THE SCALP STUDY

A. Amato 1, F. Radarelli 2, V. Cennamo 3, E. Di Giulio 4, L. Fuccio 5, G. Manes 6, G. Taranntino 7, G. Fosi 8, M. Del Bellis 9, A. Badal 10, P. Pigli 10, P. Cesaro 11
Gastroenterology, Tondela - Viseu Hospital Center, Viseu/Portugal

Aim of present study is to evaluate the management of endoscopic resections of LCLs performed over a 6-month period were collected by a web-based database. All patients undergoing LCLs resection were enrolled at procedure-time and followed-up at 15 days for adverse events and at 6 months for endoscopic/histological recurrence.

Results: 1452 LCLs (mean size 30.6 mm, SD 12.4; 41.4% lateral spreading tumor, 28.1% sessile, and 30.5% pedunculated) removed in 1329 patients (58% males, mean age 66±11.4 years) were analysed. An endoscopic mucosal resection (EMR) was performed in 57.9%, snare polypectomy in 34.7%, underwire EMR in 1.2% and endoscopic submucosal dissection in 6.2% of the lesions. Patients with LCLs, 19.4% were on ATT (62.5% aspirin, 12.2% thienopyridines, 4.8% dual antiplatelet, 15.4% vitamin K antagonists [VKAs], 5.1% direct oral anticoagulants [DOACs]). Aspirin and/or thienopyridines were withdrawn before resection in 53.6% and 91.7% of patients, respectively. Overall, intra- and post-procedural bleeding requiring endoscopic therapy occurred in 8.1% of patients; 28% of them were on ATT, which had always been withheld, but in 48% of patients on aspirin. At multivariate analysis, intra-procedural bleeding was correlated with increasing polyp size (Odds Ratio 1.02 95% Confidence Interval 1.01–1.04), and inversely with execution of pre- and post-resection prophylaxis maneuvers (Odds Ratio 0.55 95% Confidence Interval 0.37–0.82 and Odds Ratio 0.55 95% Confidence Interval 0.37–0.82 respectively). As concerns

Contact E-mail Address: armamato@gmail.com

Introduction: Endoscopic resection of large colonic lesions (LCLs, >20 mm) is effective and it is associated with an acceptable incidence of incomplete resection and complications when performed by appropriately trained endoscopists in resource centers.1,2,3 Scanty data on the management of these lesions outside referral centers are reported in the literature.

Aims & Methods: Aim of present study is to evaluate the management of endoscopic resection of LCLs and intra-procedural complications in a real-life setting. In a prospective, multicenter, observational study in 20 centers, data from consecutive endoscopic resections of LCLs performed over a 6-month period were collected by a web-based database. All patients undergoing LCLs resection were enrolled at procedure-time and followed-up at 15 days for adverse events and at 6 months for endoscopic/histological recurrence.

References

*P<0.05

Conclusion: Our large retrospective study showed that oral preparation with PEG-ES gave significantly better results than phosphate enema, which gave acceptable results in only 67.5% of the patients. As a result of this study, PEG-ES is now the preferred option at our hospitals, if there is no contraindica-
complications, delayed bleeding occurred in 4.5% of the subjects, whereas perforation occurred in 1.5% (0.9% early and 0.6% delayed) of patients, 86.7% of whom were successfully managed endoscopically. At the moment, 6-months follow-up is available for 35% of the patients, with a positive endoscopic and/or histological recurrence documented in 22.8%.

Conclusion: The management of resection of LCLs varies widely. The incidence of intra-procedural bleeding correlates with polyp size and prophylactic maneuver, and its endoscopic management is successful in most of cases. Overall, complication rate is marginal and efficacy is good, even in a real-life setting.

P1529 ENDOSCOPIC REMOVAL OF HIGH-RISK COLORECTAL ADENOMAS: SAFE AND EFFECTIVE?
M. Rutka1, K. Farkas1, A. Fabian1, R. Bot1, A. Balint1, A. Milaszin1, Z. Szepes1, T. Molnar1
1First Department Of Internal Medicine, University Of Szeged, Szeged;Hungary

Contact E-mail Address: rutka.marianna@gmail.com

Introduction: The incidence and mortality of colorectal cancer (CRC) can be decreased trough the removal of precancerous adenomas. Endoscopic removal of polyps over 2 cm is considered a high-risk procedure both for complications and malignant transformation.

Aims & Methods: The aim of this study was to evaluate the outcome and complication rate after endoscopic removal of polyps over 2 cm. In this retrospective study clinical and demographic data of patients undergoing polypectomy due to colorectal adenomas between 2012 and 2017 were collected. Data of endoscopic procedures, complications of polypectomy and histological assessments of the removed polyp were obtained.

Results: Data of 100 patients (male/female: 58/42) was analyzed in the study. Follow-up of the 106 removed polyps proved to be pedunculated, 21 were sessile and 34 flat. Six patients had more than one large polyp (>2 cm). The locations of the removed polyps were rectum in 33, sigmoid colon in 38, coecum in 12 and other parts of the colon in 23 patients. In 65 cases, polyps were excised with endoscopic mucosal resection (EMR) or hybrid endoscopic submucosal dissection (ESD). In 41 cases snare was used to remove the polyps in one or more pieces. Based on histological findings 54 (50.9%) polyps were shown to be low-grade adenomas, 34 (32.07%) high-grade adenomas, 1 (0.9%) polyp was hyperplastic, and 17 (16.03%) proved to be malignant among which complete endoscopic resection was achieved in 9 patients (52.9%). Additional smaller polyps were found in 39 patients and a synchronous cancer in 7. During polypectomies 91 hemoclips were deployed to close suspected perforation (8 cases) to cease bleeding (10) or for prevention. Postpolypectomy syndrome developed in 8 cases. Second-look colonoscopy was required in 8 cases due to bleeding within a mean of 4 days after the first examination. Hemoclip insertion was needed in 5 cases and epinephrine injection in 1 case. The bleeding stopped spontaneously in 4 days after the first examination. Surgical intervention was not needed in any case.

Conclusion: Malignant transformation was revealed in 16% of the polyps over the size of 2 cm. Complete endoscopic removal of these polyps was successfully performed in half of the patients. Endoscopic removal of high-risk polyps is safe in experienced hand.

Introduction: The choice of polypectomy technique differs according to regional preferences and availability. This year, in order to standardize the approach to this techniques, the European Society of Gastrointestinal Endoscopy (ESGE) published recommendations for colorectal polypectomy and endoscopic mucosal resection (EMR).

Aims & Methods: We aimed to evaluate the recent evolution of the adherence to the recommendations of colorectal polypectomy and EMR at a tertiary center. We conducted a univariate analysis of polypectomy and mucosectomy techniques performed consecutively between January and June of 2011 and 2016 at a tertiary center. According to the recommendations, the excision of sessile and flat polyps is considered adequate when performed with cold biopsy forceps or cold snare for polyps ≤3 mm, cold snare if 4-9 mm, or cold hot snare if 10-19 mm and EMR if ≥20 mm. Polypectomy of pedunculated polyps is considered adequate when performed with a diathermic loop in polyps ≤20 mm. Polypectomy of pedunculated polyps is considered adequate when performed with a diathermic loop in polyps ≤20 mm. Polypectomy of pedunculated polyps is considered adequate when performed with a diathermic loop in polyps ≤20 mm.

Results: We included 1721 endoscopic procedures of polypectomy and EMR, corresponding to 896 patients (64.2% men; mean age = 64±6.11.0 years). 1381 (80.2%) sessile polyps, 153 (8.9%) flat lesions and 187 (20.9%) pedunculated polyps were identified, with a mean size of 7.9±7.0 mm. Regarding sessile and flat polyps, one of the recommended excision techniques was performed in: 84.6% (n=270) of ≤3 mm polyps (75.7% in 2011 vs. 95.8% in 2016; p < 0.001); 22.2% (n=109) of 4-5 mm polyps (12.5% vs. 36.5%; p < 0.001); 13.4% (n=59) of 6-9 mm polyps (5.4% vs. 23.8%; p < 0.001); 100% (n=206) of 10-19 mm polyps and 100% (n=88) of ≥20 mm lesions. For pedunculated polyps, the recommended technique was adequate in: 99.3% (n=134) of polyps of size <20 mm (100% vs. 97.6%; p > 0.05) and in 84.6% (n=44) of those ≥20 mm (82.6% vs. 86.2%; p > 0.05). Overall, 52.3% (n=900) of endoscopic procedures of polypectomy or EMR were performed as recommended; 42.7% (n=410) in 2011 vs. 64.5% (n=490) in 2016; p < 0.001.

Conclusion: Even before publication of the European recommendations, there has already been an increase in the proportion of polypectomies performed adequately in the different groups of lesions. There is still a need to adjust clinical practice in some subgroups, especially in polyps of size 4-9 mm, in order to strictly comply with the recommendations.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
that precludes conducting a mucosal incision far from tumor margins. A careful endoscopic follow-up is mandatory to detect residual neoplasms.

Introduction: Endoscopic mucosal resection (EMR) has been shown to be a safe and effective technique for removal of large colorectal adenomas. However, local adenoma recurrence remains a significant limitation, with prior published data describing recurrence rates of 10% to 30% post EMR.

Aims & Methods: This study aimed to evaluate the outcomes of EMR for large colorectal adenomas and identify the risk factors for adenoma recurrence. We did a comparative subgroup analysis by Long-Rank test were carried out to detect the impact of real times with patients of the same risk. An adjustment for baseline covariates (high-grade dysplasia, villous component) by Cox analysis was also performed.

Results: The real follow-up times in ≥3 adenomas (n = 853, 73.16%) and ≥ lade- nona ≥ 10 mm (n = 779, 66.81%) were 38.54 ± 11.57 and 38.66 ± 11.68 months. The risk of advanced lesions were 0.26%, 1.46%, 2.83%, 9.09% and 10.38% (p = 0.046). The most important increase was at 3–4 years (p = 0.52/month). The proportion of advanced lesions within 1–2 adenomas and ≥3 adenomas subgroups at 48 months was 5.43% and 10.43% (p = 0.001), with no differences in small adenomas ≤10 mm (p = 0.478).

Conclusion: The risk of advanced lesions in high-risk patients increased significantly at 36–60 months after baseline colonoscopy, being more important in ≥3 adenomas subgroup. There were no differences for 1–3 years interval.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1534 THE INFLUENCE OF THE REAL FOLLOW-UP TIMES DURING A COLORECTAL CANCER SCREENING PROGRAM IN DAILY PRACTICE

Introduction: European colorectal screening guidelines have modified the follow-up interval times based on baseline colonoscopy findings in recent years. In addition, the waiting list and individual conditions may modify the real follow-up times and this could impact in advanced adenoma detection rate in follow-up and patients outcome.

Aims & Methods: The aim of the present study was to comparatively analyse the risk of advanced lesions (advanced adenoma, invasive cancer) in high-risk patients included in a colorectal cancer screening program with different real follow-up times. One-thousand one-hundred and sixty-six patients (mean age: 60.66 ± 5.86 years, 69.1% men) who underwent a baseline colonoscopy with ≥3 adenomas and/or ≥10 mm between 2007–2012 were included. A Kaplan-Meier regression and a comparative subgroup analysis by Long-Rank test were carried out to detect the impact of real times with patients of the same risk. An adjustment for baseline covariates (high-grade dysplasia, villous component) by Cox analysis was also performed.

Results: The real follow-up times in ≥3 adenomas (n = 853, 73.16%) and ≥ lade- nona ≥ 10 mm (n = 779, 66.81%) were 38.54 ± 11.57 and 38.66 ± 11.68 months. The risk of advanced lesions were 0.26%, 1.46%, 2.83%, 9.09% and 10.38% (p = 0.046). The most important increase was at 3–4 years (p = 0.52/month). The proportion of advanced lesions within 1–2 adenomas and ≥3 adenomas subgroups at 48 months was 5.43% and 10.43% (p = 0.001), with no differences in small adenomas ≤10 mm (p = 0.478).

Conclusion: The risk of advanced lesions in high-risk patients increased significantly at 36–60 months after baseline colonoscopy, being more important in ≥3 adenomas subgroup. There were no differences for 1–3 years interval.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1535 CLINICAL OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION OF MALIGNANT NON-PEDUNCULATED COLORECTAL LESIONS

Introduction: Conventional endoscopic resection, such as snare polypectomy and endoscopic mucosa resection (EMR) of benign polyps in colon and rectum reduces colorectal cancer (CRC) incidence and mortality but the role of endoscopic colorectal ESD in the management between EMR and December 2016. Resected lesions larger than 20 mm in diameter with at least 3 months follow up were included. Patients referred for surgery were excluded.

Results: During the study period, 201 colorectal lesions ≥20 mm in size were removed (95.2% with associated invasion). Mean lesion size was 35 mm and 137 (68.2%) were located in the rectum and left colon. 66 lesions (32.8%) were larger than 40 mm in diameter. Piecemeal resection was performed in 171 lesions (85.1%). Local adenoma recurrence occurred in 44 cases (21.9%) after a mean time of follow up of 7.6 months, and the majority was managed with polyectomy or new EMR. The cumulative risk of adenoma recurrence was 7.5% at 3 months, 15.5% at 6 months and 17.1% at 12 months. In the multivariate analysis, the variables associated with a high risk of recurrence were lesions ≥40 mm in size (p < 0.0001) and intra-procedural bleeding (p = 0.029). The recurrence rate was higher in the patients treated with argon plasma coagulation (p = 0.046).

Conclusion: After EMR of large colorectal adenomas, local recurrence rate was 21.9%. The risk factors for adenoma recurrence include lesions ≥40 mm and intra-procedural bleeding. Argon plasma coagulation was not associated with lower recurrence rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
2. X.-D. Zhao, B.-B. Cai, R.-S. Cao, R.-H. Shi. Palliative treatment for incur-
254 patients that underwent colorectal ESD at the endoscopy unit at Skane University Hospital in Malmo¨, Sweden from January 2013 to December 2016. Indications for ESD were flat and sessile lesions larger than 20 mm in diameter with low or high graded dysplasia (251 cases). Moreover, three patients with known colorectal adenocarcinoma underwent ESD due to significant morbidity excluding surgery. Lesions were identified and included 29 cases of histologically verified submucosal invasive CRC in this study.

Results: This study included 29 patients with median age of 69 years (range 44–89 years). Median tumour size was 40 mm, ranging from 20–70 mm. Tumours were either flat (Paris classification H1, 6 cases), sessile (Paris classification 1s, 19 cases) or a combination of flat and sessile (4 cases). Half of the lesions were located in the rectum and half in the colon. En bloc resection was achieved in 24 cases (83%), piecemeal resection in 4 cases (14%) and ESD was incomplete in one case (4%). Complete the procedure was 89 min (range 594 min). Macroscopic complete resection was obtained in 26 cases (90%). R0 resection was found in 20 specimen (69%), RX was found in 3 cases (10%) and R1 was found in 5 cases (17%). Lymphovascular involvement was seen in 6 cases (21%). The mean number of sessions was as follows: Sm1: 15, Sm2: 7, Sm3: 7. In total four suspected immediate perforations occurred, three of these were managed conservatively (clips, fasting and antibiotics) and in one case, ESD was aborted and the patient was taken to emergency surgery. Pathological assessment of the resected sigmoid segment revealed T3N0. No acute significant bleeding occurred during the procedures. One patient sought emergency care 12 days after the procedure with rectal bleeding, no colonoscopy was performed to determine the site of bleeding. Five patients underwent additional surgery since the pathological report stated that the resection was R1. Tumour residue was only found in one of the five resected specimens. 18 patients have undergone endoscopic follow up, to this date without any sign of recurrence. Two patients await surgery and three patients await endoscopic follow up, to this date without any sign of recurrence.

Conclusion: We herein present our findings on performing ESD on 29 patients with early CRC. Our results indicate that colorectal ESD is a safe and effective treatment in meticulously chosen patients even with malignant lesions. Further studies with longer follow up is needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1536 ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) VS HYBRID DISSECTION: WHICH TECHNIQUE TO FAVOR IN LARGE COLORECTAL LESIONS?

M. Guillaumot, S. Leblanc, H. Soliman, B. Brieau, M. Barret, R. Coriat, F. Prat, S. Chausrade
Gastroenterology, Cochin Hospital, Paris/France

Contact E-mail Address: marie-anne.guillaumot@aphp.fr

Introduction: Large colorectal lesions (> 20 mm) can be removed endoscopically by endoscopic mucosal resection (EMR), often in a piecemeal fashion resulting in low en bloc and radical (R) resection rates. In this context, submucosal dissection (ESD) allows en bloc resection whatever the size, but still remains technically difficult and time consuming. A hybrid endoscopic technique has been developed, called simplified or hybrid dissection. The aim of our study was to evaluate the different complications of endoscopic submucosal dissection by hybrid technique compared to classical endoscopic submucosal dissection.

Aims & Methods: Our study was carried out from January 2013 to June 2016 from a prospective database. The 40 lesions removed by hybrid technique were compared to the 103 lesions removed by classical ESD. The hybrid technique was performed as follow: submucosal injection around the lesion of macromolecules, circumferential mucosal incision and submucosal dissection using the tip of a single-strand snare by endo-cut Q mode, central submucosal injection of the lesion and final resection with the single-strand snare, if possible in one-bloc. Patient characteristics, tumor location and size, dissection characteristics, \"block\" resection rate, R0 resection rate (healthy margins), procedure and hospitalization time, and complications were identified and compared with the so-called \"classical\" ESD technique.

Results: Lesions were more frequently located in the colon (vs rectum) in the hybrid dissection group compared to the ESD group (72.5% versus 26.8%, p < 0.001). The lesions were type IIc according to Paris classification in 10% of the hybrid dissection group compared to 24% in the ESD group (p < 0.001). The mean size of the lesion was lower in the hybrid dissection group than in the ESD group (32.4 mm ± 13 mm compared to 54.4 mm ± 26.7 mm, p < 0.001). An en bloc resection was performed in 52.5% and 84.4% in the hybrid dissection and ESD group, respectively (p < 0.001). The procedure time (including general anesthesia time) was lower in the hybrid dissection group compared to the ESD group (105 min ± 62 min vs 191 min ± 73 min, p < 0.001, respectively). The hospitalization time was lower in the hybrid dissection group compared to the ESD group (1.1 days ± 1.13 days vs 2.8 days ± 1.8 days, p < 0.001). R0 resection rates were lower in the hybrid dissection group than in the ESD group (47.5% and 61% respectively, p < 0.001). Hybrid dissection was performed for adenocarcinoma, adenoma with high grade dysplasia and adenoma with low grade dysplasia in 12.5%, 42.5% and 40%, respectively. The rate of adenocarcinoma was lower compared to the ESD group (1.1 days vs. 2.8 days, p < 0.001, respectively). The lesions were type IIc according to Paris classification in 10% of the hybrid dissection group compared to 24% in the ESD group (p < 0.001). In case of complication, there was no need of surgical treatment in the hybrid dissection group, but was needed in one patient in the ESD group.

Conclusion: Hybrid dissection is less effective in terms of en bloc resection of large colorectal tumors. Classical endoscopic submucosal resection should be preferred, especially in case of suspected adenocarcinoma despite longer procedure and hospitalisation time.

Contact E-mail Address: d.caroli@libero.it

Introduction: Since its introduction in 1968, Endoscopic retrograde cholangio-
pancreatography (ERCP) has become a cornerstone of the diagnostic and therapeu-
tic use to diagnosed and to treat conditions associated to the pancreatico-biliary system. It is nevertheless associated to the highest risk of complications of all routine endoscopic procedures. It is important to have a thorough understanding of the potential complications and the adverse events that may be associated to ERCP procedures so that these may be managed appropriately should they occur. The aim of this study was to examine the trends in ERCP usage here in the Veneto Region (Northeastern Italian area) and, in particular, the complications and mortality rate associated to it.

Aims & Methods: Utilizing an anonymous database of hospital discharge records referring to the period between 2007 and 2015, a retrospective study was carried out to examine the complications associated to ERCP. All of the elective hospitalizations for gallstones in the bili duct during which the procedure was carried out within two days of being hospitalized were examined. Hospitalizations for neoplasms were not considered. The study considered the onset of complications or death as outcome indicators as well as the patients' post-procedure status; the patients who had undergone surgery (e.g. cholecystectomy) were excluded from our analysis; the associations between the type of hospital where the patients were being assisted both with regard to the type of organization (Hub or Spoke model) and the type of management (public/private) were also evaluated.

Results: A total of 3,136 admissions out of total of 14,626 hospital days (SD: 4.6 ± 5.8 days) were identified in a total of 40 hospitals, 6 (15%) of which presented sex ratio were provided with data and the mean age, which was equal to 68.3 ± 14.2 (range 6–98 yrs), was higher in the females (69.1 ± 14.9 vs. 67.5 ± 13.5); significant differences during the period examined were not noted. A total of 212 complications (6.8%) were registered: these included acute pancreatitis (4.5%), cholangitis (1.3%), sepsis (0.4%), acute cholecystitis (0.3%), cardiopulmonary complications (0.2%), perforations and hemorrhage (0.2%). The complications that presented, which were significantly higher in the female sex (7.3% vs. 6.2%; p < 0.05), besides a greater average hospital stay in those suffering (110 ± 13.9 vs. 42.2 ± 16.3 days). The complications, including the complications, were carried out and no differences linked to their characteristics. The stratification of complications according to the type of hospital (range 2–17%) did not change over the period examined.

Conclusion: Study findings uncovered that pancreatitis was the most common post-procedure ERCP complication in the patients studied; the total complication rate was in line with that reported in the literature. That result and the fact that no correlation was found between the type and percent of complications and the type of hospital can be attributed to the effective regional hospital organization characterized by a capillary network of specialists capable of performing complex endoscopic procedures throughout the region limiting the need for transferring patients from one hospital to another.

P1538 EFFECT OF OBESITY, DIABETES AND DIABETES MELLITUS ON THE RISK OF POST-ERCP PANCREATITIS

Gastroenterology, Habib Thameur Hospital, Tunis/Tunisia

Contact E-mail Address: hajer.hassine@gmail.com

Introduction: Risk factors for post-endoscopic retrograde cholangiopancreato-
graphy pancreatitis (PEP) have been widely investigated. Nevertheless, studies focusing in metabolic conditions especially obesity, dyslipidemia and diabetes mellitus (DM) are still limited for the frequency of PEP based on the consensus criteria. The patients with obesity (Body mass index BMI ≥ 30 kg/m²), dyslipidemia (triglyceride > 2g/L or LDL-cholesterol > 1.6g/L) and DM (history of DM or fasting glucose level
Disclosure of Interest: external biliary fistulas, jaundice and accompanying cholangitis. In some cases, ERCP is a safe and effective way to manage biliary complications of biliary stenting due to stricture of the bile duct and two others required naso-occlusion balloon and/or Dormia basket. Nevertheless, two patients required with satisfactory results. Thus, hydatid membranes (36%) or daughter cysts cyst cavity (41%) and distal stenosis (3.3%). ES was then performed in all cases cholangiographic findings were: dilation of the biliary tract (21.3%) with filling papilla was impossible in 6 cases (8.9%) and the endoscopic sphincterotomy (ES) results did not indicate any need of injection of contrast to achieve a complete ductogram. In all ERCP performed for HHD whether before or after surgical treatment over a period. The rate of obesity, dyslipidemia and DM was 23.7%, 8.1% and 19.7% respectively. A PEP occurred in 13 patients with an overall incidence of 5.8%. The rate of PEP was 3.8% in patients with obesity, 11.1% in patients with dyslipidemia and 9.1% in patients with DM. Although PEP was more frequent in dyslipidemia (11.1% vs 5.3%) and DM (9.1% vs 5.3%) groups, results did not rich a statistical significance (p = 0.30, p = 0.30 respectively). This could be explained by the protective effect of other hand, PEP was less frequent in the obesity group (3.8% vs 6.9%) but there was no statistical significance p = 0.28.

Conclusion: In our study, metabolic conditions were not associated with an increased risk of PEP. It seems not to be wise to evaluate and two others required conditions in larger prospective studies since the expanded prevalence of metabolic syn-drome in general population.

A514 USE OF MICROCATHERETERS IN ECHOENDOSCOPY-GUIDED BILIOPANCREATIC RENDEZVOUS–INITIAL EXPERIENCE
J. Pinto, C. Saldanha Dueñas, C. Lelito, I. Fernández-Urrien Sainz, J.J. Vila Endoscopy Unit, Biliary And Pancreatic Diseases Unit, Complejo Hospitalario de Navarra, Pamplona/Spain

Background: The need of injection of contrast to achieve a complete ductogram during endoscopic sphincterotomy for pancreaticobiliary strictures is a technically demanding procedure, and the intraductal manipulation of the guidewire remains the most challenging step. Passing the guidewire through the needle may cause its fragmentation on the sharp metallic bevel. We have described the method of using a microcatherer for EUS-guided rendezvous, which allows easier handling and exchange of the guidewire, while avoiding both the risk of fragmentation and the need of injection of contrast to achieve a complete ductogram.

Aims & Methods: We aimed to evaluate the early experience of the microcathereter method in EUS-guided rendezvous procedures in the biliary and pancreatic ducts. During EUS-guided biliary or pancreatic rendezvous, initial puncture of the duct of interest was attempted with a 19G needle without styllet and

cebo in the prevention of post-ERCP pancreatitis: a multicenter rando-
previously flushed with contrast. A 0.025” guidewire was then inserted through the needle into the duct and advanced anterogradely to the papilla. If further manipulation was necessary to enter the duodenum, movements were performed with caution in order to avoid fragmentation of the guidewire. Whenever the passage through the papilla was not achieved or the guidewire movements were hazardous, we performed a microcatheter technique. After removing the needle, leaving the guidewire in situ, a 3F, 150 cm microcath- eter was inserted over the guidewire into the duct. Then, manipulation of the guidewire, guidewire exchange and contrast injection were performed according to the discretion of the endoscopist. We reviewed the cases of EUS-guided pancreatic or biliary rendezvous performed in our unit using microcatheters from September 2015 to March 2017. Technical success was considered when the rendezvous could be completed.

Results: Nine patients with previous unsuccessful manipulation of the guidewire with the needle during EUS-guided biliary or pancreatic rendezvous underwent a microcatheter-guided attempt on the same procedure. Pancreatic rendezvous was attempted in 3 cases (2 chronic pancreatitis, 2 pancreas divisum and 1 pancreatic cancer) and biliary rendezvous in the other 4 (3 biliary stenosis and 1 ampulla of Vater). Technical success was achieved in 7 patients (78%) with the microcatheter technique. Technical failure occurred in 1 patient with biliary stenosis in whom a EUS-guided hepatocystogastrostomy was performed in the same procedure and in 1 patient with chronic pancreatitis with symptomatic pancreatic duct stenosis. There were no adverse events after the procedure, irrespective of technical success.

Conclusion: In our series, using a microcatheter for the indwelling manipulation of the guidewire increases the EUS-guided rendezvous technical success without increasing the complication rate, irrespective of technical success.

P1545 NEWLY DEVELOPED BASKET FOR DIGITAL Single-OPERATOR CHOLANGIOSCOPY FOR MANAGEMENT OF RESIDUAL STONES AFTER LITHOTRIPSY

Digestive Disease Center And Research Institute, Department Of Internal Medicine, SoonChunHyang University School of Medicine, Bucheon and Seoul, Korea, Republic of

Contact E-mail Address: jjmoon@schmc.ac.kr

Introduction: Detection of residual or fragmented stones after lithotripsy for retained common bile duct stones can be improved by digital, single-operator cholangioscopy (SOC) by high resolution imaging quality. However, therapeutic intervention for the removal of residual CBD stones is limited by lack of appropriate accessories.

Aims & Methods: We evaluated the role of SOC and newly developed dormia basket for the evaluation and removal of residual stones after lithotripsy. From March to October 2016, 34 patients who had undergone lithotripsy for retained CBD stones with no evidence of filling defects in occluded balloon cholangiography were included. After balloon cholangiography, the bile duct was evaluated by SOC for the complete evacuation of stones. Detected residual CBD stones were directly retrieved with newly developed dormia basket inserted into the working channel of SOC. The incidence of residual stones detected by SOC, and the success rate of residual stone retrieval under SOC were investigated.

Results: SOC was successfully performed in all patients. Of these, 11 patients (32.4%) had residual CBD stones. The residual stones were successfully removed in 10 patients (90.9%) by dormia basket under SOC. (84.6%) except residual stones of grade 1, bile duct. There were no complications associated with SOC or direct stone removal.

Conclusion: Digital SOC combined with newly developed dormia basket is useful for the detection and extraction of residual stones after lithotripsy for retained CBD stones by evaluating under SOC.

P1546 ASSOCIATION BETWEEN PREDICTIVE FACTORS AND RADIATION DOSE DURING ENDOSCOPIC RETROGRADE CHolangiopancreatography

S. Dong, C.H. Oh, J.R. Moon

Kyung Hee University College of Medicine Dept. of Internal Medicine, Seoul, Korea, Republic of

Contact E-mail Address: gidrdong@hanmail.net

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) relies on the use of ionizing radiation in the form of fluoroscopy. Because use of fluoroscopy has positive relationship with radiation exposure, it makes a risk of the development of cancer and other radiation toxicity. The increasing exposure of patients and endoscopists to radiation is concerning.

Aims & Methods: The aim of our study was to evaluate of predictive factors of radiation exposure to the patients and endoscopists during procedure as determined by radiation dose in dose area product (DAP), absorbed dose (AD) and fluoroscopy time. And we correlated them with age, sex, body mass index, diagnosis, duration of procedure, procedure name and procedure complexity.

Results: As a result of analysis of the 892 ERCPs performed during 4 years, the mean duration of fluoroscopy time was 5.52 mins (95% CI, 5.15–5.93). Mean radiation duration were as follows: CBD stones (n = 511, 5.76 mins); malignant stenosis of bile duct (n = 189, 5.78 mins); pancreatic disease (n = 95, 5.28 mins); benign stenosis of bile duct (n = 51, 5.32 mins); and periampullary stenosis (n = 30, 5.84 mins). Multivariate analysis revealed that prolonged duration of fluoroscopy time was related with specific factors of patient included age, BMI, diagnosis and procedure complexity (all p < 0.05). Among the parameters, procedure complexity was the most significant relation with radiation dose. In addition, two more procedures performed during ERCP and mechanical lithotripsy (all p < 0.05).

Conclusion: ERCPs are associated with significantly higher radiation exposure to patients and endoscopists. The endoscopic retrograde cholangiopancreatography registry is to monitor the radiation dose at the national level and will help in quality improvement. Efficacy, safety and impact on different pancreatobiliary disorders will be also measurable.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1547 DEVELOPMENT OF AN ERCP REGISTRY FOR QUALITY CONTROL AND BenchmarkING

Introduction: To obtain representative information about invasive endoscopic procedures is a principal goal to monitor efficacy and safety. A web-based, online central registry can serve this aim allowing structured data collection and analysis on a national and international level and will help in quality improvement. Efficacy, safety and impact of the specific procedure will be measured. The indication of ERCP is to observe long term outcome. Four patients (4%) died during this period, but only 1 death was related to the procedure, caused by unresolved cholangitis. The indcication of ERCP were the following: bile duct disorder based on laboratory or imaging data was in 60.7%, jaundice in 31.8%, cholangitis in 16%, acute biliary pancreatitis in 5%, pancreatic disorder in 3%. The difficulty of procedures was evaluated: grade 1–22%, grade 2–45%, grade 3–30%, grade 4–3%. Fifty-nine procedures were performed in patients with newly operated gall-bladder and 100; Billroth I–10.7% (n = 46, 4.89 mins). Multivariate analysis revealed that prolonged duration of fluoroscopy time was related with specific factors of patient included age, BMI, diagnosis and procedure complexity (all p < 0.05). Among the parameters, procedure complexity was the most significant relation with radiation dose. In addition, two more procedures performed during ERCP and mechanical lithotripsy (all p < 0.05).

Conclusion: ERCPs are associated with significantly higher radiation exposure to patients and endoscopists. The specific procedure will be also measurable.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1548 DOUBLE-BALLON ENTEROSCOPY FOR ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAHY IN PATIENTS WITH SURGICALLY ALTERED UPPER GASTROINTESTINAL TRACT

C. Ghaoui1, E. Samah1, G. Rahmi1, G. Perrod1, H. Benosman2, A. Vienna1, C. Savale1, S. Khater1, L. Abbes1, J. Danset1, G. Malamut1, C. Cellier1

1Hepato-gastro-endologie Et Endoscopie Digestive, Hopital Européen Georges Pompidou, Paris/France

Contact E-mail Address: celineghaoui@hotmail.com

Introduction: Double-balloon enteroscopy-assisted endoscopic retrograde cholangiopancreatography or DBE-ERCp allows access to the biliary ducts of patients with surgically altered upper gastrointestinal tract. We studied the feasibility and efficacy of DBE-ERCp at our institution.

Aims & Methods: This is a retrospective study of all patients with surgically altered GI anatomy who underwent DBE-ERCp at our institution between February 2011 and March 2017. The primary endpoint was the global success rate of DBE-ERCp. The secondary endpoints were (1) the success rate of enteroscopy defined as reaching the desired postsurgical anatomic target, (2) the diagnostic success rate defined as successful cannulation of the native papilla or requiring surgical and/or radiological therapy(G2), regarding recurrence of biliopancreatic pathology, major complications and post-procedure 30-days mortality.

Results: A total of 153 ERCP procedures were carried out in 103 patients with SMGA (mean age:75.4±11.3years, men:80.6%). The breakdown of surgical pathology was 62.1% Roux-en-Y (n = 80), Billroth II-10.7%(n = 11); Roux-en-Y-8.7%(n = 9); post-duodenopancreactectomy-2; gastric sleeve-1. The predominant indication of ERCP was the use of balloon-assisted enteroscopy. In 23 patients with no endoscopic technical/therapeutic success, surgical (n = 14) or the endoscopic approach (n = 11) was performed. Comparing G1 vs G2, there were no differences in the recurrence rate of biliopancreatic disease (21.5% vs 36.0%; p = 0.205) or mortality (0% vs 8.0%; p = 1.000). However, G2 group had a high rate of major complications (12.8% vs 6.0%; p = 0.016).

Conclusion: The technical and therapeutic success rates of ERCP in patients with SMGA were 62.1% and 93.7%, respectively (lower in Roux-en-Y). Given the increased number of patients with SMGA and the high rate of complications associated with radiological and surgical therapies, it is essential to optimize ERCP technique rather than conventional endoscopy/duodenoscopy, including the use of balloon-assisted enteroscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1549 ASSOCIATION BETWEEN PREDICTIVE FACTORS AND RADIATION DOSE DURING ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAHY

S. Choi, J.H. Moon

Contact E-mail Address: sjhmoon@schmc.ac.kr

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) relies on the use of ionizing radiation in the form of fluoroscopy. Because use of fluoroscopy has positive relationship with radiation exposure, it makes a risk of the development of cancer and other radiation toxicity. The increasing exposure of patients and endoscopists to radiation is concerning.

Aims & Methods: The aim of our study was to evaluate of predictive factors of radiation exposure to the patients and endoscopists during procedure as determined by radiation dose in dose area product (DAP), absorbed dose (AD) and fluoroscopy time. And we correlated them with age, sex, body mass index, diagnosis, duration of procedure, procedure name and procedure complexity.

Results: As a result of analysis of the 892 ERCPs performed during 4 years, the mean duration of fluoroscopy time was 5.52 mins (95% CI, 5.15–5.93). Mean radiation duration were as follows: CBD stones (n = 511, 5.76 mins); malignant stenosis of bile duct (n = 189, 5.78 mins); pancreatic disease (n = 95, 5.28 mins); benign stenosis of bile duct (n = 51, 5.32 mins); and periampullary stenosis (n = 30, 5.84 mins). Multivariate analysis revealed that prolonged duration of fluoroscopy time was related with specific factors of patient included age, BMI, diagnosis and procedure complexity (all p < 0.05). Among the parameters, procedure complexity was the most significant relation with radiation dose. In addition, two more procedures performed during ERCP and mechanical lithotripsy (all p < 0.05).

Conclusion: ERCPs are associated with significantly higher radiation exposure to patients and endoscopists. The specific procedure will be also measurable.
anastomosis, and (3) the therapeutic success rate. We used a 2.2-mm DBE with a 2.0-mm opening channel (EN-450 T5, or EN850 Fujinon inc Saitama Japan).

**Results:** A total of 12 patients (sex ratio 1:1) with a mean age of 65 [47–82] underwent 14 DBE-ERCP. 7 patients had Roux-en-Y gastro-jejunostomy with a biliary stent, 4 patients had Roux-en-Y with a native papilla, and 1 patient had a Billroth II gastric bypass. Enteroscopy success rate was 93% (13/14 procedures). The diagnostic success rate was 85% (11/13 procedures) with 4/5 of native papillae. Therapeutic interventions including sphincterotomy (n = 4), biliary stone extraction (n = 4) and biliary dilation (n = 2) were needed in 8/11 procedures and their success rate was 100%. The global success rate of DBE-ERCP was 78% (11/14 procedures). Our results were comparable to those of the literature (global success rate of 82%). The only complication was one case of superficial intestinal lacerations without perforation (complication rate 7%).

**Conclusion:** DBE-ERCP in patients with surgically altered UI GI anatomy is a safe and efficient procedure with a global success rate of 78%. Using shorter enteroscopes with wider operating channel in the future might improve the success rate of this technique.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1550 TRANSPANCYEREC PHINTOTOMY (TPS) FOR DIFFICULT BILIARY CANNULATION: A SYSTEMATIC REVIEW AND META-ANALYSIS**

A. Tringali1, M. Cintolo1, L. Cristofoli1, E. Forti1, E. Pugliese1, L. Dionisordi1, M. Mutignani1

1Endoscopy Unit, Niguarda Hospital, Milano/Italy

**Introduction:** Biliary cannulation may be difficult in 10–15% of patients (1) and needle-knife sphincterotomy is more often used as a rescue treatment. A more recent study showed that difficult cases is transpancreatic sphincterotomy. Both situations are well known as post-ERCP pancreatitis risk factor (2). To best of our knowledge only few studies compared success rate and adverse events in these techniques (3-7).

**Aims & Methods:** We aimed to compare the efficacy and safety of NKS comparing to TPS in difficult biliary cannulation We conducted a bibliographic search using PUBMED, EMBASE including 2 RCTS and 4 non randomized trials from January 2000 to December 2016. OR using the Manthel-Haenszel method was used for dichotomous variables. Quantitative synthesis was performed using Review Manager version 5.0. Primary outcome was success rate. Secondary outcomes were rate of overall complications, and pancreatitis. Clinical heterogeneity was assessed by I2 value, where a value exceeding 50% indicated of heterogeneity. A random effect model was used in case of heterogeneity.

**Results:** Success rate was higher in NKS group compared to TPS [OR 2.98 (95% CI 1.01–8.85, p = 0.05). Complications and risk of pancreatitis was similar in both group (OR 0.74 (95% CI 0.51–1.00, p = 0.13; OR 1.09 (95% CI 0.68–1.75 p = 0.71)].

**Conclusion:** NKS is associated with higher success rate with equal risk of complication and pancreatitis risk compared to TPS. Further and well design RCTs are needed before a firm conclusion could be made.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

CBD stones

Disclosure of Interest:

15 mm was balloon dilator combined with retrieval balloon. Intermediate Conclusion: (P choledocholithiasis with a mean stone diameter of 7.1 mm and a mean CBD 67.2%. Overall, we had a success rate of 91.3% for endoscopic removal of META-ANALYSIS OF PROSPECTIVE CONTROLLED TRIALS

Hepatology 2016 vol.65;146–181.

meter of 12.4 mm. In Group 6 we included cases which required combined tech-
group was 90% for a mean stone diameter of 14.8 mm with a mean CBD diameter of 13.3 mm. By associating the basket with a retrieval balloon (Group 4) we obtained a 100% success rate of endoscopic removal for a mean stone diameter of 9.6 mm with a mean CBD diameter of 12.9 mm. We also analyzed the para-
meters of patients who underwent endoscopic extraction by using a retrieval balloon combined with balloon dilator (Group 5). The success rate in this group was 90% for a mean stone diameter of 14.8 mm with a mean CBD diameter of 12.4 mm. In Group 6 we included cases which required combined tech-
niques (=3). We observed a mean stone diameter of 9.4 mm with a mean CBD diameter of 13.8 mm in patients solved endoscopically, compared to those referred to surgery who had a mean stone diameter of 14.2 mm with a mean CBD diameter of 14.3 mm (P < 0.001). In this group the success rate was 67.2%. Overall, we had a success rate of 91.3% for endoscopic removal of choledocholithiasis with a mean stone diameter of 7.1 mm and a mean CBD diameter of 12.1 mm, compared to 3.8% of cases referred to surgery with a mean stone diameter of 13.6 mm and a mean CBD diameter of 14.3 mm (P < 0.001).

Conclusion: The most successful endoscopic method to remove large stones ≥15 mm was balloon dilator combined with retrieval balloon. Intermediate stones ≤7.5 mm could be successfully removed by using retrieval balloon or lithotriptor or a combination of basket with retrieval balloon ± balloon dilator. Most CBD stones <7 mm were successfully removed by using basket. In conclusion, any diameter >7 mm will most probably require more elaborate techniques.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Diclofenac and indomethacin are the most studied drugs for preventing ERCP pancreatitis (PEP), but their use is controversial.

Aims & Methods: Our aim was to evaluate all trials published in full text and studied efficacy of diclofenac or indomethacin prospective controlled with placebo or non-treatment for the prevention of PEP in adult patients undergoing ERCP. Systematic search of databases (PubMed, Scopus, Web of Science, Cochrane) for relevant studies published from inception to 30 June 2016.

Results: Our meta-analysis of 4741 patients from 17 trials showed that diclofenac or indomethacin significantly decreased the risk ratio (RR) of PEP to 0.60 (95% confidence interval:0.46-0.78, P = 0.0001), number needed to treat (NNT) was 20, and the reduction of RR of moderate to severe PEP was 0.68 (95% CI 0.43–0.97, P = 0.0339). The efficacy of indomethacin compared to diclofenac was similar (P = 0.98). The efficacy of indomethacin or diclofenac did not differ according to timing (P = 0.99) nor between patients with average-risk and high-risk PEP (P ≥0.0523). The effect of intra-rectal administration of indomethacine or diclofenac was not significant (P = 0.1507), but rectal route was very effective (P = 0.0005) with a NNT of 19. The administration of indomethacin or diclofenac was avoided in patients with renal failure. Substantial adverse events were not detected.

Conclusion: The use of rectally administered inexpensive and safe diclofenac or indomethacin before or closely after ERCP is recommended in every patient (without renal failure) undergoing ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Rectal diclofenac or indomethacin reduces the risk of pancreatitis after endoscopic retrograde choledangiopancreatography (ERCP). Most studies of its efficacy included high-risk cohorts and excluded low-risk patients. We investigated the potential of rectal diclofenac to prevent post-ERCP pancreatitis (PEP) in a variety of patients.

Aims & Methods: A cohort of 1534 ERCPs performed at the Hospital Clinico of Valladolid between 2009 and July 2016 was collected. The median age of the patients was 75 years old (between 1 and 102 years). 54% were male and 45.9% female. There were 93 procedures in which cannulation of the desired pathway was not achieved but the papilla had been manipulated so they are patients who were not allocated to the study. There were 36 patients with renal failure. Substantial adverse events were not detected. There were differences in the number of sphincterotomies in which it was greater in the Diclofenac group (p=0.004). There was also a greater number of Wirsung cannulations in the group treated with Diclofenac (p=0.004). There were a total of 47 PEP (3.1%), being 78.3% mild acute pancreatitis. Taken as a whole the patients had no difference in the number of PEP between the two groups, since in those treated with Diclofenac there was 3.4% and in the non-treated patients 2.8%.

When selecting only patients with de novo sphincterotomy, there was no difference between the number of PEP between the two groups being 4.4% in those treated with Diclofenac versus 4% in the untreated patients. In those patients who were cannulated Wirsung, an incidence of PEP of 8.2% was observed in the group treated with Diclofenac, compared to 3.8% in the non-treated group (p=0.006). There were no differences between those treated with Wirsung’s prosthesis and those not treated in both groups. There was no PEP in patients treated with pancreatic prosthesis.

There was a higher incidence of PEP in women in both groups and a trend towards greater number of PEP among those treated with Diclofenac, although without statistical significance. There was also a greater number of PEP in patients under 40 years of age treated with Diclofenac compared to those not treated with 14.3% versus 7.1% (p=0.024).

No differences were found between the groups treated and not treated with Diclofenac when crossing with sphincter dysfunction of Oddi, previous PEP, number and sizes of choledocholithiasis and sizes with the appearance of PEP.
Conclusion: In this retrospective cohort study of patients undergoing ERCP that included low-risk patients, rectal diclofenac was not associated with a significant decrease in the absolute rate of pancreatitis. In our study, diclofenac decreases the impact of PEP in those patients who are cannulated the pancreas.

3Pathology, Niigata City General Hospital, Niigata/Japan

Contact E-mail Address: furukawa@hosp.niigata.niigata.jp

Introduction: The confocal laser endomicroscopy (CLE) is of two types, an endoscope-based CLE (eCLE), which is integrated in the tip of the endoscope, and a probe-based CLE (pCLE), which goes through the accessory channel of the endoscope. The biliary tract, which cannot be reached by using eCLE, is observable with pCLE by using cholangioscopy. pCLE has the advantage of obtaining a magnification image that is like taking a biopsy tissue specimen but noninvasively, without the interference of bleeding and mucous secretion. However, it is sometimes difficult because only few gastroenterologists can achieve the required level of diagnostic accuracy.

Aims & Methods: We developed a computer-aided diagnosis (CAD) system based on pCLE imaging using deep learning technology. The purpose of this study was to determine the usefulness of this CAD system for the diagnosis of bile duct cancer. We prepared the classifier of the extracted features of the bile duct cancer pCLE images by using the deep learning framework presented by Kyocera communication system Co. Ltd. Japan. The pCLE images by Cellvisio (Mauna Kea Technologies, France) were obtained through the SpyGlass DS (Boston Scientific Corporation, USA). Learning sets were constructed by using 49 images of normal area and 23 images of cancer lesion. The test sets of the pCLE images were constructed using 6 images of normal area and 14 images of cancer lesion separately from the learning set.

Results: The accuracy, sensitivity for cancer diagnosis, specificity, negative-predictive value, positive-predictive value of our CAD system by test set were 69.8%, 50%, 100%, 53.8%, and 100%, respectively. The 7 false-negative diagnoses, indicating a 1.0 probability, did not show signs of bile duct cancer at all. A constant diagnosis was possible while being extremely small. False-negative diagnoses with the appropriate learning sets.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1556 COMPARISON OF EUS-GUIDED FINE NEEDLE BIOPSY TECHNIQUES FOR CORE TISSUE ACQUISITION AND DIAGNOSTIC PERFORMANCES IN PANCREATIC SOLID LESIONS

C. Cho1, S.J. Yeo1, A.N. Seo2, H.I. Bae2

Introduction: Acquisition of core tissue in endoscopic ultrasound-guided tissue sampling (EUS-TS) is necessary for histologic diagnosis and immunohistochemical staining in the diagnosis of some solid mass lesions. Although recent studies revealed the superiority of core biopsy needle in the specimen adequacy, core biopsy still remains that which EUS-TS techniques would result in better acquisition of core tissue and diagnostic accuracy.

Aims & Methods: The aim of our study was to evaluate EUS-TS techniques with a ProCore needle using suction and slow pull suction for solid pancreatic lesions with the input of cytopathologists. Patients who referred to EUS-TS for pancreatic mass were enrolled. We performed EUS-guided fine needle biopsy (EUS-FNB) using a ProCore needle (Cook Medical, Limerick, Ireland) with two needle passes and applied each pass of different techniques (suction or slow pull suction) which were randomly allocated. EUS-TS specimens were evaluated by one experienced cytopathologist who was blinded to applied techniques. The acquisition of core tissue and diagnostic performances were compared between two techniques.

Results: From Aug. 2014 to Dec. 2016, 94 patients with pancreatic mass were enrolled and 12 patients were excluded due to no final diagnosis (n = 5), cystic lesion (n = 5) and loss of follow up after EUS-TS (n = 2). Finally, 82 patients (48 males; median age, 63 years) with 164 needle passes were included without technical failure and procedure-related adverse events. The median size of the lesion was 1.1 cm (range, 0.2–6.0 cm). There were 66 benign lesions and 14 benign lesions. Overall core tissue diagnosis and diagnostic accuracy was 84.8% (139/164) and 73.2% (120/164), respectively. There was no significant difference between suction and slow pull suction in the acquisition of core tissue (85.4% vs. 84.1%, p = 1.000) and diagnostic accuracy (72.0% vs. 74.4%, p = 0.592).

Conclusion: Although our study revealed no differences between EUS-TS techniques in the core tissue acquisition and diagnostic accuracy for pancreatic solid lesions, further prospective study including variable lesions and sizes of needle is needed to validate for optimal application and sequences of EUS-FNB techniques.

Introduction: Gallbladder drainage, performed by EUS-guided positioning of specially designed fully covered metal stents, may be considered a valid option in patients with cholecystitis unfit for surgery. We describe the first case series of patients with diagnosis of acute cholecystitis treated conservatively using a silicone-covered nitinol stent with bilateral anchor flanges (NAGI-stent).

Aims & Methods: Our aim was to evaluate the feasibility and clinical impact of EUS-guided drainage with NAGI-stent in patients with acute cholecystitis unfit for surgery. Sixteen consecutive patients (9 males; mean age: 84 yeg; 94% with diagnosis acute cholecystitis according to Tokyo guidelines criteria, not suitable for surgical approach, were conservative treated and drained with EUS-guided short flared stents positioning. The procedure was performed in 2 tertiary endoscopy units, with the use of the pCLE technology. The 7 false-negative diagnoses, indicating a 1.0 probability, did not show signs of bile duct cancer at all. A constant diagnosis was possible while being extremely small.

Conclusion: Automated diagnosis of bile duct cancer can be achieved by using the deep learning technology of pCLE imaging. Our CAD system will be improved with the appropriate learning sets.

P1561 EFFICIENCY COMPARISON BETWEEN 22 G VERSUS 25G NEEDLES DURING ENDOCOSCOPIC ULTRASOUND FINE NEEDLE ASPIRATION FOR SOLID PANCREATIC MASSES: A SYSTEMATIC REVIEW AND META-ANALYSIS BASED ON RCTS

Gastrointestinal Endoscopy Unit, Clinical Hospital of Sao Paulo University Medical School, Sao Paulo/Brazil

Contact E-mail Address: ralpahduarte@hotmail.com
EUS-guided gallbladder drainage (EGBD) is gaining popularity as an alternative method for drainage of the gallbladder in patients suffering from acute cholecystitis that are at high-risk for cholecystectomy. However, the long-term outcomes and the learning curves of the procedure are uncertain.

Aims & Methods: We intended to compare the efficiency in the diagnosis of solid pancreatic lesions through the EUS-FNA with 25G and 22G needles. Studies were analyzed from five databases (Medline, Scopus, Cochrane, LILACS and CINAHL), without year or language restriction, using an extensive search strategy. Only randomized trials comparing 22G and 25G needles were included. Two independent reviewers went through the literature search and the results were analyzed by fixed and random effects. The diagnostic characteristics were calculated for a 95% confidence interval.

Results: 50 patients were recruited during the study period. The mean (S.D.) age was 57.9 (15.3) years and 31/50 (62%) were male. 50 patients were American Society of Anesthesiologists grading of ≥3 and the mean (S.D.) age-adjusted Charlson comorbidity index was 5.96 (1.82). The mean (S.D.) size of the gallbladder was 9.94 (9.83) cm. The hospital stay was 6.78 (5.36) days and follow-up was 48.58 (31.58) days. The overall technical success and clinical success rates were 96% and 86% respectively. Clinical success was not achieved in 7 patients as they suffered from 30-day mortality, 6 were due to uncontrolled sepsis and multi-organ failure even after adequate gallbladder drainage. 1 patient had a post-operative pneumonia resulting in death. 15 patients (30%) suffered from 30-day adverse events with 6 of these being attributable to the procedure. Maldeployment of the stent occurred in 6 patients and this was managed by placement of an additional metallic stent to bridge the gallbladder to the gastric or duodenal lumen. Recurrent cholecystitis occurred in 1 patient (2%) during follow-up.

When comparing the first 25 procedures to the subsequent 25 procedures, significant differences were observed in the procedural time [29.21 (10.65) vs 15.6 (1.66) minutes, P < 0.001], the need of an additional stent [24% vs 0%, P = 0.022] and hospital stay [7.76 (5.13) vs 5.75 (5.50) days, P = 0.099]. While no differences were observed in the technical and clinical success rates and adverse events.

Conclusion: EGBD is a safe and effective method for achieving gallbladder drainage in patients that are at high-risk for cholecystectomy. Performance of 25 procedures are required to gain competency in the procedure.

Introduction: Despite advances in radiotherapy for pancreatic cancer, local gastrointestinal (GI) toxicity still remains one of the major limitations to effective dose delivery and further dose escalation due to the close proximity of the GI wall to the pancreas, particularly in the head region. One potential method to reduce local GI toxicity would be to increase the physical distance between the head of the pancreas and the duodenal wall. A novel, injectable hydrogel, synthesized as iodinated polyethylene glycol microparticles, has been FDA-approved for use as a soft tissue fiducial marker. The hydrogel remains stable for 3 months and is absorbed by 7 months. To date, there has been no reports on the technical feasibility of endoscopic ultrasound (EUS)-guided hydrogel injection into the interface between the head of the pancreas and the duodenal wall to increase the peri-pancreatic space for the course of radiotherapy.

Aims & Methods: We aimed to evaluate the technical feasibility of EUS-guided hydrogel injection into the interface between the head of the pancreas and the duodenal wall in a cadaveric model. Baseline CT was performed on three unfixed cadaveric specimens. Using a linear EUS scope, the interface between the duodenal wall and the head of the pancreas was identified in a cadaveric model. A 19G needle was used to inject the hydrogel into the peri-pancreatic space with creation of a visible separation between the duodenal wall and the pancreatic parenchyma. The procedure was repeated along the length of the head and uncinate of the pancreas. CT was performed post procedure to confirm location and to measure the distance created between the duodenum and pancreas. Gross dissection of the pancreas and duodenum was performed to evaluate localization of the hydrogel.

Results: All three cadavers underwent successful EUS-guided injection of the hydrogel. Cadaver 1 received a total injection volume of 9 cc at the peri-pancreatic space along the head of the pancreas measuring 11.77 mm in maximal diameter. Cadaver 2 received a total injection volume of 27 cc with creation of peri-pancreatic space along the head and uncinate of the pancreas measuring 13.20 mm in maximal diameter. Cadaver 3 received a total injection volume of 10 cc with creation of peri-pancreatic space along the head of the pancreas measuring 12.89 mm in maximal diameter. The hydrogel was clearly visualized during EUS with hyperechoic echogenicity and on post-procedure CT images without any artifacts in all cases.

Conclusion: EUS-guided delivery of hydrogel is feasible and results in an increase in the peri-pancreatic space in a cadaveric model. The hydrogel is clearly visualized on EUS and CT without significant artifacts. Further studies are warranted to evaluate feasibility, effectiveness and safety in a clinical model.

Introduction: EUS-guided gallbladder drainage (EGBD) is gaining popularity as an alternative method for drainage of the gallbladder in patients suffering from acute cholecystitis that are at high-risk for cholecystectomy. However, the long-term outcomes and the learning curves of the procedure are uncertain.

Aims & Methods: This was a retrospective review of all patients that received EGBD in the Prince of Wales Hospital between June 2012 to March 2017. All procedures were performed or supervised by a single operator. EGBD was performed in patients that are at high-risk for cholecystectomy and suffering from acute cholecystitis or on long-term cholecystostomy tube drainage. Outcome parameters included demographics, technical and clinical success, procedural characteristics, adverse events and follow-up duration.
P1564 EX-VIVO RADIOFREQUENCY ABLATION OF PORCINE LIVER: A PRELIMINARY STUDY OF EFFICACY OF A NEW SYSTEM

Introduction: There are few published studies about the use of a novel radiofrequency (RF) system (EUSRA RF needle; VIVA RF generator; STARMed Co, Ltd; Koyang, Korea), with poor standardization of the procedure in terms of ablation powers and ablation times, resulting in great heterogeneity of the results.

Aims & Methods: To standardize the radiofrequency ablation (RFA) procedure using this new system performing ex-vivo tests on porcine liver in order to find the best ablation power and ablation time to produce the maximum size of coagulative necrosis at histological examination. The system consists in a radiofrequency generator delivering electric energy, a 19 Gauge needle (150 cm in length with a 10 mm monopolar electrode), a peristaltic pump (to perfuse the needle with chilled saline solution, maximizing the ablation volume without tissue charring), an isolating plate and a pedal to deliver RFA. Liver samples were treated at different ablation powers (10, 20, 30 and 40 Watts (W)); each ablation power was applied for a duration of 1, 3, 5, 7 and 15 minutes, according to Fibonacci escalation dose scheme, used in phase I studies. We registered macroscopically: the size (millimeters) of the global treated area and the size of the coagulative necrosis (millimeters) around the needle insertion point, and microscopic coagulative necrosis and surrounding zone.

Results: The lower ablation power (10 W) produced the maximum macroscopic ablation area, RFA application time at 10 W showed a good linear correlation with both the sizes of total macroscopic ablative area (R = 0.92) and central macroscopic ablative area (R = 0.89). Histologically the pathologist described two different injured zones by thermal effect: a central small and well-demarcated coagulative necrosis around the needle insertion point (A zone) with a maximum diameter of 4 millimeters and a surrounded larger area of “diaphanization” (B zone), showing mild signs of cellular alterations (cytoplasmic hypochromia) without cellular necrosis. A zone sizes didn’t change among different ablation times (mean size: 3.25 mm) whilst B zone diameter increased with the increase RF application at the fixed power of 10 W. At the microscopic analysis the pathologist didn’t see any difference in size of coagulative necrosis among the different ablation powers (R = 0.24).

Conclusion: With this new system is feasible and effective to produce very small areas of coagulative necrosis (millimeters) well-demarcated in respect to the surrounding parenchyma and could be useful, in the future, to treat, with multiple passes and higher precision, target lesions with a flexible needle. Moreover, the system can produce larger zones of mild cellular alterations at lower ablation powers (10 W), increasing with the increase of ablation times, but it needs future in-vivo animal studies in order to assess the evolution of these zones (evolving into fibrosis/necrosis recovery).

Introduction: Malignant associated thromboembolic disease (TED) has a complex multifactorial pathogenesis. Tumor cells expresses procoagulant activity in response to the tumor. Thrombotic risk varies substantially according to cancer location and pancreatic cancer is one of the leading causes. The clinical spectrum includes migratory superficial thrombophlebitis, arterial thrombosis, deep venous thrombosis, portal vein thrombosis and disseminated intravascular coagulation. We want to assess the role of endoscopic ultrasound (EUS) diagnosing TED in pancreatic cancer patients.

Aims & Methods: We perform a retrospective review of all EUS cases for pancreatic cancer in two centers and assess all EUS images and findings.

Results: In a period of 6 months, a total of 55 EUS for pancreatic neoplasms were performed in two centers. TED was present in 5 patients (9%): 3 were male and the mean age was 70 (range, 46–81). In 1 patient the EUS indication was a large abdominal mass whose origin was not clear, in the remaining 4 the indication was the pancreatic neoplasm. In all of them was performed EUS with fine-needle aspiration (FNA). EUS identified a peripheral pulmonary embolism (PE) and 1 inferior vena cava thrombus (IVCT) with right atrial extension: 2 (3.6%) had previously been diagnosed by computed tomography (CT) but 3 (5.4%) were not previously known. In all these, CT confirmed diagnosis.

Conclusion: To the best of our knowledge, this is the first case series of EUS-based TED diagnosis in pancreatic cancer patients. This series underlines importance of a systematic, station approach EUS technique, namely in the mediastinum regardless the clinical indication. TED is a common complication of pancreatic cancer and has major therapeutic and prognostic implications.

Introduction: Cholecodolithiasis is the most common cause of biliary pain, leading to diagnostic and therapeutic errors. Patients admitted by cholecystitis presents an incidence of cholecodolithiasis ranging from 8% to 20%. When the suspicion of cholecodolithiasis is confirmed, stones should be removed by ERCP, but this operative measurement is associated with high rates of adverse events as post-ERCP pancreatitis, bleeding or perforation. A correct diagnosis of cholecodolithiasis, before ERCP, is mandatory to decrease the operative risk and health care costs. Endoscopic ultrasound (EUS) has a high sensitivity and specificity in the diagnosis of CBD stones and could substitute other imaging modalities as CT-scan or MRCP, when indicated.

Aims & Methods: The aim of our study was to assess the role of early EUS (<48 hours), in patients undergoing US in emergency room for suspected biliary colic. We retrospectively evaluated all the patients arrived at first aid for suspected biliary colic, (i.e. right upper quadrant pain and/or epigastric region, associated with an elevation in serum ALT, AST, GGT, ALP, or total bilirubin, but in absence of amylase or lipase elevation). All patients, irrespective of the finding at the US, performed an EUS within 48 hours since admission. Data are presented as proportions with 95%-CI and mean±standard deviation (SD). Correlation between categorical variables was evaluated by computing the “phi” coefficient. We computed the number needed to misdiagnose, i.e. the number of patients who need to be tested in order for one to be misdiagnosed by the test, as 1/(1-diagnostic accuracy).

Results: Overall, from January 2016 to December 2016, 88 patients (56% female; mean age 64 ± 17 years) were admitted to our hospital for suspected biliary colic. All the analyses were run with R Studio (version 1.1.453). Further, US documented common bile duct (CBD) stones in 58 (65%) patients, CBD sludge in 4 (5%) subjects, whereas no cholecodolithiasis was found in 26 (30%) patients. At EUS examination CBD stones were found in 70 (80%) patients. Comparing US to EUS, US gave false negative results in 16 (18%) cases and false positive findings (i.e. identifying CBD stones not documented by EUS) in 8 (9%) patients. The two diagnostic procedures showed little correlation (phi = 0.289).

The number of
patients needed to be tested by US in order to provide an incorrect diagnosis was

liathisis. Retrograde biliary cannulation during ERCP was performed over the

Aims & Methods: We aimed to evaluate the efficacy and safety of EUS-guided rendezvous to diagnose malignancy.

P1567 BILIOPANCREATIC RADIOFREQUENCY ABLATION: COMPARISON OF THE THREE CURRENTLY AVAILABLE DEVICES IN A PIG MODEL

M. Barret1, S. Leblanc1, B. Bordacahar2, A. Rouquet2, S. Chaussade1, F. Prat1
1Gastroenterology, Cochin Hospital, Paris/France
2Pathology, Cochin Hospital, Paris/France

Contact E-mail Address: maximilien.barret1@gmail.fr

Introduction: Three devices are currently available to perform radiofrequency ablation (RFA) of biliopancreatic lesions. From animal models, results are scarce.

Aims & Methods: Radiofrequency ablation was performed in four live pigs on the common bile duct and the liver parenchyma using an endobiliary probe (endoHBP), on the liver and pancreatic parenchyma using an RFA catheter through an echoendoscope and biopsy needle (EUS RFA) and using a needle-shaped endoscopic ultrasound (EUS-SSA) through an endobiliary probe. The EUS RFA ablation time and power were allowed to vary. The animals were sacrificed 2 hours after the procedure. Histopathological assessment of the maximal depth of thermal lesions was performed on three representative slides for each RFA implant.

Results: In the common bile duct, the depth of ablation ranged from 215 ± 47 (Power = 8 W, Time = 90 s) to 330 ± 43 µm (Power = 10 W, Time = 30 s), suggesting that power is the most important parameter in this location. Conversely, depth of ablation in the liver parenchyma using the endoHBP probe ranged from 947 ± 237 µm (Power = 10 W, Time = 30 s) to 1960 ± 20 µm (Power = 10w, Time = 180 s), suggesting that time is the most important parameter for RFA in the liver.

Conclusion: The EUS RFA probe in the liver parenchyma showed a tissue necrosis increasing with the power setting used, ranging from 1901 ± 451 µm (Power = 8 W, Time = 120 s) to 2457 ± 1047 µm (Power = 12 W, Time = 120 s). This was not observed in the pancreatic parenchyma, where tissue damage ranged from 3108 ± 373 (Power = 8, Time = 120 s) to 2305 ± 78 µm (Power = 12 W, Time = 15 s). The EUS-SSA ablation of the liver parenchyma resulted in tissue damage from 1573 ± 245 µm (Power = 30w, Time = 11 s) to 1545 ± 120 µm (Power = 70 W, Time = 9 s). In the pancreas, ablation depth ranged from 3616 ± 475 µm (Power = 30w, Time = 15 s) to 3805 ± 446 µm (Power = 70 W, Time = 15 s).

P1568 ENDOSCOPIC ULTRASOUND-GUIDED RENDEZVOUS FACILITATES BILIARY CANNULATION IN CASE OF INACCESSIBLE INTRA-DIVERTICULAR PAPILLA

1Gastroenterology, Cochin Hospital, Paris/France

Contact E-mail Address: dimkypraios@hotmail.com

Introduction: Endoscopic ultrasound (EUS)-guided rendezvous techniques facilitate common bile duct (CBD) access during subsequent endoscopic retrograde cholangiopancreatography (ERCP) in a single session. Cases of initial ERCP failure mainly comprise malignant biliary or ampullary infiltration and altered anatomy of the papilla, the former accounting for the majority of reports in the literature.

Aims & Methods: We aimed to evaluate the efficacy and safety of EUS-guided rendezvous in a series of distal CBD obstruction with failed initial ERCP, due to inaccessible intra-diverticular papilla. Consecutive patients with distal CBD obstruction, in whom selective biliary cannulation at ERCPP was unsuccessful due to large duodenal diverticulum, underwent EUS-guided rendezvous. CBD puncture was performed via the transduodenal approach and the guide wire was advanced antegrade across the papilla. The echoendoscope was then exchanged for a duodenoscope and a sphincterotome was inserted through the papilla alongside or over the wire, to allow further manipulations.

Results: A total of 2480 ERCPs performed over a 4-year period, 18 cases were selected to undergo EUS-guided rendezvous due to the presence of a large ampullary diverticulum. Primary indication for ERCP was CBD stones in 15 patients, pancreatic head cancer in 2 patients and cholangiocarcinoma in 1 patient. Mean age of the patients was 77 years (range 62–91) and mean diameter of the CBD was 16 mm (range 8–21). Successful CBD puncture with antegrade passing of the wire into the duodenum and subsequent ERCP, in the same session, was achieved in 2/3 (66.6%) cases of malignant obstruction and in 13/35 (38.6%) cases of
P1570 EARLY CAPSULE ENDOSCOPY PROVIDES BETTER BLEEDING LOCALIZATION VALUE IN PATIENTS PRESENTING WITH NON-HEMATEMESIS GASTROINTESTINAL BLEEDING WHEN COMPARED TO CLINICAL SYMPTOMS ALONE

S. Jawaid 1, N. Marya 2, A. Foley 1, C. Marshall 1, K. Bhattacharya 1, D. Cave 1
1University of Massachusetts Medical Center, Worcester/United States of America
2UCLA, Los Angeles/United States of America

Contact E-mail Address: sjawaid@gmail.com

Introduction: Traditionally, clinical symptoms such as melena were used as strong predictors for an upper GI bleeding source with primary evaluation with an EGD (esophagogastroduodenoscopy). Little consideration was given to the small bowel. It has been known for decades that melena can originate from the nose to the right colon and hematochezia can originate from the proximal gut to the rectum. Thus, current endoscopic approaches have limited localization value and diagnostic yields. We hypothesize capsule endoscopy (VCE) provides better localization of bleeding when compared to clinical symptoms alone.

Aims & Methods: We conducted a single-center randomized trial of 73 consecutive patients presenting to the University of Massachusetts Medical Center with NHGB (melena, hematochezia/anemia, or guaiac-positive stools/anemia). Exclusion criteria included presence of pacemaker, dementia, non-English speaking, hemodynamically significant bleeding. Patients were randomized to SOC arm versus early capsule (EC) deployment. The EC group received a primary diagnostic procedure based on clinical symptoms that was dictated by the gastroenterologist on service, who was at liberty to choose the procedure sequence as they felt appropriate.

Results: In the SOC group, 73 were included. 2 patients from the initial included group were excluded (one due to technical capsule failure and one was transferred from an outside hospital). Baseline characteristics were similar and depicted in Table 1. The EC group (n = 34) had localization of presumed source of bleeding (n = 23) of patients at the time of the first diagnostic procedure compared to 48.4% (n = 16) in the SOC group (p = 0.02). Active bleeding or stigmata of recent bleeding at the time of the first procedure was seen in 64.7% (n = 22) of patients in the EC groups compared to only 30% (n = 10) in the SOC group (p = 0.003). However, when melena was still the only symptom in the SOC (n = 26) group, EGD was the most commonly chosen primary diagnostic procedure (n = 23), but was only diagnostic 52% of the time. After complete diagnostic evaluation in the SOC group, patients presenting with anemia had lesions localized in the esophagus (33.3%), stomach/duodenum (46.2%), small bowel (11.5%), colon (11.5%), but 27% had no source identified. EC group had lesions localized to the esophagus (2.9%), stomach/duodenum (35.2%), small intestine (8.8%), colon (20.5%), and 32.3% did not have lesions identified. Patients with SB MRI evidence of bleeding symptoms in the EC group had EGD was never diagnostic as a primary procedure, colonoscopy (COLO) had a 50% diagnostic rate, and VCE was diagnostic 100% of the time.

Conclusion: VCE used as the first test in patients with NHGB detects active bleeding more often than the SB approach, since it examines much more of the GI tract than EGD and COL alone. Detection of the anatomic site of bleeding allows for better therapeutic decisions.

P1571 MUCOSAL HEALING RATES INDUCED BY ADA-LUMUMAB IN ISOLATED SMALL BOWEL CROHN’S DISEASE: PROSPECTIVE EVALUATION BY CAPSULE ENDOSCOPY

Contact E-mail Address: eyal.gal83@gmail.com

Introduction: Mucosal healing (MH) of isolated small bowel Crohn’s Disease (CD) induced by anti-tumor necrosis factor alpha agents are scarce.

Aims & Methods: 1) To evaluate MH rates by capsule endoscopy (CE) in patients with isolated small bowel Crohn’s disease (SB-CDAI) actively treated with adalimumab (ADA). 2) To correlate MH with clinical and biological indices of remission. This was a prospective observational, single center study. CD patients with isolated (per CE) active (CDAI > 220) SB disease, who were recommended ADA by their treating physician were consecutively recruited; first CE was performed prior to commencing ADA, and the second-14-week after starting ADA. All enrollees underwent a patency capsule study to confirm patency. Disease severity was assessed by the capsule endoscopy Crohn’s Disease activity index (CECDAI) score. MH was defined as CEDCAI score <3.

Results: Out of 31 patients screened, 24 were eligible, and 22 completed the study (as two patients developed an allergic reaction to ADA and were withdrawn). Females: 12 (54.5%), median disease duration: 3 years (IQR 1–7), biologic exposure: ADA (n = 23), Sanofi (n = 1). After ADA treatment, we found MH was detected in 8/22 patients (36.4%), CDCAI < 150 in 11/22 patients (50%), normal- ization of CRP in 7/22 patients (31.8%), and normalization of fecal calprotectin in 8/22 patients (36.4%). Inflammatory indices significantly decreased within 14 weeks of ADA treatment compared with baseline: median CEDCAI 5 (1–16) vs 10 (5–20), p = 0.001; median CDCAI 150.8 (109.8–211.5) vs 256 (240–252.5), p < 0.001; median CRP 0.14 (0.07–0.5) vs 1.1 (0.2–1.5) mg/dL, p = 0.002; median fecal calprotectin 83 (80–139) vs 126 (61.5–265.5), pg/gram, p = 0.014. MH detected by CE did not correlate with normalization of either CDAI <150, CRP, or fecal calprotectin in the same group.

Conclusion: ADA induced MH in 36% of CD patients with isolated active SB disease. MH did not correlate with either clinical or biological remission. Thus, further evaluation should be performed after 52 weeks of maintenance therapy.

Introduction: Capsule endoscopy (CE) is widely used to investigate the small bowel (SB). However, patients with isolated small bowel disease (IBD) are considered to be at higher risk for capsule retention. The ESGE recommends using dedicated cross-sectional imaging to assess SB patency in patients with known Crohn’s Disease (CD) prior to CE. Evidence suggests that a combination of SB MRI and faecal calprotectin (FC) may be more effective in assessing SB inflammation compared to an individual modality alone. We aimed to assess the effectiveness of this approach.

Aims & Methods: Retrospective, multicentre study; consecutive patients who had undergone both SB MRI and CE within 6 months of each other were included.

Results: 82 patients (28M/54F, Mean age 41.4yrs) underwent both CE and SB MRI at 4 centres in the United Kingdom, Israel and Portugal. Indications included suspected SB infection (n = 81), IBD reassessment (n = 21). Overall, there were 3 incomplete CEs, but no case of SB capsule retention. Of 82 SB MRIs, 4 patients had evidence of SB obstruction, 10 had SB thickening and/or inflammation, 3 had other findings (SB pneumatisos, polyps). 64/82 cases were normal and 1 study had poor contrast, precluding any conclusion. Of the 4 patients with SB obstruction, 2 had normal SB CE findings. Of the 10 patients with SB thickening and/or inflammation seen on MRI, 6 had corresponding CE findings; in particular, there were 2 cases with strictures on CE and 4 cases with mucosal inflammatory changes. 64 patients had normal SB MRI and 35 (54.7%) had a normal CE. 18/64 (28.1%) patients had mucosal inflammatory changes on CE; 2 of them had strictures which were eventually traversed by the capsule. 10 patients had other non-inflammatory findings on CE. Of 18 patients with normal SB MRI, 9 had a raised FC (> 150µg/g), 5 had borderline FC levels (50–100µg/g). None of the patients in this group had normal FC levels; the mean FC was 637±844.4µg/g. In the group of patients with both normal SB MRI and CE, 16/35 had raised FC, 7 patients had borderline FC levels. The overall mean FC for SB MRI and CE was 662±221µg/g but the mean FC between patients with SB inflammation seen on CE and patients with normal SB MRI and CE was significantly different (p = 0.004).

Conclusion: A significant proportion (28.1%) of patients with normal SB MRI to investigate possible SB inflammation had CE findings showing SB inflammation, including 2 patients with strictures. However, no retention occurred in this group. Raised FC was significantly associated with CE findings despite normal SB MRI.

Introduction: The interpretation of small bowel capsule endoscopy (SBCE) requires a high level of concentration. An abnormality may be present on just a few of the many thousands of images presented for interpretation. It is
unknown whether fatigue affects the accuracy of SBCE reporting and how many SBCE sessions can be performed in one session. Aims & Methods: Thirty-two participants (16 experienced SBCE readers and 16 novices) were invited to participate in this study. Each participant was asked to read 6 pre-selected SBCE studies consecutively. These studies were presented in a random order. All readings took place using the single-view mode, where readers were able to choose the frames per second viewed from a range of speeds. Fatigue was measured subjectively using a Likert scale and objectively using a computer-based psychomotor vigilance test. These measures were performed at prior to commencing the study and after every second capsule read. Accuracy in lesion detection was determined by comparison with a gold standard reading derived from the non-consecutive readings of two expert capsule readers. Accuracy was plotted against the order in which SBCE studies were read. The aim of this study was to determine whether fatigue influences the accuracy of SBCE interpretation and how many cases can be read before accuracy declines.

Results: In keeping with existing literature, high intra-reader variability amongst the participants was observed, with experienced readers reaching kappa values of 0.51 with the gold standard and 0.08 amongst novices. All progressive SBCE studies were read the mean speed increased for both experts and novices, with a mean reduction of 10 minutes between the first and the last study read. This was associated with faster reading speeds selected in progressive studies read. Where accuracy was analysed with respect to the reading speed chosen, a negative correlation between increasing speed and accuracy was demonstrated, with 31% of lesions detected when read at 6–10 frames per second, compared to 15% when using the 22–28 speed. There was no significant change in accuracy with progressive capsule read when the group was analysed as a whole. The accuracy of experienced readers declined after just one study read, from 38% to 27% and plateaued thereafter. Novice readers demonstrated no significant change in the time points, with a trend towards improvement, perhaps indicating skills acquisition during the study.

Conclusion: The accuracy of SBCE reporting declines after one study reporting in a given period of time by expert SBCE readers. The optimal time interval between readings needs to be explored. This does not affect novice readers perhaps demonstrating skill acquisition.

cases to obtain an automatic histological classification of colonic polyps. Our automated system is set up on the segmentation of textural elements from polyp surface and their correlation with Kudo’s pit pattern classification. Textural elements are identified as bright regions in polyp surface and there are characterized according to their shape into tubular and circular: a high presence of tubular patterns is associated to an adenomatous histology whereas the absence of prominent tubular structures is associated to non-adenomatous. Taking this into account, we characterized segmented bright regions using a tubularity metric (Tub) designed to obtain low values for circular shapes and high values for tubular shapes of the regions of the same area. We tested our method in high definition (HD) while light polyp images which were obtained with a colonoscope Olympus CF-H190 at Hospital Clinic in Barcelona. Neither conventional nor virtual chromoscopy were used. These images were selected to show as much variability in polyp appearance as possible. We used the mean of all Tub values for an image to classify it into two classes: Adenoma and Non-Adenoma. A ROC curve was constructed to select the optimal threshold value of Tub. Then, we compared the histology prediction provided by our system and the actual histology obtained after lesion removal.

**Conclusion:** A computer vision system based on bright regions in the image has a high accuracy for on-line prediction of polyp histology during colonoscopy. Though the use of shape characterization is promising, the inclusion of other polyp characteristics (i.e. shape, color, vessels...) as well as enlarging the validation database could improve the robustness of our methodology.

**Introduction:** CT colonography (CTC) may be readily used for imaging of the colon in elderly or poor risk patients with colon polyps and cancer because of its non-invasiveness and relatively short inspection time. However, there are some drawbacks to make a misdiagnosis may be inevitable. Therefore, analysis of misdiagnosis case is crucial on the new modality for the colon cancer screening examination.

**Aims & Methods:** We evaluated the misdiagnosed case of large neoplastic lesions determined by colonoscopy in JANCT by CTC with radiologist and gastroenterologist interpretations1). Out of 1257 cases enrolled in JANCT, 1181 cases were actually studied, omitting 76 cases according to the exclusion criteria. More than 16 DAS CT were used for CTC, respectively. Images were retrospectively reconstructed by using a 0.5 mm section index. The CTC examination was prepared by PEG-C solution before scanning. CO2 gas as an effervescent agent was then administrated just before scanning. This was used for the contrast medium. CTC images were analyzed by AZE Virtual Plane software. The CTC and CS were independently analyzed by endoscopist and radiologist in blind fashion. We investigated misdiagnosed lesions with CTC more than 10 mm detected by CS. We considered the pseudo-negative lesions misdiagnosed with CTC interpretation (PNL) by radiologist or gastroenterologist and also considered the true pseudo-negative lesions misdiagnosed with CTC interpretation (true PNL) by radiologists and gastroenterologists.

**Results:** PNL was diagnosed by CS at 0-Ip (8 cases, 8 lesions) and 0-Ia (17 cases, 19 lesions), respectively according to the criteria of the Paris classification. True PNL was also diagnosed at 0-Ip (1 case, 1 lesion), 0-Ia (5 cases, 6 lesions) and 0-IIa (11 cases, 13 lesions), respectively. True PNL/PNL ratio was 0-Ip 12.5%, 0-IIa 50% and 0-Ia 68.5%, respectively. There was no difference in PNL at 0-IIa.

**Conclusion:**

The accuracy of CTC for the colon cancer examination is dependent on the new modality for the colon cancer screening examination.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Of General Surgery, University of Padova, Padova

**Contact E-mail Address:** ant.caruso@hotmail.com

**Introduction:** The formation of fibrotic tissue in intestinal wall of Crohn’s Disease (CD) patients is transmural and mucosal biopsies are unrepresentative of real intestinal damage. Magnetic Resonance Enterography (MRE) allows a transmural study of the bowel loops. Recently the percentage of gain of contrast enhancement (PNL) has been proven useful to study fibrosis in CD patients. Diffusion Weighted Imaging (DWI) through the restriction of the apparent diffusion coefficient (ADC) allows an accurate evaluation of disease activity in CD patients. Diffusion Magnetic Resonance Imaging (MRI) has been proved useful to study fibrosis in CD patients. The ADC allows an accurate evaluation of disease activity in CD patients.

**Aims & Methods:** The aim of this study is to investigate if DWI sequence of MRE was able to identify intestinal fibrosis in CD patients candidate to surgery, using the histopathology specimens and percentage of gain as gold-standard. Thirty ileocolonic CD patients who have an active disease at MRE before the surgery. The histopathological examination was performed using an histologic score for inflammation (AIS) and fibrosis in the stenotic segment and in the ileum before the stenosis.

All population had an active disease at MRE. ADC value had a significant correlation with fibrosis score (r = 0.648; p < 0.0001), AIS (r = 0.763; p < 0.0001) and percentage of gain (r = 0.687; p < 0.0001). A strong correlation emerged between wall thickness and fibrosis score (r = 0.671; p < 0.0001). The...
threshold of wall thickness for fibrosis was 10 mm (95% CI 9.0–10.9). The cut-off of ADC value for fibrosis was <1.1 × 10^{-3} \text{mm}^2/\text{s} with a sensitivity of 71.79% and specificity of 94.44% (AUC = 0.85).

Conclusion: The DWI sequence with ADC value can identify fibrosis in intestinal lesions with high accuracy. The use of contrast medium may improve the accuracy of fibrosis detection.

P1580 MOLECULAR IMAGING OF c-MET IN THE CLINICAL MANAGEMENT OF GASTROINTESTINAL CANCERS
N. Mcdonald, C. Portal, I. Wilson
Contact E-mail Address: i.wilson@edinimage.com
Introduction: The primary indication for c-Met targeted optical imaging agent EMI-137 is benign lesions during colonoscopy screening, including flat lesions that are difficult to detect by normal white light endoscopy. We have evaluated the potential benefit of EMI-137 and analogues beyond colorectal cancer screening since c-Met is up-regulated in many other cancers.

Aims & Methods: We have synthesised analogues of EMI-137 where the fluoroscent reporter was replaced by a radionuclide chelating moiety for PET imaging. We performed a proof-of-concept study in mice to establish the fluorescence and PET imaging characteristics of EMI-137 and analogues.

Results: We identified a number of promising applications within Digestive Oncology; gastric cancer, locally-advanced rectal cancer, and bile duct cancer surgery are all life-threatening indications with urgent healthcare problems that could be improved by using imaging of c-Met with EMI-137. Compatible imaging systems are commercially available for these indications. There is also strong evidence for c-Met as a biomarker in stratification in Barrett’s oesophagus (BO), a potentially precancerous lesion with the risk of progression to oesophageal cancer. Progression rates are low and overall survival rates in BO patients are similar to the general population. However, due to the poor prognosis of oesophageal cancer, patients with BO lesions are managed by regular endoscopic surveillance and biopsy. This means that there is arguably a disproportionate healthcare burden relative to the level of risk.

Conclusion: Gastric cancer, locally advanced rectal cancer, and bile duct cancer surgery are all strong evidence for c-Met as a valid target, and the healthcare problems are clear and widely recognized, with EMI-137 having the potential to high-turnover active procedures in serious, life-threatening conditions. An imaging agent that enabled more accurate risk stratification of BO patients would lead to a change in patient management, with the potential to remove unnecessary biopsy and to reduce the frequency of surveillance.

P1581 HOMEMADE FIXATION OF FULLY-COVERED SELF-EXPANDING METAL STENT
Endoscopy, ICESP Sao Paulo Dept. of Endoscopy, Sao Paulo/Brazil
Contact E-mail Address: ktpennacchi@yahoo.com.br
Introduction: Esophageal self-expandable metal stents are currently used as an alternative for surgical treatment in esophageal neoplasia, benign strictures, fistulas and anastomotic leaks. Migration is a common complication after stent placement and has higher rates when fully covered stents are employed. Covered stents prevent tumor ingrowth and can be removed easily, they can be used in the closure of fistulas and leaks. External fixation of the stent with Shim’s technique seems to be efficient in preventing stent migration, but has a high cost and is not always available. Fixation by clipping or sutures has similar limitations. We developed a homemade technique for external fixation of the stent using dental floss to prevent stent migration. We pull stripes of dental floss into the stent mesh and use a method similar to exchange of a nasobiliary drainage catheter, the dental floss is drawn out through the nose, tied a knot into it and its loose end is fixed to the patient’s carbole.

Results: Upper gastrointestinal endoscopy was performed after two weeks and the proximal end of the stent was evaluated. If it was embedding the esophageal mucosa and did not separate from the esophagus with air insufflation, the external fixation was removed. Otherwise, the fixation was kept for another 2–4 weeks when a new endoscopic evaluation was performed. Patients were evaluated 15–30 days after stent placement. In cases of migration of the entire length of the stent into the stomach, the patient received a new stent and the same fixation method was employed. In cases of stents partially migrated through the cardia, the same stent was repositioned and fix and with dental floss stripes as previously described.

Conclusion: According to the results we believe this homemade technique using dental floss for external fixation of stents is a simple and cheap method that can be applied and used to prevent stent migration.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1582 CLINICAL OUTCOME WHEN USING SELF-EXPANDING METAL STENT IN OBSTRUCTIVE COLORECTAL CANCER IN 248 PATIENTS OVER 7 YEARS EXPERIENCE FROM A TERTIARY CENTER
M. Shafazad, T. Radoszni, L. Alkeln, N. Papachrysos
Gastroenterology, Sahlgrenska University Hospital, Gothenburg/Sweden
Contact E-mail Address: moterza.shafazad@vrg.se
Introduction: The reported incidence of colorectal cancer in Sweden in 2014 was 60-65/100,000 inhabitants and caused 25-30 deaths/100,000. Of all colorectal cancer, approximately 15-20% debuts with acute obstructive symptoms. There is no consensus in these indications (open surgery) have been shown to lead to mortality risk up to 20% and morbidity risk of 45–50%, followed by increased need for intensive care and more infections and stoma complications”. Self-expanding Metal Stent (SEMS) for relieving malignant colorectal obstruction is a treatment option for non-curative cases or for bridging the patient for later surgery. Studies have shown "clinical success" of SEMS at 90%. An article from 2007 concludes that SEMS in acute colon obstruction has better results regarding sickness and side effects compared with acute open surgery.

Aims & Methods: Our compilation covers the years 2010–16, when 248 SEMS interventions(53% men, 47% women, age 28–97) were performed at SU/Ostra Hospital. In 78% of cases, the obstruction was located below the left flexure. In 80%, SEMS was made for palliative purposes.

Results: Technically, SEMS succeeded in 98% of cases and had clinical success in 90% of cases(absence in need of emergency surgery). Complications (colony perforation) occurred in 6% of the cases. Mortality within 30 days was 11% and within 90 days 22%. Both SEMS and open surgery are in agreement with regard to 90-day mortality for the indication was palliative vs. bridging, 29 resp. 3%. Based on the clinical outcomes "success" vs "failure", the 90-day mortality was 19 resp. 55%.

Conclusion: Our interpretation is that SEMS is an effective method of acceptable safety regarding complications in acute malignant colon obstruction. The method is suitable for both intended intestinal relief for palliative purposes, as well as awaiting later curative measure (bridge to surgery).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Tracheoesophageal fistulas are severe complications which commonly occur secondary to malignant tumors of the esophagus. Other causes include mediastinal or respiratory tract tumors, surgery, radiotherapy and trauma. Without treatment they often lead to pulmonary and gastroenterological complications, such as pneumonia, acute respiratory distress syndrome and poor nutrition. The purpose of this study was to assess the efficacy of endoscopic treatment performed in our clinic for esophageal fistulas.

Aims & Methods: We performed a retrospective study on 43 patients admitted in our clinic between January 2015 and April 2017 for esophageal fistulas.

Results: The average age of the patients included in the study was 54 years old. The causes leading to the tracheoesophageal fistulas were the following: esophageal malignancy in 18 cases (41.8%), surgery in 8 cases (18.6%), respiratory tract malignancy in 6 cases (14%), gastric sleeve in 5 cases (14%), radiotherapy in 3 cases (7%) and trauma in 2 cases (4.6%). In every case, the treatment of choice was placement of fully-covered metallic stents. A number of 16 patients needed reinforcement, with a mean of 2 reinforcements per patient. Regarding recurrent fistulas, endoclips were used in one case (2.3%), additional stenting in 11 cases...
A total of 452 endoscopic interventions (mean 3.4 per patient, median 2 treatments) were included in this retrospective cohort study. A follow-up was available for 135 patients (female n = 68, mean age 47.5 years, BMI: 22.8 ± 4.98 kg/m², duration of illness: median 25.1 months). In 165 cases, the dominant stricture was located in the ileocecum, in 105 in the colon, esophagus (90), duodenum (54), upper gastrointestinal tract (bleeding: n = 4), and cSEMS (1). Dilatation was performed to a mean of 14 mm (SD: 2.4, range 7 to 24 mm). In seven cases complications occurred after endoscopic treatment (bleeding: n = 5; infection: n = 1; perforation: n = 1) which resulted in an extension of the hospital stay (n = 5), antibiotic therapy (1) and surgery (1). Immediate clinical success was observed in 438 of 452 cases (96.9%). A single intervention was performed in 61/135 patients (45.2%), two interventions in 36 (26.7%), and three or more in 38 (28.1%). In 41 of 135 patients (30.4%), surgical treatment of the stricture was required in the course of disease.

Conclusions: Endoscopy as first-line treatment of symptomatic stricture in CD is safe and effective. Repetitive dilation is feasible with a significant reduction of clinical symptoms, and surgery was required in about 30% of patients at long-term follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Palliative stenting is now established as a major treatment for dysphagia resulting from incurable oesophageal malignancies. The malignant stricture of the oesophagus can lead to multiple possible complications after oesophageal stent insertion; most of these present with increasing dysphagia; however pain, bleeding, and reflux are also common. Although data on rates of various complications are available, there are no agreed standards to audit performance against, nor any requirement to do so. As this is a palliative procedure, success in symptom control is paramount; if this is not being achieved, then the appropriateness of the procedure must be questioned. As with any invasive procedure, complication rates are affected by modifiables: technical (e.g. stent length and site of stent insertion), operator experience, patient co-morbidities and performance status. As a result of these variables, stated complication rates also vary. Only one study reported a rate of dysphagia (29%); migration occurred in 5-15% of cases, tumour ingrowth: overgrowth 5-20%, and food bolus obstruction in 5-15%. Quoted median survival ranged from 61-104 days, with a 30-day mortality of 20-28%.

Aims & Methods: Our aim was to scrutinise the efficacy and the safety of our palliative oesophageal stenting work. A retrospective study of all patients undergoing oesophageal stent insertion at our unit, between 01.01.2012 and 01.04.2016 was undertaken, looking for evidence of complications, repeat interventions, and for survival statistics after stent insertion. Patients who had undergone stent insertion for reasons other than oesophageal malignancy were excluded.

**P1587 LONG-TERM RESULTS: WHEN RE-STENOSIS COMES AFTER ESOPHAGEAL STENTING?**

D. Gusev, S. Kashin, N. Akhapkin
Endoscopy, Yaroslavl Regional Cancer Hospital, Yaroslavl/Russian Federation

**Contact E-mail Address:** denis_gusev83@mail.ru

**Introduction:** Self-expanding metallic stents (SEMS) is a well-established form of palliative treatment for dysphagia in esophageal cancer. Progression of the tumor after stenting with re-stenosis is a serious problem in patients with better prognosis and longer survival.

**Aims & Methods:** The aim of this study was to assess the timing and probability of esophageal re-stenosis after stenting by tumor growth. We performed a retrospective analysis of patients with advanced esophageal cancer who was under palliative total stenting treatment. Patients were included in this study if they were placed 2 cm distal and 2 cm proximal of the stenosis. Of 97 patients, 18 (18.5%) patients were bleeding, 2 (1.3%) were tracheo-oesophageal fistula formations, 1 (0.7%) was delayed perforation, 1 (0.7%) was a too short stent, 1 (0.7%) was a disintegrating stent and 1 (0.7%) was a compression of the bronchi. Median survival of the 125 patients after stent insertion was 96 days (SD 128) and 30-day mortality was 11.2% (14 patients). It is important to note that with retrospective data analysis, some data is not available, due to variations in recording at the time and a reliance on the patient to report symptoms to a clinician. Currently 2 patients are still alive.

**Results:** Palliative stenting at this centre continues to be an effective treatment for patients with dysphagia from esophageal cancer. On the whole, outcomes from stenting at this unit compare favourably with published data in terms of dysphagia, other complications, and mortality. Steps to improve post-procedure monitoring in the form of a “sten t registry” with prospective collection of data by telephone or face-to-face follow-up could be useful in future service development.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Self-expandable metal stents (SEMS) are often used for palliative treatment of dysphagia in patients with advanced esophageal cancer, with anticipated limited survival. However, due to previous reports of high adverse event (AE) rates when used long-term, concerns have been raised with the use of SEMS in patients with survival longer than 3 months.

**Aims & Methods:** We aimed to the role of esophageal SEMS in patients with advanced esophageal cancer and expected survival longer than 6 months. Technical success was defined as successful deployment of the stent in the correct position. Clinical success was defined as relief of dysphagia 1 week after placement.

This was a retrospective study of patients with clinical dysphagia and advanced esophageal cancer who underwent SEMS placement with a stent dwelling time of greater than 6 months. In all patients the indication for stent placement was dysphagia due to esophageal malignancy.

**Results:** Forty-two patients were followed for 298 days (183–861 days). At the end of follow-up the mortality was 93%. The majority of lesions were located at the proximal/middle esophagus (55%), and were traversable using an ultrathin gastro scope in 79% of patients; in no patient could a standard upper endoscope be passed. Twenty-nine-nine patients (74.6%) underwent further therapy (chemotherapy and/or radiotherapy) with SEMS in situ; however, only 14 began therapy before development of an AE (4 patients underwent further therapy after AE). Clinical improvement occurred in all patients, however 59% of patients continued to experience an AE (15 migrations, 8 overgrowth/ingrowths and 2 stent-induced fistulae). The median stent patency was 236 days (19–513). Two AEs occurred within 30 days of stenting, 7 occurred between 30–90 days, 7 occurred between 90–180 days, and 9 occurred after 180 days. Endoscopic management was attempted in every SEMS-related AE (20 patients required a second SEMS, 2 had successful SEMS repositioning and 1 was treated with argon plasma; 2 SEMS were removed without the need for further therapy), with a clinical success of 100%, however, in 7 patients the previously treated AE recurred (1 in overgrowths and 6 migrations). Multivariate analysis showed that strictures traversable with an ultrathin gastro scope were associated with a higher risk of AEs (OR 11.7, 95% CI [1.2–114.6], p = 0.035).

**Conclusion:** Long-term esophageal stenting in patients with advanced esophageal cancer in patients with a high survival rate and a high prevalence of AEs without an impact on mortality, and most could be managed endoscopically. Strictures traversable only using an ultrathin gastro scope are a risk factor for AEs.

**Contact E-mail Address:** drmahlmoudghalab@yahoo.com

**Introduction:** The incidence of iatrogenic bile duct injury (BDI) remains high despite increased awareness of the problem with significant impact on patient’s well-being and even survival despite seemingly adequate therapy. Over the past years, endoscopic and percutaneous biliary interventions became readily
available in many centers and have revolutionized the management of iatrogenic biliary vascular injuries.

**Aims & Methods:** Evaluate the role of intervention radiology procedures to manage different post-cholecystectomy complications focusing on the novel techniques to improve the final outcome. From June 2014 to June 2016, 30 patients presenting with post-cholecystectomy complications were referred to interventional radiology unit in our university hospital. They were 9 males and 21 females (age range: 18-66 years). Patients presented with biliary leaks (n=12), biliary strictures with intraparenchymal biliary dilations (n=21), postoperative hernia (n=2) and bleeding related to hepatic artery pseudo-aneurysm (n=1). Different types of interventional procedures were performed, including: Percutaneous trans-hepatic drainage (PTD) (n=16), sequential dilatation of biliary stricture with increasing catheter calibers over 6 months followed by manometric studies before catheter withdrawal (n=6), biliary stenting with plastic stent (n=2), Insertion of pigtail catheter (n=15), preoperative progressive pneumo-peritoneum for their adhesiolysis effect to manage post-operative huge incisional hernias before their surgical repair (n=1), and selective embolization of bleeding hepatic artery pseudo-aneurysm (n=1) using tissue adhesive (n-Butyl 2 Cyanoacrylate).

**Results:** All percutaneous procedures were technically successful. No recorded early or late complications. After manometric studies, all managed cases with biliary strictures did not show any clinical evidence of restenosis during 6 months follow-up. Overall, 14 out of 30 patients (46.7%) were only managed by different interventional radiology procedures. Second step surgical repair was needed for 13 patients (43.3%) and endoscopic managed for 3 patients (10%) with biliary leaks.

**Conclusion:** Minimally invasive interventions were valuable techniques in the management of different post-cholecystectomy complications. In fully equipped centers, expert multidisciplinary teams would achieve high cure rates for iatrogenic biliary injuries.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1590 WHAT IS THE ROLE OF ANGIOGRAPHY IN ACUTE COLONIC AND SMALL BOWEL BLEEDING?**

1Gastroenterology, Centro Hospitalar e Universitário de Coimbra, Coimbra/Portugal

**Contact E-mail Address:** rita.vale.rodrigues@gmail.com

**Introduction:** Angiography is a diagnostic and therapeutic modality that is widely available for upper gastrointestinal bleeding but is used less frequently when the source of bleeding is placed distally to the Treitz angle.

**Aims & Methods:** To assess the usefulness of angiography in the diagnosis of colonic and small bowel bleeding and to determine the efficacy and complications of therapeutic procedures. Retrospective study; we included all patients with colonic and small bowel bleeding that were submitted to arteriography with or without embolization, admitted to the gastroenterology department of a tertiary hospital between February 2006 and November 2016. Statistics: Chi-square/Fisher exact test, T-student.

**Results:** During the period 2006-2016 there were 68 evaluated, 63.6% male, mean age = 75 years (29–95). Angiography was done for: bleeding recurrence (36.2%), hemodynamic instability (33.3%), both (27.3%) or failure to endoscopic hemostasis (3%). The aetiology after angiographic study was: presumed diverticular (n=28), angiodysplasia (n=8), confirmed diverticular (n=6), tumoral (n=5), post-mucosectomy/polypectomy (n=4), unclarified (n=12), others (n=3): Dieulafoy, ileum ulcers, radiation proctitis. Angiography showed additional clinical information in 18.8% of patients (n=17). Twenty-three patients (34.8%) underwent arterial embolization, all with technical success, with bleeding recurrence in 3, of which only one was submitted to surgery; there were 2 cases of bowel ischemia. The reasons for deciding not to embolize were: absence of active bleeding (90.7%) and end-vessel bleeding (9.3%). There were no differences between the groups in demographic data, comorbidities, mortality, source of bleeding, haemoglobin at admission/diagnosis and coagulation (p > 0.05). Arterial embolization was more frequent if hemodynamic instability (p = 0.029); The average time of hospital stay was lower in the group submitted to embolization (8.8 vs 11.5 days, p = 0.014). Overall, 11 patients died, due to: re-bleeding/hypovolemic shock (n = 5), exacerbation of comorbidities (n = 3), hospital acquired infection (n = 2) or post embolization complication (n = 1).

**Conclusion:** Arteriography was a valid option for the diagnosis of colonic and small bowel bleeding; allowed therapeutic intervention in more than one third of patients, with 87% of clinical success and reduction of hospitalization time.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1592 PROPENSITY SCORE ANALYSIS OF 18-FDG PET/CT ENHANCED STAGING IN PATIENTS UNDERGOING SURGERY FOR OESOPHAGEAL CANCER**

1General Surgery, University Hospital Wales, Cardiff/United Kingdom
2Radiology, University Hospital Wales, Cardiff/United Kingdom

**Contact E-mail Address:** nelimalama@hotmail.com

**Introduction:** Surgery for radical treatment of oesophageal cancer carries significant inherent risk. Objectively Identifying patients that are high risk of complications is of importance. The aim of this study was to assess the prognostic value of physical fitness variables determined objectively by cardiopulmonary exercise testing (CPET) in patients undergoing potentially curative surgery for oesophageal cancer (OC) within an enhanced recovery programme.

**Aims & Methods:** Consecutive 180 OC patients (106 ACA, 11 SCC, 3HGID) underwent preoperative PET/CT with prospective recording of morbidity and survival. Non-parametric receiver operating characteristic (ROC) curves and logistic regression were used to assess the relationship between PET variables and post-operative morbidity severity score (MSS). 

**Results:** Of 180 patients, 120 were included for analysis (median age 65 yr., 100 male, 75 neoadjuvant therapy); 60 did not proceed to surgery and were excluded. Postoperative morbidity and mortality occurred in 83 (69%), CD ≥ 3 in 27, 22.5% and 4 (3.3%) patients respectively. ROC curve analysis showed oxygen uptake (peak V02) gave an area under the ROC of 0.66 (95% CI 0.55 to 0.77, p < 0.004, 0.015), and optimum cut-off of 28 ml/kg/min (sensitivity 53%, specificity 55%). Anaerobic Threshold (AT) gave an area under the ROC of 0.62 (95% CI 0.51–0.74, p = 0.048) and optimum cut-off of 10.5 ml/kg/min (sensitivity 60%, specificity 44%). Multivariable analysis revealed peak V02 to be the only independent factor to predict morbidity severity CD ≥ 3 (OR 0.85, 95% CI 0.75–0.97, p = 0.018). Cumulative survival was associated with operative MSS (Chi² 4.892, DF 1, p = 0.027) but not with PET variables. Conclusion: PET/CT is a significant predictor of morbidity after oesophagectomy with peak V02 the most important factor.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** masaty71222@gmail.com

**Introduction:** Although surgical techniques and perioperative management for esophageal cancer has been developed, it cannot be still safe to be performed esophagectomy. Therefore, endoscopic submucosal dissection (ESD) for the superficial cancer has been increased. We also need to consider the risk of lymph node metastasis before treatment in each patient and the aim of this study is to predict lymph node metastasis for superficial esophageal cancer.
Disclosure of Interest: Cancer surgery and ICW and SIR were the most important prognostic indicators.

Conclusion: In our series, patients used Positive Attitude to manage everyday life (oppositional strategies) or drugs to self-medicate (i.e. emotional indifference or drugs) were used, social abilities were compromised. Moreover, after surgical intervention coping seemed to be a stable feature. Therefore, in the early follow-up after surgery multidisciplinary team can identify and the coping features of patients in order to improve them to prevent QoL worsening.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1596 A RELIABLE AND ACCURATE ALGORITHM TO QUANTIFY THE TUMOR STROMA QTS AMONG TUMOR ENTITIES: HIGH INFLTRATION OF CD3+ AND CD8+ LYMPHOCYTES CORRELATES WITH IMPROVED SURVIVAL IN HEPATOCELLULAR CARCINOMA AND PANCREATIC CANCER

Introduction: The tumor micro environment plays a vital role in the growth of malignancies. Through for example tumor-infiltrating lymphocytes (TILs) it influences overall and disease free survival of patients in various cancer entities. Therefore, the aim of this study was to identify our own TIL quantification algorithm to optimize the accuracy of counting TILs with high reliability and reproducibility. The aim of this study is to describe coping styles and QoL after esophagectomy for esophageal cancer and therefore represent potentially reversible prognostic risk factors. Bioelectrical Impedance Analysis (BIA) is a non-invasive, easily reproducible and simple means of accurately measuring body composition.

Aims & Methods: The aim of this study was to assess the prognostic value of body composition variables determined objectively by bioelectrical impedance analysis (BIA). In this retrospective study, we evaluated potentially curvilinear surgery studies in thoracic oncology (OC) and gastric cancer (GC) within an enhanced recovery programme (ERP). Consecutive 168 OG patients [mean age 65 (24-86) yr., 131 male, 105 OC, 64 GC, 157 ACA, 8 SCC, 3 Neuroendocrine] underwent preoperative measurements of systemic inflammatory response [SIR, including FBC, CRP, Albumin, and modified Glasgow Prognostic Score (mGPS)]. Patients underwent multi-frequency (0.5 kHz, 50kHz and 100kHz) BIA assessment using a Maltron Bioscan 920 (Maltron International Ltd., Essex, UK), and Cardio Pulmonary Exercise (CPX) assessment was performed selectively (70 OC, 27 GC). Primary outcome measure was Clavien Dindo (CD) morbidity severity score (MSS) of 3.

Results: Oesophagectomy was performed in 106, gatrectomy in 64, and laparotomy only in 25 patients. Postoperative morbidity and mortality occurred in 75 (49 OC, CD ≥ 3 in 35, 21%) and 4 (2%) patients respectively. On univariable analysis, MSS ≥ 3 was associated with anaerobic threshold (p = 0.001), CRP (p = 0.001), mGPS (p = 0.011), intra-cellular water (ICW, p = 0.041), and extra-cellular water content (p = 0.015). Multivariable binary logistic regression revealed ICW content [IQ vs. UQ CD ≥ 3, 35, 37%, OR 1.32 (95% CI 1.06–1.61). ICC ≥ 3, 37%, OR 1.03 (0.99-1.06) p = 0.076] to be independently associated with MSS.

Conclusion: Flow variability in morbidity severity was observed after OG cancer surgery and SIR were the most important prognostic indicators.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1594 PROGNOSTIC SIGNIFICANCE OF CARDIORESPIRATORY FITNESS, BODY COMPOSITION ANALYSIS, AND SYSTEMIC INFLAMMATORY RESPONSE IN UPPER GASTROINTESTINAL CANCER

2Esophageal And Digestive Tract Surgical Unit, Regional Centre For Esophageal Surgery, Vercelli Hospital Onlus, Vercelli/Italy

Contact E-mail Address: luca.saadeh@gmail.com

Introduction: Coping is one the most challenging and burdening opera-
tion for its length and the variety of anatomical districts involved. Nowadays, as consequence of the improved postoperative mortality, effects of esophagectomy are chronic and quality of life (QoL) has become one of the main outcome measures of esophagectomy. In fact, QoL after esophagectomy is a relevant issue nowadays, especially after potentially curvilinear surgery studies in thoracic oncology (OC) and gastric cancer (GC) within an enhanced recovery programme (ERP).

Aim and methods: The aim of this study is to describe coping styles and QoL after esophagectomy for esophageal cancer. The aim of this study was to assess the prognostic value of body composition variables determined objectively by bioelectrical impedance analysis (BIA). In this retrospective study, we evaluated potentially curvilinear surgery studies in thoracic oncology (OC) and gastric cancer (GC) within an enhanced recovery programme (ERP). Consecutive 168 OG patients [mean age 65 (24-86) yr., 131 male, 105 OC, 64 GC, 157 ACA, 8 SCC, 3 Neuroendocrine] underwent preoperative measurements of systemic inflammatory response [SIR, including FBC, CRP, Albumin, and modified Glasgow Prognostic Score (mGPS)]. Patients underwent multi-frequency (0.5 kHz, 50kHz and 100kHz) BIA assessment using a Maltron Bioscan 920 (Maltron International Ltd., Essex, UK), and Cardio Pulmonary Exercise (CPX) assessment was performed selectively (70 OC, 27 GC). Primary outcome measure was Clavien Dindo (CD) morbidity severity score (MSS) of 3.

Results: Oesophagectomy was performed in 106, gatrectomy in 64, and laparotomy only in 25 patients. Postoperative morbidity and mortality occurred in 75 (49 OC, CD ≥ 3 in 35, 21%) and 4 (2%) patients respectively. On univariable analysis, MSS ≥ 3 was associated with anaerobic threshold (p = 0.001), CRP (p = 0.001), mGPS (p = 0.011), intra-cellular water (ICW, p = 0.041), and extra-cellular water content (p = 0.015). Multivariable binary logistic regression revealed ICW content [IQ vs. UQ CD ≥ 3, 35, 37%, OR 1.32 (95% CI 1.06–1.61). ICC ≥ 3, 37%, OR 1.03 (0.99-1.06) p = 0.076] to be independently associated with MSS.

Conclusion: Flow variability in morbidity severity was observed after OG cancer surgery and SIR were the most important prognostic indicators.

Disclosure of Interest: All authors have declared no conflicts of interest.

Comparison of manual counting to the computed methods showed mostly excellent accuracy of the obtained results using intraclass correlation with reliability analysis (ICC) and coefficient B with linear regression (B):
computed counting methods achieve mostly excellent accuracy. ISC is accurate for sections with high background staining. IAC can be used in sections with low background staining. With the QTS Algorithm quantification of cells in the tumor stroma is reliable and accurate. Furthermore, clinical correlations after the use of this algorithm show results according to the literature: High infiltration of CD8 + T lymphocytes correlates with favorable prognosis in HCC and PCa. The future use of immunoscopy systems may help to predict prognosis after resection.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1598 LIVER RESECTION IN OBESE PATIENTS WITH HEPATOCELLULAR CARCINOMA

Contact E-mail Address: iwama333b7@hotmail.com

Introduction: Liver resection disease has been recognized as a risk factor for hepatocellular carcinoma (HCC). On the other hand, there are few reports concerning liver resection (LR) in obese patients.

Aims & Methods: We performed curative LR in 471 patients with HCC between 2001 and 2015. In this study, we defined an obesity as no less than 25 of body mass index (BMI). We compared clinicopathological findings, operation details, and surgical outcomes of the obese and non-obese patients. Furthermore, we assessed the safety and the benefit of laparoscopic partial hepatectomy and left lateral segmentectomy in the obese patients.

Results: Among 471 patients, 123 patients (26.1%) were defined as obese. Among them, 20 patients (4.2%) showed no less than 30 of BMI. Diabetes, hypertension, and hyperlipidemia were significantly more common, and the patients with hepatic tumors in the obese patients group than in the non-obese patients group (p < 0.05). The two groups showed no differences in the liver function tests except the indocyanine green retention rate at 15 minutes. There were no significant differences between the two patients group in the number of tumors, diameter of tumor, prevalence of cirrhosis, frequency of portal invasion, the operative procedure, operative duration, blood loss, incidence of postoperative complications, postoperative hospital stay, and in-hospital mortality (3.3% vs. 1.4%). No significant difference was found in relapse-free survival rate, or overall survival rate between the two groups, too. Thirteen patients underwent laparoscopic surgery, and 34 patients had open surgery. The two groups showed no difference in the background, including BMI. However the operation time (265 min vs. 397.5 min) and the postoperative hospital stay (14 days vs. 18 days) were significantly shorter, and the blood loss (50 ml vs. 600 ml) was less in the laparoscopic surgery group than in the open surgery group (p < 0.05).

Conclusion: Liver resection in the obese patients with HCC was safe, and laparoscopic liver resection might be more useful for reducing the surgical stress and reducing the hospital stay.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1599 TIMING OF ELECTIVE CHOLOECYSTECTOMY AFTER ACUTE CHOLECYSTITIS - A POPULATION-BASED STUDY
A. Popowicz, G. Sandblom Department Of Clinical Science, Intervention And Technology, Karolinska Institute, Stockholm/Sweden

Contact E-mail Address: agnieszka.popowicz@ki.se

Introduction: Acute cholecystectomy as treatment of acute cholecystitis is standard of care. However, many patients are still treated conservatively and undergo elective surgery 2 weeks following the primary admittance is postulated as a good timing for an elective surgery but there are no studies on the optimal timing for delayed cholecystectomy.

Aims & Methods: The aim of our study was to determine when it is most advantageous to perform surgery less than 2 weeks after an episode of acute cholecystitis. All patients treated for acute cholecystitis in Sweden during the years of 2006 and 2013 were identified through the Swedish Inpatient Register. This cohort was cross-linked with the Swedish register for gallstone surgery. Choice of surgical outcome was retrieved with definition of a new arrival of endoscopy in the hospital. The impact of time from admission to surgery with regards to operative time, percentage of procedures completed with minimally invasive technique, peri and postoperative complications and bile duct injury or bile leakage was analysed with logarithmic transformation of time and multivariable logistic regression adjusting for gender and age.

Results: During the years 2006 to 2013, 31091 patients were treated for acute cholecystitis in Sweden. After exclusion of patients that did not perform surgery, were not registered in GallRiks and patients that were treated with acute cholecystectomy 5352 patients were identified that underwent planned surgery. In multivariate linear regression analysis with adjustment for gender and age the risk for peri- and postoperative complications, bile duct injuries and bile leakage and amount procedures not completed with minimally invasive technique decreases with time from the last hospitalization to surgery. All p-values < 0.05.

Conclusion: For those undergoing elective cholecystectomy after an acute cholecystitis the safety increases if surgery is performed later than 30 days after discharge.

P1600 MIXED REALITY SURGERY USING CT-BASED PATIENT-SPECIFIC IMMERSIVE 3D HOLOMAG ENHANCED SPATIAL IMMERSION IN HEPATO-PANCREATO-BILIARY AND GASTROINTESTINAL SURGERY
M. Sugimoto Graduate School Of Health Welfare Science, International University of Health Welfare, Tokyo/Japan

Contact E-mail Address: sugimotomaki@mac.com

Introduction: We developed a CT-based patient-specific holographic surgical simulation navigation system of immersive mixed reality (MR).

Aims & Methods: The aim of this study is to identify its benefit of simulating, analyzing and evaluating operative surgical treatment options in gastrointestinal and hepato-pancreato-biliary surgery.

We used our original immersive MR application using HoloLens, that is a pair of MR smartglasses built-in head-mounted display. By reconstructing the patient-specific 3D surface polygons of each organ out of the patient’s MDCT images, MR anatomy was displayed on the glasses three-dimensionally during actual surgery. The multi-touch interface and the gesture controlled manipulation by surgeons’ hands with surgical gloves was useful for intraoperative anatomical references of tumors and vascular position under sterilized environment. It allowed the user to manipulate the spatial attributes of the virtual and real anatomies, which can enhance spatial awareness. The use of our systems reduced the length of the operation and discussion time.

MR navigation assistance could support complex procedures with the help of pre- and intra-operative imaging with better visualisation of the surgical anatomy and spatial awareness with visualisation of surgical instruments in relation to anatomical landmarks.

Conclusion: We report illustrative benefits of the immersive MR in surgical planning, simulation, education, and image-guided navigation. This could overcome the limitations of the conventional image-guided surgery.

P1602 EFFICACY OF DOUBLE PIGTAIL STENT FOR POST OESOGASTRIC SURGICAL LEAKS NON LINKED TO BARIATRIC SURGERY: A PILOT BI-CENTRE RETROSPECTIVE STUDY

1. Dept. De Endoscopie Digestive, CHU Poitiers, Poitiers/France 2. Digestive Surgery, CHU Limoges, Limoges/France 3. Dept. De Endoscopie Digestive, CHU Poitiers, Poitiers/France

Contact E-mail Address: la.pagnon@gmail.com

Introduction: Post-surgical leaks are the first complication after non-bariatric oeso-gastric surgery in terms of frequency and morbidity. Anatomistic fistulae change the prognostic of the operated patient increasing the length of stay, increasing costs, increasing mortality and increasing risks of oncological recurrence. Surgery is still a possibility of treatment in particular in case of severe sepsis but the role of endoscopy developed with development of a new armamentarium of endotherapy dedicated to such complications. In cases of post laparoscopic sleeve gastrectomy leaks, a shift is ongoing between closure or diversion methods (Ovesco, clips, covered self expandable metal stents (SEMS)) and internal drainage (double pig tail stents). Two large studies have just reported a high efficiency and a low complication rate with internal drainage with double pig tail stents for post sleeve gastrectomy leaks. No data are available for such an endoscopic internal drainage in fistulas of the upper digestive tract non-linked to bariatric surgery. Here we report the results of a pilot bi-centre retrospective study.

Aims & Methods: A retrospective study of all upper digestive tract leaks non linked to bariatric surgery and treated by double pig tail stent (DPTS) in two...
Introduction: Abdominal compartment syndrome (ACS) is serious complication of big number of surgical interventions. According the data of the World Society of the Abdominal Compartment Syndrome (WSACS), rate of mortality without treatment is more than 90%, after treatment from 25% to 75% [1]. Patients with ruptured abdominal aortic aneurysms (rAAA) are the group of high risk regarding complication. Rate of incidence ACS at these patients is between 8% to 25%[2]. According to data of various authors, from one third to one half of them have died [3]. One of the main cause of this is the absence of good monitoring of intraabdominal pressure in this group of patients[4]. Currently, we have one effective way of treatment for this pathology: decompressive laparotomy[5]. But prophylaxis becomes more important point, if we take to attention mortality after start the develop of abdominal compartment.

Aims & Methods: We aimed to investigate the impact of implantation polypropylene mesh in abdominal wall on rate of development ACS and it severity for patients after open repairing of ruptured abdominal aortic aneurysm. Patients with rAAA (total amount n = 87 patients) were operated in standard volume. Before finish of surgery in study group (n = 49, 34 males, 15 females, average age 64 years (ages range from 25 to 77 years) patients had infrarenal type of rAAA. Middle laparotomy or thoracophrenodiaphragmal access was used. After surgery intraabdomenral pressure was controlled by intravesical method during first seven days after operation. We fixed rate of complication and mortality in both groups. We followed-up patients after surgery and controlled far outcomes too. First mesh implantation was performed at 24 February 2014, last at 03 March 2017.

Results: In study group we fixed 5 cases of ACS (10.2%), including 3 cases of light ACS (intraabdominal pressure (IAP) – 12–15 mmHg), 1 case of moderate ACS (IAP – 15–21 mmHg), and 1 case of severe ACS (IAP > 21–25 mmHg). Decompressive laparotomy was performed in one case with satisfactory result. In general, mortality in study group was 18.4% (9 cases). In control group we fixed 9 cases of ACS (23.7%), including 3 cases of light ACS (intraabdominal pressure (IAP) – 12–15 mmHg), 2 cases of moderate ACS (IAP 16–20 mmHg), and 3 cases of severe ACS (IAP 21–25 mmHg) and 1 case with very severe ACS (IAP more than 25 mmHg). Decompressive laparotomy was performed in three cases, satisfactory result was achieved in one case, in two cases patients have died from polyorgan insufficiency. In general, mortality in control group was 28.9% (11 cases). We did not find any specific complication, related with implantation of polypropylene mesh during all three years of follow-up.

Conclusion: 1. Implantation of polypropylene mesh is a safe and effective procedure for prophylaxis of ACS for patient with rAAA. 2. Implantation of mesh allows to avoid ACS for patient with rAAA and related with it complication and outcomes. 3. It is possible to implantate polypropylene mesh for other deseases, not only for rAAA, but this point requires further investigations.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: altorgebaptista@gmail.com

Introduction: Peritoneal collections and abscesses after Bariatric Surgery (BS) leaks are dreaded complications. Laparoscopic or open surgery and percutaneous CT drainage are the current indications. Endoscopic management of pancreatic collections is a rationale for Endoscopic Peroral Drainage (EPOD) approach in cases of BS leaks with abdominal collections.

Aims & Methods: The aim of this study is to evaluate utility and safety of EPOD to treat peritoneal collections and abscesses secondary to BS leaks. Methods: This retrospective study included 65 consecutive patients from 2007 to 2015 at a single center (40 Sleeve gastrectomy, 25 gastric bypass) after 5 to 21 days from...
surgery. Patients presented heart rate over 120 bpm. Images from CT showed left side free abdominal wall with no free abdominal membranes. An Upper Gastrointestinal (UGI) was performed to localize the leak opening and enter to peritoneal cavity. Either 9.8 or 5.8 mm diameter gastroscopy were used. In 10 patients with orifices smaller than 5.8 mm balloon dilatation of the leak opening allowed peritoneal access. The technique was performed under local anesthetic (100 to 700ml). Sample was taken for bacterial cultures. The cavity was flushed and suctioned out with sterile saline solution (200ml to 1000ml). In cases of inadequate location surgical drains catheters were repositioned or replaced using endoscopic forceps and snare. Fluid drainage was conducted using a ureter catheter. Replacement of urinary catheters was performed advancing with endoscopes through the leak all the way down to the skin. Once the tip of the endoscope was outside the peritoneum the latex drains were removed. Catheters were snared or grabbed and pulled back into the peritoneum leaving the proximal end close to the fistula opening. In 5 patients without surgical drainage systems one laparoscopic port was localized inside peritoneum and re-opened under endoscopic vision to allow drainage catheters placement. In 8 patients peritoneal adhesions were endoscopically lifted using endoscopic forceps and knives to facilitate peritoneal navigation.

Results: Heart rate returned to normal within 24 hours and leukocytosis improved after 72 hours. In 50% of patients heart rate returned to normal immediately. Average time for the whole procedure was 45 minutes. Abdominal catheters were removed between 7 and 18 days once full resolution of the drainage was achieved. Twenty patients were discharged within the first 24 hours. The rest were discharged between 3 and 8 days. Partially covered SEMS were placed for 6 to 8 weeks leading to complete closure of leaks. There were no adverse events related.

Conclusion: EPOD for peritoneal collections and abscesses secondary to BS leaks is feasible, safe and highly effective.

Introduction: Urinary metabolic profiling has been shown to distinguish patients with inflammatory bowel disease (IBD) from healthy controls (HC), and also separate ulcerative colitis (UC) from Crohn’s disease (CD) in Caucasian (Cau) cohorts (1). Diet and lifestyle also have an effect on metabolic profiles (2), and separate ulcerative colitis from Crohn’s disease from UC, replicating previous studies. South Asian IBD patients could not be separated from healthy controls which may be due to lower numbers of South Asian patients in this study, and specifically less Crohn’s disease patients where stronger discriminating models have been shown in Crohn’s disease in previous studies. In Crohn’s disease, Caucasians and South Asians could be separated, but Caucasian and South Asian patients could not be distinguished in the UC cohort, possibly suggesting the metabolic milieu in Crohn’s disease is stronger and less influenced by the impact of ethnicity.

Introduction: Reduced saccharolytic fermentation has been described in patients with quiescent ulcerative colitis (UC). Such defects may differ across colonic regions along with acute variations in dietary fibre intake. These aspects deserve further study.

Aims & Methods: We aimed to define regional colonic fermentation by direct intestinal pH-transit profiling in patients with quiescent UC following acute variations in fermentable fiber intake. A randomized, double-blind, crossover trial was performed. Patients with quiescent UC (Partial Mayo Score ≤1; faecal calprotectin <150μg/g) and healthy controls who were not taking any

Results: The phenotype of South Asian Crohn’s disease was not significantly different to Caucasian Crohn’s disease in this cohort. In the South Asian UC group there was more pancolitis (p = 0.051) and less proctitis (p = 0.008). There were more vegetarians in the South Asian group. OPLSDA was able to separate patients with IBD from healthy controls, and also UC from Crohn’s disease, in the Caucasian cohort, but this separation could not be replicated in South Asians (negative Q2 values).

Conclusion: The separation between Caucasian and South Asian healthy controls may reflect differing lifestyles including diet. Caucasian IBD patients could be separated from healthy controls, and Crohn’s disease from UC, replicating previous studies. South Asian IBD patients could not be separated from healthy controls which may be due to lower numbers of South Asian patients in this study, and specifically less Crohn’s disease patients where stronger discriminating models have been shown in Crohn’s disease in previous studies. In Crohn’s disease, Caucasians and South Asians could be separated, but Caucasian and South Asian patients could not be distinguished in the UC cohort, possibly suggesting the metabolic milieu in Crohn’s disease is stronger and less influenced by the impact of ethnicity.

Table 1: Colonic pH and transit responses to acute changes in fermentable fiber intake

Conclusion: A high fermentable fiber diet partially increased colonic fermentative activity in patients with quiescent UC compared to controls. Moreover, contrary to controls, UC patients exhibited an increase in distal pH and heterogeneous colonic transit responses after a high fermentable fiber intake. Our findings suggest that abnormalities in motility and regional defects in the function of the colonic microbiota exist despite quiescent disease.

P1610 FECAL MICROBIAL DYSBIOSIS IN CHINESE PATIENTS WITH INFLAMMATORY BOWEL DISEASE

H. Ma, H. Zhang
Department Of Gastroenterology, First Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu, China

Contact E-mail Address: mahaiqin2010@163.com

Introduction: Microbial dysbiosis in the gut has been suggested to play an important role in the pathogenesis of inflammatory bowel disease (IBD).

Aims & Methods: In this study, we aimed to analyze the fecal microbiota in Chinese patients with IBD. Fecal samples from 15 patients with Crohn’s disease (CD), 14 patients with ulcerative colitis (UC) and 13 healthy individuals were subjected to 16S rDNA sequencing. The V4 hypervariable regions of 16S rDNA were sequenced by the Illumina MiSeq2500 platform. Quality control and operational taxonomic units (OTUs) were calculated with QIIME software.

Results: Significant differences in community richness and microbial structure were observed both in CD and UC compared with normal controls. At the phylum level, analysis of the microbial compositions revealed that the Proteobacteria percentages, were significant higher in IBD than in controls. While at the genus level, we found that the abundance of Ruminococcus gnavus was 23 genera in UC, particular the Escherichia genus, were significantly different when comparing with controls. We next surveyed the taxonomic composition distribution between different phases of disease, detecting that the abundance of the Bacteroides was significantly decreased in active UC group compared with inactive CD group. However, the Proteobacteria was only nominally increased in active CD relative to inactive CD, which did not hold significance after correction. Furthermore, the relative abundance of the Bacteroidetes, especially the Bacteroides, was negatively correlated with the calculated Crohn’s disease activity index (CDAI).

References: Our findings showed the specific characteristics and dysbiosis of fecal microbiota within Chinese IBD patients. In addition, the abundance of the Bacteroides was significant lower in active UC group than in inactive CD group which was negatively correlated with the CDAI, indicating that the Bacteroides could be related with the disease activity.

P1612 OGR1 (GPR80) EXPRESSION IS INCREASED IN INTESTINAL INFLAMMATION AND CORRELATES WITH DISEASE ACTIVITY IN PATIENTS WITH IBD

Gastroenterology And Hepatology, University Hospital Zurich, Zurich/Switzerland

Contact E-mail Address: karatharina.baebler@usz.ch

Introduction: The aim of this study was to elucidate the effects of iron supplementation on hypoxia-mediates responses in the intestinal epithelium. For this purpose, serum starved Caco-2 monolayers were subjected to normoxia (21% O2) or hypoxia (0.2% O2) in the presence and absence of ferric ammonium iron citrate (FAc) and the iron chelator deferoxamine (DFO). Total RNA was isolated and changes in the expression of tumor necrosis factor (TNF), interleukin (IL)-1β, MIT-1, and ferritin was assessed by real-time quantitative PCR. Western blot analysis was performed with antibodies against ferritin, p-CAF, HIF-1α, p-PTOR, and LC3. mRNA synthesis in Caco-2 cells under hypoxia was blocked using actinomycin D. Chromatin immunoprecipitation experiments were carried using antibodies against NF-κB and primers for promoter binding regions of TNF and IL-1β. Healthy volunteers (n = 10) were subjected to hypoxic conditions resembling an altitude of 4,000 m above sea level for 3 h using a hypobaric chamber. Serum samples were collected the day prior to hypoxia, and one day, one week and one month after hypoxia.

Methods: Environmental hypoxia has been established to influence the development of inflammatory bowel disease (IBD). Adaptation to low oxygen tension are mediated through hypoxia inducible factor (HIFs), which are tightly regulated by oxygen and iron levels through the action of hypoxiastylases. Dietary iron is mainly absorbed by duodenal enterocytes through the divalent metal transporter (DMT)-1. Iron is inside the enterocytes, it is either sequesentered into ferritin or transported out of the enterocyte into the circulation by ferroportin (FPN). Regulation of uptake, storage and export of iron is mediated by signals reflecting oxygen and intracellular iron levels in enterocytes, and systemic iron requirements. Central to systemic iron regulation is the liver hormone hepcidin, which regulates and is regulated by systemic iron levels. Heptcind expression is induced by cytokines and results in anemia of inflammation.

Results: Hypoxia induced the mRNA expression of TNF and IL-1β concomitantly to the pro-inflamatory role of NF-κB, which has been found that the abundance of Ruminococcus gnavus was significantly decreased in active UC group compared with inactive CD group. However, the Proteobacteria was only nominally increased in active CD relative to inactive CD, which did not hold significance after correction. Furthermore, the relative abundance of the Bacteroidetes, especially the
P1616 MICROBIAL PROFILE OF NEWLY DIAGNOSED PATIENTS WITH ULCERATIVE COLITIS DIFFERS WITH ETHNICITY: RESULTS OF AN INCEPTION COHORT TIME SERIES ANALYSIS

Contact E-mail Address: rm399@imperial.ac.uk

Introduction: Ulcerative colitis (UC) phenotype in South Asian (SA) migrants differs to Caucasians with a predominant pan-colonic extent. A separate study showed mucosal profiles with lower bacterial diversity in the SA group.2 The significance of these findings is unclear due to small sample size. Henceforth, a larger study was performed with a comprehensive analysis of microbiota in UC patients from different ethnicities.

Methods: Samples were collected from 48 UC patients recruited in a prospective inception cohort study at diagnosis (time point 1; months 0–3) and 2 further time points over one year (time point 2: months 4–8, time point 3: months 9–12). Patients were stratified by ethnic group (SA, Caucasian, Other), treatment (none, 5-ASA, Azathioprine and Steroids) and disease duration. Health controls (HC) were recruited locally among the staff at St. Marks Hospital. For 16S pyrosequencing the hypervariable region (V1) of the 16S rRNA gene was amplified by PCR. The amplicons were subjected to sequencing using Illumina MiSeq technology. The sequences were loaded onto the QiIME pipeline. Statistical analysis was performed using STAMP 2.1.2 software with Welch’s two-sided t-test for comparing two groups. Microbial richness was calculated based on Chao index. Weighted Unifrac metrics were applied to construct Principal Coordinate Analysis (PCoA) plots.

Results: Ninety-four faecal samples were collected. Sample collection for all time points included SA (n = 13), Caucasian (n = 9), healthy SA (n = 11) and healthy Caucasian (n = 12). There was no significant difference in relative abundance of bacteria between treatment groups (5-ASA, Azathioprine, Steroids, None) and time points (1 vs 3), comparing healthy SA and healthy Caucasians, there was only one significant difference in relative abundance of Clostridiales at the family level. (Increased in SA group). The Chao1 diversity index showed a trend towards lower diversity in the SA group compared to Caucasians although there was no significant difference. There were significant increases in Bifidobacterium, Bikenellaceae, Lactobacillaceae and Streptococaceae (Table 1) and significantly decreased relative abundance in Barnesiellaceae, Anaerostipes and Ruminococcaceae.

Conclusion: Increased Bifidobacteria and Lactobacillaceae in the SA group is consistent with the previous study. A possible explanation is the consumption of fermented foods in the SA group although there was no difference between healthy SA and Caucasian controls. There is a trend towards lower diversity in the SA group and reduced Bacteroides which are consistent with the UC dysbiosis described in the literature. Functional analysis of this unique microbial profile through metagenomic and metabolomic techniques may explain the different disease behaviour in the SA group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1614 VITAMIN D SUPPLEMENTATION REDUCES FAECAL CALPROTECTIN AND ALTERS INTESTINAL MICROBIOTA COMPOSITION IN PATIENTS WITH ACTIVE ULCERATIVE COLITIS

M. Garg1, P. Hendy1, S. Shaw1, N. S. Ding2, G. Hold3, A. Hart1
1Ibd Unit, St Mark’s Hospital, Harrow/United Kingdom
2School Of Medicine, University of Aberdeen, Aberdeen/United Kingdom
3Centre For Computational Systems Medicine, Imperial College, London/United Kingdom

Contact E-mail Address: philipendy14@gmail.com

Introduction: There is evidence for vitamin D as an immunomodulator in patients with IBD, but results from clinical trials to date are inconclusive. It is uncertain whether vitamin D supplementation may affect the intestinal microbiota.

Aims & Methods: This study aimed to assess the effect of vitamin D replacement in deficient patients with and without ulcerative colitis (UC) on inflammation and faecal microbiota. Vitamin D was replaced over 8 weeks to patients with active UC, inactive UC, and non-IBD controls with baseline 25(OH) vitamin D < 30 nmol/L, and markers of inflammation and stool collected for microbiota analyses by next generation sequencing.

Results: Eight patients with active UC, 9 with inactive UC and 8 non-IBD controls received 40,000 units of vitamin D weekly over 8 weeks. No demographic differences were noted across the groups. Mean baseline 25(OH) vitamin D levels were 34 (range 12–49) nmol/L. Vitamin D supplementation increased mean 25(OH) vitamin D to 111 (range 71–158) nmol/L (P < 0.001), and reduced parathyroid hormone levels from mean 4.3 to 3.3 pmol/L (p = 0.017). No change in baseline medications for UC took place in patients with UC, except for one patient with active UC who ceased his 5-aminosalicylic acid. Faecal calprotectin levels reduced from median 275 to 91 μg/g (p = 0.023) in patients with active colitis, but did not change in patients with inactive colitis or non-IBD controls. Similar improvements in albumin, platelet count and symptomatic disease activity indices were noted. No changes in overall bacterial diversity were noted. There was a trend towards an increase in abundance of Ruminococcus gnavus post vitamin D supplementation in active UC patients, but this did not reach statistical significance.

Conclusion: Vitamin D supplementation was associated with reduced intestinal inflammation in patients with active UC. A randomised controlled trial evaluating vitamin D in IBD is required along with further investigation of potential mechanisms by which vitamin D may alter specific microbial composition.

P1615 SUPPRESSION OF PHOSPHOLIPASE A2 OF INTESTINAL MICROBES MEDIATES ACUTE INFLAMMATION IN A GENETIC MOUSE MODEL OF ULCERATIVE COLITIS

W. Strengell1, S. Staffer2, N.C. Stuhrmann1, A. Gauss1, N. Burger1, D. Hornuss1

Aims & Methods: Attack by commensal microbiota is one component for induction of inflammatory episodes in ulcerative colitis (UC). In UC, the mucus layer is intrinsically devoid of phosphatidylcholine (PC) resulting in low hydrophobicity which facilitates bacterial invasion. Colonic ectophospholipase-carrying bacterial strains are likely candidates to break the PC mucus barrier. Therefore we aimed to evaluate the effect of phospholipase A2 (PLA2) inhibitors on inflammation in a genetic UC mouse model.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1616 THE IMPACT OF THE RS800516 POLYMORPHISM ON G PROTEIN-COUPLED RECEPTOR GPR65 (TDAG8) PH-ASSOCIATED SIGNALLING IN INTESTINAL INFLAMMATION

Aims & Methods: Attack by commensal microbiota is one component for induction of inflammatory episodes in ulcerative colitis (UC). In UC, the mucus layer is intrinsically devoid of phosphatidylcholine (PC) resulting in low hydrophobicity which facilitates bacterial invasion. Colonic ectophospholipase-carrying bacterial strains are likely candidates to break the PC mucus barrier. Therefore we aimed to evaluate the effect of phospholipase A2 (PLA2) inhibitors on inflammation in a genetic UC mouse model.

Result: Luminal UDCA-LPE reduced the PLA2 activity in stool by 36.4%.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1617 B2-STRUCTURING AND B3-PENETRATING PHENOTYPE IN CROHN’S DISEASE: CHANGING PATTERN OF MACROPHAGES POPULATION AND WNT SIGNALING

D. Ortiz-Masia1, P. Salvador1, D. Macias-Ceja1, L. Gisbert-Ferrándiz1, C. Hernández1, J.V. Esplugues3, M.D. Barrachina1, L. Gisbert-Ferrándiz1, J.V. Esplugues3, M.D. Barrachina1

Aims & Methods: The aim of the present study is to analyze the pattern of expression of macrophage markers and Wnt ligands in surgical resections from Crohn’s disease (CD) patients with different disease behavior. CD patients were categorized according to Montreal classification (age at diagnosis, location and behavior). mRNA was isolated from resections patients presenting an strictureing (B2) or a penetrating (B3) behavior or from patients with colorectal cancer (control). The expression of macrophage markers (CD206, CD68, iNOS, Arginase) and Wnt ligands was analyzed by RT-

Conclusion: B3-patients seem to present a higher infiltration of macrophages since increased expression of markers classically used to detect pro-inflammatory (CD86) and regulatory/pro-resolving/pro-fibrotic phenotypes (CD206, ARG) was detected in this group. These patients also presented a generalized overexpression of Wnt ligands together with augmented DKK1 mRNA levels. B2- patients showed a more complex situation with ligands that present increased (Wnt3), reduced (Wnt2B) or unchanged expression in the absence of significant variations in the levels of macrophage markers (Table). Relative expression levels were measured as fold change and compared with control group.

Introduction: The intestinal inflammation is reduced by electrical stimulation of the different vagus nerves. Cholinergic neural output may be a target to minimize tissue damage in autoimmune disease. Cholinergic neural output can modulate innate immune responses through stimulation of α7 nicotinic acetylcholine receptors (α7nAChR). GTS-21, a selective α7nAChR agonist, has previously demonstrated to inhibit the inflammation associated with rheumatoid arthritis (RA). In this study we investigate whether GTS-21 protects against DSS-induced colitis and its potential mechanism.

Aims & Methods: Male BABL/c mice (8–10 weeks old, n = 32) were randomly divided into 4 groups: normal control group, DSS-induced group, GTS-21 treatment control group (DSS-induced mice treated with GTS-21), -BGT group (DSS-induced mice treated with a-BGT and GTS-21) (n = 8, each group). DSS group was given final concentration of 3.5% DSS drinking water, the treatment group was treated with GTS-21 (20mg/kg intraperitoneal injection) per day, a-BGT group was pre-treated with a-BGT (0.1 mg/kg/day, intraperitoneal injec- tion) for 30 min prior to GTS-21 injection, and the control group received saline. Caco2 cells were randomly divided into 4 groups: normal control group, TNF-α-induced group, GTS-21 treatment control group, a-BGT group. TNF-α group of Caco2 cells were exposed to 25 ng/ml TNF-α, GTS-21 group were given 100 ng/ ml GTS-21 for 30min prior to TNF-α; a-BGT group pre-treated with a-BGT (50 ng/ml) for 30 min prior to GTS-21 injection. BAY 11-2058 (NF-κB inhibitor) group were given 50 ng/ml BAY-11-2058 for 30min prior to TNF-α. Disease activity index, macroscopic scores, and colonic damage were determined. The intestinal permeability of mice was measured by fluorescein-isothiocyanate-dex- tran (FITC-Dex). Western blot was used to detect the tight junction protein and NF-κB associated protein expression.

Results: Compared with DSS-induced mice, DAI score decreased and colonic length improved after administration of GTS-21 (9.1±0.74 cm vs 6.85 ± 0.53 cm, P < 0.01). The HAI score decreased (1.25±1.32 vs 10.5±2.64, P < 0.05). The α7nAChR antagonist a-BGT can eliminate those protective effects (Figure 1).

2. The intestinal permeability improved after administration of GTS-21 compared with DSS-induced mice (49.52 ± 28.59 µm vs 157.7 ± 32.40 µm/g P < 0.05), whereas a-BGT can block the effect (115.50 ± 11.0 µm/g vs 49.52 ± 28.59 µm/g P < 0.05) (Figure 2, 3). The expression and distribution of tight junction protein in DSS-induced mice were enhanced after treatment with GTS-21 (p < 0.05) (Figure 4, 5). GTS-21 attenuated the NF-κB activation (p < 0.05) (Figure 6). A-BGT induction reversed the inhibitory effect of GTS-21 (p < 0.05) (Figure 6). GTS-21 improves the distribution of tight junction proteins in the intestinal epithelial cells induced by TNF-α (Figure 7). GTS-21 reduces nuclear translocation of NF-κB in Caco2 cells induced by TNF-α (Figure 8).

Conclusion: Tha7 nicotinic acetylcholine receptors agonist GTS-21 can attenuate the intestinal inflammation in DSS-induced mice, which may be due to improving intestinal mucosal barrier function by enhancing the expression of tight junction protein.

P1621 ANAEMIA PREVALENCE AND TREATMENT APPROACH FOR INFLAMMATORY BOWEL DISEASE

G. Bengi1, H. Keyvan1, H. Akpinar2
1Gastroenterology, Dokuz Eylul University Hospital, Izmir/Turkey
2Internal Medicine, Dokuz Eylul University Hospital, Izmir/Turkey

Contact E-mail Address: drgokselbengi@hotmail.com

Introduction: For inflammatory bowel disease (IBD), anaemia is the most frequently observed extra intestinal finding, prevalence of which varies from 6% to 74%. It’s of great importance to determine and treat anaemia as it lowers patients’ life quality and leads to labour loss. The main causes of anaemia in IBD are iron deficiency anaemia (IDA) and anaemia of chronic disease (ACD).

In this study, we aim to specify the type and prevalence of anaemia along with a treatment approach for inflammatory bowel disease (IBD). We conducted a retrospective study on 465 patients, who were diagnosed with IBD and followed up at our hospital from June 2015 to June 2016 (male: 254; female: 211; average age: 47 ± 14.4, Crohn disease: CD: 257, Ulcerative Colitis (UC): 108; Crohn disease vs. Ulcerative Colitis: P < 0.001). According to WHO criteria, severe anaemia is defined as haemoglobin value is below 13g/dl in men and 12g/dl in women.

Results: In our study, we determined that 50.3% of total 465 patients had anae- mia, which was more frequent in women then men (64% vs. 39%, p < 0.001). Anaemia frequency was higher in CH cases (57%) then in UC cases (41%) (p = 0.001). CD involvement were as follows: 54.5% in ileal involvement, 60.4% in colonic involvement and 58.5% in ileocolonic involvement. Furthermore, 27.5% of UC patients had proctitis (E1) involvement while 41% of CD patients had involvement in left colon (E2) and 31.5% had pancolitis involve- ment. There was no significant relation between anemia frequency and duration of disease (p = 0.216). We specified the following types of anaemia: IDA only 32.9% (77), ACD only 5.5% (13), IDA and ACD combination 6.8% (16), anae- mia stemming from B12/folic acid deficiency 6.4% (15), and anaemia with no etiology 30.7% (72). 50% of patients with anemia received treatment; 23% of IBD patients had oral iron intake and 41% of them had parenteral iron treatment while 53% of patients who were suffering from megaloblastic anaemia got B12/folic acid treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference

A718 United European Gastroenterology Journal 5(5S)
Conclusion: We found out that almost half of all IBD patients (50.3%), whom we followed up, had anaemia, the most frequent reason of which was IDA. Almost half of these patients received anaemia treatment. We should increase the treat- ment rate in our IBD patients that have anaemia.

Aims & Methods: To analyse the interactions between immune and enteric neural cells, EGC isolated from the myenteric plexus of the rat digestive tract were co-cultured with CFSE-labeled T cells. Impact of T cell activation on neuro-immune interactions was investigated by treating T cells with anti-CD3/anti-CD28 antibodies. To determine whether inflammatory conditions favored the contacts between glial and immune cells, EGC were treated with LPS or TNF/IL1 prior their exposition to T cells. After 2 hours, non-adherent cells were removed and the T cells interacting with EGC (S100+) were counted. Immunocytochemistry were also used to characterize the subpopulations of T cells (CD4+, CD8+) that contact glial cells.

Results: Analyses reveal that non-activated T lymphocytes are capable of interacting with EGC. They also show that activation of T cells with anti-CD3/anti-CD28 antibodies increases the number of T lymphocytes interacting with EGC. Interestingly, an increased number of EGC-T cell interactions was observed after pre-treatment of EGC with inflammatory stimuli. This phenomenon was also noted with activated T cells. Characterization of T cells show that both CD4 and CD8 cells are capable of contact with EGC.

Conclusion: Our present data reveal that EGC interact with T cells. These contacts are favored by T cell activation but also by EGC exposure to inflammatory cytokines. Further experiments are required to characterize these neuro-immune interactions but they suggest that EGC-T cell contact may play a crucial role in case of inflammatory bowel diseases. This work is supported by the Association François Aupetit.

Introduction: Enteric glial cells (EGC) are essential to intestinal epithelial barrier (IEB) homeostasis. In healthy intestines, EGC reduce IEB permeability and promote mucosal healing. In inflammatory bowel disease (IBD) such as Crohn’s Disease (CD) and Ulcerative Colitis (UC), both EGC phenotype and IEB functions are altered, but putative involvement of EGC in IBD pathogenesis remains unknown. If the astrocyte reactivity is well studied, the reaction of EGC to chronic inflammation is not well documented. We investigated whether EGC impact on IEB permeability was altered in an inflammatory environment and in IBD patients.

Aims & Methods: Rat EGC as well as human EGC from control, CD and UC patients were stimulated with the cytokine T1 (TNFα+IL1beta; 1 to 100ng/ ml) or LPS for 2 or 4 days. Reactive EGC phenotype where characterized and reactive EGC functional impact on IEB permeability was studied (i) in vitro using human intestinal epithelial cells (IEC) in a non-contact co-culture model, or (ii) in vivo by grafting the treated rat EGC in colon wall of Sprague Dawley rats.

Results: Rat and human control EGC induced a significant reduction of IEB permeability after T1 treatment when compared with untreated or LPS treated EGC. LPS or T1 treatment had no significant effects on IEB. In vivo colon wall grafting with control EGC did not modify the permeability whereas colon wall grafting with EGC preconditioned by T1 significantly reduced

Conclusion: ZIP7 induces disruption of the intestinal barrier, which was associated with activation of endoplasmic reticulum stress in IBD. It is expected to provide a novel mechanism of IBD and provide a new target for the treatment of IBD.

Disclosure of Interest: All authors have declared no conflicts of interest.
the permeability when compared to control animals. Human EGC from control or UC patients treated with T1 induced a decrease in IEB permeability too, but EGC from CD patients did not.

Conclusion: This work is not only the first evidence showing that reactive EGC can have beneficial effects upon IEB permeability, but also shows that EGC from CD but not UC patients have lost these reactivity. This could define EGC as active players in CD pathogenesis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1626 PROSTACYCLIN REVERSES COLITIS THROUGH THE DOWN REGULATION OF INTESTINAL EPITHELIAL PERMEABILITY

Introduction: In inflammatory bowel disease (IBD) both intestinal epithelial barrier (IEB) permeability and PTGIS expression are altered. Nevertheless the role of the lipid mediator PG12 produced by PTGIS in IEB regulation is unknown. The present study concerns the control of IEB permeability by PG12 and its involvement in the development of colitis.

Aims & Methods: Induction of permeability from control or IBD biopsies was established using high sensitivity liquid chromatography tandem mass spectrometry. Consequences of flosan PG12 analogous supplementation were evaluated in a DSS-induced mice model of colitis, measuring disease activity index (DAI), inflammation (pro-inflammatory cytokine mRNA) and IEB permeability (sulfonic acid flux). Molecular mechanisms involved were assessed by quantification of junctional and pro-proliferative vs pro-apoptotic protein expression (western blot and immunostaining). Eventually PG12 impact on reversing IEB breakdown was assessed ex vivo measuring permeability of mice or human mucosal explants treated with staurosporine apoptosis inducer, or permeability of IBD biopsies both treated or not with flosan.

Results: Biopsies from IBD patients had lower PG12 production compared to control patients, and addition of flosan reduced their permeability. In vivo PG12 supplementation significantly reduced DAI, and inflammation (Interferon mRNA) as well as reduced IEB permeability. DSS-inducedavage of Caspase 3 is normalized by flosan. Ex vivo, staurosporine-induced permeability of mice or human mucosal explants is entirely inhibited by flosan.

Conclusion: This study not only presents a role of PG12 in controlling IEB permeability by the regulation of apoptosis mechanisms, but also reveals that increased permeability in IBD patients can be fixed by PG12 supplementation.

Introduction: 7α-hydroxy-4-cholesten-3-one (7HCO) is a reliable method to diagnose bile acid malabsorption (BAM). Since 7HCO is an intermediate metabolite in the bile acid synthesis, increased levels reflect bile acid production, which is the case in BAM.

Aims & Methods: We evaluate retrospectively, prospectively collected clinical data during the first year after implementation of a new test using ultrahigh performance liquid chromatography coupled to mass spectrometry to measure 7HCO (see reference). In adult patients with clinical suspicion of BAM, unexplained diarrhea and a subgroup with obesity 7HCO was measured. Levels <30 ng/mL are considered as normal values. The decision to treat with cholestyramine was at the discretion of the treating physicians.

Results: We performed 126 7HCO analysis in 112 patients (62% female, mean age 51+-16 years) with a mean level of 84 +/- 91 ng/mL. Cholestyramine treatment was more likely initiated in patients with Crohn’s disease (RR 1.8; 95%CI 0.9-3.7) or ileocecal resection (RR 3.1; 95%CI 1.7-5.7). Diarrhea improved in 60% of patients with a 7HCO level above 40 ng/mL. Thresholds of 60 or 100 ng/mL do not improve prediction of response to cholestyramine treatment.

Conclusion: A 7HCO measurement above 40 ng/mL seems to be associated with a good response to cholestyramine treatment, which suggests clinical bile acid malabsorption. However, most patients have higher levels, particularly in Crohn’s disease after ileocecal resection. These preliminary results warranted confirmation on a larger scale.

Introduction: Ulcerative colitis (UC) is a clinical type of inflammatory bowel diseases, The pathogenesis of UC remains unclear. Nowadays the role of T-helpers type 17 (Th17) as well as cytokines they release is discussed in pathogenesis of autoimmune inflammation in UC.

Aims & Methods: The aim of study is to analyze the serum levels of following cytokines: interleukin (IL)-17A and F, 21, 22, 23 in UC patients both in the acute stage of disease and remission.Forty eight UC patients in the acute stage and twenty patients in remission were included into the study. Serum cytokine levels were analyzed using multiplex immunoassay for Th17 cytokines (Bio-Rad, USA). Statistical analysis was performed using STATISTICA 6.0 Software Package. The control group consisted of 11 healthy volunteers.

Results: Statistically significant increase of IL-17A level (15 pg/mL [12.11;23.38]; 14.68 pg/mL [11.29;17.19] respectively) was observed in patients with UC both in acute stage and remission compared to controls (7.36 pg/mL [5.18;8.06], p=0.00007, #Validation Range 5–300 ng/mL respectively). The same trend was observed regarding IL-7, which median values were higher both in acute stage (156.51 pg/mL [133.44;233.53]) and remission (144.02 pg/mL [133.44;154.43]) compared to control group (98.31 pg/mL [89.14;124.86], p=0.00007, p=0.00029 respectively). The same trend was observed regarding IL-21, which median values were higher both in acute stage (5.1 pg/mL [4.03;6.01] compared to controls, however differences were not statistically significant (p=0.06; p=0.172 respectively). Increase of described cytokines levels could be a sign of Th17 functional overactivity suggesting autoimmune type of inflammation.Statistically significant increase of IL-10 in remission (27.99 pg/mL [17.53;33.55]) compared to controls (4.36 pg/mL [3.26;15.25], p=0.0046) was found as well. IL-10 was also higher in patients with acute stage (21.93 [3.61;33.55] compared to controls, however differences were not statistically significant (p=0.06; p=0.172 respectively).

Conclusion: Increase of IL-17A, IL-17F, IL-21, IL-22 levels could be a sign of Th17 functional overactivity suggesting autoimmune type of inflammation. IL-17A and IL-21 produced by Th17 cells might be considered as markers of active autoimmune inflammation in UC patients.

Introduction: The steroid-refractoriness is a common complication of ulcerative colitis (UC), and an unpreventable clinical mechanism of action (MoA) has been implicated in corticosteroid failure. However, there are no conclusive studies on the molecular functions involved in UC steroid-refractoriness.

Aims & Methods: Therefore, we decided to know in depth the MoA related to the steroid-refractoriness. Aims of this study were: 1) to look for the expression of ANP32e in steroid-refractory UC patients with UC steroid-refractoriness involved chromatin remodeling modifications. The results of these comparisons were integrated into mathematical models generated by means of Systems Biology.

Results: These models reproduced the updated molecular interactions on glucocorticoids and UC, and integrating our experimental data, we identified a potential MoA that includes 64 key proteins, 18 of them capable of perfectly classifying patients with a good response to glucocorticoids and the non-responders. The biological functions of these proteins have been associated with inflammation (e.g. RelA), glucocorticoid receptor transcription (e.g. NRC1 and NCOA3) and angiogenesis (e.g. VEGF), mainly. But among these 18 proteins, the APN32e has never been related to either steroid-refractoriness or ulcerative colitis. APN32e is a putative NACHT-H2A.Z exchange (H2A.Z is part of the nucleosomes 26) and DNA from rectal biopsies was obtained before and on the 3rd day of glucocorticoid treatment. Then, whole-genome expression profiles using microarrays (Illumina, USA) and profiles microRNA by sequencing (Illumina, USA) were analysed. After quality control, omics data were compared between phenotypes. The ANP32e expression was significantly correlated with the CDAI score at 4 years (r = 0.01) and at 5 years (r = 0.68). Differently, in the ileal biopsies at 6 months, colonic phenotype of the ileum and the expression of ANP32e had a negative correlation (r = -0.003). The percentage of expression of sulfomucins in the ileal biopsies at 12 months was higher in patients with UC steroid-refractoriness involved chromatin remodeling modifications. The Spearman correlation test, differences between groups by".

Introduction: The intestine is populated with myriads of bacteria, which form a complex ecosystem and have tremendous impact on our health. In inflammatory bowel disease (IBD), shifts in microbiota composition and a reduction in overall diversity have been described. There are attempts to therapeutically transfer the microbiota might have beneficial effects during intestinal inflammation and opens the possibility to systematically study the effect of genetic alterations in donor and/or recipient on the outcome of FMT.

Methods: To analyse the effect of co-housing of experimental mice with healthy mice, results of expression of ANP32e and in the nuclear localization at baseline, between patients with a good response to glucocorticoids and the non-responders. The MoA was significantly correlated with the CDAI score at 4 years (r = 0.01), and at 5 years (r = 0.68; p = 0.001). A total of 132 patients with IBD were randomly assigned to single each influenza strain was measured by inhibition of hemagglutination. (end of influenza season) in the single group and 4 points in the booster group collected at 3 points (before vaccination, 4 weeks after vaccination and after the rivalent influenza vaccine was administered subcutaneously. Serum samples were assigned to adult patients with crohn’s disease or ulcerative colitis, and quad-monotherapy and 20 received anti-TNF-alpha single agent therapy. Nineteen patients received combination therapy of immunosuppressant and anti-TNF-α agents.

Aims & Methods: Single vacation group and booster group were randomly assigned to adult patients with crohn’s disease or ulcerative colitis, and quadrivalent influenza vaccine was administered subcutaneously. Serum samples were collected at 3 points (before vaccination, 4 weeks after vaccination and after the end of influenza season). Antibody titers against each influenza strain were measured by inhibition of hemagglutination.

Results: A total of 132 patients with IBD were randomly assigned to single vacation and booster groups. Eighteen patients received immunomodulatory monotherapy and 20 received anti-TNF-alpha single agent therapy. Nineteen patients received combination therapy of immunosuppressant and anti-TNF-α agents. No significant difference between the single vacation group and booster group was observed (geometric mean titer: H1N1: p = 0.81; H3N2: p = 0.79; B:Phuket: p = 0.82; B:Texas: p = 0.84). In patients treated with infliximab, serum levels of anti-influenza A antibodies were higher than in patients receiving no immunosuppressant therapy. In patients treated with infliximab, serum levels of anti-influenza B antibodies were also higher than in patients receiving no immunosuppressant therapy.

Conclusion: Serological response rate to influenza vaccination was low in IBD patients receiving immunosuppressant therapy, especially infliximab, even with a quadrivalent influenza vaccine.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The aim of the study was to assess AC HPV infection prevalence and its risk factors in a gastroenterology population. The "Human PAPILLOMAVIRUS Anal infection - PAPILLAN" study took place in a French university hospital gastroenterology unit. Consecutive patients were prospectively recruited at the occasion of a colonoscopy, whatever the indication. On the colonoscopy day, under local anesthesia, AC smear was sampled with a dedicated brush for molecular analysis. HPV detection and genotyping was performed with the INNO-LiPA assay. Risk factors for any HPV, and high risk (HR) HPV infection were assessed by bivariate and multivariate analysis after logistic regression.

Results: A total of 469 consecutive patients (median age 54 years, 52% women) had suitable anal swabs for HPV DNA detection. Among them 101 had immunosuppressive bowel disease (IBD), 70 had CD. 112 patients had at least one immunosuppressive treatment for IBD or another condition. Overall 34% of the population had a detection of any HPV type in AC smears. HR HPV prevalence was 18%, LR HPV prevalence was 9% and HPV16 prevalence was 7%. Most prevalent HR HPV types were, by decreasing order, HPV16, HPV51, HPV52 and HPV39. Among all patients with HPV positive or HR HPV positive samples, 65.6% and 65.9% were women, respectively (p = 0.0001; p = 0.0035, compared to men). Regarding medical history, HR HPV and HPV16 prevalence were significantly higher in Crohn’s disease (CD) patients (35.4% vs. 30.4% and 9.7% vs. 4.7%, p < 0.001; 14% vs. 7.1%, compared to the rest of the study population). Eleven/12 patients (50%) with perianal CD had an AC infection with any HPV. Multivariable analysis associated female gender and history of sexually transmitted disease with the presence of any HPV in AC; and female gender, history of sexually transmitted disease, lifetime and past year number of sexual partners, active smoking and immunosuppressive treatment (OR 5.3) with the presence of HR HPV.

Conclusion: We demonstrated that CD patients harbor more frequent AC infection with HR HPVs and that immunosuppressive treatment is an independent risk factor for HR HPV infection at this site. These findings strongly support prophylaxis with vaccination and adequate screening in our patients.

Introduction: Extended spectrum beta-lactamase producing Enterobacteria (ESBL-E) is the most frequently found multi-drug resistant bacterium colonizing the gut of inflammatory bowel disease (IBD) patients. Changes in the microbiome may act as a trigger in IBD inflammation process. Aims & Methods: The aim of the study was to analyze whether gut colonization with ESBL-E is associated with clinically relevant disease activity increase in ulcerative colitis (UC) and in Crohn’s disease (CD). All consecutive patients with confirmed UC and CD diagnosis, previously hospitalized in two largest tertiary medical care centres in Riga, Latvia during a 7-year period (2010-2016) were included in the study, interviewed, rectal swabs were collected, Enterobacteria were cultured and analyzed for ESBL presence according to EUCAST guidelines. To clinically evaluate disease activity UC patients were evaluated according to Mayo score, Montreal classification, adapted Truelove and Warren's criteria and CD patients according to Crohn's disease activity index (CDAI), suggested by ECCO IBD guidelines (2016).

Results: A total of 101 patients with UC and 47 patients with CD were tested for gut colonization with ESBL-E. We found that 12 (11.9%) of the UC patients and 5 (10.6%) of the CD patients were colonized with ESBL-E. Statistical significant differences were found in all UC clinical disease activity scores between patients with and without gut colonization with ESBL-E and showed tendency towards statistical significance in CD. The mean disease activity according to Mayo score in UC patients without ESBL-E colonization was 3.44 (SD = 2.07), whereas in patients with ESBL-E colonization it was 5.08 (SD = 2.84) (p = 0.015). Most of the UC patients without ESBL-E colonization (n = 63; 70.8%) were in clinical remission, whereas half of the patients with ESBL-E colonization (n = 6;
50% had mild to moderate to severe disease activity, according to Montreal classification disease activity section (p = 0.037). Most of the UC patients with out ESBL-E colonization (n = 88; 91%) had mild disease activity, whereas half of the patients with ESBL-E colonization (n = 6; 50%) had moderate disease activity, according to modified Truelove and Witt’s criteria (p < 0.001). Most of the CD patients without ESBL-E colonization (n = 38; 90%) had moderate disease activity, whereas most of the patients with ESBL-E colonization (n = 3; 60%) had severe disease activity, according to CDAI (p = 0.05).

Conclusion: Gut colonization with ESBL-E might increase disease activity in outpatients. Further studies could be clinically relevant and help to improve diagnostic and treatment protocols for IBD patients, because eradication of ESBL producing bacteria might reduce IBD disease activity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Smoking has a differential effect on inflammatory bowel diseases (IBD); deleterious for Crohn’s disease (CD) and protective for ulcerative colitis (UC). Thickness of the mucus layer, immune system (cytokines production), microvascular and intestinal microbiome are potential mechanistic factors influenced by the nicotine and numerous other substances. It has been hypothesised that smoking cessation is associated with the second peak of diagnosis in UC patients after 50 years old. Our aim was to confirm this hypothesis using data on smoking status at IBD diagnosis.

Aims & Methods: Adult IBD patients included in the Swiss IBD cohort from November 2006 to November 2015 were asked about their smoking status at diagnosis. We compared the proportion of former smokers in 10-year groups of UC and CD patients.

Results: 2361 IBD patients (1366 CD, 995 UC) were included in the analysis. Among them 52% of CD ans 24% of UC patients were smokers at diagnosis (proportion of smokers in Switzerland (2014): 29%). The higher proportion (66%) of former smokers at diagnosis was in the 30 to 60 years old group of UC patients compared to only 26% in CD patients between 40 to 50 years old (p = 0.001). On a gender basis, the higher proportion of former smokers is particularly significant high among male 50–60 years old with UC (68%) and CD (62%) and among female 40–50 years old with UC (36%) and CD (29%). The proportion of former smokers at diagnosis increases dramatically and significantly over 60 years old (52%).

Conclusion: The proportion of former smokers at diagnosis increases dramatized and significantly over years in UC patients compared to CD patients. A possible explanation for this could be the indirect effect of smoking cessation on the second peak of diagnosis in ulcerative colitis.

Introduction: In aetiology of inflammatory bowel disease (IBD) role of microorganisms including those from the oral cavity is taken into account. Oral bacteria are known for biofilm formation and enamel demineralisation leading to the formation of cavities.

Aims & Methods: The aim of the study was to determine the state of hard teeth tissues measured by DMFT index in adult patients with ulcerative colitis (UC) and Crohn’s disease (CD). The study involved 119 UC and CD patients aged from 18 to 72 (mean 34.45). Disease phenotype at diagnosis was classified according to the Montreal classification and only the patients who had undergone surgical intervention of the entire UC tract were included. Following, the data on the occurrence of extraintestinal symptoms, the incidence of IBD in the family, type of treatment, including surgery, were also collected. The complete assessment of the hard teeth tissues based on the DMFT index (decayed, missing, filled teeth) was performed.

Results: The study population was characterized by a high DMFT index with mean value 19.35. There was a significantly higher number of filled (F) and lower number of lost teeth (M) among patients who underwent respective surgery.

Conclusions: Smoking increased in women with CD, unrelated to disease activity, compared to healthy women. The study population was characterized by a high DMFT index with mean value 19.35. There was a significantly higher number of filled (F) and lower number of lost teeth (M) among patients who underwent respective surgery.

Introduction: Crohn’s disease (CD) is a chronic inflammatory disease that can affect any section of the gastrointestinal tract. Malnutrition is a common sequela in these patients and many pathogenic mechanisms could be involved such as poor dietary intake, altered energy expenditure, nutrient malabsorption and/or losses.

Aims & Methods: This cross-sectional study aimed to evaluate the resting energy expenditure (REE) in CD patients, in accordance with clinical status of disease, compared to a control group.

Methods: All consecutive adult CD women were prospectively enrolled, while a group of healthy women, matched for age and weight, served as control group (C). CD women were classified in clinically active disease (CD-A) and clinical remission (CD-R) according to Crohn’s Disease Activity Index (CDAI) (>150 and <150, respectively). All subjects underwent REE measure by indirect calorimetry with a canopy system, while body composition variables, such as fat-free mass (FFM) and fat mass (FM), were assessed by bio-impedance analysis (BIA).

Results: Finally, forty-two women with CD, 23 with clinically active disease (CD-A; CDAI = 219 ± 53) and 19 in clinical remission (CD-R; CDAI = 83 ± 41) were recruited for the study, while 40 matched-healthy women were enrolled as control group (C). We found that body weight, FFM and phase angle (PA) differed among groups; nevertheless when it was adjusted for FFM, we observed that body weight was significantly lower for CD-A in comparison with C (CD-A: 6.5 ± 3.5 kg vs C: 6.9 ± 3.8 kg; p = 0.02). FFM was reduced in women with CD than C (CD-A: 39.6 ± 4.3 kg and CD-R: 39.5 ± 6.8 kg vs C: 44.4 ± 4.8 kg; p < 0.01) while PA was lower for CD-A compared to both CD-R and C (CD-A: 45.5 ± 0.6 vs CD-R: 60.0 ± 5.4 and C: 61.1 ± 5.4; p < 0.001). REE did not differ among groups; nevertheless when it was adjusted for FFM, we observed that REE/FFM increased for both CD-A and CD-R groups compared to C (CD-A: 4.96 kcal/kg vs C: 4.63 kcal/kg; p < 0.01). REE did not differ among CD-A and CD-R groups.

Conclusion: These preliminary results show that REE, when adjusted for FFM, is increased in women with CD, unrelated to disease activity, compared to healthy subjects and this could negatively affect the energy balance and contribute to weight loss.

Contact E-mail Address: arthurbelle@hotmail.fr
Introduction: Primary sclerosing cholangitis (PSC) is a rare and devastating complication of inflammatory bowel disease (IBD). There is no standard for the screening of primary sclerosing cholangitis (PSC) in patients with IBD. Magnetic resonance cholangiography (MRC) may replace liver biopsy in this clinical situation. The main objective of this prospective observational study was to assess the frequency of MRC-detected liver diseases, including PSC, in adult IBD patients with liver function abnormalities and to identify clinical and biological characteristics associated with these findings.

Aims & Methods: From June 1, 2009 to January 31, 2017, 421 patients were included and screened with MRC: cohort 1 included 206 IBD patients with liver abnormalities; cohort 2 included 28 IBD patients without liver abnormalities; and cohort 3 included 187 non-IBD patients with liver abnormalities. Two senior radiologists independently evaluated MRC findings.

Results: MRC abnormalities were observed in 18% of patients in the cohort 1; 3.6% in the cohort 2 and 31% in the cohort 3 (Table 1). Based on MRC, we found respectively 11.2%, 0%, and 7% of PSC in cohorts 1, 2, and 3. 29.2% of IBD patients with liver abnormalities had infra-clinical PSC. A history of post-intestinal resection (P = 0.0357), abnormal gamma-glu-tamyl transferase values (P = 0.0064), and abnormal alkaline phosphatase values (P = 0.021) were significantly associated to suspected PSC.

Table 1: MRC abnormalities in cohorts 1, 2 and 3

Conclusion: Using MRC in patients with IBD, we found a higher prevalence of PSC than based on clinical symptoms. Systematic screening for PSC using MRC could be recommended in routine practice for IBD patients.

Introduction: Malnutrition and altered body composition can develop in patients with inflammatory bowel diseases (IBD) for a variety of reasons. Malnutrition and sarcopenia may worsen disease outcome in chronic disorders, raise the risk of infections and hospitalisation.

Aims & Methods: We followed 198 IBD outpatients (144 CD and 54 UC) for 3 years to indentify potentional risk factors of unfavourable disease outcome. Baseline body composition were measured by bioelectrical impedance analysing (BIA) method to evaluate nutritional status. Penalized logistic regression was used for the multivariate modelling of the outcome, with two sets of -prespecified - predictor variables age, sex, CU/CD, BMI, FFMI.

Results: According to our results 19.2% of the patients (n = 38) were underweight (had BMI < 18.5 kg/m²) and 29.8% (n = 59) had alarming low fat-free mass index (FFMI) and were at risk of sarcopenia. Overall 31.5% (n = 62) of the patients needed steroid therapy and 53.5% (n = 106) was given anti-TNF. Almost third of the participant (30.8%, n = 61) was hospitalized due to disease flair or its complication at least once during the follow-up time. The mean period of hospitalization was 19.14 ± 32.7 days. 20.2% (n = 40%) of all participants have undergone intestinal surgery. Hospitalization was positively associated with sarcopenia risk: alarming low FFMI was associated with an OR of 3.06 (95% CI: 1.01–9.40, p = 0.0456). The risk of operation was higher in patients with lower BMI: OR = 1.55 (95% CI: 1.05–2.29, p = 0.0277) for 5 units decrease; no other association was significant in the models.

Conclusion: Our results suggests that low BMI is a risk factor of surgery in inflammatory bowel disease patients. Furthermore alarming low FFMI is a pre- dictor of need of hospitalization and that suggests more serious flares. Identification of malnutrition and altered body composition has notable impor- tance in disease outcome among IBD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.
P1643 CONTRAST-ENHANCED ULTRASOUND IS HELPFUL IN THERAPEUTIC DECISION MAKING IN PATIENTS WITH STRICTURING CROHN’S DISEASE

Z. Zelinkova1, B. Kadlecova2, D. Podmanicky1
1Department Of Gastroenterology, St Michael's Hospital, Bratislava/Slovak Republic
2IBD Center, Bratislava/Slovak Republic
3Department Of Surgery, St Michael's Hospital, Bratislava/Slovak Republic

Contact E-mail Address: zuzana.zelinkova@nmss.sk

Introduction: The majority of Crohn’s disease (CD) develop structuring complications of the disease at some point. The proper selection of patients with potential benefit of therapy escalation is crucial in order to avoid unnecessary bowel resections and to avoid the affected bowel segment. At intravenous contrast-enhanced ultrasound (CEUS) has been shown to correlate with disease activity but there are no data available on the benefit of CEUS for the therapeutic decision making in this clinical setting.

Aims & Methods: The aim of the study was to evaluate the clinical outcomes of CD patients with stricturing disease managed based on the CEUS findings. CD patients with stricturing disease were recruited from two IBD centre between June 2015 and February 2017. Patients with penetrating disease complications were excluded. CEUS was performed using 2.4 mL of intravenous contrast (SonoVue, Bracco Imaging). Patients having rapid uptake (within 20 second after injection) were indicated for therapy escalation, patients without uptake with obstructive symptoms were referred for surgery, patients without uptake and no obstructive symptoms remained at the stable medication. In patients with the minimal follow-up of one year clinical and endoscopic remission was evaluated.

Results: In total, 27 patients were included (10 men; median age 37 yrs, range 23–67; 22 pts with ileo-coecal localization, 3 pts with multiple small bowel segments involvement, 2 pts with colonic disease). Seventeen patients (63%) had rapid uptake at the CEUS; 13 of these patients had therapy escalation (3 pts intensification or switch of another biological; 10 pts had therapy step-up to antiTNF or immunomodulator). Remaining 10 pts were stable on their ongoing medication. Patients who underwent surgery in the group with rapid uptake, all but two patients achieved sustained remission after therapy escalation. Two patients initially responded to therapy but have lost response and eventually needed surgery. For surgery. Three patients had no symptoms and no therapeutic changes were made. Twenty-five patients had follow-up longer than 12 months (median 18 months, range 13–23). In the group of patients with rapid uptake, all but two patients achieved sustained remission after therapy escalation. Two patients initially responded to therapy but have lost response and eventually needed surgery. In the group with rapid uptake, patients without surgery remained in remission without any changes in the medication. Patients who underwent surgery in the group with rapid uptake, all but two patients achieved sustained remission after therapy escalation. Two patients initially responded to therapy but have lost response and eventually needed surgery. In the group with rapid uptake, patients without surgery remained in remission without any changes in the medication. Patients who underwent surgery in the group with rapid uptake, all but two patients achieved sustained remission after therapy escalation. Two patients initially responded to therapy but have lost response and eventually needed surgery.

Conclusion: Contrast-enhanced ultrasound might be helpful in guiding the therapeutic decision making between surgery and therapy intensification in patients with strictureting Crohn’s disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1645 DIAGNOSTIC DELAY AND PREDICTIVE FACTORS FOR CROHN’S DISEASE IN AN ALGERIAN POPULATION

V. Chelli, R. Boulares
Constantine, Ben Badis Hospital, Constantine/Algeria

Contact E-mail Address: Yacinechelbi4@yahoo.fr

Introduction: Crohn’s disease (CD) is a chronic inflammatory bowel disease whose diagnostic delay (DD) is highly variable. A delay in diagnosis of CD may be detrimental to the patient, delaying appropriate therapeutic management. Factors Influencing SD may be a function of the country’s health system, but also linked to the particular clinical and evolutionary profile of the disease. The objective of this study was to measure the DD of CD, to describe its distribution and evolution over time and to The factors associated with a long DD (>Q3).

Aims & Methods: All patients with certain or probable CD between 2004 and 2016 identified by The department’s inflammatory disease hospital registry was included. The socio-demographic characteristics collected included: the patient’s medical, reproductive and socio-economic characteristics. The factors associated with a long DD (>Q3).

Results: Among 247 patients with CD; 90 had a median SD of 3 months. A DD > 7 months was considered a diagnostic delay observed in most patients is 157. In univariate and multivariate analysis at diagnosis, the female sex (54.25%), young age (37.24%), absence of evacuation (27%), presence of extra-digestive manifestations (25.91%) and Isolated lesions (L1) (34%) and penetrating phenotype (B3) (28.67%) were associated with a long delay. Diagnostic delay factor was not associated with a long delay.

Conclusion: This study shows that most of the patients, 63.56% have a diagnostic delay significantly associated with the female sex. The young age, the absence of weight loss and a localization of the disease limited to the bowel had the delay in the penetrating phenotype of disease. No socioeconomic variables or reflective of access to care were found to influence.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Inflammatory bowel disease (IBD) commonly affects patients during their reproductive years, making the interaction between fertility, pregnancy and IBD an important issue for both genders. As these are the reproductive years, patients and physicians often have concerns regarding the interaction between fertility, pregnancy outcomes, and neonatal outcomes.

Aims & Methods: The aim of the study was to evaluate the lifestyle habits and the fertility of IBD patients and evaluate the factors that affect fear of family planning. Finally we investigated the factor which have influence on family planning.

Methods: A personal questionnaire was sent to 148 patients with IBD (72 with CD and 76 with UC) from our IBD population. Personal questionnaires were reviewed one year before conception and throughout pregnancy.

Results: In 2017 total 27 patients were included (10 men; median age 37 yrs, range 23–67; 22 pts with ileo-coecal localization, 3 pts with multiple small bowel segments involvement, 2 pts with colonic disease). Seventeen patients (63%) had rapid uptake at the CEUS; 13 of these patients had therapy escalation (3 pts intensification or switch of another biological; 10 pts had therapy step-up to antiTNF or immunomodulator). Remaining 10 pts were stable on their ongoing medication. Patients who underwent surgery in the group with rapid uptake, all but 2 patients achieved sustained remission after therapy escalation. Two patients initially responded to therapy but have lost response and eventually needed surgery. In the group with rapid uptake, patients without surgery remained in remission without any changes in the medication. Patients who underwent surgery in the group with rapid uptake, all but 2 patients achieved sustained remission after therapy escalation. Two patients initially responded to therapy but have lost response and eventually needed surgery.

Conclusion: Contrast-enhanced ultrasound might be helpful in guiding the therapeutic decision making between surgery and therapy intensification in patients with strictureting Crohn’s disease.

P1646 TUBERCULOSIS IN INFLAMMATORY BOWEL DISEASE: UNDER TUMOUR NECROSIS FACTOR ALPHA ANTAGONIST–THE RISK BEYOND SCREENING

L. Carvalho, M.A. Túlio, J. Carmo, J. Rodrigues, T. Bana, E Costa, C. Chagas
Gastroenterology, Centro Hospitalar Lisboa Ocidental, Lisboa/Portugal

Contact E-mail Address: lilipcarvalho@gmail.com

Introduction: Tumour necrosis factor alpha antagonist (anti-TNFa) has revolutionized the treatment of the inflammatory bowel disease (IBD). Considering that it plays a central role in immune-mediated modulation, there are some concerns about safety and ongoing treatment. The main patient-related reasons for “voluntary infertility” were fear of congenital abnormality secondary to medications of IBD (68%) and concern about genetic risk of IBD in child (56%). 30% of male and 75% of female patients had concerns about safety and ongoing treatment. The main patient-related reasons for “voluntary infertility” were fear of congenital abnormality secondary to medications of IBD (68%) and concern about genetic risk of IBD in child (56%). 30% of male and 75% of female patients had concerns about safety and ongoing treatment. Pregnancy was planned in 77% of cases, the childbearing and delivery was without any complication. Prematurity and low birth weight occurred in 6-6 cases (10%-10%). IBD was in remission in most cases, during pregnancy 25% of the patients had flare. 40% of women could breastfeed their baby after 6 months.

Conclusion: The management of IBD in women during their reproductive years should include consideration of their family planning decisions, and education counseling regarding the overall safety of medications and the importance of medication adherence should occur prior to conception. Disease control prior to desired conception and throughout pregnancy is the most important factor to keep in mind when caring for the IBD patients. Educating the patients will help to achieve successful outcomes both for patients and babies.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: We intend to know the incidence of tuberculosis in IBD patients under anti-TNFα therapy in a single tertiary referral centre, analyzing the tuberculosis screening methods and demographic characteristics. IBD patients treated with anti-TNFα therapy between January 2000 and December 2016 were retrospectively analyzed.

Results: During this period, 166 patients received anti-TNFα therapy. Before anti-TNFα treatment, screening for LT was performed through medical history, chest X-ray, tuberculin skin test (TST) and/or IGRA. Forty-two patients (25%) had positive screening and received tuberculosis prophylaxis prior to anti-TNFα therapy. Seven patients were exposed to tuberculosis while under anti-TNFα treatment (four women, mean age 44 ± 7 years and mean IBD duration 10 ± 8 years). Six of them had a negative LT screening (methods: 4 TST and 2 IGRA) and one patient had positive TST screening, been treated with isoniazid before starting anti-TNFα therapy. During screening three patients were under immune suppressive and one under corticosteroid therapy. In the IGRA negative screening patients, the diagnosis of tuberculosis occurred within the first 10 weeks after starting anti-TNFα. There were five cases of miliary tuberculosis and two of pulmonary disease. Despite difficult diagnosis, all patients were treated successfully, six of whom needed hospitalization.

Conclusion: In our centre the incidence of tuberculosis in IBD patients under anti-TNFα therapy was 4.2% and most of them presenting with a severe disease pattern. The therapeutic regime of tuberculosis was effective and no mortality was recorded. This patient had a previously negative screening, two of them with IGRA, been considered a high sensitivity and specificity screening method. Therefore, a surveillance strategy for IBD patients with anti-TNFα therapy is needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: The HBI score self-administered by the patient through a mobile app resulted in a high percentage of agreement with the gastroenterologist evaluation, and high negative predictive value for disease activity. Results of the MedCron study encourage the use of this mobile app and gives some hints on its conditions of use as a support for the involvement of patients in the management of their disease. Future studies will help to define its precise role in clinical practice.

P1649 EVALUATION OF MODIFIED MAYO ENDOSCOPIC SCORE AND DUBLIN ENDOSCOPIC SCORING SYSTEM IN PATIENTS WITH ULTRACOLONIC ULCERATIVE COLITIS EXTENSION, IN THE PREDICTION OF RELAPSE

1Gastroenterology, CHVNG/E, Vila Nova De Gaia/Portugal
2Gastroenterology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova De Gaia/Portugal

Contact E-mail Address: jaimepeireirarodrigues@gmail.com

Introduction: Current endoscopic activity scores for Ulcerative Colitis (UC) do not take into account the extent of mucosal inflammation. Recently, two endoscopic scores that combine the assessment of severity and disease extension were developed, the Modified Mayo Endoscopic Score (MMES)1 and Degree of Ulcerative Colitis Burden of Luminal Inflammation (DUBLIN).2

Aims & Methods: We aimed to evaluate the relation of the scores with disease activity and as predictive factors of clinical relapse. Patients with UC in clinical remission (partial Mayo score [pMS] ≤ 1) who underwent colonoscopy between January/2010 and December/2013 were included. MMES and DUBLIN scores were calculated. Analytical and histological activity (defined by Geboes score ≥ 3.1 and Nancy score = 2.4) as well as predictive factors of relapse and relapse-free time were evaluated. Relapse was defined as pMS > 2, therapy to induce remission, hospitalization and/or colectomy.

Results: 82 patients were selected, 51.2% (n = 1,342) female, mean age 49.4 ± 13.7 years. MMES ranged between 0–13.8 and DUBLIN between 0–9. MMES and DUBLIN scores presented good correlation (r = 0.945, p < 0.001). MMES was higher in patients with histological activity defined by Nancy (3.7 ± 4.0 vs. 0.8 ± 1.5; p < 0.001) and Geboes (4.0 ± 4.2 vs. 1.3 ± 2.4; p = 0.005). DUBLIN was also higher in patients with histological activity defined by Nancy (1.9 ± 2.1 vs. 0.5 ± 0.8; p = 0.001) and Geboes (2.0 ± 2.3 vs. 0.7 ± 1.2; p = 0.002). There was no significant correlation between both scores and analytical activity. Relapse occurred in 36.6% (n = 30) of patients, with a cumulative risk of 9.8, 18.4, 25.9, and 42.0% at 12, 24, 36, and 60 months, respectively. Mayo Endoscopic Subscore (MES) (p < 0.001), MMES (p < 0.001), DUBLIN (p < 0.01), Geboes (p = 0.03) and Nancy scores (p = 0.001) presented a significant association with relapse. In multivariate analyses, MES (OR = 2.32; p < 0.001), MMES (OR = 1.19; p < 0.001) and DUBLIN (OR = 1.36; p < 0.001) were predictive of relapse independently from histology. Areas under the ROC curve were 0.71 (MES), 0.75 (MMES), 0.74 (DUBLIN), and were predictive of relapse, with MMES significantly higher than MES by a difference of 0.037 (0.002–0.072); p < 0.001), MMES (OR = 5.21 vs. 0.55; p = 0.001), and DUBLIN (OR = 5.09 vs. 0.53; p = 0.001) presented a significant association with relapse. In multivariate analyses, MES (OR = 2.32; p < 0.001), MMES (OR = 1.19; p < 0.001) and DUBLIN (OR = 1.36; p < 0.001) were predictive of relapse independently from histology. Areas under the ROC curve were 0.71 (MES), 0.75 (MMES), 0.74 (DUBLIN), and were predictive of relapse, with MMES significantly higher than MES by a difference of 0.037 (0.002–0.072); p = 0.03.

Conclusion: MMES and DUBLIN scores correlate with each other and with histological activity. They are independent predictors of relapse. MMES was superior to MES in the prediction of relapse.

Introduction: Crohn’s disease (CD) is a chronic progressive destructive disease, resulting in cumulative structural bowel damage, which may predict long-term disability. The Lémann Index (LI) has been developed to measure CD-related bowel damage, including bowel surgery, presence of strictureting and penetrating lesions (Pariente and al, Gastroenterology 2015). The first Inflammatory Bowel Disease - Disability Index (IBD-DI) has recently been validated (Gower-Rousseau, Gut 2015).

Aims & Methods: The aim of the present study was (1) to identify factors associated with bowel damage and with disability in CD and (2) to evaluate the correlation between the LI and the IBD-DI. We performed a prospective study in the tertiary referral center of the Claude Huriez Hospital in Lille from September 2016 to November 2016, including all consecutive CD outpatients. Bowel damage was assessed by the LI calculated according to the published LI protocol. Abdominal and pelvic Magnetic resonance imaging (MRIs) were reviewed and read by the same couple of one gastroenterologist and one radiologist. The IBD-DI was also calculated for all patients. Factors associated with LI and IBD-DI levels were identified by means of bivariate analyses of variance.

Results: 130 patients were prospectively and retrospectively included. Median age was 34.0 (interquartile range [IQR]: 26.0–46.0) and median disease duration was 10.0 (IQR: 5.0–17.0) years. 65 patients (50%) underwent at least one resection surgery. The median LI was 10.8 (IQR: 6.0–17.5). Disease duration (p < 0.0001), cumulative anal location (p < 0.0001) and CD activity (p < 0.0001) were associated with higher LI scores. Median IBD-DI was 25.0 (IQR: 14.7–41.1). Female gender (p = 0.02), CD activity (p < 0.0001) and current anoperineal lesions assessed by clinical examination and pelvic MRIs (p = 0.001) were associated with higher IBD-DI scores. The correlation coefficient between the LI and the IBD-DI was 0.12 (t = -0.05, 0.29; p = 0.154).

Conclusion: In a large cohort of CD patients from a tertiary referral CD center, disease duration, anal location and CD activity are associated with bowel damage assessed by the LI, while female gender, disease activity and current anoperineal lesions are associated with disability assessed by the IBD-DI. Correlation between the LI and the IBD-DI was low.

In UC patients, we observed higher expression of IL-8.

Results: CD and UC patients.

expression of cytokines in inflamed and non-inflamed mucosa separately for and reversely transcribed. We normalized the expression of the target genes to the mRNA was extracted from mucosal biopsy samples, isolated by a RLT buffer from inflamed mucosa from sigma (CD, UC) and terminal ileum (CD).

Hospital Bratislava. We took biopsies from non-inflamed and if present also section of study. The cohort consisted of 87 consecutive IBD patients (47 CD, 40 UC) who underwent colonoscopy at the IBD centre of University Hospital Bratislava. We performed biopsies and paired samples from inflamed mucosa from sigma (CD, UC) and terminal ileum (CD).

mRNA was extracted from mucosal biopsy samples, isolated by a RLT buffer from inflamed mucosa from sigma (CD, UC) and terminal ileum (CD).

mRNA was extracted from mucosal biopsy samples, isolated by a RLT buffer and reverse transcribed. We normalized the expression of the target genes to the expression of the house-keeping gene (GAPDH). Finally, we compared the expression of cytokines in inflamed and non-inflamed mucosa separately for CD and UC patients.

Results: In UC patients, we observed higher expression of IL-8 (p = 0.04), IL-23 (p = 0.019) TLR2 (p = 0.002), CCR1 (p = 0.007), CCR2 (p = 0.037), CCR5 (p = 0.001), CD206 (p = 0.001), TNFz (p = 0.002) and IL-6 (p = 0.006) in the inflamed mucosa from sigma. In CD patients, we observed increased expression of CCL5 (p = 0.005) and IL-8 (p = 0.001) in the inflamed mucosa of a terminal ileum and decreased expression of CCL5. Also, in group of patients with CD we did not observe the difference of the expression of mRNA cytokines between the inflamed and non-inflamed mucosa of sigma.

Conclusion: There was a significant difference in the mRNA cytokine profiles between CD and UC patients.

Introduction: The aetiology of Crohn’s disease (CD) and ulcerative colitis (UC) is not known. Recent data suggest a different cytokine profile between CD and UC.

Aims & Methods: The aim of this study was to analyse the expression of mRNA of proinflammatory, regulatory anti-inflammatory cytokines, chemokines and their ligands (IL-6,-8,-10, 12, IL-23, TNFz, CCR1, CCR2, CCR5, CCL5, and transcription factor FoxP3) in the inflamed and non-inflamed intestinal biopsy samples of IBD patients. We performed a cross-sectional study. The cohort consisted of 87 consecutive IBD patients (47 CD and 40 UC) who underwent colonoscopy at the IBD centre of University Hospital Bratislava, Bratislava/Slovak Republic.

Introduction: Although thiopurine-induced myelotoxicity and hepatotoxicity rarely occur during maintenance thiopurine therapy for inflammatory bowel disease (IBD), current guidelines advise laboratory monitoring every 3 months. This study was performed to assess the current laboratory monitoring regime in thiopurine maintenance therapy with regards to consequences of myelotoxicity and hepatotoxicity.

Aims & Methods: In this multicenter cohort study, we evaluated adult IBD patients with quiescent disease who were on maintenance thiopurine therapy between 2000–2016. Data collection started after 12 consecutive months of thiopurine treatment. The primary outcome was therapy adjustment, i.e. therapy cessation or dose reduction, due to myelotoxicity (leukocyte count < 4.0 10^9/l, platelet count < 150 10^9/l) and/or hepatotoxicity (alkaline phosphatase (AP), gamma-glutamyltransferase (>GT), alanine aminotransferase (ALT) and/or aspartate aminotransferase (AST) above the upper limit of normal (ULN)). The secondary outcomes were prevalence of myelotoxicity and hepatotoxicity and additional diagnostic procedures due to this toxicity.

Results: This study included 223 IBD patients (55% female, 64% with Crohn’s disease, mean age at diagnosis 27.2 years (SD 11.5)). Median follow-up was 3.2 years (IQR 1.9–4.7). The mean monitoring frequency was 3.3 assessments per treatment year (SD 1.8). Toxicity was observed in 445/2402 laboratory assessments (18.5%) in 120 patients. In total, 20 (0.8%) therapy adjustments were performed and 25 laboratory assessments (1.0%) led to additional diagnostic procedures. Myelotoxicity, observed in 244 assessments, led to 11 dose reductions and in 3 patients therapy was stopped. For hepatotoxicity, observed in 201 assessments, 2 dose reductions were performed and in 4 patients therapy was stopped. Ninety percent of observed toxicity were mild leukopenia (leukocyte count 3.0–4.0) or mild hepatotoxicity (< 2 ULN), primarily in the first years of treatment. Dose adjustments were more often associated with moderate leukopenia (leukocyte count < 3.0) than with mild leukopenia (p < 0.01). In total, 2 complications were recorded, 1 patient was hospitalized because of pancytopenia and received red blood cell transfusion, and 1 patient was treated for a CMV infection. Both patients presented with symptoms in clinic with preceding normal laboratory values. No mortality due to thiopurine-induced toxicity was observed.

Conclusion: Although mild toxicity is common during maintenance thiopurine therapy, adjustments based on laboratory assessments are rare. Therefore, a less intensive regime to monitor thiopurine-induced toxicity should be considered.

P1656 ULTRASOUND ELASTICITY IMAGING PREDICTS THERAPEUTIC OUTCOMES IN PATIENTS WITH CROHN’S DISEASE TREATED WITH ANTI-TUMOR NECROSIS FACTOR ANTIBODIES

S. Orlando, M. Fraquelli, M. Coletta, F. Branchi, A. Magarotto, C.B. Conti, S. Mazzu, D. Conte, G. Basilisco, F. Caprioli

Introduction: Intestinal fibrosis represents one of the main sources of morbidity for patients with Crohn’s disease (CD), as its onset is associated with the development of CD-related complications which increase the likelihood of hospitalization and surgery. Ultrasound elasticity imaging (UEI) is a non-invasive ultrasonographic technique developed to evaluate tissue fibrosis by measuring tissue strain after application of a force. We have recently demonstrated that UEI can reliably detect severe ileal fibrosis in patients with Crohn’s disease. We therefore hypothesized that a more severe range of fibrosis might influence the therapeutic response to anti-tumor necrosis factor (TNF) treatment.

Aims & Methods: The aim of this explorative study was to assess the ability of UEI to predict therapeutic outcome in active CD patients treated with anti-TNF antibodies. 30 patients with ileal or ileocolic CD (20 males, age 38.8 ± 14.5 years) initiating anti-TNF treatment were enrolled in the study. All patients completed the induction phase and underwent scheduled maintenance therapy with anti-TNF for 16.1 ± 8.5 months. Patients underwent bowel ultrasound and UEI at baseline and 14 weeks after initiation of anti-TNF. Bowel wall stiffness at UEI was quantified by calculating the strain ratio (SR) between the bowel wall and the surrounding mesenteric tissue. Receiver operating characteristic curve analysis was used to identify the best SR cut off able to predict surgery/bowel obstruction.

Results: Five patients (16.6%) underwent surgery or hospitalization for bowel obstruction during the follow up. Frequency of CD-related surgeries or hospitalizations was significantly greater in patients with SR ≥ 2 at baseline than in patients with SR < 2 (p = 0.02). A significant reduction in bowel thickness was observed after 14 weeks of anti-TNF treatment (from 5.8 ± 1.5 mm to 5.1 ± 1.7 mm, p < 0.005), while SR values remained unaltered (1.5 vs 1.3, p = 0.5). A significant inverse correlation was observed between values of strain ratio at baseline and thickness variations following anti-TNF therapy (p = 0.007). Eight out of 30 patients (27%) achieved transmural healing at 14 weeks. Baseline SR was significantly lower in patients with transmural healing than in patients not achieving this endpoint (1.06 ± 0.16 vs 1.67 ± 0.17, p < 0.05).

Conclusion: This explorative study shows that UEI is able to predict therapeutic outcomes, including CD-related surgeries and transmural healing, in patients with Crohn’s disease treated with anti-TNF therapy.

P1657  CLINICAL CHARACTERISTICS OF RECTAL-SPARING ULCERATIVE COLITIS

A. Ito, O. Teppel, T. Katutoshi
Dept. Medicine, Inst. Gastroenterology, Tokyo Womens Medical University, Tokyo, Japan

Contact E-mail Address: itoayumi@ige.twmu.ac.jp

Introduction: Ulcerative colitis (UC) generally involves the entire large intestine except for the rectum to the ileocecal junction. However, some patients with moderate or severe UC lack any obvious rectal involvement (known as rectal-sparing (RS)-UC).

Aims & Methods: In this study, we evaluated the differences in the clinical characteristics between patients with rectal sparing UC with or without RS. Of the 437 inpatients with rectal UC who achieved remission between April 2001 and September 2016 (follow-up period: 915 ± 53 days, mean ± SD), 57 patients were classified as RS-UC and 340 patients without RS (standard [S]-UC) group. Patients of the two groups were compared for gender, age at onset, site of involvement, disease duration, pretreatment clinical activity index (CAI, Lichtiger score), Hb, C-reactive protein (CRP), total dose of prednisolone (PSL) before the achievement of remission, duration of hospitalization, emergency admission and endoscopic response (UCEIS), and relapse rate (UCEIS-100%, S-UC: 30%, RS-UC: 50% 1000 days post-remission). Patients with RS were defined as those without any detectable rectal inflammation despite not receiving local treatment, such as rectal enemas, suppositories or suppositories. Remission was defined as CAI ≤ 5.

Results: RS was observed in 57 (10.4%) patients. There were significant differences in CRP (RS-UC: 5.1 ± 6.0, S-UC: 2.3 ± 3.4 mg/l) and pretreatment endoscopic scores (Mayo: RS-UC: 2.7 ± 0.3, S-UC: 2.4 ± 0.5; UCEIS: RS-UC: 6.02 ± 3.1, S-UC: 4.9 ± 3.2). However, there was no significant difference in the relapse rate at 100 days after remission (RS-UC: 18%, S-UC: 15%). However, the two groups showed significant differences in the relapse rates at 300 days (RS-UC: 38%, S-UC: 17%), 500 days (RS-UC: 52%, S-UC: 68%), and 1000 days (RS-UC: 77%, S-UC: 62%) after remission.

Conclusion: Our results showed that RS is not an uncommon finding among patients with UC. Based on the higher CRP, endoscopic score, and relapse rates in the RS group, than the standard UC group, we recommend aggressive treatment with RS.

P1658  EVALUATION OF COLONIC MUCOSA WITH FLEXIBLE SPECTRAL IMAGING COLOR ENHANCEMENT (FICE) IN PATIENTS WITH LONG TERM ULCERATIVE COLITIS DURING DYSPLASIA SCREENING

G. Bengt1, S. Kaya Ozdogan1, H. Akpınar1
1Gastroenterology, Dokuz Eylul University Hospital, Izmir/Turkey

Contact E-mail Address: sedozinc@yahoo.com

Introduction: Ulcerative colitis (UC) associated colorectal cancer risk (CRC) is related to the age of onset and duration and anatomic extent of the disease. The risk correlates with the duration of the disease (1). Current guidelines recommend beginning the surveillance colonoscopy after eight to ten years of disease; random biopsies should be obtained from 4 quadrants of every 10 cm of the colon. In addition, any suspicious lesions should be biopsied. Recent endoscopic imaging technologies provide a more detailed visualization of the superficial microstructure of the mucosa and vascularity. Thus it is possible to get targeted biopsies. The purpose of this study is to evaluate the image patterns of dysplasia in ulcerative colitis, and their histopathological correlation, by using a virtual chromoendoscopy technique, FICE and to investigate the effectiveness of this technique.

Aims & Methods: The purpose of this study is; to evaluate the image patterns of dysplastic changes in ulcerative colitis, and their histopathological correlation, by using a virtual chromoendoscopy technique, FICE and to investigate the effectiveness of this technique.

Results: In a total of 18 patients, by evaluating 123 colonic segments, 1831 images were evaluated. Biopsies were taken from 258e34 tissue samples. The examination of FICE images showed that the best imaging channels are 2, 6, 9 for normal mucosa; 3, 7, 9 for polyps; and 2, 3, 9 for colitis. When all the images are analyzed, channels 2 and 9 were found to be significantly different from other channels. When the most rated channels, 2 and 9, were compared to the WLE, the FICE image is better for evaluation of the mucosal and vascular structure. However, there were no significant difference between channels 2 and 9.

Conclusion: There were no significant superiority of FICE, in dysplasia screening. Consistent with the literature, this study showed us that FICE, with its ability to detect diminutive polyps, and evaluating surface patterns without magnification, can be used in the assessment of the severity of inflammation. For this purpose, more clinical trials should be conducted. Our study showed no superiority of FICE in UC. Channels 2 and 9 are the best image channels of FICE in UC.

Introduction: The gut microbiome is thought to be relevant to the pathogenesis of inflammatory bowel disease (IBD). We aimed to explore associations between microbial gut microbiota and clinical as well as inflammatory disease activity in an inception cohort of treatment-naive IBD patients as well as with inflammatory activity in symptomatic non-IBD patients and healthy controls. The term ‘dysbiosis’ expresses alterations in the gut microbial community.

Aims & Methods: Patients were classified according international criteria, including endoscopic and histopathological assessment. Clinical disease activity in Crohn’s Disease (CD) patients was measured by the Harvey-Bradshaw index (HBI), and in ulcerative colitis (UC) patients by the Simple Clinical Colitis Activity Index (SCCAI). Inflammatory activity was assessed by CRP and faecal calprotectin (Fcal). (FCAL® ELISA, Buthmann laboratories AG).

Stool samples were collected within 60 days prior to and 14 days after the diagnosis, and stored at –80°C. Antibiotic treatment within the last two months or an exclusion criteria such as fecal calprotectin (Fcal) levels of > 175 mg/g were generated by 16S rRNA analyses, using the GA-map™ Dysbiosis Test. Dysbiosis was defined as none, mild or severe (1). Differences in disease activity between levels of dysbiosis severity were analysed using ANOVA at a significance level of P < 0.05. Differences in correlations between dysbiosis severity and gut microbiota profiles were generated using ANCOVA. P-values corrected for multiple testing, using Benjamini-Hochberg correction, are presented.

Results: There were associations found between Fical and dysbiosis in CD patients (P < 0.02), while not for UC and symptomatic non-IBD patients. No association was found between HBI and dysbiosis in CD patients (P = 0.23), and between SCCAI and dysbiosis in UC patients (P = 0.32). Microbiota: Increasing dysbiosis severity in UC, CD and non-IBD patients yielded lower abundance of Faecalibacterium prausnitzii, and higher abundance of Proteobacteria, a profile typically observed in gut inflammatory conditions. In addition, the commensal bacteria Bifidobacterium yielded lower abundance with increased dysbiosis severity in UC and non-IBD patients, and in combination with elevated levels of Fcal and/or in UC patients. In the healthy controls, increasing dysbiosis severity yielded higher abundance of Proteobacteria.

Conclusion: In conclusion, a relationship between faccial dysbiosis in subgroups of the patient population and the disease activity in IBD is possible. According to gut bacteria profiles and abundance may potentially be used to differentiate between severity in UC and CD patients, as a non-invasive tool to monitor disease activity in IBD.

Introduction: Crohn’s disease (CD) is a lifelong inflammatory bowel disease. Evaluating the extent and severity of the disease is critical to determine appropriate therapeutic strategies in patients with Crohn’s disease. MR imaging is one of the most recommended technique for detection of large and small bowel lesions, with high reliability and clinical utility of the 3-point MR enterocolonography (MREC) classification for assessing CD activity based on endoscopic findings.

Aims & Methods: 120 patients (70 for derivation cohort and 50 for validation cohort) with CD were enrolled and underwent MREC and ileocolonoscopy or balloon-assisted enteroscopy (BAE). MREC was evaluated for each bowel segment: rectum, sigmoid, descending, transverse, ascending colon, terminal ileum, and jejunum, according to the consensus of two observers in the derivation phase, and independently by three observers in the validation phase, using a 5-point MREC classification based on a lexicon of MR findings. The conventional MR score, or MaRIA, was evaluated simultaneously. Areas under the receiver operating characteristic curves (AUCs) were obtained to assess the accuracy of discriminating deep ulcers. Inter-observer reproducibility was assessed using weighted Kappa coefficients.

Results: BAE was performed in 49 (47%) and 37 (74%) patients in the derivation and validation cohorts, respectively. The AUCs of MREC classification were 89.0% in the derivation phase and 88.5, 81.0, and 77.3% for three observers in the validation phase. The AUCs of MREC classification were statistically non-inferior to those of MaRIA (p < 0.001). The cross-validation accuracy was 81.9% in the derivation and 81.3% in the validation phase. The MREC classification showed good reproducibility.

Conclusion: For clinical use, radiological reporting systems should be simple and provide appropriate levels of accuracy and reproducibility. The 5-point MREC classification meets these requirements, and is useful for evaluating CD activity in the large and small bowel segments.

Introduction: Metabolic syndrome (MetS) is a combination of biochemical and anthropometric disturbances and a recognized risk factor for cardiovascular disease. A higher prevalence of this condition has been previously reported in IBD patients, correlating to age as in the general population.

Aims & Methods: The aim of this study was to assess the effect of individual disease activity–related putative risk factors for MetS in a group of IBD patients, as well as any protective effects of treatment on MetS or its components. Consecutive IBD patients and age- and sex-matched controls were included during a 1-year period. MetS was diagnosed according to the “harmonized” criteria as the presence of ≥ 3 criteria among elevated waist circumference, blood pressure, blood glucose, serum tryglicerides, or reduced HDL levels. All subjects underwent colonoscopy; endoscopic disease activity was assessed according to SES-CD and Mayo endoscopic scores. CRP, falciparum (FC), hemoglobin and ferritin levels were also measured.

Results: We enrolled 145 consecutive IBD patients (53 Crohn’s disease and 92 ulcerative colitis; 58 M:87 F; mean age 51 ± 18 y3) and 250 age- and sex-matched controls. Overall MetS prevalence was 37% in IBD and 21.6% in controls (OR = 2.1, 95%CI:1.32–3.39). Prevalence according to sex or disease type did not show significant differences. At multivariate analysis, age and BMI > 25 were associated to an increased probability for a positive MetS status both in IBD (OR = 1.341, and OR = 1.601) and controls (respectively OR = 1.374 and OR = 3.74). In patients under 50 years, age (OR = 1.24), CRP (OR = 1.9) and FC (OR = 1.35) positively were associated to MetS status, while a BMI > 25 increased risk at any age (< 50y OR = 3.8, > 50y OR = 1.56). Demographic factors did not associate to MetS status at any age. Interestingly, anti-TNFα treatment was protective in both groups, but reached statistical significance only in older subjects (> 50y OR = 0.08). Regarding individual MetS components, in the < 50y subgroup, age and CRP positivity associated with an impaired glycemic (respectively, OR = 1.15 and OR = 2.28) and lipidemic status (respectively, OR = 1.23 and OR = 2.3). In older patients, CRP positivity only associated to impaired HDL status (OR = 1.6). Importantly, anti-TNFα treatment favourably associated to HDL status (OR = 0.2).

Conclusion: MetS prevalence is increased in IBD compared to healthy controls at any age, and treatments with increased BMI and/or inflammatory markers are at higher risk for MetS, while anti-TNFα agents appear to be protective. The components associated to MetS are differently distributed according to age, with the inflammatory ones prevailing in subjects < 50 years and metabolic disturbances in older patients. These results indicate that efforts should be made to reduce MetS occurrence and associated risks in subjects > 50 years, in younger patients more effective inflammation control measures may prevent MetS and its related long-term neoplastic and cardiovascular complications.

P1662 C-REACTIVE PROTEIN/ALBUMIN RATIO IS A GOOD PREDICTOR OF RESPONSE TO INTRAVENTHROUS CORTICOSTEROIDS IN ACUTE SEVERE ULCERATIVE COLITIS
S. Monteiro1, T. Cárdira Gonzalvez1, E. Díaz De Castro2, S. Leite1, M.J. Moreira3, J. Cotter2

Introduction: Patients with acute severe ulcerative colitis (ASUC) have a high risk of rescue medical therapy or colectomy. Recently, the C-reactive protein (CRP)/albumin ratio at the 3rd day of treatment, with intravenous corticosteroids, has been shown to be a predictor of early colectomy in patients with ASUC.

Aims & Methods: To evaluate the accuracy of CRP/albumin ratio on admission, to predict response to intravenous corticosteroids in patients with ASUC. Retrospective assessment of systematically hospitalized patients with first episode of ASUC, who required intravenous corticosteroids. Demographic, clinical, laboratory and endoscopic variables were evaluated on admission. The response to intravenous corticosteroids was defined as absence of complications during a 1-year period. CRP/albumin ratio was considered as non-responsive patients, rescue medical therapy with infliximab or cyclosporine has been instituted. The accuracy of CRP/albumin ratio in predicting non-response to intravenous corticosteroids was assessed by the area under the ROC curve.

Results: 51 patients were included, 30 (58.8%) of them female, with a mean age 34.3 ± 14.5 years. Twelve patients (23.5%) required medical rescue therapy. No patient underwent colectomy. The presence of deep ulcers and a shorter evolution of the disease were associated with lack of response to CRP/albumin ratio of cortico- steroids, p < 0.001 and p = 0.008, respectively. Patients with no response to intravenous corticosteroids had higher CRP admission values and lower albumin values, compared to patients with response, 111 vs 67.5 (mg/L), p = 0.028, 2.8 v.s 3.5 (g/dL), p = 0.005, respectively. The CRP/albumin ratio was 1.4 higher in unresponsive patients 40.06 vs 22.14, p = 0.022, showing a good accuracy for predicting non-response to intravenous corticosteroids with an AUC of 0.746, p = 0.01.

Conclusion: A high value of CRP/albumin ratio was significantly associated with the occurrence of non response to intravenous corticosteroids, at the 3rd day of treat- ment. This index may allow a better risk stratification on admission, of patients with acute severe ulcerative colitis.

P1663 INSUFFICIENT VARIATION OF MEDIUM CORPOSCULAR VOLUME (MCV) IN INFLAMMATORY BOWEL DISEASE UNDER THYOPURINES PREDICTS DIFFICULTY IN ACHIEVING MUCOSAL HEALING AND MUCOSAL DEEP REMISSION COMBINATION WITH ANTI-TNF - THE OTHER SIDE OF THE MCV FLOW STUDY

Introduction: The MCV flow study confirmed the association ΔMCV ≥ 7fl at week 26-28 of Azathioprine monotherapy (mAzA) with favourable outcomes in a Portuguese IBD population.

Aims & Methods: For this work, our aims were to evaluate the need for step-up therapy in those under mAzA with ΔMCV < 7 and to identify predictors of combined deep remission outcomes (DeepRem), at the same timepoint, for the patients who subsequently began combination therapy with Anti-TNF (AzAExpered + Anti-TNF). Evaluation of patients under mAzA with ΔVMC < 7 at key timepoint week 26-28 treatment, included for The MCV flow study. Demographic characterization and severity of pre-treatment disease was evaluated (Montreal classification, previous surgery status, Mayo score and Crohn’s disease activity index [CDAI]). ΔMCV’s association with DeepRem [Steroid-free clinical remission (CDAI < 150, Mayo < 2) + mucosal healing (MH) + C-reactive protein (CRP) < 10] and need for biological therapy at the end of DeepRem was verified. The independent predictors in patients who subsequently started combination therapy. Statistic: Chi-square test; Binary logistic regression.

Results: A total of 106 IBD patients were evaluated [56.6% men, mean age 39 ± 15.2 years; 58 (14%) operated at week 26-28 of mAzA]. Identified strong association between an average ΔVMC ≥ 7 (n = 70; 66%) with DeepRem (p < 0.05), while a ΔVMC < 7 was associated with biological therapy need (p < 0.05). 45 patients were later started with Anti-TNF therapy

Reference
with fasting hyperglycemia (only 12.5%) had elevated C-reactive protein level but not fasting insulin level - it was within normal range. The highest level of the fasting insulin (over 10 IU/ml) in this group was observed in 3 patients who had to undergo immediate surgical treatment - two of them because of the bowel obstruction and one of them because of the perforation.

**Conclusion**: In our opinion there is a strong connection between fasting glucose, CRP level and exacerbation of the disease in CU patients but not in case of the Crohn’s Disease. In this group the elevated fasting insulin may be a marker of severe illness.

**Disclosure of Interest**: All authors have declared no conflicts of interest.

**P1664 Fecal Calprotectin Predicts Short-Term Relapse in Inflammatory Bowel Disease Patients in Deep Remission**

R. Nakov1, V. Nakov1, V. Gerova1, L. Tankova2, T. Kundurzhiev2, H. Vladimirov1

1Gastroenterology, Clinic of Gastroenterology, 2Tarasova Asanka - ISUL1 University Hospital, Medical University - Sofia, Sofia/Bulgaria

**Introduction**: Most inflammatory bowel disease (IBD) patients with clinically successful treatment seem to have some degree of residual mucosal inflammation. Elevated fecal calprotectin (FC) concentrations can be found despite clinical remission and may indicate relapse risk in asymptomatic IBD.

**Aims & Methods**: The aim of this prospective study was to evaluate whether elevated FC levels can predict short-term clinical and/or endoscopic relapse. We enrolled 60 IBD patients (30 ulcerative colitis - UC, 30 Crohn’s disease - CD) who were in clinical and endoscopic remission. FC was measured using quantitative immunochromatographic point-of-care test (Quantum Blue® Calprotectin, Bühlmann Laboratories AG, Switzerland). Patients were followed-up by FC examination and clinical activity assessment every second month until relapse or up to 24 months.

**Results**: During the follow-up 36 (60%) relapsed and 24 (40%) remained in remission. The mean time to relapse in all patients was 13.9 (range 2-20) months. Significant increase in median FC levels was seen 2 months before relapse (p < 0.001) before endoscopic relapse. ROC analysis indicated that a cut-off of >90 μg/g (OR 24, 95% CI 1-217, p < 0.001) in mean FC values 2 months before relapse could predict relapse in UC patients with 83.3% sensitivity and 82.5% specificity. In CD patients a cut-off of >155 μg/g (OR 193, 95% CI 22-1682, p < 0.001) could predict relapse within two months with 91.7% sensitivity and 94.6% specificity. Constantly normal FC values during the follow-up were predictive for deep remission.

**Conclusion**: It seems that FC elevates two months before clinical and/or endoscopic relapse. FC is a suitable marker for predicting relapse and building a follow-up strategy for IBD patients in clinical practice.

**Disclosure of Interest**: All authors have declared no conflicts of interest.

**P1665 Glycemic Control and Insulin Resistance in Patient with Inflammatory Bowel Disease - Preliminary Results from the Pblid Study**

R. Filip1, J. Sztembis2, P. Kiela3, A. Rybak4

1Gastroenterology, The Central Department Of Endoscopy, Clinical Hospital No.2 Rzeszow, Poland, Rzeszow/Poland

**Introduction**: Hyperglycemia associated with critical illness - also called stress hyperglycemia - has much higher prevalence of severe ill patients. It is connected with many factors, including increased cortisol level, catecholamines uptake, glucagon production, glucoseogenesis, insulin resistance and inflammatory markers. It is not considered as an adaptive response anymore. Hypoglycemia associated with hyperglycemia is associated with poor outcomes and significantly increases mortality rates. That is why stress hyperglycemia and insulin resistance may be a marker of severe illness.

**Aims & Methods**: We analysed the data (glycemia, insulin level, HOMA IR level, C-reactive protein level, HbA1C) of 62 patient aged 18 years and older (20 women and 42 men, 32.26 +/- 13.8 years of age) with IBD hospitalized in our clinic from 2016 to 2017. 16 patient were with Ulcerative Colitis (UC) and 48 patients with Crohn’s Disease.

**Results**: The analysis of patients with Ulcerative Colitis showed that only one of the patients had hyperglycemia within the range of 140-200 mg/dl (the patient had type 2 DM) but interestingly 37.5% of the patients had fasting hyperglycemia over 100 mg/dl. Over 65% of these patient were admitted to our clinic with the exacerbation of the disease and had abnormal level of C-reactive protein, calprotectin (>1800) and fasting insulin level over 10 IU/ml. The analysis of the group of patients with Crohn’s Disease showed different results which may be connected with different metabolic profile of these patients. Most of the patients having diabetes had fasting hyperglycemia (over 12.5%) had elevated C-reactive protein level but not fasting insulin level - it was within normal range. The highest level of the fasting insulin (over 10 IU/ml) in this group was observed in 3 patients who had to undergo immediate surgical treatment - two of them because of the bowel obstruction and one of them because of the perforation.

**Conclusion**: In our opinion there is a strong connection between fasting glucose, CRP level and exacerbation of the disease in CU patients but not in case of the Crohn’s Disease. In this group the elevated fasting insulin may be a marker of severe illness.

**Disclosure of Interest**: All authors have declared no conflicts of interest.

**P1666 THE ROLE OF MR IMAGING IN ASSESSMENT OF LEEMANN INDEX IN THE COURSE OF CROHN’S DISEASE**

J.M. Pienkowska, V. Nakov1, V. Gerova1, L. Tankova2, T. Kundurzhiev2

1Gastroenterology, Clinic of Gastroenterology, 2Tarasova Asanka - ISUL1 University Hospital, Medical University - Sofia, Sofia/Bulgaria

**Introduction**: Crohn’s disease (CD) is a progressive, chronic and destructive inflammatory bowel disease process which, during its course, can lead to complications such as strictures and penetrating lesions (fistulas and abscesses), which may consequently require operative treatment. In some patients, bowel damage is present at the moment of diagnosis. The aim of the study is to assess the initial Lemann Index (LI), which comprehensively evaluates the entire gastrointestinal tract damage in patients with newly diagnosed Crohn’s disease.

**Aims & Methods**: In 209 patients with clinical suspicions of Crohn’s disease MR imaging and histopathology were performed. In 151 patients with confirmed active/chronic CD the Lemann Index has been calculated on the basis of radiological and clinical information for initial assessment of cumulative digestive tissue damage. To create the Lemann Index the gastrointestinal tract was divided into 4 organs: upper digestive tract, small bowel, colon, rectum and anus. Each organ was divided into segments (3 for the upper digestive tract, 6 for the colon/rectum and 1 for anus). Structures and penetrating lesions were assessed at each segment on 4-degree scale (0–3) according to the severity of lesions.

**Results**: Based on the findings of the initial radiological examination, active inflammation process was found in 76 patients and chronic process in 75 patients. The baseline study demonstrated such complications as strictures in 14 patients, fistuluses in 15 and abscesses in 4 patients. For all patients the LI was calculated. The obtained values were within the range from 0 to 22.

**Conclusion**: Over the years, the progression of Crohn’s disease leads to an increase in the value of Lemann Index, therefore, it seems that the evaluation of Lemann Index is a useful method for the first, baseline stage of all following control MR examinations will allow for a more complete assessment of patients in terms of progressive bowel damage and modification of the therapeutic process.

**Disclosure of Interest**: All authors have declared no conflicts of interest.

be required to obtain a 2x2 contingency table. Pooled analysis was done using a random-effects model. Sub-group analysis was performed at real-time Kudo pit pattern based and real-time CLE for characterization of visible lesions. Heterogeneity was assessed using Chi squared and I² statistics.

Results: Our search strategy identified 172 studies of which only 20 met the inclusion criteria. The pooled results are outlined in the table.

Conclusion: Real-time CLE and magnification endoscopy had the best performance characteristics. However there was a lot of heterogeneity in the results. Most CLE and magnification studies were single centre, single expert user which could explain these results. CLE studies were also affected by attrition bias with some studies reporting non-interpretable mages in a significant proportion.

P1669 ENDOSCOPIC FINDINGS AND COLONOSCOPIC PERFORATION IN MICROSCOPIC COLITIS: A SYSTEMATIC REVIEW OF THE LITERATURE

W. M. Maticevski1, I. Loniewski2, K. Skontetza-deck2, D. E. Yung3, A. Koulouzzidis4
1Department Of Gastroenterology, Pomeranian Medical University, Szczecin/ Poland
2Department Of Biochemistry And Human Nutrition, Pomeranian Medical University, Szczecin/Poland
3The Royal Infirmary of Edinburgh, Edinburgh/United Kingdom

Contact E-mail Address: diana.e.yung@gmail.com

Introduction: Microscopic colitis (MC) is a clinical syndrome of severe watery diarrhoea with few or no endoscopic abnormalities. The incidence of MC is reportedly similar to that of other inflammatory bowel diseases. The need for histological confirmation of MC frequently guides reimbursement health policies. With the advent of high-definition (HD) colonoscopes, the incidence of distinct endoscopic findings reported in MC has risen. This has the potential to improve diagnosis times, increase cost-effectiveness of MC management and diminish the workload and costs of busy modern endoscopy units.

Aims & Methods: Observations on distinct endoscopic findings in MC available until 31st March 2017 were searched systematically (electronic and manual) in PubMed. The following search termsDescriptors were used: collagenous colitis(CC) OR lymphocytic colitis(LC) AND endoscopy, colonoscopy, findings, microscopic colonoscopy, erythema, macroscopic, vascular pattern, perforation, fractures. An additional search for MC AND perforation was made.

Results: Eighty (n= 80) articles, predominantly single case reports (n= 45), were retrieved. Overall, 1,582 (1,159 female; 61.6± 14.1 years) patient(pts) with MC and endoscopic findings were reported. The majority of articles (n= 62) were on CC (756 pts; 77.5% female). We identified 16 papers comprising 779 pts (68.9% female) with LC and 7 articles describing 47 pts (72.3% female) confirmed to have MC. The youngest patient was 10 and the oldest 97 years old. Aside from diarrhoea, symptoms included abdominal pain, weight loss, bloating, flatulence and oedema. In the study group we found 616 (38.9%) pts with macroscopic findings. The most common colonoscopic findings were non-ulcerous lesions i.e. pseudomembranes, a variable degree of vasculature pruning & dwindling, mucosal lacerations & abnormalities such as erythema/or labial nodularity, or surface textural alteration (n= 537; 87.2% pts). Isolated linear ulcerations were identified in 5 pts(0.8%) and in conjunction with non-ulcer lesions in 74 pts(12.9%). The location of endoscopic findings was not reported in 26 articles. Distinct endoscopic findings were described in the left (descending, sigmoid, rectum <20/20 studies), right (cecum, ascending–7/21 studies) & transverse colon (14, as well as duodenum (4), and terminal ileum (2). Colonic perforation was reported in 9 patients (0.57%).

Conclusion: Endoscopic findings are recognized with increased frequency in pts with MC. This could improve MC diagnosis by prompting a more extensive biopsy protocol in such cases and an earlier initiation of treatment. Procedure-related perforation has been reported in this group, therefore, cautious air insufflation is advisable when endoscopic findings are recognised.

Disclosure of Interest: All authors have declared no conflicts of interest.

2Dr. Carol Davila Central Military Emergency University Hospital, Bucharest/Romania 
3University of Medicine and Pharmacy Carol Davila, Bucharest/Romania

Contact E-mail Address: iulianenache.89@gmail.com

**Introduction:** It is well recognized that patients with inflammatory bowel disease (IBD) are at risk for nonalcoholic fatty liver disease (NAFLD). Our aim was to evaluate the prevalence and to quantify hepatic steatosis in IBD patients using the controlled attenuation parameter (CAP).

**Aims & Methods:** We prospectively recruited all IBD patients presenting for a disease flare or follow-up visit in our clinic, during a 18 month period. Patients who reported alcohol intake (more than 20 g/day) and those with coexisting viral hepatitis were excluded from analysis. Clinical characteristics and laboratory data were recorded. Hepatic steatosis was evaluated by conventional ultrasound, hepatic steatosis index (HSI) and transient elastography with CAP (Fibroscan, Echosens, Paris). Significant steatosis (S ≥ 1) was defined for a CAP value over 236 [1], and the cut-off of HSI for detecting NAFLD was set at ≥ 36 [2].

**Results:** Altogether 62 IBD patients (35 ulcerative colitis, UC and 27 Crohn’s disease, CD), mean age 45 ± 15 years, 50% female, were included in the analysis. The two groups (UC, CD) were similar regarding disease activity (remission/flare-48.5/31.4% in the UC group, 55.6/44.4% in the CD group), BMI (24.1 and 24.3) and liver function markers (ALT 21 and 21.1; AST 498 and 513 mg/dl). UC patients had higher mean cholesterol values (205.9 vs. 176.4 mg/dl) and 11% of them were diabetic (compared to none in the CD group). Mean CAP was higher in CD compared to UC-246 vs. 225 dB/m, while HSI values were similar between two groups 49.9 vs. 34.6 mg/dl, respectively. US identified 18/29 (62%) patients with fatty liver, HSI detected 3 more patients (21/ 62, 359%) and CAP even 2 more (23/62, 37.1%), yielding an extra 8% detection rate. NAFLD-IBD patients were more likely to have CD phenotype, history of resection, steroid use and longer disease duration.

**Conclusion:** In our cohort, about one in three IBD patients had fatty liver disease, as quantified by CAP. Diagnostic performance of CAP was better than conventional ultrasound and HSI in detecting fatty liver in IBD patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Irritable Bowel Syndrome (IBS) is a common gastrointestinal disorder that affects around 11% of global population. Despite the high prevalence of IBS, the cause of this disorder remains unknown and the criteria used to diagnose IBS are still unclear. In recent years, disturbances in the intestinal microbiota have been associated to the pathophysiology of IBS. Recently, two accurate biomarkers (Fpra and Eco) have been shown to discriminate between Inflammatory Bowel disease (IBD) and Healthy subjects (H). Therefore, the purpose of this study was to verify the capability of Fpra and Eco abundances to distinguish among healthy subjects, IBS, and IBD patients, in order to create a non-invasive system of diagnostic support for IBS patients.

**Aims & Methods:** A cohort consisting of 33 H, 14 IBS and 18 IBS was enrolled. IBS patients were separated by subtypes: IBS with constipation (C-IBS), IBS with diarrhea (D-IBS) and alternating IBS (A-IBS). Rome IV criteria were used to diagnose IBS patients. Moreover, 29 ulcerative colitis (UC) and 15 Crohn’s disease (CD) patients were also included. All subjects were recruited by the Gastroenterology Services of the Hospital Universitari Dr. Josep Trueta (Girona). At recruitment, patients were separated by subtypes: IBS with constipation (C-IBS), IBS with diarrhea (D-IBS), and alternating IBS (A-IBS) without significant differences were observed, although Fpra abundance was lower in C-IBS. We also used Fpra in combination with Eco as a complementary indicator of dysbiosis (Ratio Fpra/Eco). This ratio allows a good discrimination between H and IBS (P = 0.004). When it comes to discrimination between IBS and IBD patients, significant differences were observed in Fpra/Eco ratio between UC and IBS patients (P = 0.008), but not between IBS and CD patients (P = 0.775). Concerning disorders different to IBS, significant differences were also observed between CD and UC (P > 0.001), between H and UC (P = 0.037), and between CD and UC (P = 0.027).

**Conclusion:** Fpra abundance is a good biomarker to discriminate between healthy subjects and IBS patients. The use of Fpra/Eco ratio allows to distinguish IBS from H and UC patients. In contrast, none of the used biomarkers was able to differentiate IBS and CD patients. These results show that IBS and CD patients share similar dysbiosis parameters opening the need of further study to stabilize any eventual pathogenic link.

**Introduction:** Inflammatory Bowel disease (IBD) and irritable bowel syndrome (IBS) may present in a similar manner [1] [2]. Measuring faecal calprotectin concentration is often recommended to rule out inflammatory bowel disease, however, there are no tests to positively diagnose irritable bowel syndrome and investigative tests are still used to rule out other pathologies [3, 4]. There is a chance, therefore, for novel, non-invasive diseasespecific biomarkers. Volatile organic compounds (VOCs), originating from physiological metabolic processes in the human body, are excreted as waste products through stool samples. For this reason, several biological, non-invasive, simple and low-cost biomarkers of inflammation that are useful in clinical practice for both diagnostic screening and therapeutic or course response monitoring are being evaluated in recent years Evolution of the disease. In this sense, stool markers, and especially calprotectin, have become of great importance in recent years as screening to select patients requiring more diagnostic studies and as a marker of activity for therapeutic follow-up [5]. Can the VOCs from stool samples show differences between ulcerative colitis and Crohn’s disease?

**Aims & Methods:** Five healthy individuals (control group- CON) and nineteen patients diagnosed with IBD were selected for the analysis of their stool VOCs. Healthy participants Healthy control samples (Control) (n = 5) were collected from healthy volunteers workers in the Digestive Diseases Area and they were not related to illnesses related to the gastrointestinal tract and had not undergone antibiotic treatment in the 3 months before sampling. Active patients were defined as a Mayo Clinical score of 3 or more for ulcerative colitis (UC) and a Harvey Bradshaw clinical index of 4 or more for Crohn’s disease (CD). In both cases calprotectin > 300 mg/g or relevant endoscopic lesions. Patients were classified according Montreal and ECCO criteria. This preliminary study is based in a group of CD-UC-CON where was analyzed 10 CD patients, 9 UC patients and 5 controls with 455 samples. Data from stool samples was obtained using eNose MOOSY32 [6].

**Results:** Figure 1 shows the scatter 3D plot with three voltage parameters for the group CD-UC-CON. These parameters mean the voltage from the eNose’s signals on saturation slope (vB) and late saturation (vE) and the number of sensor from the MOOSY32. Table 1 shows the comparative between relative error absolute and classification.

**Conclusion:** In this preliminary research to distinguish between Ulcerative Colitis and Crohn’s Disease, the best algorithm for patient’s classification was the MLP with 30% to train and 70% to test. Although the high classifications result it is hopeful is necessary continue working to understanding how the eNose’s signals affect to the relative absolute error and improving the algorithms to decrease the error.

Introduction: In patients with inflammatory bowel diseases (IBDs), comprising Crohn’s disease (CD) and Ulcerative colitis (UC), a patient-tailored therapy is an unmet need that requires accurate monitoring of the intestinal disease activity. We demonstrated recently, that the expression of microRNA (miR)-320a follows the disease activity in murine colitis models. In this prospective study we evaluated the potential of miR-320a as a biomarker to monitor the disease activity in IBD patients as well as its potential to distinguish UC/CD from infectious colitis.

Aims & Methods: The miR-320a was measured by qRT-PCR analysis in peripheral blood samples from 36 CD and 34 UC patients with acute flare of disease (n = 51) and in remission (n = 37) as well as in healthy control patients (n = 20) and in patients with infectious colitis (n = 9). Disease activity was assessed clinically applying the Crohn’s disease activity index (CDAI) and the partial Mayo score (pMayo) for UC patients as well as the simple endoscopic score Crohn’s disease (SES-CD) and the endoscopic Mayo score (eMayo) to score endoscopic disease activity.

Results: Both in CD and in UC patients, miR-320a expression in remission was significantly increased as compared to healthy controls (49±8.7/±17 vs. 17±3; both p < 0.001) but distinctly lower as in CD/UC patients with acute flare (1718±488; p = 0.006; 531±107, p = 0.001). In CD patients with acute clinical flare (CDAI > 220), miR-320a expression level were significantly increased as compared to CD patients in clinical remission (CDAI < 15; 267±637 vs. 57±9; p < 0.001) and showed a strong correlation with endoscopic disease activity (r² = 0.70). Similarly, in UC patients, miR-320a also revealed a significant increase in patients with low (pMayo 3-4), moderate (pMayo 5-6) and severe clinical disease activity (pMayo > 6) as compared to UC patients in remission (259±47; 281±26; 1090±204 vs.76±13, all p < 0.001). Furthermore, we detected a significantly enhanced miR-320a expression with increasing endoscopic disease activity (eMayo 1: 99±14 vs. eMayo 2: 301±60, p = 0.006; vs. eMayo 3: 775±245; p = 0.002). Most importantly, miR-320a expression in CD and UC patients with acute flare of disease was significantly increased as compared to patients with infectious colitis (p = 0.001).

Conclusion: The miR-320a expression in peripheral blood from IBD patients follows the clinical and endoscopic disease activity and may distinguish between IBD and infectious colitis. Therefore, miR-320a might serve as biomarker to non-invasively assess the disease activity in IBD patients.

Reference
3.2 s.d. 4.39 (0.035–14.4)); Quantum Blue level mean 6.31; median 3.7 s.d. 6.27

Results: The IFX levels measured by the point-of-care method were higher than those measured by established ELISA (Promonitor level: mean 4.67, median 3.7 sd 2.67). According to the manufacturer, the lower and upper limits of quantification are: In the Quantum Blue assay 0.4 mg/ml and 20,ug/ml respectively. In the Promonitor assay 0.053 u/g/ml and 14.4 u/g/ml, respectively. All statistics were carried out using the statistical programs IBM SPSS statistics 21 and Epipad version 4.2.

Conclusion: In this cohort of patients with complex perianal fistulae, although in the majority of cases the diagnosis of IB was suggested by the presence of intestinal symptoms, these were absent in 16.7% patients. There should be a higher suspicion of IB in young patients and in those who have perianal disease of greater complexity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: In patients with IBD the addition of an immunosuppressant is an effective and safe optimization strategy after loss of response to anti-TNF alpha monotherapy. Low doses of IM are sufficient to achieve a clinical response in this setting.

P1680 THE PRESENCE OF IRRITABLE BOWEL SYNDROME-TYPE SYMPTOMS IN MICROSCOPIC COLITIS IS ASSOCIATED WITH INCREASED PSYCHOLOGICAL COMORBIDITY AND IMPAIRED QUALITY OF LIFE

J. S. Kane1, A. J. Irvine1, Y. Derwa1, O. Rotimi2, A. C. Ford3
1Leeds Gastroenterology Institute, St James’s University Hospital, Leeds/United Kingdom
2Department Of Histopathology, St James’s University Hospital, Leeds/United Kingdom
3Contact E-mail Address: jackjohnkane@gmail.com

Introduction: Patients with microscopic colitis (MC) often present with abdominal pain and diarrhoea, and small cross-sectional surveys suggest that up to one-third may meet diagnostic criteria for irritable bowel syndrome (IBS). However, the impact of IBS-type symptoms in patients with MC, in terms of their effect on psychological health and quality of life has not been assessed.

Aims & Methods: We conducted a cross-sectional survey of individuals with MC. We analysed demographic data, symptoms that met the Rome III criteria for IBS, mood (via hospital anxiety and depression scale (HADS)) and somatiform-type behaviour (via patient health questionnaire-15 (PHQ-15)) and quality of life (QOL) (via SF-36) in order to examine risk factors for, and impact of, IBS-type symptoms in patients with MC.

Results: In total, 157 individuals with MC returned completed questionnaires, 53 (36.6%) of whom met the Rome III diagnostic criteria for IBS. The commonest histological subtype of MC was collagenous colitis (52.9%, n = 83), followed by lymphocytic colitis (38.2%, n = 60), and MC-not otherwise specified (8.9%, n = 14). Individuals meeting the Rome III criteria for IBS had significantly higher levels of anxiety (HADS-anxiety score 8.6 vs. 5.0, P = 0.001), depression (HADS-depression score 6.1 vs. 3.5, P = 0.001), and somatiform-type behaviour (PHQ-15 score 12.5 vs. 7.9, P = 0.001) compared with individuals who did not. Individuals meeting the Rome III criteria scored significantly worse on all domains of the SF-36, except for physical functioning. There were also trends towards these individuals being younger (65 years vs. 69.2 years, P = 0.011) or taking proton-pump inhibitors (58.5%, n = 31 vs. 42.4%, n = 39, P = 0.062).

Conclusion: More than one-third of individuals with MC met diagnostic criteria for IBS and these individuals reported higher levels of anxiety, depression, and somatisation plus impaired quality of life. Management strategies for these symptoms are required.

Contact E-mail Address: soniamcb@hotmail.com

Introduction: Anaemia is one of the most common extraintestinal manifestations in inflammatory bowel disease (IBD), with iron deficiency being the most frequent cause.

Aims & Methods: To characterize anaemia in a population of patients with IBD and to evaluate the efficacy of anti-TNF and carrier therapy. We retrospectively analysed 169/1166 patients with IBD followed in a tertiary center between 2010-2016. All the patients received replacement therapy with ferric carboxymaltose, ferric saccharum or transfusional support. We analyzed the effect of immune suppressive therapy with and without anti-TNF: group 1 and 2 respectively.

Active disease was defined as C-reactive protein (CRP) ≥0.5 mg/dl, faecal calprotectin (FC) ≥50 μg/ml or presence of ulcers in colonoscopy. Anaemia was defined according to ECOCC criteria (iron deficiency anaemia (IDA), anaemia of chronic disease (ACD) and mixed anaemia (MA)). Multifactorial anaemia (MFA) was diagnosed when there was also vitamin B12 or folate deficiency.

Results: 169 patients were included: 111 with Crohn’s Disease (CD), 54 with Ulcerative Colitis (UC) and 4 with unclassified IBD. 44.4% were male and the mean age was 32.2 years (range 7-82). 98.2% had anaemia and 1.8% had only iron deficiency; 3.5% and 18.3% had a deficit of vitamin B12 and folate. The mean age was comprised in C and UC were IQR: 30.06–36.74 and 24.96–34.18 years respectively. There was no significant difference in mean UST trough levels in patients who responded to UST induction (median 1160 ng/ml; IQR: 603–1644) as compared to patients who did not respond (median 1556 ng/ml; IQR: 494–2758, p = 0.24). Forty-three (90%) patients received at least 4 injections of UST, with 12 patients who were optimized at the time of dosages. Clinical response was observed in 30.43 (70%) patients. Median UST concentration in clinical responder was 1359 ng/ml (IQR: 554-2068) and 2392 ng/ml in non-responder (IQR: 1496–3494), with no significant difference between the two groups of patients (p = 0.20).

U ST antibodies were undetectable for the 48 patients.

Conclusion: We confirmed that UST treatment is effective in the majority of CD patients refractory to anti-TNF agents. Median trough levels to U ST are not correlated to response and remission to U ST induction and maintenance treatment, with no antibodies developed against UST.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Inflammatory bowel diseases (IBDs) are chronic conditions characterized by elevated costs (both direct and indirect). Over the last years also a significative healthcare burden associated with IBD has emerged, due to an increasing use of biological therapies and hospitalization costs. Despite the creation of local or regional databases in Italy data regarding healthcare expenditure are lacking.

Aims & Methods: The aim of this study was to evaluate costs comprehensive of biological treatments and hospitalizations in a series of patients with ulcerative colitis (UC) and Crohn’s disease (CD) and their correlation with demographic and clinical variables. Disease severity was evaluated by clinical scores (partial Mayo score for UC, Harvey Bradshaw Index for CD). We analyzed retrospectively patients treated by biologics referred to our IBD Unit between May 2015 and April 2016 who underwent at least six months follow-up (last visit October 2016). As regards biological therapies costs burdened by our Centre pharmacy for each drug (Infliximab, Adalimumab, Golimumab, Vedolizumab) and for single patient were evaluated. About hospitalizations the average costs of hospital care specific for a department through fares for homogeneous groups of patients i.e. Diagnosis Related Group (DRG) were collected. The mean overall monthly expenditure for each case was then evaluated.

Results: We collected clinical-economical data of 142 patients in biological treatment. We evaluated costs of UST (infliximab, adalimumab, golimumab, vedolizumab) and for each single patient were evaluated. About hospitalizations the average costs of hospital care specific for a department through fares for homogeneous groups of patients i.e. Diagnosis Related Group (DRG) were collected. The mean overall monthly expenditure for each case was then evaluated.

Conclusion: In our study the main cost is due to biological therapy but the subjects enrolled were the most severe in comparison to the whole IBD population under conventional therapy. No differences were found between the type of biologic administered and the way of administration (intravenous or subcutaneous) so the therapeutical choice could be driven by clinical reasons and not only economic ones.

Disclosure of Interest: All authors have declared no conflicts of interest.

I}
Aims & Methods: We aimed to evaluate all these issues in Sicily through a web-based network of all prescribing centers. The Sicilian Network for Inflammatory Bowel Disease (SN-IBD) is composed by a super Hub coordinator centre and five Hub plus ten Spoke centres. From January 2013, all IBD patients starting a biological agent (incident cases) or already on treatment (prevailing cases) were entered in a web based software. Herein we report data of incident cases about the efficacy of biological therapy after twelve weeks and one year of treatment.

As clinical end-point, we set remission (corresponding to a Mayo Partial Score ≤2 for UC, and to a Harvey-Bradshaw Index ≤5 for CD), and response (reduction of Harvey-Bradshaw Index ≥5 for CD and Mayo Partial Score ≥5 for UC compared with baseline).

Results: From January 2013 to January 2017, 1578 patients were included. Incident cases were 1151 (808 Crohn’s disease [CD], 335 ulcerative colitis [UC]), and 427 were represented as prevalent cases. No significant difference in efficacy was observed between IFX originator and biosimilars. Several factors were identified as predictor of response - independently of the drug employed - at multivariable logistic regression analysis (table 1).

Conclusion: In one of the largest “real-life” series of IBD patients on biological therapy reported to date, ADA in CD had a higher success compared to IFX at both 12 and 52 weeks; however, this results could be influenced by the preference of ADA as first-line anti-TNF drug in CD. IFX in UC was superior to GOL and ADA at 52 weeks; once again, this result could be influenced by the preference of IFX as first-line anti-TNF agent in UC; no difference was found between GOL and ADA in UC. Being naïve to biologics is a relevant predictor of response in both CD and UC at any time point. No significant difference in efficacy was observed between IFX originator and biosimilars.

Introduction: Recent studies have shown that FODMAPs (Fermentable Oligosaccharides, Disaccharides, Monosaccharides, and Polyols)-free diet is effective in subjects with Irritable Bowel Syndrome (IBS). Patients with Inflammatory Bowel Diseases (IBD), and colic disease (CD) can experience functional gastrointestinal symptoms unrelated to inflammation, but data about the use of low FODMAPs diet in these settings is still scarce.

Aims & Methods: To evaluate the usefulness of a low FODMAPs diet on patients with IBS, non-active IBD, and CD on strict gluten-free diet (GFD), we performed a dietetic interventional prospective study evaluating the effect of a low FODMAPs diet on patients subjects affected by IBS, CD following at least a 1-year-GFD and IBD who had been experiencing abdominal symptoms without signs of active inflammation. Each subject was put on a low FODMAPs diet after being evaluated by filling out questionnaires concerning on quality of life and symptoms experienced (IBS-SSS and SF-36), and was re-evaluated twice, first after 1 month and second after 3 months.

Results: 127 subjects were enrolled: 56 with IBS, 30 with IBD and 41 with CD. The analysis of the IBS-SSS survey showed that abdominal symptoms improved after 1 month and low FODMAPs diet in all subjects, with statistically significant difference within each group at T0 (average score in IBS: 293 ± 137 SD, average score in IBD: 206 ± 86 SD, average score in CD: 222 ± 65 SD, p < 0.0001). Furthermore, by analyzing the SF-36 questionnaire, while we didn’t observe any significant difference between the three groups in terms of response to diet (p = NS), we observed a clinical improvement from T0 to T3, after the start of the diet, for most of the questionnaire’s domains.

Conclusion: A low FODMAPs diet could be a valid option to counter abdominal symptoms in patients with IBS, non-active IBD or CD on GFD, and, thus improve their quality of life and social relations.

Introduction: Vedolizumab (VDZ) is a new biologic agent approved for the treatment of adult patients with moderately to severely active ulcerative colitis (UC) and Crohn’s disease (CD).

Aims & Methods: The Sicilian Network for Inflammatory Bowel Disease (SN-IBD) was born to represent all the Sicilian centres prescribing biologics. These centres continuously enter in a web based software all real-life data about pre-scriptions and outcomes of biological therapy in patients with inflammatory bowel disease (IBD). Herein we report data on efficacy of VDZ on intestinal and articular symptoms at week 10, and week 24 of treatment. As clinical end-point, we set steroid-free remission (corresponding to a Mayo Partial Score ≤ 5 for UC, and to a Harvey-Bradshaw Index ≤ 5 for CD), and clinical response (reduction of Harvey-Bradshaw Index ≥ 3 for CD and Mayo Partial Score ≥ 5 for UC compared with baseline with a concomitant reduction of steroid dosage at week 10, and complete discontinuation at week 24).

Results: From July 2016 to April 2017, 163 patients (84 with CD and 79 with UC) were included (table 1). At week 10, a steroid-free remission was obtained in 71 patients (43.6%), while a clinical response in 37 (22.7%). Out of 71 patients reaching 24 weeks of follow-up, 29 (40.8%) were in steroid-free remission, and 10 (14.1%) had a clinical response. No significant difference in terms of clinical benefit (rate of remission plus clinical response) among patients with UC and CD was reported at week 10 (61.5% vs. 67.7%, respectively; p = 0.48) and at week 24 (54.3% vs. 55.6%, respectively; p = 0.91), and no difference was observed comparing naive and non naive patients, neither at week 10 (61.5% vs. 67.7%, respectively; p = 0.48) nor at week 24 (30.0% vs. 39.0%, respectively; p = 0.11). At multiple logistic regression analysis, a longer duration of disease (OR 0.961, p = 0.047) and presence of steroid-dependence (OR 0.189, p = 0.033) were predictors of reduced rates of clinical benefit at week 10, while a low serum level of C-reactive protein at baseline (OR 0.950, p = 0.031) was predictor of clinical benefit at week 24. An improvement of articular symptoms was reported in 39.5% of patients with active spondyloarthritides at baseline at week 10, and in 45.4% of patients at week 24. The only factor associated with articular response was the coexistence of clinical benefit on intestinal symptoms, both at week 10 (OR 3.871, p = 0.05) and week 24 (OR 3.600, p = 0.08). Three inductions or flares of spondyloarthritides during treatment with VDZ were reported.

</table>

Conclusion: In this large cohort of Sicilian IBD patients, VDZ showed good efficacy after 10 and 24 weeks of treatment, particularly in those with a shorter duration of disease and a limited inflammatory burden. A subset of patients reported improvement also on articular symptoms, probably as a consequence of the concomitant control of gut inflammation.

Introduction: Combined immune suppression of anti-tumour necrosis factor (antiTNF) biologicals and thiopurines is superior to respective monotherapies in remission induction and maintenance of response in inflammatory bowel disease (IBD). The positive mechanistic evidence of this clinical benefit is mutually supported by a positive pharmacokinetic effect of thiopurines on antiTNF levels and vice versa. It has been suggested that for this synergistic effect, reduced dose of thiopurines might be sufficient but the data supporting this hypothesis are still limited.

Aims & Methods: The aim of the study was to assess the differences of infliximab trough levels according to the dose of concomitantly used thiopurines. All IBD patients treated with infliximab (Remicade®) in two IBD centres between November 2015 and April 2017 were eligible. Infliximab trough levels were routinely measured in all patients with maintenance infliximab therapy using commercially available ELISA kit (Ridscreen®, R-Biopharm). All patients in remission with stable dose regimen of 5mg/kg every 8 weeks at the time of the first ex vivo analysis were included. All patients were identified retrospectively from the medical records. The differences in the proportion of patients with adequate trough levels (3-12μg/mL) between patients on infliximab monotherapy, reduced (below 2mg/kg) azathioprine (AZA) dose vs. full (2 to 2.5 mg/kg) AZA dose were assessed statistically.

Results: Out of a total of 214 IBD patients treated with infliximab, there were 154 in remission at the time of the first assessment of infliximab trough levels. After excluding patients with previously intensified dose regimen, 125 patients were further evaluated. Among these 125 pts, 41 pts (33%) were on infliximab monotherapy, 58 pts (46%) were using combined immune suppression with a reduced dose of AZA and 26 (21%) were using the full AZA dose concomitantly with infliximab. Both groups, patients with infliximab monotherapy as well as patients using reduced AZA dose had significantly lower percentage of patients with therapeutic levels of infliximab compared with the group using the full dose of AZA co-medication (41% vs. 64% vs. 81%; infliximab monotherapy, reduced AZA dose and full AZA dose, respectively; p < 0.001 for both comparisons, infliximab monotherapy vs. reduced AZA dose vs. full AZA dose).

Conclusion: The proportion of patients with adequate infliximab trough levels is significantly higher in patients with full dose of concomitant azathioprine compared with the patients using a reduced dose of azathioprine. Thus, in order to maintain and sustain benefit of infliximab maintenance treatment, the combined immune suppression should comprise full dose of azathioprine.

P1670 C60 FULLERENES ATTENUATE THE INTENSITY OF COLON DAMAGE AND EXTRATESTINAL MANIFESTATIONS ON RAT ACUTE ULCERATIVE COLITIS MODEL

H. Kuznetsova1, I. Bylinska2, N. Dziubenko1, O. Gurniak1, O. Lynchak1, Y. Prylutsky1, V. Rybalchenko1

Introduction: The primary drugs used for treatment of inflammatory bowel disease (IBD) treatment have some adverse effects and often are ineffective, so the need for more potent and more reliable medications is clear. A significant role at all the stages of the inflammatory process is attributed to reactive oxygen species, therefore the use of antioxidants is a promising direction of the IBD therapy.

Aims & Methods: C60 fullerene are the effective free radical scavengers [1], therefore the evaluation of possible protective properties of water-soluble pristine C60 fullerene using the simulation of acute ulcerative colitis (UC) in rats was aimed to be discovered. The pristine C60 fullerene aqueous colloid solution (C60FAS; initial concentration 0.15mg/ml) was prepared according to the protocols developed before [2]. UC was simulated by acetic acid intracolonic instillation. C60FAS was intraperitoneally or intrarectally applied at dose of 0.5mg/kg C60FAS daily for 2 times after UC induction. The colonic injury was estimated semi-quantitatively on macro- and light microscopy levels using 10- and 14-grade scale respectively, and the grade of total injury (GTI) was calculated. Permeability of colon epithelium was estimated by phenol red dye daily excretion. The states of the colon, liver, pancreas and spleen were assessed by histological (hematoxylin-eosin staining) and biochemical (plasma blood liver enzymes activity) methods. Quantitative blood indices were calculated and leukograms were analyzed.

Results: Colon wall edema, hyperemia and hemorrhage on bowel internal surface, ulcers of different size, epithelium desquamation and inflammatory features manifested by submucosa lymphoid and histiocytic infiltration and extravasation appeared under UC condition. Further UC MODIFICATION ON INFlixIMAB TROUGH LEVELS IS DOSE-DEPENDENT equal to 12 (GTI=12). Repeated oral administration of phenol red dye excretion exceeded the control one 6-6.5 times suggesting the damage of colon epithelial barrier. Degenerative features of exocrine pancreas and liver injury were also observed in UC rats. Anemia features manifested by hemoglobin concentration and red blood cell counts of patients normalized the platelet and neutrophils counts, AST and the state of spleen. In addition, C60FAS intraperitoneally restored the state of the pancreas but increased liver functional upload (as evidenced by elevated ALT activity), whereas its rectal application normalized both ALT and AST activities but didn’t affect the pancreas. Moreover, C60FAS rectally increased monocytes number, which could be explained by involving the latest in mucosa healing process.

Conclusion: C60FAS corrects local and systemic morphofunctional changes, conditioned by the induction of acute UC. The protective properties of C60 fullerene against bowel, hematopoietic system and liver due to its local application are more expressed compared to their systemic one, but their impact on pancreas is controversial. Thus, water-soluble pristine C60 fullerene could be used as efficient therapeutic agents at ulcerative colitis.

Introduction: UC is a potentially severe disease that carries an increased risk of complications and colecotomy. Immunosuppressant and biological therapies are relevant tools for complex patients. The ACCENT study showed that in Crohn’s disease (CD), scheduled IFX infusions vs. episodic are associated with greater efficacy. The historical difficulties of economic access had conditioned to our IBD center, to use IFX in moderate to severe UC to a bridge to thiopurines in pts 6mp/aza naïve. In UC, the mentioned strategy was insufficiently compared with a regimen of scheduled IFX treatment, that currently we use.

Aim: To compare (retrospectively) in moderate to severe UC the results of induction with IFX (in thiopurine naïve pts) continuing with 6mp/aza maintenance vs. similar induction followed by scheduled IFX maintenance strategy.

We included a cohort of moderate to severe UC treated with IFX in an IBD center (2006 to 2015) comparing results between IFX bridge followed by thiopurines (re-induction when available for moderate to severe relapse) vs. scheduled IFX (reinduction when available for moderate to severe relapse and need for corticosteroids maintenance). Optimization (by frequency of intervals) was allowed in both modalities.

Comparisons: Kaplan Meier/Log rank test: a) Cumulative incidence of colectomy, b) survival times relapse free, c) survival times corticosteroid free.

Results: UC patients received IFX for moderate to severe UC (M 60, F 7, Age (mean±SD) 35.9±13.2, UC duration 5.8±5.9 yrs; Extent: extensive 58.5%, Left-sided 41.5%, Activity: severe 78.5%, moderate 21.5%, mean Mayo score: 10.1±1.8. Primary no responders at week 12 (n 25: 21.5%). UC patients improvement in maintenance strategies, which were performed in 110 out of the 135 pts. (Follow-up 37.5±24.0 months) Groups: IFX bridge (n = 51) and scheduled IFX (n 59), which were different in extent, and mean age, UC duration, Mayo score. Cumulative incidence of colectomy was significantly different scheduled strategy (HR 0.8331 95% CI 1.107-0.571; p = 0.0349), survival times free of relapse (HR 3.1026, 95% CI 0.8368 to 5.2405, p < 0.0001) and free of corticosteroids (HR 2.6057, 95% CI 1.5516 to 4.3757, p = 0.0003). A proportion of UC significantly higher within the re-induced pts (HR 0.5148) requiring a shift of biological drug compared with the scheduled strategy (p = 0.016, Fisher), despite of similar rates of optimization. Infusion reactions needing definitive IFX suspension were more frequent as a trend (p < 0.06) in re-induced pts.

Conclusion: Similarly to was described for CD pts, in the CU, the scheduled IFX treatment strategy regimen, after a moderate-severe outbreak, seem to be associated with better long-term outcome regarding colecotomy requirement, relapses, and need for corticosteroids, compared with a bridge IFX strategy followed by thiopurines

Introduction: Ulcerative colitis (UC) patients, may provide an important target for behavioural and physical interven-

Aims & Methods: The aim of this study was to evaluate the efficacy of CT-P13 therapy in maintaining mucosal healing in UC. Patients diagnosed with UC, who were administered CT-P13 from June 2014 at 4 Hungarian and one Czech IBD Centre were prospectively enrolled. Sigmodoscopy was performed at week 14 and week 54 to assess mucosal healing. Mucosal healing was defined as Mayo endoscopic subscore of 0 or 1. Complete mucosal healing was defined as Mayo endoscopic subscore of 0. CT-P13 trough levels, antibody positivity, serum inflammatory markers as CRP level, fecal calprotectin at weeks 14 and 54, concomitant steroid and azathioprine therapy at the time of endoscopic examination and at weeks 14 and 54, previous use of anti TNF drug and the drug of dose intensification as possible predictive factors for mucosal healing at week 54 were evaluated. Result: Seventy-five UC patients were included in the study of which 74 patients completed the induction therapy and 54 patients had already completed the 54 week treatment period. Mucosal healing was shown in 54.5% of the patients at week 14 and 61.7% at week 54 (p = 0.033). Complete mucosal healing was patient in 24.3% at week 14, but in 34.8% at week 54. The position values of CRP (p = 0.017), leucocytes (p < 0.001), thrombocytes (p < 0.001), and albumin (p = 0.002) showed significant difference at baseline and week 54. Mean trough level of CT-P13 was 5.02µg/ml and 4.4µg/ml at week 14 and 54. Serum antibody positivity was assessed in 7.7% and 26.2% of patients at week 14 and 54, respectively. Dose escalation was necessary in one third of patients. None of the patients need surgery who completed week 54, however 4 subjects who stopped CT-P13 therapy after induction regimen required colectomy.

Conclusion: Mucosal healing was observed in two thirds of the patients during CT-P13 maintenance therapy. Our study confirmed the long-term efficacy of CT-P13 therapy on mucosal healing in UC.

Introduction: Anti-Tumor necrosis factor (anti-TNF) agents, infliximab (IFX) and more recently adalimumab (ADA) and golimumab (GOL), have been shown effective and safe in the treatment of moderate-to-severe ulcerative colitis
Vedolizumab (VDZ), a gut-selective monoclonal anti-α4β7-integrin antibody, is used for treatment of Crohn’s disease (CD) and ulcerative colitis (UC). Lack of head-to-head RCTs makes the choice among the three anti-TNFs (IFX, ADA and GOL) challenging. Some data from real-world clinical practice are not fully elucidated in a clinical trial setting, such as the risk of serious infections, serious adverse events (SAEs) and biological discontinuations.

We performed a meta-analysis of randomised controlled trials (RCTs) comparing IFX, ADA, and GOL for induction or maintenance of clinical response and remission in CD or UC. Pooled analysis of AE rates across multiple studies support the favourable, long-term benefit–risk profile of VDZ in real-world clinical practice, with low rates of infusion-related reactions, serious infections and malignancies as a consultant for AbbVie, Janssen, UCB, Takeda, Immune Pharmaceuticals, Janssen, UCB, Takeda, Pfizer, GlaxoSmithKline, Amgen, Bristol-Myers Squibb, Genentech, Mitsubishi, Ferring, Norgine, Tillots, Vifor, Therakos, Pharmacosmos, Piéle, BMS, UCPharma, Hospira, Celltrion, Takeda, Biogaran, Boehringer Ingehelm, Lilly, Pfizer, HAC-Pharma, Index

### Results:

Among the 61 patients, 36 were males; mean age was 43.6 ± 15; no significant difference was present in baseline characteristics (extent and disease activity); 39 patients were thiopurine failure; 38 were naive to anti-TNFs, most were treated with IFX (p = 0.001). ADA and GOL were more often used as a second-line or third-line. The principal indication for steroid-resistant patients was IFX. No significant difference was observed between IFX and ADA both at week 8 (response p = 0.03; remission p = 0.07) and at week 16 (response p = 0.5; remission p = 0.97), though there was a trend towards a higher rate of response at week 8 with IFX (79% vs 64%). IFX and ADA were more effective than GOL at week 8 (response IFX vs GOL p = 0.02; remission: ADA vs GOL p = 0.027). At week 16 only IFX seems to be more effective than GOL in inducing clinical response (p = 0.048) but not remission. No significant difference among the three drugs was observed in patients naive to anti-TNFs. Treatment was discontinued in 2 patient in IFX group and in 6 patients in GOL group and in 6 patients with ADA because of persististent disease activity.

### Conclusion:

This single-center study shows that IFX is more effective than GOL both in the induction (8 weeks) and in the maintenance of response (16 weeks). ADA is more effective than GOL in inducing remission at 8 weeks but no significant difference is observed in the medium-term. However, GOL was used mainly as a second or third-line. In naïve patients, efficacy among anti-TNFs is comparable. Our results may help clinicians in the choice of an anti-TNF in UC. We believe in steroid-resistant patients to get a faster response, ADA and GOL should be the first options in steroid-dependent patients naive to anti-TNFs.

### Contact E-mail Address:

S. Schreiber: s.schreiber@mucoasa.de

### Introduction:

Vedolizumab (VDZ), a gut-selective monoclonal anti-α4β7-integrin antagonist used for treatment of Crohn’s disease (CD) and ulcerative colitis (UC). Data from large real-world cohorts can further characterise safety events not fully elucidated in a clinical trial setting, such as the risk of serious infections, as identified with anti-tumour necrosis factor-alpha (TNFα) therapy in the TNFα-2 and ENACT-2 RCTs.

### Aims & Methods:

We conducted a systematic review and meta-analysis of real-world safety outcomes reported for VDZ in UC and CD. MEDLINE-, Cochrane-, and EMBASE-indexed publications and conference abstracts (n ≥ 10) from May 1, 2014–January 10, 2017 were searched for studies reporting real-world VDZ safety outcomes. Reports for patients < 18 years of age or for off-label VDZ use were excluded. A meta-analysis was conducted using the DerSimonian–Laird random effects method to obtain a weighted mean of adverse events (AEs).

### Results:

Two hundred and eighty studies were identified, with 33 reporting safety rates on 2857 VDZ-treated patients (CD: 1532; UC: 829); unspecified otherwise: 36, three studies [n=460] did not report individual UC/CD data) over a VDZ exposure/follow-up range lasting 0.5–18 months (20 studies). Among included studies, the mean age of patients ranged from 21 to 67 years, with mean disease duration ranging from 7 to 16 years. Most VDZ-treated patients (62–100%) had prior exposure to ≥1 anti-TNF therapy and 66–64% of VDZ-treated patients were receiving concomitant corticosteroids and immunomodulators. The most common non-infectious AEs were acne or acne-like lesions (7%; 95% confidence interval [Cl] 3–11%), fatigue (6%; 95% CI 3–15%) and arthralgia (5%; 95% CI 3–10%) (Table 1). The most common infections were upper respiratory tract infections (6%; 95% CI 3–11%) and sinustitis (4%; 95% CI 1–19%) (Table 1). Infusion-related reactions occurred in 2% (95% CI < 1–4%) of patients (n = 811), and malignancies were reported in <1% of patients (<1–4%; 2 studies). Overall, the pooled AE rate reported in VDZ-treated patients was 21% (95% CI 14–32%); 10% (95% CI 6–16%) for infections, 8% (95% CI 6–10%) for serious AEs and 7% (95% CI 3–13%) for serious infections (Table 1).

### Conclusion:

Pooled analysis of AE rates across multiple studies support the favourable, long-term benefit–risk profile of VDZ in real-world clinical practice, with low rates of infusion-related reactions, serious infections and malignancies reported, and no identification of new safety signals. These results are consistent with integrated safety data reported for VDZ in six clinical trials (>4000 patient-years), despite the selection of complex patients failing previous immunosuppressive or biologic therapies. Limitations of incident reporting in real-world studies include potential underestimates of AE rates and the reporting of AEs not regularly observed in clinical trials;

Introduction: Although many biologics (Bs) have been approved for the treatment of moderate-to-severe Ulcerative Colitis (UC) in patients who have responded inadequately to conventional therapy, the selection of Bs is controversial due to the lack of head-to-head trials. Indirect economic comparisons of these costly drugs are available from National Healthcare perspectives that are not always current.

Aims & Methods: The objective is to evaluate cost-utility of Bs for the treatment of refractory moderate-to-severe UC both in Italy and in the Lombardy Region. A Markov model (considering 3 transition states: remission, clinical response, relapse) was constructed using the software R 3.3.1 markovchain-package to evaluate incremental cost-utility ratios (ICUR) of adalimumab (ADA), infliximab (IFX), infliximab biosimilar (IFX-B), golimumab (GOL) and vedolizumab (VED) treatments of patients over a 10-year time horizon from the perspective of the Italian (N) and Lombardy Region (R) healthcare system. Clinical parameters were derived from clinical trials. Costs (actualised by –1.5%) were obtained from the National database and Regional public tender. Utility was expressed as QALY (Quality Adjusted Life Years).

Results: Costs per treatment were different from a N and R perspective (ADA –55%; IFX –16.7%; IFX-B –29.6%; GOL –9.6%; VED –10%). Direct healthcare costs (treatment cost, visits, lab tests, hospital admissions) were calculated over 10 years of treatment per patient: ADA (N: €114,227; R: €86,314, –40.2%); IFX (N: €110,595; R: €103,081, –21.5%); IFX-B (N: €110,438; R: €78,852, –28.6%); GOL (N: €118,602, R: €96,922, –18.3%); VED (N: €113,852, R: €102,932, –9.6%) with associated QALY respectively of 6.68, 6.66, 6.66, 7.02. From a N perspective, IFX-B was dominating compared to all other treatments. The ICUR of VED/IFX-B was €9,483 for 10 years. From a R perspective, IFX-B was dominating compared to all other treatments. The ICUR of VED/ADA was €101,818 for 10 years.

Conclusion: National and Regional cost-utility analyses produced different results. As Regional price discounts can occur, local analysis is needed to estimate the economic impact of therapies to ensure optimal choice.

P1698 ENDOSCOPIC SUBMUCOSAL DISSECTION OF ULCEERATIVE COLITIS-ASSOCIATED DYSPLASIA: A SINGLE CENTER-BASED EXPERIENCE

Gastroenterology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of

Contact E-mail Address: gi.dry.yang@gmail.com

Introduction: Dysplasia is considered as the precursor of colitis-associated cancer in the long standing ulcerative colitis (UC). Although endoscopic submucosal dissection (ESD) has been suggested as an endoscopic resection technique for non-polypoid dysplasia, only a few studies investigated the feasibility of ESD as a treatment option for non-polypoid dysplasia.

Aims & Methods: We aimed to investigate the feasibility of ESD for the resection of ulcerative colitis-associated dysplasia in UC. From January 2009 to January 2017, 19 UC patients with low grade dysplasia (LGD), high grade dysplasia (HGD) or early colon cancer were admitted for ESD and their medical records were retrospectively reviewed.

Results: Mean age of the 19 patients was 55.5±15.4 years and mean duration between UC diagnosis and dysplasia diagnosis was 13.7±6.5 years. Nine were male. Five of 19 patients directly underwent colectomy without ESD trial due to non-lifting sign (n = 4) or surface ulceration (n = 1). Of these, preoperative single HGD (n = 3) or ECC (n = 1) patients showing non-lifting sign were diagnosed as invasive cancer and a single preoperative LGD case with non-lifting sign had multifocal LGDs in the colectomy specimen. As a result, ESD was performed for 14 of 19 patients. Major and minor axes of the lesion was 23.4±9.0mm and 18.1±9.1 mm, respectively. The lesions were located at the rectum (n = 9), sigmoid colon (n = 2), descending colon (n = 1), and transverse colon (n = 1). The gross morphology showed Paris IIa (n = 7), IIb (n = 4), Is (n = 1), and IIb + Is (n = 2). No lesions contained ulcerations. The borders were distinct in 6 and vague but endoscopically assumable in 8 cases. Mean UC endoscopic index of severity scores of the surrounding mucosa was 0.3±0.1. Mean resection time was 54.8±25.7 minutes. En bloc resection and R0 resection rates were 92.9% and 71.4%, respectively. There was no perforation or clinically significant bleeding. Mean hospitalization period after ESD was 1.14±0.36 days. Final histology of ESD specimens revealed 1 indefinite for dysplasia (IND), 1 sessile serrated adenoma/polyp, 7 LGDs, 3 HGDs, and 1 intramuscal adenocarcinoma. Synchronous lesions were present in 5 patients. Synchronous dysplasia in 4 patients were removed endoscopically. However, colectomy was done in one patient during synchronous metachronous invasive cancer and endoscopically unresectable dysplasia diagnosed by the surveillance biopsy specimens taken during ESD. Metachronous or recurrent dysplasia was identified in 2 of 9 patients who under went follow-up colonoscopy after ESD (median follow-up period 12.3 months, range: 1.4–22.2 months). One developed metachronous LGD at 18 months after ESD and the other developed both metachronous and recurrent LGDs at 8 months after ESD.

Conclusion: According to our ESD series for dysplasia, ESD seems to be feasible for the endoscopic resection of UC-associated dysplasia. However, meticulous surveillance colonoscopy is mandatory to monitor local recurrence and metachronous dysplasia. Non-lifting sign and surface ulceration are highly suggestive of invasive colitic cancer.

P1699 EVALUATION OF ADHERENCE TO INFlixIMAB THERAPY IN IBD PATIENTS

3Budd Medical Center, Santiago, Chile

Contact E-mail Address: ariadna.closparals@gmail.com

Introduction: Biological therapies are effective treatments for inflammatory bowel disease (IBD) but represent an important economic burden to the healthcare system. Adherence surveillance is necessary to optimize the efficacy of treatment and its costs. This issue has been evaluated just in a few studies.

Aims & Methods: We aim to describe the adherence to infliximab in patients with IBD and identify causes and factors associated with poor adherence. WE identified all IBD patients treated with infliximab in a single center since 2009. Fulfillment of the prescribed schedule was assessed for every single infliximab infusion. For every patient, we grouped infusions in “courses of treatment” defined as the administration of infliximab at the same dose and schedule for a minimum of six months. Therefore, restarting the treatment after a holiday of more than 4 months, or changing the interval of doses were considered as a new course of treatment. We defined “infusion well administered” when it was done within seven days before or after the date prescribed.

Results: We included a total of 147 courses of treatment, administered to 100 patients. Seventy-four percent of courses were Crohn disease patients, and 25% in ulcerative colitis patients. In 89% of courses combo therapy with immunosuppressants was used. The prescribed regimens were: every 8 weeks (76.2%), every 4 weeks (7.5%), every 6 weeks (8.8%), every 12 weeks (5.4%) or every 4 weeks (2%). The mean duration of the course was 23 months (range: 6–103). Only 69 out of 1714 infusions (4%), were not properly administered. The reported causes for that included: 36 “unknown” (52%), 18 “change requested by patient” (28%), 12 “due to logistic reasons” (15%) and 4 “other” (5%). In 107 courses (73%) all the infusions were well administered; in 143 (97%)>80% of infusions were well administered and only 4 courses (2.7%) had less than <80% of adherence. In more than an half of the infusions the cause could not been identified, for that reason analysis of predictive factors could not be performed.

Conclusion: The adherence to the scheduled infliximab regimen was very high and it would contribute to maintain the drug efficacy. The reasons for changing the date of administration should be indicated in the clinical history to identify associated factors and minimize the lack of adherence.

P1700 TNF-EXPRESSION OF MONOCYTES IS A PREDICTIVE MARKER FOR RESPONSIVENESS TO INFlixIMAB TREATMENT IN PATIENTS WITH ULCERATIVE COLITIS AND INFLAMMATORY BOWEL DISEASE

D. Issen, B. Jessen, E. Sonnenberg, F. Schmidt, A. Kuehl, B. Sigmund
Department For Gastroenterology, Infectious Diseases And Rheumatology, Charité–Universitätsmedizin Berlin, Campus Benjamin Franklin, Berlin/Germany

Contact E-mail Address: domata.issen@charite.de

Introduction: One-third of all patients with inflammatory bowel diseases (IBD) do not respond to initial treatment with the anti-TNF-antibody Infliximab. Thus, predictive markers for response to anti-TNF-treatment are required.

Aims & Methods: The study was designed to investigate whether levels of TNF produced by peripheral blood mononuclear cells (PBMCs) can predict response to anti-TNF-treatment. Fourteen patients with proven Crohn’s disease (CD) or ulcerative colitis (UC) without treatment with biologicals in the past six months were included prior to first Infliximab infusion. Disease activity was measured by the use of Harvey-Bradshaw-Index (HBI) or partial Mayo Score. C-reactive protein (CRP) and ultrasound (Limberg Score). TNF-expression of LPS-stimulated PBMCs was measured by ELISA before treatment. Additionally PBMC’s...
intracellular TNF-expression was analysed by flow cytometry. According to a cut-off of 300 pg/ml, patients were divided into low- and high-producers. Primary endpoint was clinical response, secondary endpoints were decrease in CRP and Limberg Score. Clinical response was defined as a decline in Score of ≥2 (HBI) or ≥3 (partial Mayo Score). A HBI <5 or a partial Mayo-Score <2 was defined as remission. Results were analysed using the Fisher’s exact test.

Results: Nine patients reached the endpoint at week 6 and were available for further analysis (5 patients with CD, 4 patients with UC). The median TNF-expression was 653.84 pg/ml (49.53–1154.78 pg/ml). TNF was mainly produced by CD14+ monocytes. Four patients were identified as low-producers and five as high-producers. All high-producers responded well to the treatment regarding clinical scoring as compared to only half of the low-producers, but statistical significance was not reached due to the small number of patients (high: 100% vs. low: 33% clinical response, p = 0.167). However, remission rates after 6 weeks were significantly higher in high-producers compared to low-producers (high: 80% vs. low: 0% remission; p = 0.048). Secondary endpoints showed no significant difference in the two groups.

Conclusion: Quantification of TNF-expression in PBMCs and the resulting classification in low- and high-producers could be a potential predictive marker for response to anti-TNF-treatment in IBD patients.

Introduction: Corticosteroids (CS) are often used concomitantly with biologics in treatment of inflammatory bowel disease (IBD). However, their side-effect profile causes significant clinical and economic burden in long-term treatment. In this study, we investigated the impact of concomitant CS use on vedolizumab treatment persistence in patients with Crohn’s disease (CD) and ulcerative colitis (UC).

Aims & Methods: This was a nationwide (Finland), retrospective, non-interventional, multi-center chart review. From 27 centers, we included adult (≥18 years of age) IBD patients who received at least one vedolizumab infusion since 2014. Disease activity charts were standardized case report form. The key data collection points were at baseline, week 14 and month 6 of vedolizumab treatment. The main aim of the study was to analyze vedolizumab treatment persistence among IBD patients using CS in real-world clinical setting.

Results: 247 patients (CD 108, UC 139) were included. At baseline, 47 (43.5%) CD and 84 (60.4%) UC patients were using CS. Higher percentage of patients using CS at baseline discontinued vedolizumab during the 6-month follow-up compared to CS non-users (CD, 14/47 (29.8%) vs. 13/61 (21.3%); UC, 31/84 (37.3%) vs. 16/55 (29.1%). CS users had less vedolizumab discontinuations due to primary inefficacy (p = 0.04) and more discontinuations due to adverse events (p = 0.04), than CS non-users. Over half of the patients on CS at baseline and who persisted on vedolizumab were able to discontinue CS before 6 months (CD, 18/33 (54.5%); UC, 37/53 (69.8%). Among CD patients, CS users had higher baseline disease activity than non-users. Such difference was not observed in UC. CS users had shorter disease duration in both CD and UC. There was no difference in the number of prior TNF-alpha inhibitors between CS users and non-users.

Conclusion: Use of CS at the time of initiating vedolizumab treatment was more common in UC than in CD. Vedolizumab treatment persistence was lower in CS users than in non-users in both CD and UC. The data suggests that CS users have less vedolizumab discontinuations due to primary inefficacy and more discontinuations due to adverse events, than CS non-users. The majority of patients on CS at baseline who persisted on vedolizumab were steroid-free by 6 months, potentially relieving the burden of CS-induced side-effects for both patients and society.

Results: In the context of ~77,382 patient-years of VDZ exposure and a total of 30,927 adverse events (e.g. 13 serious, one non-serious) occurred in 15 patients with pre-existing viral hepatitis B (n = 5, including 2 chronic cases) or hepatitis C (n = 10). Of the 15 patients, six had ulcerative colitis, seven had Crohn’s disease, and in two the indication was not specified (NR). Eight patients received prior/concomitant anti-TNF therapy; NR = 2. Events reported were reflective of the general VDZ safety profile in patients without viral hepatitis. Liver-related events were reported in two patients with hepatitis C—one patient who was a smoker reported hepatic neoplasms; the other reported hepatic masses (history of skin cancer, cholecystectomy, bladder tumour removal, and right radical orchidectomy). Both events resulted in VDZ discontinuation. Of events with a reported outcome, 22/26 (84.6%) were resolved or resolving at the time of reporting and 4/26 (15.4%) were unresolved; NR = 2. VDZ treatment was continued in 10/14 (71.4%) patients and discontinued in 4/14 (28.6%); NR = n.

Conclusion: In the post-marketing setting, there was no evidence of increased risk of viral reactivation in patients with hepatitis B or hepatitis C receiving VDZ. Limitations associated with post-marketing safety reporting (nature of reporting and incomplete patient medical history) and currently limited availability of VDZ in regions with endemic hepatitis B and hepatitis C infection should be considered when interpreting these results.

Introduction: Randomized controlled trials provide efficacy data of novel IBD drugs. The majority of patients included in these trials however, especially for novel biologics, are highly selected patients from referral centres and are included in a variety of countries with very different health care systems. Inclusion criteria and follow-up protocols are strict and do not reflect routine care. Long-term country specific effectiveness and safety data for novel drugs are therefore warranted. Development and implementation of a novel protocol and electronic case reporting registry for every new compound is however time consuming and expensive. Therefore, the Initiative on Crohn and Colitis (ICC) aimed to develop a web-based registry suitable for capturing, managing, and reporting data for all drugs and all IBD phenotypes in everyday practice in all centres.

Aims & Methods: Here, we aim to test the feasibility of the web-based registry in patients starting vedolizumab. With a structured iterative process with IBD-specialists from the ICC, case report forms and lab-evaluation forms were developed to assess key elements of disease activity, safety and a PROM. Furthermore the ICC decided on a uniform follow-up protocol reflecting everyday practice.

A web-based registry for capturing, managing and reporting follow-up data of IBD patients starting a new drug was developed (ICC-case series). The registry automatically reminds the treating physician or nurse prior to novel follow-up visits. Feasibility of the ICC-case series was assessed in 6 centres in the Netherlands in patients who started vedolizumab. To test data extraction and reporting, the baseline characteristics of the first cases were assessed. The characteristics were compared to baseline characteristics of subjects in the vedolizumab registration studies.

Results: A total of 230 IBD (4 IBD-U) patients starting vedolizumab were included. All users found the ICC-case series easy to use and received the reminder mails for follow-up visits. Baseline characteristics were successfully extracted and are reported in table 1.

Conclusion: The ICC developed a uniform web-based registry to study post-marketing safety and effectiveness of novel IBD-drugs. A feasibility study with 230 patients starting vedolizumab showed successful data-capture, managing, and reporting with the ICC-case series in 6 centres. Table 1 shows clear differences between baseline characteristics of real-life Dutch patients and patients in the GEMINI studies underlining the importance of country specific post-marketing data.

Introduction: Azathioprine (AZA) and thiopurine are widely used for induction and maintenance of remission in patients steroid-resistant or dependent with inflammatory bowel disease (IBD). The treatment must be withdrawn in 5–30% of patients due to the occurrence of adverse events.

Aims & Methods: Aim of this study has been to investigate its efficacy and safety in maintaining steroid-free remission in steroid dependent IBD patients six year after the institution of treatment. Data from consecutive IBD outpatients referred in our Institution, between 1985–2015, were reviewed and all patients treated with AZA were included in this retrospective study. AZA was administered at the recommended dose of 2–2.5 mg/kg. Blood chemistry was analysed before administration of the drug, every 10–15 days for the first 3 months and then every 1–2 months following the institution of treatment.

Results: Out of 2722 consecutive IBD outpatients visited in the index period, AZA was prescribed to 415 patients, 227 (54.7%) were affected by Crohn’s disease (CD) and 188 (45.3%) by ulcerative colitis (UC). One hundred and fifty-eight patients with a follow-up < 72 months were excluded from the study. Two hundred and fifty-seven patients were evaluated, 143 (55.6%) with CD and 114 (44.4%) with UC. One hundred and forty-two (55.2%) were male

</table>
and 115 (44.8%) female (average age of 35.68 ± 14.22 SD years, range 14–74 y.). Six years after the institution of treatment, 130 (50.6%) patients still were in steroid-free remission (85 CD vs 45 UC, 59.5% and 39.5%, respectively, p = 0.0017), 71 (27.6%) had a relapse requiring retreatment with steroids (29 CD vs 24 UC, 20.3% and 36.8%, respectively, p = 0.0048), 56 (21.8%) discontinued the treatment due to side effects (29 CD vs 27 UC, 20.2% and 23.7%, respectively). Loss of response from 1st to 6th year of follow-up was low, about 20%.

Conclusion: Six years after the onset of treatment 56% of patients did not require further steroid courses. After the first year loss of response was low in five subsequent years. In the present series the maintenance of steroid-free remission was significantly higher in CD than in UC patients. The occurrence of side effects leading to the withdrawal of AZA treatment has been low.

P1708 CLINICAL EFFICACY AND SAFETY OF ANTI-TNF THERAPY IN INFLAMMATORY BOWEL DISEASE IN THE ELDERLY: A UK TERTIARY REFERRAL CENTRE EXPERIENCE

J. Digby-Bell
Dept. Of Gastroenterology, St. Thomas’ Hospital, London/United Kingdom

Contact E-mail Address: jdigbybell@doctors.org.uk

Introduction: Many patients, especially the elderly or those with comorbidities, are excluded from clinical drug trials and little real-life data exists on the safety and efficacy of anti-TNF.

Aims & Methods: We aimed to compare the clinical efficacy and safety of anti-TNF therapy in patients over 60 years in a tertiary IBD centre in London, UK. We interrogated our IBD databases from January 2009 to November 2015 and performed retrospective data analysis until end of follow up in April 2017. Data was collected on demographics, endoscopy, calprotectin, CRP, clinical scores, serious infections, malignancy, drug levels and anti-drug antibodies. Patients with an age of ≥60 when starting anti-TNF therapy were identified and <60 comparators were selected at random in a 1:1 ratio. Primary endpoints: week 14 and week 54 steroid free clinical remission (Harvey Bradshaw Index < 5 or Simple Colitis Activity Index < 3) Secondary endpoint: proportion of patients remaining on anti-TNF at the end of follow up

Results: See table.

Conclusion: Only a small number of ≥60 years patients started anti-TNF (29 out of greater than 650). This may reflect our local population or that clinicians favour non-anti-TNF therapies in this older group. Overall there was similar clinical efficacy at weeks 14 and 54 of anti-TNF therapy between the ‘young’ and ‘old’ groups. There was a higher discontinuation rate after 1 year of therapy in the older group (p = 0.043). There were more adverse events in the older group (7/29) including 3 new cancer diagnoses compared with the younger group (3/58). 4 patients had detectable anti-drug antibodies in the older group despite 2 of them having therapeutic thiopurine suggesting that the elderly may have more immunogenicity than the young. Further studies with more patients across multiple sites are required to clarify safety and efficacy in the elderly.

P1709 TACROLIMUS IN REFRACTORY ULCERATIVE COLITIS—12 MONTH OUTCOME IN A SINGLE-CENTRE UK DISTRICT HOSPITAL

N. Jayasooriya, L. Everson, S. Mann
Gastroenterology, Barnet and Chase Farm Hospital, Royal Free Trust NHS, Barnet/United Kingdom

Contact E-mail Address: nishani.jayasooriya@yahoo.co.uk

Introduction: Rescue therapy is required for patients with moderate - severe ulcerative colitis (UC) who have failed to respond to steroids and thiopurines. Anti-Tumour Necrosis Factor Agents (Anti-TNFs) are widely used before considering a colectomy. Calcineurin inhibitors such as ciclosporin and Tacrolimus may be considered as alternatives to biologics. There have been some case series in assessing the use of Tacrolimus in such patients although the United Kingdom experience is limited. (1, 2)

Aims & Methods: We aimed to review the outcome of patients who received Tacrolimus as rescue and subsequent maintenance therapy for refractory symptoms of UC. This was a retrospective single-centre case review series. All patients who were refractory to standard medical therapies and being considered for a colectomy were reviewed by a Gastroenterologist with an interest in Inflammatory Bowel Disease. Demographic data, indications for treatment, clinical course and outcomes were reviewed from Electronic Patient Records (EPR).

Results: Fourteen patients (F = 6; mean age of 54 years) received Tacrolimus. 8 patients (57%) had evidence of pancolitis and six patients (43%) had distal colitis. All patients had previously received thiopurines and 11 patients (78.6%) had also received anti-TNFs. Three patients declined Anti-TNF treatment. All patients were steroid-dependent prior to commencing Tacrolimus. One patient received ciclosporin before the switch. The remaining 13 patients were initiated on Tacrolimus in the out-patient setting at a starting dose of 0.1 mg/kg/day in 2 divided doses. Patients took Tacrolimus for a mean period of 18.8 months (range: 2 months to 49 months). Eight patients (57%) achieved a steroid-free remission within 6 months. An additional 3 patients (23%) had a clinical response within 6 months, but required one course of steroids during this time period. Three patients (23%) failed to respond to Tacrolimus; 1 patient remains steroid-dependent and does not wish to proceed to surgery, 1 patient was switched to infliximab and 1 patient proceeded at 10 months to have an elective subtotal colectomy. Tacrolimus was withdrawn in all 3 non-responders. Of the 11 (78.6%) initial responders, 12-month outcome included withdrawal of Tacrolimus in 7 patients (63.6%). Reasons for withdrawal included: n = 1 renal impairment; n = 1 started on infliximab; n = 3 referred for leucapheresis; n = 1 restarted on Azathioprine and n = 1 referred for proctocolectomy. Three patients (21.4%) remain in steroid-free clinical remission with a good quality of life and

</table>
no adverse effects on maintenance treatment with Tacrolimus. 11 patients (9.4%) reported adverse effects at any time during maintenance therapy. These were considered by the investigators as drug-related in the first 12-months of follow-up. Conclusion: Tacrolimus should be considered as an alternative therapy for patients with refractory UC in the out-patient setting. This is particularly useful if the patient is unwilling to consider a colectomy. With close monitoring and supportive care, it is safe and feasible allowing patients an alternative immunosuppressant which may either avoid the need for a colectomy or, give some time to adjust to its implications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1710 A REAL LIFE COMPARISON OF THE EFFICACY OF ADA AND GOLIMUAB IN MODERATE-TO-SEVERE ULCERATIVE COLITIS: A MULTICENTER EXPERIENCE FROM THE SICILIAN NETWORK FOR INFILTRATIVE BOWEL DISEASE (SN-IBD)

S. Renna1, F. Moccio1,2, M. Ventimiglia1, F.S. Macaluso1, R. Orlando1, M. Billeci1, M. Cappello4, M. Mendolaro5, A.C. Privitera6, C. Ferracane6

Aims & Methods: Aims & Methods: We reported the Sicilian Network experience on the comparability of efficacy of ADA and GOL in patients (pts) with moderate-to-severe UC. From June 2015 until April 2017, 197 consecutive pts with moderate to severe UC were treated with ADA or GOL. The efficacy was evaluated at 8 weeks and at the end of the follow-up considering "clinical response" (reduction of at least 2 points of Partial Mayo Score with concomitant steroid reduction or discontinuation) and "clinical remission" (Partial Mayo Score ≤ 2 without steroids). The presence of clinical response or clinical remission was defined as "clinical benefit". Endoscopic Mayo Score was evaluated at the end of the follow up in pts who underwent colonoscopy.

Results: 118 pts were treated with ADA and 79 with GOL for a median follow up of 40.21 [20.32, 69.14] weeks for ADA and 34.00 [17.43, 54.79] weeks for GOL (p = 0.08). Eighty-eight pts were naïve to anti-TNFα (59 ADA, 29 GOL, p = 0.09). No difference in Mayo Score value was observed between the 2 groups at the time of first drug injection (p = 0.92). After 8 weeks clinical benefit was achieved in 93/118 (78.8%) pts treated with ADA and 50/79 (63.3%) pts treated with GOL (p = 0.026). Clinical remission was achieved in 48/118 (40.7%) pts treated with ADA and 20/79 (25.3%) pts treated with GOL (p = 0.038). At the end of the follow up clinical benefit was achieved in 79/118 (66.9%) pts treated with ADA and 37/48 (76.4%) pts treated with GOL (p = 0.088). Clinical remission was achieved in 50/118 (42.4%) pts treated with ADA and 23/79 (29.1%) pts treated with GOL (p = 0.088). No difference was observed in clinical outcomes at 8 weeks and at the end of the follow up between naïve and non naïve pts (p = 0.187). At the end of the follow up the mean Endoscopic Mayo Score was 3.00 [0.00, 5.00] in pts treated with ADA and 4.00 [1.00, 7.00] in pts treated with GOL (p = 0.025). No difference was observed in clinical outcomes at 8 weeks and at the end of the follow up between ADAtreated and GOL-treated pts (p = 0.088).

Conclusion: This is the first study where the comparable efficacy of ADA and GOL was evaluated. These real life data confirmed the efficacy of subcutaneous anti-TNFα in the treatment of moderate to severe UC. ADA resulted to be more effective than GOL in inducing and maintaining clinical benefit.

Larger prospective studies with longer follow up are warranted to confirm this data.

Introduction: The efficacy of golimumab for the induction and maintenance of clinical remission in adult subjects moderately to severely active Ulcerative Colitis (UC) has been studied in two completed clinical trials. However, patients enrolled in clinical trials are not entirely representative of those encounters in the real clinical practice. This study aims to evaluate the durability of treatment with golimumab in the context of real-life clinical practice.

Methods: An observational, multicenter, retrospective, phase IV study, enrolling all patients starting golimumab from March to December 2015, from 21 IG-IBG centers. This study consists of two different parts: 1) retrospective, regarding data until December 2016 and 2) a prospective one, still ongoing, that will be concluded at the end of 2017. The co-primary outcomes were the overall durability of treatment with golimumab, defined as persistence on golimumab therapy because of sustained clinical benefit, and safety. Results for the first 54-week period are reported.

Results: 121 patients (47.4% female) were enrolled. The mean age of 45.7 years (SD 14.3) and a median duration of disease of 8 years, (range 0–28) were included. Sixty-seven patients (55.4%) had severe endoscopic activity (Mayo 3). Clinical activity was defined as moderate (Partial Mayo Score (PMS) 5–6) in 55 patients (45.5%) and severe (PMS 7–9) in 66 patients (54.5%). Pre-treatment exposure to anti-TNFα was reported in 32% of patients (38 Infliximab, 4 Adalimumab, 21 both). Steroid-dependence and refractoriness were reported in 78.5% and 16.5% of patients, respectively. After 54 weeks, the cumulative persistence on golimumab therapy was 31%. Seventy-seven patients withdrew from treatment, without significant difference among anti-TNFα naïve vs exposed patients (55.2% vs 71.4%, p = 0.11 Chi-Square test). Among 90% of patients who completed week 8, 48% of patients were still on golimumab therapy at week 54. Thirty patients (25%) withdrew within the first 54 weeks. Among the remaining patients, at week 54 the persistence on golimumab therapy was 57.1%. Ten patients reported an adverse event, but only 6 of them withdrew from treatment. Four patients reported paradoxical skin lesions, unresponsive to topical therapy. Fifteen patients (12.4%) underwent surgery within the first 54 weeks, with a greater percentage among anti-TNFα exposed (20.6% vs 3.4%, p = 0.02 Chi-Square test).

Conclusion: This preliminary real-life data study endorses golimumab’s promising results, showing 57.1% of durability treatment at week 54 in those patients.
who completed first 14 weeks of treatment and confirming it as a safe drug. Anti TNF-α naïve patients were more likely to avoid colectomy.

Disclosure of Interest: None declared.

Introduction: Ciprofloxacin is one of the most frequently used antibiotics in hospitalized inflammatory bowel disease (IBD) patients. Also discrepancies between clinical guidelines and real clinical situations are observed in terms of antibiotic use in patients with IBD. In the last few years an emerging resistance to ciprofloxacin, ranging from 43% to 82%, has been described in extended spectrum beta-lactamase producing bacteria (ESBL-E) colonizing the gut.1,2

Aims & Methods: The objective of this study was to evaluate the gut colonization with ESBL-E in IBD patients, determine the resistance to ciprofloxacin and bacterial plasmid genes associated with that. Rectal swabs were collected from all consecutive patients with confirmed ulcerative colitis (UC) and Crohn’s disease (CD) hospitalized in two largest tertiary medical care centres in Riga, Latvia during a 7-year period (2010–2016). Enterobacteria were cultured and identified for ESBL presence according to EUCAST guidelines, resistance to ciprofloxacin and bacterial plasmid genes CTX-M, TEM and SHV were detected.

Results: A total of 148 patients with confirmed IBD diagnosis were included in the study: 47 (32%) UC, 47 (32%) CD with CTX-M (n = 4; 80%) and TEM (n = 3; 60%). In UC 6 (50%) and in CD 1 (20%) of the isolated ESBL producing strains from CD patients included only Escherichia coli (n = 5). The isolated bacterial plasmid genes associated with ESBL production in UC included CTX-M (n = 11; 92%), TEM (n = 4; 33%), SHV (n = 1; 8%), in CD–CTX-M (n = 4; 80%) and TEM (n = 3; 60%). In UC 6 (50%) and in CD 1 (20%) of the isolated plasmid genes associated with ESBL were resistant to ciprofloxacin. In 1 case of the ciprofloxacin resistance CTX-M, TEM and SHV gene combination was observed, in 1 case CTX-M and TEM gene combination was observed, in 4 cases only CTX-M gene was present and in 1 case only TEM gene was present. Colonization rate with ESBL-E in IBD patients, mostly with E. coli, expressing CTX-M gene was found comparing with the literature. 2. Higher resistance to ciprofloxacin was found in ESBL-E isolated from UC patients, comparing to UC patients. 3. CTX-M and TEM genes are associated with resistance to ciprofloxacin.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Anti-TNFs are well-established in therapeutic management of Crohn’s disease (CD). Real-life data on their pattern of use in a French clinical setting are, however, limited to this day.

Aims & Methods: The objective of this study was to examine for characteristics of CD patients and anti-TNF use in a real-life setting in France through the general sample of health insurance beneficiaries (EGB database) which includes reimbursement data from a sampled 1/97th of the French population. A cohort of 1280 patients with CD in the EGB database between 01/01/2010 and 31/02/2014 was retrospectively constituted, of which 189 (14.8%) initiated an anti-TNF treatment during that period and were studied for this analysis. An additional analysis was performed based on French hospital discharge data (medical information systems program [PMSI]) from 8142 CD patients to compare results from the EGB database but only support infliximab use due to its exclusive hospital availability in France (adalimumab can be prescribed in both hospital and retail markets).

Results: 47.8% of anti-TNF treated patients were male and the mean age at the initiation of an anti-TNF treatment was 38 years. The mean duration between diagnosis and first anti-TNF treatment was 3.4 (2.3–4.8) years. Concomitant treatments such as corticosteroids and immunosuppressants were prescribed at least once in 63% and 47% of patients respectively. Around 35% of patients initiated a treatment with infliximab and 43% with adalimumab. Results at 12 months after anti-TNF initiation are presented in the table below:

Table 1: Anti-TNF use in patients initiating an anti-TNF treatment with at least 12 months of follow-up at 12 months, 13.6% of patients underwent surgery. Results from the hospital discharge database confirmed some of our observations. Optimization rate for infliximab 12 months after initiation was similar (33.1% at 12 months for infliximab). Treatment discontinuation rate was also within the same range observed and stable over time, with 10% of patients discontinuing infliximab treatment each year and a discontinuation rate after 12 months of treatment of 27.2%.

Anti-TNF use at 12 months after initiation N Results
Drug survival rate for the first line anti-TNF 108 69.8% [62.3–76.1]
Survival rate for first line adalimumab 47 71.7% [59.9–80.6]
Survival rate for first line infliximab 61 66.3% [55.9–74.8]
Anti-TNF dose optimization rate 85 41.5% [34.5–49.3]
Dose optimization rate for adalimumab 53 33.6% [25.2–43.8]
Dose optimization rate for infliximab 63 38.2% [30.1–47.8]
Switch rate to another anti-TNF 126 17.5% [12.6–24.1]
Switch rate from adalimumab to infliximab 70 13.6% [8.1–22.4]
Switch rate from infliximab to adalimumab 88 14.9% [9.6–23.0]
Anti-TNF treatment discontinuation rate 108 31.4% [25.0–38.9]
Discontinuation rate for adalimumab 47 28.2% [19.4–40.0]
Discontinuation rate for infliximab 61 33.7% [25.2–44.0]

Conclusion: The general sample of health insurance beneficiaries’ database provides a unique representative sample to analyze and describe real-life usage of anti-TNF in Crohn’s disease patients in France.

Disclosure: None.

Introduction: Anti-perineal fistulas (APF) are a common location of Crohn’s disease (CD). Their treatment is still disappointing. Identifying the predictive factors of response could guide the practitioner to adapt the anti-TNF α treatment of each patient.

Aims & Methods: We performed a descriptive, longitudinal and retrospective study over a period of 14 years. We included all patients with a definite diagnosis of complex APF of CD treated with anti-TNF α with a minimum follow-up of one year. Patients less than 16 years of age or over 70 years were excluded and non-observing patients were also excluded. A univariate and multivariate statistical analysis was then carried out using the SPSS software to identify the predictive factors of response to the treatment.

Results: A total of 49 patients had complex APF treated with anti-TNF α. 10% of the patients had also recto-vaginal fistulas. The mean age was 31 years. The sex ratio women/men was 1.35. All of the patients had an MRI at diagnosis. Patients had concomitant antibiotics and seton drainage in all cases. 76% of the patients received azathioprin. After the induction phase, 53% of the patients received a second line of treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

achieved clinical remission, 31% a partial clinical response and 12% a primary failure. These were maintained a year after the anti-TNF therapy. After a mean time of 13 months, 42% of the patients had a loss of response. The analytical study found that the absence of recto-colic involvement, CRP negativity and normalization of platelet count under treatment and achievement of clinical remission after the induction phase were predictive factors of long term good response to anti-TNF therapy. Clinical remission after the induction phase was the only independent predictive factor of long-term remission under maintenance treatment after multivariate analysis. However, prospective studies assessing early therapeutic adaptative actions as well as the presence of a recto-vaginal fistula and young age at diagnosis.

Conclusion: According to our results, the type of response obtained after the induction phase seems to be closely related to the subsequent development of other drugs. Further studies assessing early therapeutic adaptative actions could better evaluate this perspective in the event of a partial clinical response. In addition, rectal involvement and recto-vaginal fistulas are factors of poor response for which aggressive and specific treatment is essential.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1715 COMPARISON OF ORIGINAL AND BIOSIMILAR INFliximab in patients with inflammatory bowel disease: A RETROSPECTIVE AND MULTICENTRIC STUDY IN SPAIN

Contact E-mail Address: helena18.3@hotmail.com

Introduction: The management of chronic inflammatory bowel disease (IBD) has experienced significant advance with the development of biologic therapy. Infliximab (IFX) was the first monoclonal antibody approved for IBD. The patent expiry of biologics and their relatively high costs result in a significant system burden. The demonstration of biosimilar IFX efficacy and safety equivalence was based on two pivotal clinical trials in rheumatic diseases. As a result of the extrapolation to IBD, there is growing controversy regarding the appropriate use of biosimilar IFX. The efficacy and safety of infliximab refer to inducing and maintaining remission in IBD has been extensively proven in clinical trials. However, the role of biosimilar IFX, has not been systematically investigated in clinical practice.

Aims & Methods: We aimed to compare the safety and efficacy in inducing and maintaining remission in IBD, between the reference IFX group and biosimilar IFX group. This retrospective, multicenter study was carried out on 4 tertiary hospitals in Spain from January 2013 to December 2016. The analysis included all the patients with IBD in consecutive cohorts of 48 cases. All authors have declared no conflicts of interest.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1717 BASELINE CALPROTECTIN DOES NOT PREDICT RESPONSE TO BIOLOGICAL THERAPY IN ULCERATIVE COLITIS

J. Storey1, T. Skouras2, A. Bond3, S. Dodd3, S. Subramanian4
1Division Of Gastroenterology And Hepatology, Royal Liver and Broadgreen University Hospitals NHS Trust, Liverpool/United Kingdom
2Gastroenterology, Royal Liverpool University Hospital, Liverpool/United Kingdom
3Royal Liverpool University Hospital, Liverpool/United Kingdom
4Division of Medicine, Duke University School of Medicine, Durham, NC, USA

Contact E-mail Address: Thomas.skouras@nhs.net

Introduction: Response to biological drugs in ulcerative colitis (UC) is variable with induction response rates of 64.5% (vs 29.3% for placebo), 50.4% (vs 34.6% for placebo), 51.0% (vs 30.3% for placebo), 47.1% (vs 25.5% for placebo) for infliximab, adalimumab, golimumab and vedolizumab, respectively. Apart from prior entry into anti-tumour necrosis factor (anti-TNF) agents and concurrent immunomodulatory therapy, predictors of clinical response and remission to biological drugs have not been identified. We sought to investigate the utility of baseline faecal calprotectin (FC) and early change in FC in predicting clinical response and remission to biological therapy in UC.

Aims & Methods: Patients who were commenced on any biological therapy for UC and had a baseline FC at the time of commencement were included in this retrospective study. Disease activity was monitored serially by calculation of Simple Clinical Colitis Activity Index (SCCAI) or by Physician global assessment (PGA) or by treatment persistence. Clinical response was defined as decrease in SCCAI or PGA score of 3 or more in PGAs of 0-3 to vedolizumab with a mean age of 41.8 (SD: ±18.2). Fifty-one (72%) and 39 (55%) patients commencing anti-TNF therapy were on concurrent immunomodulators (IM) and steroids respectively. Apart from prior exposure to anti-tumour necrosis factor (anti-TNF) agents and concurrent immunomodulatory therapy, predictors of clinical response and remission to biological drug were identified. We sought to investigate the utility of baseline faecal calprotectin (FC) and early change in FC in predicting clinical response and remission to biological therapy in UC.

Introduction: The prevalence of Crohn’s disease is important for planning of health care and allocation of clinical resources. In 2005, a National Patient’s Registry in Poland was established to collect demographic and clinical data. A total of 35 IBD patients (27 Crohn’s; 8 ulcerative colitis) were included from different groups (mesalamine, prednisone, azathioprine, methotrexate, anti-TNF), and medications efficacy and tolerability was assessed. The efficacy assessment was evaluated according to subjective 4-step scale. Similarly treatment tolerance was assessed according to 2-step scale.

Results: No gender effects were observed on the use or efficacy of individual drug classes, although greater tolerability of prednisone and azathioprine was observed in men (respectively 95.56 vs 93.82 and 93.94 vs. 91.65, both p = 0.05). Smoking did not affect the effectiveness and tolerability of the used medications. However surprisingly fewer smokers were treated with azathioprine, methotrexate, and anti-TNF in comparison to non-smokers (38 vs 45%, 0.5 vs 1.55%, 0.5 vs 11%, all p = 0.05) In patient’s declaring casual alcohol use, the efficacy and tolerability of prednisone was significantly better than in patients declaring abstaining (89 vs 84 and 96 vs 93%, p = 0.05). Referring to the Montreal classification, efficacy of mesalamine, prednisone and azathioprine was significantly higher in A1 group with the lowest in A2 patients (A1: 90, A2: 83, A3: 86 for prednisone, p < 0.05). Regarding relation to localization of the disease, the efficacy of treatment with immunosuppressive agents (azathioprine and methotrexate) in L3 was significantly lower compared with L1 and L2, despite of increased use of immunosuppressive drugs in L1 (76 vs 82%, p = 0.05). As predicted, the use of immunosuppressive and anti-TNF drugs was higher in complicated disease behavior (B2 and B3) than in B1, however efficacy of infliximab was similar in B1 in comparison to others (B3: 15.5% B1: 7% of infliximab use).

Conclusion: This is the first study comparing efficacy and tolerability of treatment methods used in “real-life” practice in Poland during last 8 years. Most observations are in compliance with data from clinical trials. Positive effect ofcasual alcohol consumption on efficacy of medications requires further observation. Interestingly some unexpected relationships, concerning similar efficacy of infliximab in different disease behavior was found. This effect requires also further observations in regards to more frequent use of anti-TNF drugs in last years.

Introduction: Vedolizumab (VDZ) is the first gut-specific monoclonal antibody alternative to anti-tumor necrosis factor alpha therapy in patients with moderate-to-severe inflammatory bowel disease (IBD). It has been registered since 2016 in Hungary, but currently the high treatment costs are considerably limiting the availability of VDZ. All newly initiated VDZ therapy is individualized, it should be approved by the steering committee of five Hungarian IBD-specialists. This results in that VDZ therapy is available exclusively for patients in whom conventional treatment was ineffective or contraindicated.

Aims & Methods: The aim of our non-interventional retrospective study was to assess the efficacy of induction VDZ therapy. 41 patients with Crohn’s disease (CD) and 25 with ulcerative colitis (UC) received VDZ induction therapy between September 2016 and April 2017 in Hungary. Efficacy of induction therapy was assessed based on the changes of activity indices on week 14.

Results: No gender effects were observed on the use or efficacy of individual drug classes, although greater tolerability of prednisone and azathioprine was observed in men (respectively 95.56 vs 93.82 and 93.94 vs. 91.65, both p = 0.05). Smoking did not affect the effectiveness and tolerability of the used medications. However surprisingly fewer smokers were treated with azathioprine, methotrexate, and anti-TNF in comparison to non-smokers (38 vs 45%, 0.5 vs 1.55%, 0.5 vs 11%, all p = 0.05). In patient’s declaring casual alcohol use, the efficacy and tolerability of prednisone was significantly better than in patients declaring abstaining (89 vs 84 and 96 vs 93%, p = 0.05). Referring to the Montreal classification, efficacy of mesalamine, prednisone and azathioprine was significantly higher in A1 group with the lowest in A2 patients (A1: 90, A2: 83, A3: 86 for prednisone, p < 0.05). Regarding relation to localization of the disease, the efficacy of treatment with immunosuppressive agents (azathioprine and methotrexate) in L3 was significantly lower compared with L1 and L2, despite of increased use of immunosuppressive drugs in L1 (76 vs 82%, p = 0.05). As predicted, the use of immunosuppressive and anti-TNF drugs was higher in complicated disease behavior (B2 and B3) than in B1, however efficacy of infliximab was similar in B1 in comparison to others (B3: 15.5% B1: 7% of infliximab use).

Conclusion: This is the first study comparing efficacy and tolerability of treatment methods used in “real-life” practice in Poland during last 8 years. Most observations are in compliance with data from clinical trials. Positive effect ofcasual alcohol consumption on efficacy of medications requires further observation. Interestingly some unexpected relationships, concerning similar efficacy of infliximab in different disease behavior was found. This effect requires also further observations in regards to more frequent use of anti-TNF drugs in last years.

Contact E-mail Address: ramos.guilherme@mayo.edu

Introduction: Tuberculosis (TB) reactivation is of particular concern in patients with inflammatory bowel disease (IBD) treated with biologic therapies. Screening for latent tuberculosis infection (LTBI) is indicated prior to initiating treatment. Infliximab was calculated using McGill University’s ‘The Online TST/IGRA Interpreter. Results: A total of 35 IBD patients (27 Crohn’s; 8 ulcerative colitis) were included in the study. Their mean age was 38.3 ± 14.4 years and 68.6% were male (Table 1). The median time from diagnosis of IBD to LTBI was 9 years (0–48 years). Prior IBD therapies included corticosteroids (86%), aminosalicylates (83%), other immunosuppressants (69%). At least 43% of patients have been previously exposed to at least 1 biologic agent. The most common LTBI treatment regimen wasisoniazid (INH) for 9 months (n = 26, 74%). Biologic therapy used were infliximab (n = 14, 40%), adalimumab (n = 10, 29%), vedolizumab (n = 7, 20%), and certolizumab pegol (n = 4, 11%). Combination therapy with an immunomodulator and a biologic agent was administered in 57% of cases (n = 20). All patients were treated for LTBI and the majority (83%) was treated prior to
starting biologic therapy. The median time from initiation of LTBI treatment to biologic was 43 days (IQR 19–34) years. The median duration of follow-up was 2.9 ± 3.3 years. The median calculated annual risk of developing active TB without treatment was 0.52%/year (range: 0.08%–1.3%). Of the cohort studied, only one patient taking adalimumab monotherapy after completing 6 months of INH therapy developed reactivation of TB. The estimated TB reactivation rate in our cohort was 0.98 cases per 100 patient-years of follow up.

Table 1: Cohort Characteristics and Estimated Post-treatment Tuberculosis Reactivation Rate

<table>
<thead>
<tr>
<th>Type of Biologic Therapy</th>
<th>INH for 6-months (74%)</th>
<th>Retreatment (11%)</th>
<th>Vedikuzumab (20%)</th>
<th>Adalimumab (40%)</th>
<th>Infliximab (40%)</th>
<th>Certolizumab (11%)</th>
<th>Biotherapy Not Specified (29%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Median time to POR</td>
<td>43 days (4–3653)</td>
<td>123 days (9–3653)</td>
<td>152 days (9–3653)</td>
<td>33 days (13–77)</td>
<td>2 months (1–6)</td>
<td>3 months (1–6)</td>
<td>1 year (1–6)</td>
</tr>
</tbody>
</table>

Conclusion: Treatment for LTBI in patients with IBD treated with biologics is effective, but does not eliminate the risk of reactivation, which occurred at a rate of 0.98 cases per 100 patient-years in our cohort. Additional studies with extended follow-up are warranted to further characterize the efficacy of LTBI treatment in these patients.

P1722 SEVERITY OF BILE ACID MALABSORPTION CORRELATES WITH LENGTH OF ILEAL RESECTION IN CROHN’S DISEASE

T. Skouras1, Y. Prasad2, S. Dodd3, S. Subramanian4

1Gastroenterology, Royal Liverpool University Hospital, Liverpool/United Kingdom
2Royal Liverpool University Hospital, Liverpool/United Kingdom

Contact E-mail Address: Thomas.skouras@nhs.net

Introduction: Bile acid malabsorption (BAM) is a common cause of diarrhoea in Crohn’s disease (CD) patients with ileal resection and can lead to complications such as renal and biliary stone disease. BAM is usually diagnosed by selenium labelled homoaurocholic acid test (75SeHCAT) but its availability is limited. Thus, a large proportion of resected CD patients either remain undiagnosed or subject to empirical therapy. There is a paucity of studies examining the correlation between length of ileal resection and severity of BAM which will be of particular use to clinicians with no recourse to diagnostic testing for BAM.

Aims & Methods: We identified all CD patients with a prior surgical resection who underwent 75SeHCAT testing at our institute. Testing was based on the treating clinician’s discretion. The length of resected ileum was recorded from histopathology report. We conducted a Spearman’s correlation test to check for correlation between length of resected ileum and percentage retention on 75SeHCAT.

Response to treatment with bile salt sequestran and 75SeHCAT retention values was tested using Mann-Whitney test.

Results: A total of 97 patients were identified with a mean age of 46.4 (SD 14.5). The median length of resected ileum was 22.5 cms (range 1.5–95 cms) with a median of 1 resection (range 1–4). Overall, 90 patients (92.8%) had ≥75SeHCAT retention values of <5% and 5 (5.2%) patients between 5–10% and only 2 patients had values of >10%. There was moderate correlation between ≥75SeHCAT retention and length of ileal resection (Spearman’s rho: 0.4041, P < 0.001). Data on response to treatment was available for 60 patients, of which 41 (42%) responded and 19 (19%) failed to respond to bile salt sequestrans. The ≥75SeHCAT retention values was comparable among responders (median 0.02%, range 0.1–6.6) and non-responders (median 0.02%, range 0.1–6.6, Mann-Whitney test, P = 0.72).

Conclusion: There was moderate correlation between length of ileal resection and severity of BAM as defined by ≥75SeHCAT retention values. Response to bile salt sequestран therapy was not dependent on ≥75SeHCAT retention values.

POTENTIAL MECHANISM IN THE PROTECTION AGAINST ANTIBIOTHERAPY IN HEALTHY VOLUNTEERS: A NEW FECAL CHOLIC ACID CONCENTRATIONS DURING P1724 SACCHAROMYCES BOULARDII CNCM I-745 LOWERS

Introduction: America whether SB enhances transformation to ‘protective’ secondary BA in human. It appears to become protective against CDI. The goals of this work in healthy and lithocholic). CA loses its germinating properties after transformation and one of its primary actions is a change in the balance of microbiota. The effectiveness of SB in preventing recurrent CDI may be explained, in part, through modulation of microbiota changes that influence the balance of pro- and anti-germination BAs.

Results: Thirty-one patients (65%) showed psychological distress, 22 (31%) anxiety, and 10 depression (21%). Psychological distress was uncorrelated with IBS severity (Spearman’s ρ = 0.05, p = 0.736). Microbial beta diversity was significantly associated with distress and depression (q = 0.044 each). A random forest model using 148 microbial estimators was able to correctly classify patients regarding presence of psychological distress (AUROC = 0.98). Patients exceeding thresholds of distress, anxiety, depression and stress perception showed significantly higher abundances of Proteobacteria (LDA = 2.5). Patients with anxiety were characterized by higher abundances of Bacteroidetes (LDA = 3.0). Distinctly with Lachnospiraceae with Lachnospiraceae (ρ = 0.58, q = 0.018), anxiety positively with Alistipes (ρ = 0.65, q = 0.001). Conclusion: A microbial signature accurately predicted the presence of psychological distress. Psychological variables significantly segregated gut microbial features, underlining the role of brain-gut-microbiota axis. Previous studies have suggested a parallel segregation of microbial features with psychological burden in IBS (1,2,3). The results support a link between the abundance of F. nucleatum oral microbiota, but it is not known if F. nucleatum plays a role in other part of the digestive tract. F. nucleatum may affect metabolic pathways for the carcinogenesis1,2. We examined whether there is relationship between F. nucleatum oral cavity and CRC.

Aims & Methods: We assessed the abundance of Fusobacterium in CRC, colorectal mucosa and saliva. We extracted DNA from mucosal biopsies and measured bacterial levels by quantitative PCR of the 16S ribosomal RNA gene. We also investigated the homology of F. nucleatum in oral cavity and CRC.

Results: In 51 CRC cases, Fusobacterium positivity was significantly higher in CRC compared to controls (p < 0.005). Fusobacterium was more detected in CRC (12.9%) than in normal tissue (3.9%) selectively. The detection rate of F. nucleatum was 96% in saliva and 95% in CRC by next-generation sequencer. A total of 15 patients with CRC were included to check the homology of F. nucleatum in saliva and CRC. From the 15 patients, 9 were F. nucleatum-positive in saliva (60%) and 8 (53.3%) in CRC. From these patients who were F. nucleatum-positive in saliva and CRC, we next looked for the results of AP-PCR and 6 patients have shown common band patterns.

Conclusion: The results support a link between the abundance of F. nucleatum in oral cavity and CRC. Our data also indicate that there may be a route from the oral cavity to the CRC in F. nucleatum positive cases. We are now identifying DNA sequences, particular for the objective strains.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: While particular imbalances in the gut microbiota have been linked to colorectal adenomas and cancers, some specific bacterium have been identified as a related factor. Recent studies have reported a high abundance of Fusobacterium nucleatum (F. nucleatum) in colorectal cancer (CRC) subjects compared to normal subjects1,2. F. nucleatum is also known as a pathogenic species of oral microbiota, but it is not known if F. nucleatum plays a role in other part of the digestive tract. F. nucleatum may affect metabolic pathways for the carcinogenesis1,2. We examined whether there is relationship between F. nucleatum oral cavity and CRC.

Aims & Methods: We assessed the abundance of Fusobacterium in CRC, colorectal mucosa and saliva. We extracted DNA from mucosal biopsies and measured bacterial levels by quantitative PCR of the 16S ribosomal RNA gene. We also investigated the homology of F. nucleatum in oral cavity and CRC.

Results: In 51 CRC cases, Fusobacterium positivity was significantly higher in CRC compared to controls (p < 0.005). Fusobacterium was more detected in CRC (12.9%) than in normal tissue (3.9%) selectively. The detection rate of F. nucleatum was 96% in saliva and 95% in CRC by next-generation sequencer. A total of 15 patients with CRC were included to check the homology of F. nucleatum in saliva and CRC. From the 15 patients, 9 were F. nucleatum-positive in saliva (60%) and 8 (53.3%) in CRC. From these patients who were F. nucleatum-positive in saliva and CRC, we next looked for the results of AP-PCR and 6 patients have shown common band patterns.

Conclusion: The results support a link between the abundance of F. nucleatum in oral cavity and CRC. Our data also indicate that there may be a route from the oral cavity to the CRC in F. nucleatum positive cases. We are now identifying DNA sequences, particular for the objective strains.

HUMAN MILK OLIGOSACCHARIDES: A NEW STRATEGY AGAINST POST-ANTIBIOTIC CLOSTRIDIUM DIFFICILE INFECTION?

L. K. Vignaes
Business Development, Glycom A/S, Horsholm/Denmark

Contact E-mail Address: lise.vignaes@glycom.com

Introduction: Human Milk Oligosaccharides (HMOs) are a family of complex carbohydrates found in high concentrations in human milk and which are now becoming commercially available. In clinical studies, in both infants and adults, HMOs powerfully and specifically modulate the gut microbiota by increasing bifidobacteria and reducing certain pathogenic bacteria (1,2). Also, HMO bacterial consumption results in the production of beneficial metabolites such as short chain fatty acids and the lowering of pH. Hence, the selective growth of bifidobacteria on HMOs can create an ecological niche that is more colonization resistant against pathogens. Bifidobacteria may also have a direct impact on microbial toxins by reducing their level and cytotoxic effect (3). Antibiotics, especially broad-spectrum antibiotics, dramatically impact the microbiota and its balance, and have been implicated in the pathogenesis of many health conditions including gastrointestinal symptoms such as diarrhea (4). The most commonly cited mechanism for antibiotic-associated diarrhoea is intestinal overgrowth of the pathogenic bacterium, Clostridium difficile.

Aims & Methods: The aim of this study is to investigate, in *in vitro* models of *C. difficile* infection, (i) the impact of HMOs on the microbial community and activity (e.g. bacterial metabolites and pH), and (ii) the anti-pathogenic activity of HMOs against *C. difficile*, with a focus on preventing recurrence of the infection. *Two in vitro* models, each using human faecal microbiota infected with *C. difficile*, were used to examine the impact of HMOs on bacterial metabolism and *C. difficile* infection. One model is a 48 hour batch fermentation system, while the other is a simulated gut model, run for 3 weeks post infection, which simulates the infection cycle of *C. difficile* after antibiotic treatment.

**Results:** The study revealed that the HMOs increase the level of bifidobacteria, increase the concentration of beneficial metabolites such as short chain fatty acids and decrease pH compared to a control with no added HMOs. Additionally, HMOs reduced the level of *C. difficile*; in some cases completely eradicated *C. difficile* below detection limits. This antimicrobial effect of HMOs on *C. difficile* was pH-independent, hence another mechanism is causing the anti-pathogenic activity of HMOs.

**Conclusion:** Conclusively, the results show that HMOs can impact *C. difficile* infection in an *in vitro* system, which suggests HMOs as a potential approach to reduce risk of antibiotic associated diarrhoea and post-antibiotic *C. difficile* infection.

Introduction: Due to its high incidence, sporadic colorectal cancer (CRC) remains one of the leading causes of death in developed countries. The most important ones. Bacteriocins possess antibiotic, antineoplastic, pro-apoptotic and probiotic effect.

Aims & Methods: The aim of this prospective study was to evaluate bacteriocin production by mucosal large intestinal bacteria in colorectal neoplasia. We used an original methodology reported by our group (1). Mucosal biopsies were taken in the caecum, transverse colon and rectum within the colonoscopy in patients with non-advanced colorectal adenoma, non-a-A (11 men, 10 women, mean age 63 ±10), advanced colorectal adenoma, a-A (which was defined as neoplasia larger than 10 mm and/or containing villous component and/or containing high-grade dysplasia; 13 men, 7 women, mean age 66 ±6). In the controls (average risk population with normal findings on colonoscopy and with negative history of colorectal neoplasia and/or inflammatory bowel disease; 7 men, 13 women, mean age 57 ±14). Of importance, the family members of patients suffering from colorectal cancer, CRC (12 men, 10 women, mean age 70 ±10) and in the controls (average risk population with normal findings on colonoscopy and with negative history of colorectal neoplasia and/or inflammatory bowel disease; 7 men, 13 women, mean age 57 ±14).

**Results:** A total of 229 mucosal biopsies were taken (60 controls, 63 non-a-A, 60 a-A, 66 CRC) and samples were further investigated. Colicin producing strains were isolated in 22% (13/60) controls, 59% (37/63) non-a-A, 55% (33/60) a-A and in 76% (50/66) CRC. Significantly higher production of colicins was confirmed in patients with CRC compared to patients with a-A, p < 0.001. Microcin producing strains were isolated in 23% (14/60) controls, 56% (35/63) non-a-A, 78% (47/60) a-A and in 62% (41/66) CRC. Significantly higher production of microcins was observed in patients with CRC compared to patients with a-A, p = 0.016. Microcin producing strains were isolated in 23% (14/60) controls, 56% (35/63) non-a-A, 78% (47/60) a-A and in 62% (41/66) CRC. Significantly higher production of microcins was observed in patients with CRC compared to patients with a-A, p = 0.008.

**Conclusion:** Strains isolated from large bowel mucosa in patients with colorectal neoplasia produce bacteriocins more frequently compared to those with normal findings on colonoscopy. We presume, that mucosal large intestinal microbiota with their products including bacteriocins play an important role during the development of colorectal neoplasia.

Introduction: The production of bacteriocins is considered as the key metabolic function of gut microbiota and as the inherent property of probiotic strains. Bacteriocins and metabolites of probiotic microorganisms (metabiotics) can optimize host-specific physiological functions related to human health.

Aims & Methods: This study aims to: (a) detect the bacteriocin genes of probiotic *Lactobacillus helveticus* D75 (NCBI Reference Sequence NC_020829.1) and *Lactobacillus helveticus* D76 (NCBI Reference Sequence NC_CP16827.1) and (b) evaluate in vitro effects of the carboxylic and amino acids mixture identical to the metabolites of the probiotic *Escherichia coli* strain M7 (components with antibiotic activity) on *Lactobacillus helveticus* D75 and *Lactobacillus helveticus* D76 strains was estimated by the deferred antagonism method. The identification of bacteriocin genes was performed by PCR using helveticin J gene primers. Amplified fragments were sequenced using ABI PRISM® 310 Genetic Analyzer and were analyzed using NCBI/BLASTX.

**Results:** The identical sequences of 537 bp homologous to gene fragment of helveticin of *Lactobacillus helveticus* DPC 4571 (hle_1632 gene) were detected.
in DNA of both probiotic strains. Sequencing of these fragments showed differ-
ces in the nucleotide sequences compared to the reference DNA of DPC 4571 strain (A instead of G at position 46, C instead of T at position 249 and A instead of T at position 537), but all these replacements do not lead to changes in the amino acid sequence of a bacteriocin. For Lactobacillus acidophilus D76 another bacteriocin gene fragment of 283 bp was identified (in addition to 537 bp fragment). The latter had 95% homology with the helveticin J gene of Lactobacillus helveticus R0052 (R0052_09025 gene). In NCBI/BLASTX database the sequences homo-
logous to the helveticin gene of Lactobacillus helveticus DPC 4571 were found in 17 different organisms related to Lactobacillus acidophilus, Lactobacillus amylovorous, Lactobacillus crispatus, Lactobacillus gallinarum, Lactobacillus helveticus and Lactobacillus kitasatonis. The addition of the carboxylic and amino acids mixture (Actoflor®-S) results in 2-2.5 fold enhanced antimicrobial activity of both tested probiotics with 48000 MU/ml against pathogens Escherichia coli O75 and Salmonella Enteritidis 209, most likely due to an increase in bacteriocin gene expression.

Conclusion: Study shows that there are at least two bacteriocins in Lactobacillus helveticus D76 and one bacteriocin in Lactobacillus helveticus D75. Carboxylic acid and amino acids mixture identical to the metabolites of the probiotic Escherichia coli strain M17 probably induces bacteriocin synthesis in probiotic strains Lactobacillus helveticus D75 and Lactobacillus helveticus D76 and enhances their antimicrobial activity against test pathogens Escherichia coli O75 and Salmonella Enteritidis 209, most likely due to an increase in bacteriocin gene expression.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Fecal microbiota transplantation (FMT) has been shown to be effective in treating recurrent Clostridium difficile infection. Concern has been raised about the long-term safety of FMT.

Aims & Methods: The aim of this study was to determine the long-term safety of fecal microbiota transplantation (FMT), and its effect on gastrointestinal symptoms (GI) in Clostridium difficile (CDI) patients. We studied 84 patients of which 45 received an FMT treatment via colonoscopy and 39 served as controls receiving antibiotic treatment (AB) for the recurrent CDI and followed their recovery process for a period of 3.8 years. All together 130 patients (55 patients in the FMT group and 75 patients in the AB group were sent a 45-item questionnaire collecting information about the patient demographics, their physical and mental health, including allergies, infections, gastroenterological conditions such as IBD and IBS, diabetes, autoimmune diseases, neurological disorders, mental wellbeing and malignancies. Response rate for the questionnaire was 64.6%.

Results: There were no differences in the incidence of severe diseases between the groups including the incidence of IBD, diabetes, diseases of the nervous system, autoimmune diseases, incidence of colon polyps and cancer. Change of weight was neither different between groups (kg/SD): FMT = + 2.5 (5.6) and AB = + 1.3 (5.6), p = 0.51. The AB treated subjects recorded more frequently that their bowel function had become worse and more irregular after the treatment (40% vs 35.9%, FMT = 11.1%, p = 0.001) compared to FMT group. 77.8% of the patients treated with FMT experienced GI symptoms related to IBS whereas 92.3% of antibiotic-treated patients reported these symptoms (P = 0.006). AB patients experienced more symptoms of the upper intestinal tract than the FMT group (35% vs 15%, FMT = 51.3%, p = 0.045). In this cohort 97.6% of the FMT-treated patients and 60% of AB treated patients would prefer in the future that their initial treatment to be FMT instead of antibiotics.

Conclusion: FMT is a rational, durable, safe, and acceptable treatment option for patients with recurrent CDI. No severe diseases appeared after FMT and FMT seem to relieve GI symptoms better than antibiotic treatment. FMT and AB treated patients would prefer in the future that their initial treatment for recur-
rent CDI to be FMT instead of antibiotics.

Introduction: Clostridium difficile-associated disease (CDAD) is an infection caused by Clostridium difficile, gram-positive, anaerobic, spore-forming and toxigen-producing bacteria. Infection is recognized as the leading cause of diarrhea associated with health care services in the developed countries. In Portugal epidemiological data are limited.

Aims & Methods: Characterize Clostridium difficile-associated disease episodes in a Portuguese Hospital Center. Retrospective analysis of 250 hospitalized patients with CDAD, in Centro Hospitalar do Algarve, between 2011 and 2015. The data obtained from clinical processes and statistical analysis was performed with SPSS version 23.

Results: The patients were mostly women (52%). The mean incidence of CDAD was 0.21% and the patients had an associated mortality of 28%. The year with the highest incidence was 2015 (0.53%) but with a lower associated mortality rate. CDAD was mostly acquired at the hospital level (75.6%) and the mean length of hospital stay was 33 days. About 82.4% of the cases were first occurrence and the remaining (18.6%) were recurrences of CDAD. The majority of the population under study performed Proton Pump Inhibitors (52.8%) and antibiotic therapy (74.4%) (26.8% made a single antibiotic, and 23.6% 2 or more distinct antibiotics). Penicillin antibiotic class was the most used, followed by Cephalosporins (21.5%), Fluoroquinolones (11.4%) and Macrolides (10.1%).

Conclusion: A significant increase in the incidence of CDAD was observed in this study. The increase may be related to several factors, such as the improvement of laboratory diagnostic methods, increased antibiotic prescription, hospital contamination with Clostridium difficile spores or with the appearance of new and more virulent Rybotypes.

Introduction: Colonic diverticular bleeding is the most common cause of lower gastrointestinal bleeding. Persistent bleeding or acute massive bleeding of pre-
senting with hemodynamic disorders requires an interventional treatment. The question of what is the best treatment for acute diverticular bleeding remains
Aims & Methods: The aim of our study is to clarify the efficacy of TAE for colonic diverticular bleeding. 229 patients were diagnosed as diverticular bleeding from Jan 2010 to Dec 2016 in our institution. Bleeding stopped spontaneously in 126 patients. 103 patients were performed colonoscopy. Overt bleeding occurred in 8 patients after colonoscopy, and those were eligible for this study who underwent TAE. Conservative management or endoscopic procedure were not successful in all the patients. 7 patients were male and 1 was female with a median age of 62.6 years (range 39–85 years). The average opportunity for enhanced CT was 2.1, 7 patients were in shock, and all of 8 the patients were treated with blood transfusion. Those who were extravasation-positive in enhanced CT underwent angiogram from a recta near the extravasation at least 3 times. In case radiopaque clips were placed at the bleeding site via colonoscopy to mark embolization site, regardless of whether or not active extravasation was identified on angiogram, coil embolization was performed using 0.018inch coils in vasa recta. Technical success rate and complications were evaluated. Technical success was defined as immediate complete cessation of bleeding confirmed by digital subtraction angiography showing no further contrast extravasation at the end of each TAE. Clinical success was defined as no recurrent bleeding in observation period.

Results: Technical success rate was 88%(7/8), and clinical success was also 88%(7/8). 6 patients were extravasation-positive in enhanced CT, and 5 patients were extravasation-positive in angiogram. Although 3 patients were extravasation-negative in angiogram, 2 patients underwent TAE. After TAE, no recurrence of bleeding was observed. Severe adverse events such as bowel infarction did not occur in all cases.

Conclusion: As the transcatheter technique has recently improved further, adverse events are rare. Therefore superselective coil embolization could be first choice for diverticular bleeding with extravasation-positive in enhanced CT.

P1734 ACCURACY OF THE NASOGASTRIC TUBE AND THE BUN/CREATININE RATIO FOR DISTINGUISHING BETWEEN UPPER AND LOWER SOURCES OF GASTROINTESTINAL BLEEDING. A SYSTEMATIC REVIEW

Contact E-mail Address: stmachlab@tauli.cat

Introduction: The insertion of a nasogastric tube (NGT) and assessment of the BUN/creatinine ratio were recommended as initial measures to distinguish between upper and lower gastrointestinal bleeding (American College of Gastroenterology 2016). As the nasogastric tube is one of the most bothersome interventions for the patient, we evaluated the evidence supporting these recommendations.

Aims & Methods: The aim of the study was to identify the diagnostic accuracy (sensitivity, specificity, positive predictive value, negative predictive value and likelihood ratios) of the NGT and the BUN/creatinine ratio for distinguishing between upper and lower sources of gastrointestinal (GI) bleeding. We conducted a systematic review of the literature in order to identify studies assessing the diagnostic accuracy of the NGT or BUN/creatinine in patients with melena, hematochezia or rectorrhagia without hematemesis. The search was performed in November 2016 in five data bases (Pubmed, Scopus, Web of Science, Cochrane Plus Library and OpenGrey).

Results: Four studies met the selection criteria (two evaluating the NGT, one BUN/creat and one both). The two methods had a low sensitivity for detecting upper GI bleeding source. Both a positive NGT aspiration and BUN/creatinine ratio above 30 markedly increased the probability of an upper GI source with a positive likelihood ratio ranging from 2 to 11. Unfortunately, the sensitivity of both tests for upper GI bleeding was very low (negative likelihood ratios around 0.1). Characteristics and results of the studies selected are shown in table 1.

Conclusion: For patients with gastrointestinal bleeding without hematemesis, BUN/creat ≥30 indicates a high probability of an upper GI source. Nasogastric tube aspiration provides little additional information and so is not necessary. Neither test reliably rules out an upper GI source of bleeding.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: The GBS was superior to the 3 LGB risk scores for predicting the need for transfusion and clinical intervention. The GBS may be an useful tool for risk stratification in acute LGB.

Disclosure of Interest: All authors have declared no conflicts of interest.

Therefore, in cases of uncertainty, an upper GI endoscopy will be necessary to respectively rule out an upper GI source.
Aims & Methods: All patients with ALGB on anticoagulation therapy treated in our hospital during a seven year period were evaluated. Characteristics and clinical outcome were compared between patients on warfarin and patients on NOACs.

Results: Out of 587 patients with ALGB, 43 (7.3%) were on NOACs and 68 (11.6%) on warfarin with an age 75.9 ± 9.5 vs 77.1 ± 7.9. The bleeding site was in the small bowel in 2/43 and 6/68 respectively. Causes of bleeding were not different between the two groups except for polyps/neoplasia (8/43 vs 6/68, p = 0.003). Endoscopic hemostasis was more commonly needed in patients on NOACs 17/43 vs 14/68 (p = 0.049), while they required less hospitalisation days (6.1 ± 4.2 vs 4.5 ± 3.6, p = 0.04). Blood transfusions and need for other interventions (embolization and/or surgery) were not different. Also recurrence of bleeding (4/43 vs 11/68) and mortality (3/43 vs 0/68) were low and not statistically different between the two groups.

Conclusion: ALGB in patients on NOACs although presents some differences it has a similar clinical outcome to patients with ALGB on warfarin.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute lower gastrointestinal bleeding (ALGB) occurs in patients taking anticoagulants either warfarin or non Vitamin K oral anticoagulants (NOACs). The use of NOACs has been increasing compared with warfarin in recent years. We investigated patients with ALGB on anticoagulation therapy and we analyzed characteristics, management and clinical outcome in patients treated with NOACs versus warfarin.

Aims & Methods: All patients with ALGB on anticoagulation therapy treated in our hospital during a seven year period were evaluated. Characteristics and clinical outcome were compared between patients on warfarin and patients on NOACs.

Results: Of 587 patients with ALGB, 43 (7.3%) were on NOACs and 68 (11.6%) on warfarin with an age 75.9 ± 9.5 vs 77.1 ± 7.9. The bleeding site was in the small bowel in 2/43 and 6/68 respectively. Causes of bleeding were not different between two groups except for polyps/neoplasia (8/43 vs 6/68, p = 0.003). Endoscopic hemostasis was more commonly needed in patients on NOACs 17/43 vs 14/68 (p = 0.049), while they required less hospitalisation days (6.1 ± 4.2 vs 4.5 ± 3.6, p = 0.04). Blood transfusions and need for other interventions (embolization and/or surgery) were not different. Also recurrence of bleeding (4/43 vs 11/68) and mortality (3/43 vs 0/68) were low and not statistically different between the two groups.

Conclusion: ALGB in patients on NOACs although presents some differences it has a similar clinical outcome to patients with ALGB on warfarin.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The management of antithrombotic agents during the peri-endoscopic period concerns the risks of bleeding and thromboembolism. The Japan Gastroenterological Endoscopy Sociaity (JGES) guidelines revised in 2012 emphasizes the risk of thromboembolism rather than bleeding. So heparin bridge of anticoagulants is recommended at high-bleeding-risk procedure such as endoscopic mucosal resection (EMR). However heparin bridge in colorectal EMR raises the bleeding rate to approximately 20%, that is very high-rate incident compared with the bleeding rate of 0.3-6.1% generally. It is doubtful whether heparin bridge is appropriate.

Aims & Methods: The aim of this study to clarify the safeness of colorectal EMR under taking anticoagulants without a heparin bridge in anticoagulated patients.

Method: We performed a prospective study in our hospital regarding colorectal EMR at NOBLADS centers (UMIN000021416). The subjects are colorectal polyps resectable by EMR. Inclusion criteria of patient is good performance status (ECOG) 0–1, without organ failure. Warfarin is continued as usual if PT-INR is less than 2.6, and direct oral anticoagulants (DOAC) is continued until an evening of the day before and is discontinued only on the day. Primary endpoint is post-EMR bleeding required any interventions (major bleeding). Major bleeding is defined as active bleeding or adherent clot on the resection site by emergent colonoscopy, or conservative treatment required blood transfusion. Conservative bleeding with no intervention (minor bleeding), thromboembolism, and comparison between warfarin and DOAC are clarified as secondary endpoint. The procedure-related period is defined as up to 30 days after EMR or is finished for two weeks after hemostasis.

Results: 41 patients (154 lesions) were performed EMR from February 2015 to March 2017. Patients’ characteristics were as follow, the median age was 74 years old (50–91, n = 41) and the average of polyp size was 11.6 (range 5-22) mm in diameter. Anticoagulants were divided into 19 cases of warfarin and 22 cases of DOAC. The incidence of major bleeding was none in all cases. On the other hand, minor bleeding which did not require any intervention was recognized at 14.6% (6/41), but there was no case to interrupt anticoagulants. The rate of minor bleeding is no difference between warfarin and DOAC. There was no correlation between minor bleeding and PT-INR value in three cases of warfarin. All three cases of DOAC were medicine once a day. Thromboembolism was not observed.

Conclusion: In colorectal EMR, we clarify the safeness with continuation of warfarin and short discontinuation of DOAC on that day, compared with heparin bridge. We expect to lead to reconsideration of current guideline for safer treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1740 RISK OF COLORECTAL CANCER IN ASYMPTOMATIC INDIVIDUALS WHOSE FIRST DEGREE RELATIVES WERE AFFECTED BY CRC AT DIFFERENT AGES OF ONSET: A SYSTEMATIC REVIEW AND META-ANALYSIS OF 9.28 MILLION SUBJECTS

J.L. Huang, M.C. Wong, C. Chan, J. Lin, W.W. Cheung, M. Liang, Y. Fang, C. Yu, D. Fung
Chinese University of Hong Kong, Hong Kong/Hong Kong Prc

Contact E-mail Address: martin.wong@cuhk.edu.hk

Introduction: The current literature is mixed regarding whether first-degree relatives (FDRs) affected by colorectal cancer (CRC) at a younger age are at substantially increased risk of CRC.

Aims & Methods: The present systematic review and meta-analysis examined the CRC risk conferred by family history of CRC in FDRs according to their age of onset. We searched Ovid Medline, EMBASE and grey literature from their inception to December 2016, and included all screening studies that investigated the relationship between family history of CRC and incidence/prevalence of CRC. Two reviewers independently worked on selection, assessment and data extraction of eligible articles. A random effects meta-analysis was employed to pool relative risks (RR) and odds ratios. Subgroup analyses were performed according to the age of onset of CRC in FDRs of asymptomatic subjects (<40 vs. ≥40; ≤50 vs. >50; <60 vs. >60 years). Statistical heterogeneity was assessed by the I² statistic. Publication bias was evaluated by an inverted funnel plot analysis with Begg’s regression model.

Results: Fifty-six case-control and seven cohort studies involving 9.28 million subjects were included in the analysis. A family history of CRC in FDRs of asymptomatic subjects conferred a significantly higher risk of CRC (RR = 1.76, 95% CI = 1.57–1.97; p < .001, I² = 95.7%). Earlier age of onset of CRC in FDRs was associated with significantly higher risk of CRC in index subjects (RR = 3.29, 95% CI = 1.67–6.49 for ≤40 years vs. RR = 1.42, 95% CI = 1.24–1.62 for >40 years, p = 0.017; RR = 2.81, 95% CI = 1.94–4.07 for <50 years vs. RR = 1.47, 95% CI = 1.26–1.69 for >50 years, p = 0.001). The Begg’s test did not identify any publication bias (Kendall’s τ = 0.122, p = 0.159).

Conclusion: A family history of CRC in FDRs whose age of onset is earlier than 40 or 50 years conferred a significantly higher risk of CRC to asymptomatic individuals, implying that age of onset could potentially enhance the discrimina-
tory capability of CRC prediction scores.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1741 IS THERE ANY DIFFERENCE IN RISK OF COLORECTAL CANCER AMONG ASYMPTOMATIC SUBJECTS WHOSE SIBLINGS VS. PARENTS WERE AFFECTED? A SYSTEMATIC REVIEW AND META-ANALYSIS

J.L. Huang, M.C. Wong, C. Chan, J. Lin, W.W. Cheung, M. Liang, Y. Fang, D. Fung, C. Yu
Chinese University of Hong Kong, Hong Kong/Hong Kong Prc

Contact E-mail Address: martin.wong@cuhk.edu.hk

Introduction: Few studies compared the risk of colorectal cancer (CRC) among individuals with probands who were parents, siblings, and those with two or more probands.

Aims & Methods: This systematic review and meta-analysis tested the hypothesis that the risk of CRC conferred by family history of CRC in parents vs. siblings vs. ≥2 first-degree relatives (FDRs) was similar. The Ovid Medline, EMBASE and grey literature were searched from their inception to December 2016, and all screening studies that examined the association between detection of CRC and family history of CRC in FDR were included. Two reviewers independently searched, assessed and extracted data from eligible studies. The relative risks (RR) and odds ratios were pooled based on a random effects meta-analysis. We conducted subgroup analyses according to the identity of FDRs affected (parents vs. siblings vs. ≥2 FDRs), and examined statistical heterogeneity by the I² statistic. Potential publication bias was explored by funnel plot analysis with Begg’s regression test.

Results: We identified 56 case-control and 7 cohort studies, consisting of 9.28 million subjects who were finally included in the meta-analysis. Asymptomatic individuals with siblings affected (RR = 2.44, 95% CI = 1.90–3.13); parents affected (RR = 2.18, 95% CI = 1.95–2.45) and ≥2 FDRs affected (RR = 2.68, 95% CI = 1.93–3.70) had statistically similar risk of CRC. We did not identify any publication bias based on the Begg’s regression test (p = 0.159).

Conclusion: The risk of CRC was similar among subjects whose siblings; parents or ≥2 FDRs were affected by CRC. Information on the identity of the FDRs affected does not seem to be necessary when the risk of CRC in asymptomatic individuals is predicted.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1742 GILBERT SYNDROME IS NOT THAT INNOCENT!

N. Arber1, M. Menachem1, L. Ari2, G. Lion2, B. Ezra3, H. Gill4, H.G. Amir5, J. Mayazer1, S. Shapira1
1Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel
2Tel-Aviv Sourasky Medical Center, Tel Aviv/Israel

Contact E-mail Address: nadira@tvme.gov.il

Introduction: Gilbert’s syndrome is considered to be entirely benign. Some studies have shown a reduced risk for cardiovascular disease (CVD). There is conflicting data regarding cancer risk in Gilbert’s syndrome patients.

Aims & Methods: We aimed to evaluate the association of Gilbert syndrome with CVD and cancer. Clinical and epidemiological data was obtained from consecutive healthy subjects undergoing annual screening at the Integrated Cancer Prevention Center in Tel Aviv. The annual check-up includes: thorough examination by specialists in internal medicine, surgery, dermatology/plastic surgery, OB/GYN, urology, oncology, oral surgery, gastroenterology. Blood work (smac 24, blood count, TSH, CRP, PSA), vaginal, PSA and mammography (>40ys), LDCT in heavy smokers and all needed imaging when clinically indicated. Peripheral blood DNA was extracted from all subjects. Gilbert syndrome was determined by clinical criteria (normal liver function tests but to mild elevation in unconjugated bilirubin <3mg/dl without any hemolysis. In the majority of the cases the diagnosis was confirmed genetically by the homozygous mutation (TA)7TA in the promoter region of UGT1A1 enzyme. Prevalence of CVD and cancer were compared between subjects with/without Gilbert syndrome.

Mortality data was obtained from the Israeli ministry of health and cancer incidence from the Israeli registry.

Results: A total of 6258 (49%) men and 6461 (51%) women, mean age 47.0±11.5 years, were included of which 1,019 had clinical Gilbert. Gilbert was significantly more common among men (11.5% versus 4.6%; p < 0.001). The prevalence of Gilbert syndrome was equal in Sephardic and Ashkenazi Jews. Malignancy and CVD were diagnosed in 678 (5.3%) and 1,837 (14.4%) subjects respectively. The prevalence of any CVD was significantly higher in the Gilbert group (OR 1.23, 95% CI 1.04–1.46; p = 0.017), as well as coronary artery disease (OR 1.37, 95% CI 1.12–1.68; p = 0.003) and CVA (1.1% versus 0.6%; p = 0.06). Higher rate of kidney and bladder cancers (OR 2.64, 1.22–5.70, p = 0.019) was also observed in the Gilbert group. In contrast, the prevalence of breast cancer was much lower among Gilbert patients (OR 0.36, 0.13–0.97, P = 0.034).

Conclusion: In Israel Gilbert syndrome is not that innocent. In a large cohort it seems to be associated with increased risk of hypertension, CVD and CVA. Bladder cancer is higher but females are protected from breast cancer. Further studies are mandated in order to better understand these findings and determine proper screening and surveillance practices in Gilbert disease.

P1743 CHARACTERISTICS AND PREDICTORS OF INTERVAL CANCER: A CASE-CONTROL STUDY

I. Laih1, J. Mizrahi2, F. Konikoff1
1Meir Medical Center, Kfar Saba/Israel
2Stony Brook University Hospital, New York/United States of America

Contact E-mail Address: ido.laihi@gmail.com

Introduction: Interval colorectal cancer is largely related to a poor endoscopic performance (missed lesions, incomplete resection or different polypectomy technique). Significant factors like technical issues and biological factors may contribute to the development of the polyed (accelerated growth). Thus, quality endoscopic measures and Lynch syndrome were highly investigated for their association with interval cancer. However, most reports came from the Western world and not the Middle East, and differences in ethnicity or environmental factors might potentially have impact on the biology of tumor progression. In addition, patient-related factors were less investigated for their association with interval cancer. The aim of this study was thus to assess tumor and patient characteristics and predictors of interval cancer in a population from Israel.

Aims & Methods: This retrospective cohort study included all patients that were diagnosed with colon cancer in our institution between 2005–2014. Cases included patients with a previous colonoscopy within 1–10 years before the diagnosis of cancer, with either negative or indented or benign polyps. Only full colonoscopies with at fair or good preparation were included. Interval cancer was defined on an individual basis, when cancer occurred within the recommended surveillance interval according to accepted guidelines. Cases were further stratified according to time since index colonoscopy (<3 years, 3–10 years).

Positive controls were cancer patients without previous colonoscopy, and "negative" controls were sex- and age-matched patients with two negative colonoscopies within the study period who were randomly selected on a 1:5 ratio. Tumor characteristics (location, staging) and patient-related features (age, gender, positive family history of colon cancer, aspirin use, diabetes, diverticulosis) were compared between cases and control groups.
P1744 THE RELATIONSHIP BETWEEN QUANTITATIVE FIT RESULTS AND NEOPLASTIC FINDINGS

J.S. Megrath, M. Bagoankaar, D. Pace, A. Antle, S. Stone, E. Randell, J. Quinan
Dept. Of Gastroenterology, Memorial University, St. John’s/Canada

Contact E-mail Address: jmegrath@mun.ca

Introduction: Fecal Immunochemical Testing (FIT) is currently used in most Canadian provinces to screen for colorectal cancer. Newfoundland and Labrador is one of the provinces in which colorectal cancer screening program over the past five years. Newfoundland and Labrador selects patients for colonoscopy if one of two FIT values ≥100 nm/g. Aim(s) & Methods: The goal of this study is to assess the effectiveness of different FIT cut-offs and number of FIT tests for detecting adenomas and colorectal cancer.

Results: Data for this study were obtained in a prospective fashion using the Newfoundland and Labrador Colon Cancer Screening Program. 21,371 patients underwent between the ages of 50-74 and at average risk for colorectal cancer between July 1, 2012 and June 30, 2016. 16,152 participants returned their FIT tests. 1500 individuals were enrolled; 726 persons (494 men, 68%) and the target group (metabolic syndrome) and 774 persons (253 men, 46%) in the control group (without metabolic syndrome). The significantly higher prevalence of advanced adenomas was observed in the target group (18%; 95% CI 15–21%) compared to the control group (9%; 95% CI 7–11%); OR 1.8; p=0.002. Similarly, the prevalence of all adenomas was higher in the target group (48%; 95% CI 44–51%) than in the control group (35%, 95% CI 32–38%); however, the difference was not statistically significant (p=0.179). Individuals with isolated high cardiovascular risk (SCORE ≥10%) had higher prevalence of both, non-advanced adenomas (51%, 95% CI 46–56% ; p=0.327) and advanced adenomas (22%, 95% CI 18–26%; p=0.049) comparing to the individuals with isolated DM2. Advanced adenomas were more likely in patients aged 65–75 years.

Conclusion: Colon cancer is positively associated with metabolic syndrome. Cardiovascular risk factors (SCORE ≥10%) is a stronger risk factor than the presence of diabetes mellitus type 2. Individuals with SCORE ≥10% should be considered as a high-risk group and targeted colorectal cancer screening. SPs are classified into hyperplastic polyps (HPs), sessile serrated polyps (SSPs) with or without dysplasia and traditional serrated adenomas (TSAs). The serrated polyposis syndrome (SPS) is characterised by multiple SPs throughout the colon. 0.2% of all individuals with detected SPs none fullfilled the diagnostic criteria for SPS. Hence, we determined a prevalence of SPS of 0% in our cohort. 0.2%. Of all individuals with detected SPs none fulfills the diagnostic criteria for SPS. Hence, we determined a prevalence of SPS of 0% in our cohort.

3Gastroenterology, Hospital České Budějovice, České Budějovice/Czech Republic

Introduction: The prevalence of colorectal cancer (CRC) and related risk factors such as diabetes mellitus type 2 (DM2) and/or dyslipidemia was up to 30%. Our aim was to determine the prevalence of SPS in average-risk individuals participating in the German CRC screening programme. We retrospectively analyzed screening colonoscopies performed by gastroenterologists in 4 medical practices and 1 tertiary academic hospital between 01/01/2011 and 14/12/2016. Individuals <50 years, with an increased risk for CRC (i.e. a family history of CRC, cancer, adenoma, or colorectal cancer, colorectal polyps, and colorectal cancer, colorectal polyps, and colorectal cancer, colorectal polyps), and colorectal cancer, colorectal polyps, and colorectal cancer, colorectal polyps).

Results: A total of 3089 individuals were analyzed. 47.5% were male, median age was 62 years (interquartile range 57, 68). 33.9%. Detection rates for SPs, HPs, SSSs and TSSs were 21%, 14%, 4%, and 0.2%. Of all individuals with detected SPs none fulfills the diagnostic criteria for SPS. Hence, we determined a prevalence of SPS of 0% in our cohort.

Conclusion: In our study, the prevalence of SPs in average-risk individuals undergoing screening colonoscopy was 0%. Because overall ADR was above the recommended values for screening colonoscopies, we conclude that this low prevalence might be attributed to a lack of awareness for SPS rather than to low quality of screening procedures. However, we were not able to determine detailed information about first-degree relatives of SPS from medical records of individuals with SPS to check the second diagnostic criterion for SPS. We also included only one colorectal polyp per individual. It has been shown that prevalence increases when follow-up colonoscopies are included. SPS may have caused an underestimation of the true prevalence of SPS in our cohort.

P1747 CONTRIBUTION OF GERMLINE MUTATIONS TO NON FAMILIAL EARLY ONSET CANCERS

A. Mannucci1, F. Calabrese1, A. Russo Raucci2, R. Rosati2, P.A. Testoni3, G.M. Cavestro1

Introduction: Early onset colorectal cancers lacking a positive family history are an increasingly worrisome entity. One on hand, early onset is the cornerstone of genetically determined oncological problems, but on the other negative family history does not support the suspicion of familial syndromes.

Aims & Methods: We addressed the contribution of germline mutations to non familial early onset cancers. Patients with pancreatic, gastric, esophageal, duodenal and colorectal cancers were enrolled from 2015 to 2017 at the Gastrointestinal Personalized Medicine unit. Eligibility criteria were the juvenile onset and the negativity for clinical criteria of hereditary cancer syndromes. Early onset colorectal cancer was defined as <45 yrs. For the other cancers, the threshold was defined as 50. Eligible patients provided informed consent. Genes were sequenced by means of a validated Next Generation Sequencing panel of oncological susceptibility genes and confirmed by means of Sanger sequencing.

Results: Among 12 colorectal cancer patients (7F, 5M), NGS analysis showed: 2 mutations of MSH2 (clone 4) and MSH6 (clone 17) occurring de novo, given the absence of family history; 3 variants of unknown significance (VUS) (2 MSH2 and 1 MLH1); and 7 were negative. Age-stratification revealed that, among those <35 years (n = 4), 1 had MSH2 gene mutation and 3 were negative. In the 36-40 age group (n = 3), 1 had MSH2 gene mutation and 2 were negative. In the age group 41-45 (n = 5), 1 MSH6 mutation and 2 VUS were found, alongside 2 negative results. Among the colorectal cancers, 17% of patients had a de novo mutation of Lynch Syndrome, 25% had a VUS, and 58% were negative.

Conclusion: A significant percentage (17%) of early onset colorectal cancers resulted in Lynch Syndrome even when family history is not suggestive of hereditary cancer. We reliably infer the determinant role of genetics, even when the family history does not support the hypothesis. Elsewhere, our results suggest that the already known susceptibility genes seldom contribute to sporadic early onset cancers. Other genes and mechanisms may explain the early onset phenotype. Our data show that NGS is often non conclusive in early onset GI cancers, and further development is needed to better classify VUS (25%).

Introduction: Evidence links the immune microenvironment, microbiome and colorectal cancer (CRC). Colibactin-producing E. coli are more frequently detected on mucosa CRC patients and exhibit prooncogenic properties on CRC murine models. Aim of this work was to evaluate the impact of colorectal cancer by colibactin-producing E. coli on immune cells in preclinical models.

Aims & Methods: Min mice were per os inoculated with a CRC-colibactin-producing E. coli strain (11G5), non pathogenic E. coli (K-12 MG1655) or PBS. Using optical in vivo imaging (IVIS spectral), we evaluated oxidative stress induction with a bioluminescent inflammation probe in Min mice chronically infected. After 7 weeks, number and volume of polyps were evaluated and colonic samples were histologically analysed. Detection of immune cells was quantified by immunofluorescent labelling using a specific and innovative algorithm created with Tissue Studio software. Then, the density and localization of immune cells were performed in the three colon regions of interest: lymphoid follicle, mucosa and tumor.

Results: Using optical imaging, we detected a significant increase of luminescent signal and tumor volume at the site of infection suggesting an increase of oxidative stress and inflammation. Histological analyses showed no difference about intra-tumoral immune infiltrate density on 11G5 and K12-infected mice. However, using our specific algorithm, we observed a significant increase of lymphoid follicle size in the gut of mice infected with the 11G5 strain compared to mice feeding with non-pathogenic K12 strain. Interestingly, follicle size was positively correlated with tumor volume, on the 11G5 infected group suggesting an association between pro-carcinogenic properties of this strain and gut immune response. In addition, we observed an increase of neutrophils (Ly6G+ cells) on mucosa and lymphoid follicle of mice infected with 11G5 compared to K12 and non-infected mice. These results can be linked with our in vivo optical imaging observations and our results about the increase of neutrophils in chemo-attractants CXCL1 and CCL20 measured by qRT-PCR after infection. Analyses of T cells, macrophages, B cells and myeloid suppressive cells are in progress.

Conclusion: Here we can observe an increase of lymphoid follicle associated with tumor volume after colibactin-producing E. coli infection. Our first results suggest that neutrophils can be one of the immune cells implicated in this process. This work shows a link between immune microenvironment, pathogenic E. coli and tumor development.

Introduction: CD24 is a glycosylphosphatidylinositol-linked protein that functions as an adhesion molecule and is overexpressed at an early stage of CRC (Sagiv et al., 2006). The Wnt/b-catenin signaling pathway plays an important role in the CRC carcinogenesis process. C57BL6/J mice carrying the ApcMin mutation developed ~24.3 ± 3.7 adenomas and several carcinomas in the small intestine by the age of 16 weeks compared to the ~7 ± 1.7 polyps that ApcMin/CD24−/− (double KO) mice developed. Mice colonscopy showed a significant reduction in the number and size of polyps upon depletion of CD24 alleles. The ApcMin mice displayed severe splenomegaly (355 ± 68 mg) compared (141 ± 49 mg) in double KO mice similar to WT mice. Hb level in the ApcMin was 5.8 ± 2.5, significantly lower than in the double KO mice (8.2 ± 0.9) and their WT littermate.

Aims & Methods: We aimed to study the cellular interactions between CD24 and b-catenin, and effects of their interaction on intestinal tumorigenesis. CD24-inducible 293T-Rex cells previously developed in our lab (Shapira et al., 2011) and SW480 CRC cells stably transfected with CD24 (Naumov et al., 2014) were used to study this interaction in vitro. Co-immunoprecipitation and immunofluorescent staining were used to investigate the interaction between the two proteins. Far western blotting (WB) analysis was used to confirm this direct interaction by probing the standard WB membrane with the purified CD24 protein.

Results: In vitro: Western blotting analyses showed that expression of CD24 in 293T-Rex cells induced the activation of b-catenin, while down-regulation of CD24 in SW480 cells caused a decrease in the level of active b-catenin. Cytoplasmic/nuclear fractionation showed that more active b-catenin entered the nucleus in cells that expressed compared to control cells (clone 4). In addition, in both cell lines, TOP/FOP luciferase reporter assay showed a significant increase in Luciferase activity upon CD24 expression induction. Co-immunoprecipitation studies of CD24 and b-catenin indicated that these two proteins might be interacting. In addition, in HEK-293T cells and SW480 cells, immunofluorescent staining of CD24 and b-catenin showed that these two proteins co-localize on the cellular membrane. Furthermore, far western blotting analysis suggests that a direct interaction between the proteins exist.

Conclusion: 1. CD24 plays a major role in intestinal tumorigenesis. 2. CD24 interacts with the Wnt pathway by activating b-catenin. 3. CD24 interacts directly with b-catenin. 4. Down-regulation of CD24 may be an important aim in the therapy of CRC.

Introduction: Cancer stem cells survive as the leading reason to tumor recurrence after tumor repressive treatments. Therefore, it is worth discovering specific and efficient inhibitors against cancer stemness for applications in reducing tumor recurrence. Previously, literature has indicated that YM155 can significantly reduce the number of tumorspheres in vitro. The aim of this study attempted to investigate the potential mechanism of YM155 against cancer stemness in ENS-positive cancers.
Aims & Methods: The aim of this study attempted to investigate the potential mechanism of YM155 against cancer stemness in ENS-positive cancers. The tumorspheres derived from EGFR-mutant HCC827 and EGFR-wild-type HCT116 and A549 cells expressing higher cancer stemness markers, CD133, were used as cancer stemness models.
Results: We found that higher EGFR auto phosphorylation (Y1068) in HCC827,- A549, and HCT116- derived tumorspheres compared to the parental cells, which induced tumorsphere formation through activating G9A-mediated stemness property. YM155 was demonstrated to inhibit the tumorsphere formation by unexpectedly blocking the autophosphorylation of EGFR and G9A-mediated stemness pathway. The chemical and genetic inhibitions of EGFR and G9a revealed the significant role of GFR-G9a pathway in maintaining the cancer stemness property.
Conclusion: In conclusion, this study not only revealed that EGFR triggered the formation of tumorspheres through elevating G9A-mediated stemness, but also demonstrated that YM155 inhibited the formation of tumorspheres by simultaneously blocking auto phosphorylation of EGFR and activity of G9a as a potent anti-stemness agent against EGFR-positive cancers.

Introduction: Promoter hypermethylation-induced epigenetic silencing of tumor related genes played a key role in the initiation and development of colorectal cancer (CRC). Using Methylated DNA Immunoprecipitation (MeDIP), we identified that Fibroblast Growth Factor 14 (FGF14) was preferentially methylated in CRC.
Aims & Methods: We aimed to investigate the epigenetic regulation and biological function of FGF14 in CRC. The expression of FGF14 in 10 CRC cell lines and 24 pairs of CRC tissues and paired adjacent normal tissues by real-time PCR. CRC cells were treated with DNA demethylating agent 5-aza-2'-deoxycytidine (5-Aza). The methylations of FGF14 in CRC cell lines and CRC were determined by real-time MSP. The biological function of FGF14 in CRC was interrogated by cell viability assay, colony formation, immunofluorescence and flow cytometry, as well as in vivo study.
Results: FGF14 was downregulated or silence in all (10/10) CRC cell lines, while it was readily expressed in normal colonic tissues. The expression of FGF14 was significantly lower in primary CRCs as compared to their adjacent normal tissues (P < 0.01). The loss of FGF14 gene expression was restored by treatment with DNA demethylating agent 5-Aza. Re-expression of FGF14 in CRC cell lines inhibited colony formation, suppressed cell viability, and induced cell apoptosis via AMPK/mTOR pathway, accompanied with enhanced protein expression of cleaved caspase-3, cleaved caspase-7, cleaved caspase-9 and PARP. In xenograft mouse model, overexpression of FGF14 significantly reduced tumor growth (P < 0.001).
Conclusion: FGF14, which induces cell apoptosis via AMPK/mTOR pathway, is a novel tumor suppressor down-regulated by epigenetic inactivation.

Introduction: A cancer with a number of somatic mutations is defined as “hypermutator”, and shows therapeutic features, such as high sensitivity to immune checkpoint inhibitor. However, to date, analyses of hypermutator have not been done with a large number of cases.

Aims & Methods: The aim of this study is to analyze the incidences and characteristics of hypermutator in digestive system cancers. We analyzed somatic mutation in digestive system cancers in 1145 cases (age: 67.4±11.3 yrs, M:F=755:390), those underwent surgery after full informed consent during 2014 to 2015. Genewide sequencing was performed on 47 inherited cancer-associated genes and 411 cancer-associated genes using next generation sequencing (Illuma Torrent Proton) and Exome RDY kit, Thermo Fisher Scientific. Hypermutator was defined when a tumor having >500 mutations in the somatic DNA.

Results: The 1145 subjects included 583 colorectal cancers (CRC), 229 gastric cancers (GC), 103 metastatic liver tumors, 100 hepatocellular carcinomas (HCC), 45 pancreatic cancer, 23 GISTs, 15 esophageal cancers and 14 neuroendocrine tumors, etc. Hypermutator was recognized in 66 cases (5.8%). Age and gender were not associated with hypermutation. Hypermutator was recognized in 6.2% (36 cases) of CRCs, 11.8% (27 cases) of gastric cancers, 2% (2 cases) of HCCs, and one case of small intestinal cancer. Within the hypermutator group, multiple cancers developed in 13.9% of CRC patients and 25.9% of GC patients. Mutations were restricted to 33.3% (22 cases), that of mismatch repair genes (either of MLH1, MSH2, MSH6, PMS2) in 13.6%, POLE in 9.1%, and POLD1 in 4.5%, respectively, in the hypermutator group.

Conclusion: Hypermutator was recognized in 5–10% of digestive system cancers, particularly CRCs and GCs. Cases of hypermutator sometimes develops multiple cancers, associated with a somatic mutation of mismatch repair genes. Further research must be needed to clarify the characteristic of hypermutator of the digestive organs in the therapeutic aspects.

Introduction: In the intestinal epithelium, stem cells are located at the bottom of the crypt and maintain the structure and differentiation is essential for sufficient organ function. Accumulation of mis- or unfolded proteins in the endoplasmatic reticulum, so-called ER-stress, leads to an unfolded protein response (UPR) which sustains epithelial stem cells (iESC) into differentiation. However, the molecular mechanism of this differentiation process upon ER stress is largely unknown. A prominent feature of the UPR is translation inhibition which can force an intestinal epithelial stem cell (iESC) into differentiation. We identified tran-

Introduction: Location and somatic gene signature of CRCs may impact prognosis strongly. A specific CRC-related dysbiosis has been characterized.

Aims & Methods: The aim was to characterize colon microbiota in CRC patients regarding location, gene markers and outcome. Patients (N=173) signed consent form. DNA was extracted and sequenced using Illumina HiSeq2000 analysis of stool DNA: 72 CRC (53 sporadic-S, 19 Lynch-L), 87 asymptomatic subjects (normal colonoscopy), 14 first degree healthy relatives from Lynch families. 3MOCA1 pipeline was used, library sorted (Piped quality score 20) and filtered (FDR < 0.05). Classification was done with a large number of cases.

Results: There was no difference for gender, age (p = 0.08) and BMI (p = 0.187) in the L and S CRCs. Significant differences were observed between Normal and CRCs, C-CRC and L-CRC, L-CRC and first degree relatives based on the common component (similarity of sequences): 13 species differentiated Normal and C-CRCs, two were more prevalent in L-CRCs. The analysis of related bacteria linked with location, MSI, Ras mutations, methylation phenotypes and survival were identified. No significant link was observed with TNM Staging (I=17, 2L and 15S), II (N = 12, 5L and 7S), III (N = 20, 10L, 10S), IV (N = 22, 11L, 21S). DFS might be dysbiotic dependent.

Conclusion: CRC dysbiosis is location-dependent. Several bacteria are associated with Ras mutation, MSI, and methylation status. They may directly or through their metabolites impact the prognosis. Microbiota signature should be taken in consideration in trials.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal serrated lesions (Sls) include hyperplastic poly (HP), traditional serrated adenoma (TSA) and sessile serrated adenoma (SSA/P). SSA/Ps are well-known precursors of colorectal cancer (CRC) characterized by BRAF mutation and microsatellite instability (MSI), whereas the molecular characteristics of TSAs are not fully understood.

Conclusion: Using an unbiased transcriptional approach we identified transcription factors that are lost on protein level upon ER stress. Furthermore, our data suggests that the significant loss of the transcriptional regulator CtBP2 contributes to intestinal epithelial stem cell differentiation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We aimed to improve simple, noninvasive blood test that could predict the risk of colorectal cancer. Blood was taken from patients with various malignancies (CRC, Pancreatic Cancer (PC), gastric cancer (GC), sarcoma and HM), that was confirmed by histology. Age, gender and ethnic matched healthy individuals served as controls. Hemoglobin level were very healthy. They underwent an extensive workout at the Integrated cancer prevention center at Tel Aviv Medical Center (Eur J Intern Med. 2013) All samples were collected and processed identically. For each sample, 20,000 leukocytes were analyzed by flow cytometry for the expression of CD24. An initial template data has been generated using gates within the software to create a hierarchical population tree at the beginning of the screen. All additional analyses were accomplished after data acquisition have been completed. The template file include compensation adjustment, which is uniformly applied to all the data collected in order to minimize fluorescence overlap between detection channels.

Results: The novel assay was improved significantly, distinguished healthy from CRC (Fig (1a) (P < 0.013), PC (Fig (1b) (P < 0.018), biliary tract (P < 6.45E-12), MDS (P < 0.003) and haemophagocytosis, MDS (P < 0.01), and Lymphoma (P < 2.1E-07) patients. CD24 expression levels were higher by up to 25% in cancer cases as compared to normal subjects. The sensitivity and specificity for CRC were 79.2% and 74.7%, and for PC 70.0% and 75.9%, respectively.

Aim: We designed the study to identify individuals with different types of cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We aimed to improve simple, noninvasive blood test that could predict the risk of colorectal cancer. Blood was taken from patients with various malignancies (CRC, Pancreatic Cancer (PC), gastric cancer (GC), sarcoma and HM), that was confirmed by histology. Age, gender and ethnic matched healthy individuals served as controls. Hemoglobin level were very healthy. They underwent an extensive workout at the Integrated cancer prevention center at Tel Aviv Medical Center (Eur J Intern Med. 2013) All samples were collected and processed identically. For each sample, 20,000 leukocytes were analyzed by flow cytometry for the expression of CD24. An initial template data has been generated using gates within the software to create a hierarchical population tree at the beginning of the screen. All additional analyses were accomplished after data acquisition have been completed. The template file include compensation adjustment, which is uniformly applied to all the data collected in order to minimize fluorescence overlap between detection channels.

Results: The novel assay was improved significantly, distinguished healthy from CRC (Fig (1a) (P < 0.013), PC (Fig (1b) (P < 0.018), biliary tract (P < 6.45E-12), MDS (P < 0.003) and haemophagocytosis, MDS (P < 0.01), and Lymphoma (P < 2.1E-07) patients. CD24 expression levels were higher by up to 25% in cancer cases as compared to normal subjects. The sensitivity and specificity for CRC were 79.2% and 74.7%, and for PC 70.0% and 75.9%, respectively.

Aim: We designed the study to identify individuals with different types of cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Diabetics require a more intense bowel preparation aided by bowel cleaning agents to help others. They tolerated both doses of LCI and 8 hours and preparation should end no later than 8 hours prior to colonoscopy. Patients should be instructed to drink a minimum of 8 glasses of water with each dose of policol.

Introduction: Colonoscopy is the gold standard method of colorectal cancer screening. However, polyp detection during a colonoscopic examination at a rate that varies from 6% to 27%. Improved adenoma detection rates can be achieved by optimizing endoscopic visualization techniques. A recently developed new Fujinon endoscopic system, Eluxeo carries a new function of electronic chromoendoscopy, Linked Color Imaging (LCI), that enhances the coloring and contrast of mucous membranes and blood vessels which are difficult to see with the conventional endoscopes. In our prospective randomized study, we evaluated the effectiveness of LCI, a new endoscopic visualization technique that may enhance image quality to improve colon adenoma detection.

Aims & Methods: Up till now 247 eligible patients, older than 45 years, admitted for screening outpatient colonoscopy were randomly enrolled to undergo high-definition white-light colonoscopy (WLC) or LCI colonoscopy during instrument withdrawal. The colonoscopic procedures were performed by three experienced endoscopists on 7000 patients. Colonoscopy access was either the conventional high-definition Fujinon EC 590Z or a new EC 760Z VS Eluxeo colonoscope. All of the colonoscopic procedures were made under Propofol deep sedation guided by an anesthesiologist team. The minimum withdrawal time was defined as more than 6 minutes. All colonoscopies were routinely assisted with pure CO2 insufflation. The primary outcome parameter of our study was to assess and compare the polyp and adenoma detection rate with the two endoscopic techniques.

Results: A total of 247 patients were randomized (mean age 58.7 years), 101 patients enrolled in the WLC group and 146 patients in the LCI group. No significant differences have been observed in the patient demographics and colonoscopy withdrawal time between the two groups. Patients having both colorectal polyps and adenomas were detected more frequently in the LCI group than in the control group: 69.9% and 43.8% versus 55.4% and 33.6% respectively, however, this was not statistically significant (p = 0.32 and 0.16). In contrast, the total number of adenomas relative to the total number of polyps detected with LCI withdrawal were significantly higher than with conventional WLC: 105 vs. 67, respectively (p < 0.0498).

Conclusion: The LCI enhancement of the Fujinon Eluxeo colonoscopy system was superior to the conventional HD-WLC in detecting patients with colorectal adenomas, which was mainly due to the ability of the more sensitive detection of minute (less than 5 mm) adenomas. The study was supported by ECT grant GINOP-2.1.1.1-15-2015-00128.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1764 AI-ANTITRYPSIN (SERPIN-A1) AS A POTENTIAL BIOMARKER FOR COLORECTAL CANCER

Introduction: Serine protease inhibitors (Serpins) play an important role in the regulation of enzymes involved in proteolytic cascades. Members of the family are: alpha-1-antitrypsin, alpha-antichymotrypsin, C1 inhibitor, antithrombin and neuroserpin. Kalikrein-related peptides (KLKs) are involved in proteolytic cascades of different tissues. KLK14, acting via PAR-2, represents an autocrine/paracrine regulator of colon tumorigenesis and alpha-1-antitrypsin is a natural inhibitor of KLK14. Therefore its role in regulating the proteolytic cascade in colorectal tumorigenesis is of great importance.

Aims & Methods: The aim of this study was to analyze A1-antitrypsin (AAT) expression in tissue samples at different stages in the process of colorectal cancer development. We examined a total of 245 colon samples. Of those, there were 101 colorectal carcinoma tissues, for 70 of which paired normal mucosa was also examined. A total of 74 colorectal adenomas were examined. Quantitative real time PCR was used to measure AAT expression. Clinical evaluation of AAT levels was demonstrated in terms of disease-free survival (DFS) and overall survival (OS).

Results: Alpha-1-antitrypsin expression was found to be significantly associated with tumor stage (p = 0.028). A significant proporitional hazard regression model using univariate analysis revealed that high status alpha-1-antitrypsin expression is a significant factor for disease-free survival (DFS) (p = 0.002) and overall survival (OS) (p = 0.026) in patients with colorectal cancer. Kaplan-Meier survival curves demonstrated that low alpha-1-antitrypsin expression is significantly associated with longer DFS (p = 0.001) as well as OS (p = 0.021).

Conclusion: Our data suggests that alpha-1-antitrypsin expression could be considered as a potential biomarker of unfavorable prognosis for colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Real-time differentiation between neoplastic and non-neoplastic colorectal lesions may be crucial during colonoscopy. While adenomas are
neoplastic, and therefore should be resected, hyperplastic polyps never turn malignant and do not require specific endoscopic therapy. The aim of our prospective, randomized study was to distinguish subcentimetric hyperplastic and adenomatous polyps based on Fujinon FICE versus Eluexo BLI electronic chromoendoscopic technology with high-definition colonoscopy with and without optical magnification.

Aims & Methods: In order to create a video and digital picture library of polyps, patients undergoing screening or diagnostic colonoscopy were considered for inclusion. Patients with at least one histologically verified <10mm polyp were included. Short (20sec) video-clips and at least the still picture of each polyp without and with 50x optical zoom at standard white-light (WLI), and with FICE-light or BLI-light were recorded with Fujinon EC 590Z and EC760Z endoscopes and stored in an anonymized database. Once the video-library was complete, each of our 5 colonoscopic experts (ML, SZM, OL, DZS, and SZA) independently and randomly reviewed all of the cases with a standardized electronic questionnaire. In each case, all of the observers had to assess the color, the vascularization and the surface of the polyps, and the pit pattern was also assessed. Kudo classification was then carried out, independently, with the definition of confidence (low/medium/high on VAS), the histological prediction and the final decision which was clarified on each lesion as neoplastic or non-neoplastic (hyperplastic).

Results: Up till now 115 polyps were enrolled and recorded into our digital web-based library, 59 were assigned into the FICE and 56 into the BLI group. All of the detected 115 polyps were endoscopically removed and histologically analyzed and this was regarded as gold standard. The overall accuracy with WLI versus FICE versus BLI technology of the 5 experts without zoom and with 50x magnification to differentiate between hyperplastic and adenomatous lesions were 77.62% and 84.31%, vs. 74.58% and 83.90%, vs. 83.93%, and 88.84%, respectively. There was an excellent correlation between the histopathological results and our KUDO classification with both FICE and BLI technology. Both 50x times optical zoom and BLI technology were independently and significantly improved our confidence rate that was associated with a more precise histologic prediction as compared to non-zoom, WLI or FICE endoscopic polyp assessment. Conclusion: The new electronic chromoendoscopic technology with Eluexo BLI significantly improved the reliability of the histology prediction as compared to FICE technology of Fujinon and high-confidence predictions for the differentiation of neoplastic and non-neoplastic polyps with Eluexo BLI electronic chromoendoscopy provide a potential for real-time endoscopic diagnosis of hyperplastic polyps to support resect and discharge strategy. (Study was supported by ECT grant GB/15-5/00128)

Introduction: Till now, narrow-band imaging (NBI) could make it possible to analyze the surface microvessels of colorectal lesions for differentiating neoplasms from non-neoplasms and for predicting the histopathological diagnosis. Narrow-band imaging (NBI) or electronic chromoendoscopy (EC) is the next generation of ultramagnification endoscopy that allow visualization of the glandular structure and cellular atypia. EC has visualized living tumor cells in vivo and obtained a ultra-magnification pathological image simply by applying the scope to the target mucosa during an endoscopic examination. However, in colorectal lesion visualization, the low-magnification system (i.e., methylene blue) is always required. Since dye staining complicates the procedure, new observation method without use of dye has been strongly desired. On the other hand, EC with NBI (EC-NBI) allows ultra-magnified microvesSEL observation without using any dye solution.

Aims & Methods: The aim of this study was to validate the evidence whether the observation of surface microvessels using EC-NBI was useful in predicting the histopathology of colorectal lesions. The study included 438 patients who underwent complete colonoscopy and endoscopic or surgical treatment between April 2006 and June 2015. A total of 576 lesions (45 Non-neoplastic polyps, 304 adenomas, 71 intramucosal cancer, 21 slightly invasive submucosal cancer (SMs) and 135 massively invasive submucosal cancer) were retrospectively evaluated. We used the Kudo classification for the diagnosis of submucosal invasion and classified cancers accordingly. SMs cancer without vessel perforation does not metastasize. In contrast, SMm lesions show a substantial proportion (~10%) of lymph node metastasis. We named the ultra-magnified microvesSEL findings as endoscopic vascular pattern (ECV) pattern and classified into the following 3 groups; ECV, the surface microvessels were very fine obscure; EC-V2, the surface microvessels were more clearly seen and showed a regular vessel network, and their caliber and arrangement were uniform; and EC-V3, the surface microvessels were thick, and their caliber and arrangement were early wavy and homogeneous.

Results: The sensitivity, specificity and accuracy of ECV-V1 for diagnosis of hyperplastic polyp were 86.89%, 98.5% and 97.7%, respectively. As regards the sensitivity, specificity and accuracy of ECV-V3 for diagnosis of SMm were 82.2%, 98.0% and 94.3%, respectively.

Conclusion: Endoscopic vascular pattern was helpful in predicting the histopathology of colorectal lesions.

Introduction: The use of IN derived peptides together with the CD24-targeted antitoxin (RGC-MazE-GFP) were designed under the regulation of RAS bacterial toxin can improve the efficacy of this system (Shapira et al, 2015). Furthermore, we showed a protective effect of the RAS pathway in combination with the antitoxin (RGC-MazE-GFP) was engineered and fused to the lentivirus vector. Cell death was measured qualitatively using fluorescein diacetate and was quantified by the enzymatic MTT assay. Human colorectal, pancreatic, lung and triple negative breast cancer cells were used for testing the potency of the lentiviral-based system.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We aimed to develop and specifically direct lentiviruses (Cervical, Bladder, Esophageal squamous cell carcinoma, Glioma, Breast etc.). The use of IN derived peptides together with the CD24-targeted antitoxin indeed actively protects cells with WT p53. Similar results were obtained in a colony formation assay using fluorescent microscopy and was quantified by the enzymatic MTT assay. Human colorectal, pancreatic, lung and triple negative breast cancer cells were used for testing the potency of the lentiviral-based system.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Inactivation of TP53 is the most frequent genetic damage in human cancer. In addition, hyperactivation of the RAS pathway is common in many human malignancies (Lung (LC)–40%, pancreatic (PC)–95%) and colorectal cancer (CRC)–50%). Despite multiple attempts, targeting these pathways for the treatment of cancer, for example through the development of RAS pathway inhibitors has not proven to be effective thus far. Herein, we propose to exploit the hyperactive RAS pathway and TP53 mutation status of human cancer to deliver targeted antitumor therapy. We had previously reported that a recombinant adenovirus, carrying a pro-apoptotic gene (PUMA) under the regulation of RAS responsive elements (PY4) effectively suppressed the growth of human cancer cells harboring hyperactive RAS (Giladi et al, 2007). Furthermore, we had shown, both in vitro and in vivo, that replacing the pro-apoptotic gene with a bacterial toxin can improve the efficacy of this system (Shapira et al, 2015).

Aims & Methods: We aimed to establish a tight regulated dual system by expressing a toxin under a PY4 element in cancer cells, while sparing normal cells by expressing the anti-toxin under a p53 responsive elements (RGK) specifically in non-malignant cells. Adenoviral vectors carrying the toxin (PY1-MaxF-echerry) and the anti-toxin (RGK) were used, either alone or in combination (GFPI) were used. The toxin and anti-toxin were quantified by the Endo Point Dissolution Assay and their potency was tested in vitro. Cell death was measured qualitatively using immunofluorescence microscopy and was quantified by the enzymatic MTT assay.

Results: In vivo, the combination of the two toxins was more effective than either toxin alone. In vitro, the combination of the two toxins was more effective than either toxin alone.

Conclusion: The combination of two toxins was more effective than either toxin alone.

P1771 ILF3 STABILIZES AND ACTIVATES EGFR-MEDIATED G9A PATHWAY FOR MAINTAINING CANCER STEMNESS PROPERTY IN EGFR-POSITIVE CANCERS
C. Cheng1, A. Ho2
1Hematology And Oncology, Mackay Memorial Hospital, Taipei/Taiwan
2Division Of Gastroenterology, Cheng Hsin General Hospital, Taipei/Taiwan

Contact E-mail Address: aisheng49@gmail.com

Introduction: A specific inhibitor of interleukin enhancer binding factor 3 (ILF3), Y15515, suppresses EGFR phosphorylation and significantly reduces the expression of cancer stemness tumourspheres in vitro, suggesting that ILF3 as an oncogene participates in the maintaining of cancer stem cell property through stabilizes EGFR-mediated stemness pathway. Since cancer stemness cell is the leading reason for tumor recurrence in the tumor repressive treatments, and ILF3 activates the formation of cancer stemness, it is worthy of investigating the role of ILF3 for maintaining the cancer stemness property in the EGFR pathway.

Aims & Methods: The tumourspheres derived from EGFR-wild-type and KRAS-mutant colorectal HCT116 and lung A549 cells expressing higher cancer stemness markers, CD133, were used as cancer stemness models in this study. Y15515 was utilized to select the putative growth in vivo, involving the formation of tumourspheres as the cancer stemness markers. Meanwhile, the differentiating stemness markers were also compared between ILF3-knockdowned and the control shLuc cells. Then, the protein level and phosphorylation of EGFR were investigated in the Y15515-treated and ILF3-knockdowned cells, that was also transplanted into SCID mice for evaluating the function of ILF3 in vivo.

Results: We found that higher EGFR autoposphorylation (Y1068) in HCT116- and A549-derived tumourspheres compared to the parental cells. The results of RNAseq evaluated that CD133 was a positive stemness marker, whereas MARCH4 as a negative marker. Knockdown of ILF3 reduced the protein level and expression of EGFR, which was activated in cancer cell survival. Moreover, inhibition of ILF3 by Y15515 blocked the autoposphorylation of EGFR and inhibited the EGFR-downstream G9a activation, leading to a reduction of stemness property. Moreover, Knockdown of G9a reduced the ILF3 expression and increased MARCH4 expression, revealing that G9a was essential for maintaining for cancer stemness property in the ILF3-positive cancers.

Conclusion: In conclusion, this study demonstrated that ILF3 played an important role in maintaining the EGFR-mediated stemness pathway in HCT116 and A549 EGFR-positive cancer cells. We demonstrated that ILF3 stabilized and phosphorylated EGFR to enhance the activation of G9a, leading to increasing CD133 and decrease MARCH4 expressions. Therefore, we suggested that the ILF3 inhibitor, Y15515, was potential for utilization in cancer therapy against the EGFR-positive cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Lentiviral replication is driven by a molecular motor consisting of transcription/endoogenous nucleocapsid and viral enzymes: the reverse transcriptase, protease and integrase (IN). The genomic RNA of the virus is used to produce a copy of viral DNA by reverse transcription, and the integrase catalyses the covalent insertion of this DNA into the chromosomes of the infected cells. Integration of the viral DNA—which is driven by 12 bp palindromic LTR sequences—leads through a combination of cleavage and ligation resulting in the appearance of double-stranded breaks in the host genome that eventually leads to apoptosis. CD24 is a heavily glycosylated cell-surface GPI-anchored protein. We have previously shown that CD24 is an important player in the multistep process of GI carcinogenesis (Gastro 2006, Clin Can Res 2007, Can Res 2008) as well as in many other human malignancies (Cervical, Bladder, Esophageal squamous cell carcinoma, Gioma, Breast etc.).

Aims & Methods: We aimed to develop and specifically direct lentiviruses (Cervical, Bladder, Esophageal squamous cell carcinoma, Glioma, Breast etc.). The use of IN derived peptides together with the CD24-targeted antitoxin indeed actively protects cells with WT p53. Similar results were obtained in a colony formation assay using fluorescent microscopy and was quantified by the enzymatic MTT assay. Human colorectal, pancreatic, lung and triple negative breast cancer cells were used for testing the potency of the lentiviral-based system.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: INS was able to stimulate the viral Integrase enzyme in test tubes and in viral infected cells. The antitoxin, RGS and specific peptide to CD24, allowing targeted precision of viral transduction (Figure 1). These Lentiviruses particles contain DNA molecules with flanked LTRs, allowing their integration into the CD24-expressing target cells DNA and formation of double-stranded breaks to the disease at the site of the integrase particles whose activity was stimulated by the IN derived peptides. Massive cell death was induced upon exposure of the infected cells to the INS peptide compared to the control mock peptide. The use of IN derived peptides together with the CD24-targeted lententherapy approach suggest a novel strategy to specifically promote death of CD24-expressing cancer cells.

P1772 Efficacy and Safety of Twelve Chemopreventive Regimens for the Recurrence of Colorectal Adenomas: A Network Meta-Analysis

H. Chen
Jiangsu Province Hospital, Nanjing/China

Contact E-mail Address: chenhan068@hotmail.com

Introduction: Although various pharmacological agents have been trialed for recurrent colorectal adenomas, their comparative effectiveness remains unknown. We conducted both direct and indirect comparisons of twelve chemopreventive agents for recurrent colorectal adenomas.

Aims & Methods: MEDLINE, EMBASE, Scopus, Web of Science, and Cochrane Central Register of Controlled Trials, and ClinicalTrials.gov were searched up to May 1, 2016.RCTs were assessed by a random-effects model within a Bayesian framework. Agents for each outcomes were ranked by surface under the cumulative ranking area (SUCRA). This study is registered with PROSPERO, number CRD42016041923.

Results: 33 RCTs were eligible, enrolling 44,647 participants treated by twelve regimens: 9 aspirin and other NSAIDs, 11 antioxidants, 4 dietary supplements, and 1 calcium, 4 folate acid, 2 calcium plus antioxidants, 2 aspirin plus folic acid and 1 vitamin C. The pooled estimate showed that aspirin was more effective than placebo in both pairwise (OR, 0.73 [95%CI, 0.59 to 0.90]) and NMA (OR, 0.75 [95%CrI, 0.57 to 0.98]). Subgroup analysis showed the highest increase in sensitivity to EPA. Whilst the response of MC38 cells to EPA was increased 2-fold [IC50 (EPA + aspirin) = 19 ± 1 μM], MC38 cell response was increased 3.8-fold [IC50 (EPA + aspirin) = 42 ± 1 μM]. Aspirin increased IC50 of MC38 cells treated with both EPA and aspirin compared to EPA alone. A similar pattern of response was measured in vivo. EPA administration exerted anti-tumour activity in MC38 subcutaneous tumour-bearing CD1-nude mice (n = 14, 37% decrease in mean tumour volumes, p = 0.02), but not in CT26 mice treated with both EPA and aspirin compared to EPA alone.

Conclusion: Human and mouse CRC cell lines display differential sensitivity to EPA in vitro. Our data indicate that COX2 mediates resistance to EPA in CRC cells by downregulating the expression of a COX2 substrate, thereby suppressing the synthesis of EPA in vivo. Aspirin sensitisation CRC cells to EPA in vitro and in vivo may be a clinically relevant candidate for prevention and treatment of CRC in combination therapy.

Introduction: Colorectal cancer (CRC) is the third most common cancer worldwide. The management of CRC has been undergoing change as investigations of risk factors and its genetic predisposition have dramatically developed, the long-term survival rate of patients with CRC remains low. In recent years, great efforts have been made to identify inflammation-related factors for precise prediction of disease prognosis. Glasgow Prognostic Score (GPS) is a simple and useful tool that is based on the combination of the level of serum C-reactive protein (CRP) and albumin, which are indicators of systematic inflammatory response and nutritional status respectively. Growing evidence suggested that GPS was served as an independent prognostic index in a variety of malignan cancers. For patients with CRC, the GPS system was also widely studied, but the results were controversial.

Aims & Methods: To investigate the correlation between GPS and prognosis of patients with CRC to further clarify its clinical significance. A comprehensive search of PubMed, Embase, Cochrane central register of controlled trials, and Chinese National Knowledge Infrastructure was performed to identify eligible studies, from which the risk of overall survival (OS) and cancer-specific survival (CSS) were extracted. A random-effect model was adopted to combine hazard ratios (HR) and 95% confidence interval (CI). Heterogeneity and publication bias among studies were assessed.

Results: 25 articles with a total of 5660 participants were included. The pooled results indicated that elevated GPS was associated with poor OS (HR = 2.83, 95%CI: 2.00–4.00, P < 0.01) and CSS (HR = 1.94, 95% CI: 1.51–2.49, P < 0.01). This correlation was confirmed both in primary operable and advanced inoperable patients. Increased GPS was also closely related to advanced tumour-node-metastasis (TNM) stage (odds ratio [OR] = 1.44, 95%

10. Rocks, D. et al. Population participation at 33.1%. This has influenced the increase of number of colorectal cancer screening program in the Czech Republic from year 2000. In January 2014, the transition to population based setting has been implemented. From January 2014, the annual immunochromatographic FOBT (FIT) is offered at the age 50-54, followed by FIT+ colonoscopy, if positive. In age of 55, there is a choice of either FIT biannually or screening colonoscopy in 10 years’ interval. In other age groups, the annual immunochromatographic FOBT (FIT) is offered at the age 50-54, followed by FIT+ colonoscopy, if positive. In age of 55, there is a choice of either FIT biannually or screening colonoscopy in 10 years’ interval. Aims & Methods: We aimed to assess the impact of the first 30 months of the colorectal cancer screening program in the Czech Republic. The study demonstrates favorable technical and short-term clinical outcome of colorectal ESD, but further studies are needed to confirm the long-term efficacy. Disclosure of Interest: All authors have declared no conflicts of interest.
P1778 LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOUS DISSECTION FOR EARLY CANCER AND HIGH GRADE DYSPLASIA IN COLORECTUM

P. Zhou1, T. Chen1
1Gastroscopy Center, Zhongshan Hospital, Fudan University, Shanghai/China

Contact E-mail Address: chentia06@yahoo.com

Introduction: Although endoscopic submucosal dissection (ESD) is a widely accepted treatment for colorectal neoplasia, little is known about large consecutive studies evaluating long-term outcomes of early cancer and high grade dysplasia. We assessed the efficacy and safety of ESD for early cancer and high grade dysplasia in colorectum and evaluated the long-term outcomes, including local recurrence and metastasis.

Aims & Methods: We performed a retrospective analysis of data collected from 5 consecutive years of patients with 520 colorectal early cancer and high-grade dysplasia treated with ESD between January 2007 and December 2013. Histology and patient data were collected during an average follow-up time of more than 5 years to determine tumor stage and type, resection status, complications, tumor recurrence, and distant metastasis.

Results: The overall rates of en bloc resection, complete resection, R0 resection, major complications were 94.4%, 91.3%, 89.2% and 2.1%, respectively. Large tumors and snare-assisted ESD were independent factors of piecemeal resection. ESD of colon tumors increased the risk for complications. During the follow-up period, all patients remained free from metastasis. However, local recurrence occurred in 4 patients (0.8%); large tumors and piecemeal resection were risk factors.

Conclusion: ESD is effective and safe for resection of early cancer and high grade dysplasia in colorectum and long-term outcomes are favorable. ESD is indicated for the treatment of colorectal early cancer and high grade dysplasia to obtain curative resection and prevent the local recurrence.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1779 LOW UPTAKE OF PSYCHOLOGICAL THERAPIES AMONG PATIENTS WITH IRRITABLE BOWEL SYNDROME IN SECONDARY CARE

O. Craig1, C. Black1, L. Houghton2, A.C. Ford3
1Leeds Gastroenterology Institute, St. James’s University Hospital, Leeds/United Kingdom
2Leeds Institute Of Biomedical & Clinical Sciences, St.James’s University Hospital, Leeds/United Kingdom

Contact E-mail Address: ofcraig@gmail.com

Introduction: Patients with irritable bowel syndrome (IBS) often have co-existent mood disorder and psychological illness. Meta-analyses of randomised controlled trials consistently demonstrate that psychological therapies, such as cognitive behavioural therapy (CBT) and hypnotherapy, are effective treatments for IBS. In the UK the National Institute for Health and Care Excellence (NICE) recommends considering the use of these in patients with no response to pharmacological therapies, and for refractory symptoms.

Aims & Methods: We performed a cross-sectional survey to examine willingness of patients with IBS to engage with psychological therapies. We collected complete symptom data from consecutive, unselected referrals to secondary care seen in a specialist IBS clinic. All participants completed the validated Rome IV questionnaire for IBS, the IBS severity scoring system (IBS-SSS), the hospital anxiety and depression scale (HADS) to assess mood, and the patient health questionnaire-12 (PHQ-12) to examine somatoform-type behaviour. They also provided their opinion on possible treatment options, and were asked to rank medical therapies, dietitian input, psychological therapies, including CBT and hypnotherapy, and explanation of the condition and/or reassurance in order of preference.

Results: Among 93 adults with confirmed IBS (74.7% female), median age 36.0 years (range 16 to 77 years), 35 (37.6%) had high levels of anxiety, 22 (23.7%) had high levels of depression, and 23 (24.7%) had severe levels of somatoform-type behaviour. Despite this, only 10 (10.8%) of 93 patients ranked psychological therapies as their first-choice treatment option. In total, 88% of patients with high levels of anxiety ranked psychological therapies as their first-choice treatment option, versus 13.2% without (P = 0.64), 9.5% of those with high levels of depression, versus 12.1% of those without (P = 0.91), and 17.4% of patients with severe somatoform behaviour, versus 9.2% of those without (P = 0.26). Those with severe symptoms according to the IBS-SSS were no more likely to select psychological therapies as their first-choice treatment option than those with mild or moderate symptoms (7.7% versus 21.7%, P = 0.10).

Conclusion: Despite high levels of psychological morbidity and NICE recommendations, patients with IBS in a specialist clinic were generally reluctant to consider psychological therapies such as CBT or hypnotherapy. Those with anxiety, depression, somatoform-type behaviour, or severe symptoms were no more willing to consider these therapies than those without.

P1780 GUT SYMPTOMS AND TRANSIT DISTURBANCE IN PARKINSON’S DISEASE ARE PAN-ENTERIC BUT NOT UBQUITOUS: A WIRELESS MOTILITY CAPSULE STUDY

V. Passananti, N. Zarate Lopez, R. Sweis, A. V. Emmanuel
GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassananti@gmail.com

Introduction: Symptoms of gastrointestinal dysfunction are among the most common non-motor complaints in Parkinson’s patients. These may involve muscles from the oropharynx to the anorectum, and the autonomic and enteric nervous system are often involved, resulting in secondary bowel dysmotility.

Aims & Methods: The objectives of this study were to evaluate a technology measuring the spectrum of gut dysfunction, the Wireless Motility Capsule (WMC), in Parkinson’s disease. We also wanted to correlate transit measures with gastrointestinal symptoms. Fifteen PD patients and 7 controls (table1) were included. PD severity were scored with the modified Hoehn and Yahr (H&Y) staging scale. GI symptoms were assessed using the Wexner constipation score and Gastropareasis Cardinal Symptom Index (GCSI). Acidity, motility and transit data were obtained, as standard, by WMC. All medications affecting pH and motility, including L-dopa, were discontinued for 5 days before and for the duration of the study. Data were analyzed using a chi-square test (GET), small bowel transit time (SBTT), colonic transit time (CIT) and whole gut transit time (WGTT).

Results: One patient could not swallow the capsule, and of the 14 patients completing the study, 8 reported GI symptoms. Compared to non-symptomatic patients, those with GI symptoms showed significant delayed transit in the stomach, colon and whole gut (table 1). However, small bowel transit did not significantly differ. GI dysfunction was not correlated with H&Y score in this small sample, used the risk factor constipation scores were correlated, suggesting a pan-enteric problem in symptomatic individuals. There was a significant correlation between the Wexner constipation score and CIT in all patients (p < 0.01) but not GCSI and GET (p > 0.10). The results of Wireless Motility Capsule did not differ between non-symptomatic PD and controls.

Conclusion: We have shown that Parkinson’s patients with gut symptoms have both upper and lower complaints. Symptomatic PD patients also have markedly delayed transit times throughout the whole gut compared to asymptomatic PD patients and controls. Whilst severity of constipation is related to delayed colonic transit no such relationship is present between gastroparesis symptoms and gastric emptying. The implication is that treating symptomatic Parkinson’s patients should address the whole gut, whether with prokinetics or dual therapy.

the handling of gas is a relevant underlying mechanism in FGID patients with bowel dysfunction. In these patients, there are no manometric alterations, but there are abnormal anal sphincter function. Aims & Methods: Our aim is to study the relationship between the defecation pattern, the severity of bleeding and the abdominal girth measurements in FGID patients consulting for bleeding as primary complaint with/without visible abdominal distension unresponsive to diet advice. We performed a prospective, multi-center study of patients with severe abdominal bloating (VAS score ≥ 24 on a 100-mm scale) as primary complain with/without visible abdominal distension. Patients were recruited at 4 gastroenterology outpatient clinics in Italy. Concomitant proctological examination and Rome III criteria. All patients were prescribed a lactose-free diet supplemented by dietary advice according to the NICE guidelines for two weeks. A belt around the abdomen at standardized sites provided assessment of abdominal girth measurements. During the 2-week run-in period patients completed a daily diary log including abdominal bloating and pain/discomfort scores (100-mm VAS), Bristol Stool Form and stool frequency. At randomization visit, all patients filled in a questionnaire on adequate bowel retraining as potential treatment option for functional bloating.

Results: 76 patients (66 female, 39.5±12.2 mean age, 6 IBS-D, 6 IBS-M, 30 IBS-C, 9 IBS-U, 6 FC, 16 FB, 3 FD) completed the 2-week run-in period. A significant negative correlation was found between adequate relief and both bloating and abdominal girth changes (r = -0.53 and -0.52, p < 0.001, respectively). 53.76 (70%) patients reported inadequate relief (worse or no improvement). Among the non-responders the vast majority (68%) failed the BET. Multiple regression analysis demonstrated that BET (successful or failed) as a dependent variable, was significantly related to bloating severity. No relationship was demonstrated for abdominal girth changes, FGID diagnosis and straining questionnaire. Conclusion: In this prospective, multicenter trial simple diet advise was of benefit in approximately 30% of FGID patients consulting for severe bloating. In the non-responders outcome disability was prevalent and related with subjective bloating perception. The study is ongoing, but our data may support bowel retraining as potential treatment option for functional bloating.

Introduction: Faecal Incontinence (FI) is a common and socially disabling condition, more prevalent among females over 50 years old. Detailed anatomical and physiological assessment of each patient is important to determine the correct cause of FI and selection the most appropriate therapy. Conventional and High Resolution (HR) Anorectal Manometry (ARM) is a useful tool to categorize anal and/or rectal dysfunction in addition to provide physiological assessment of both anal sphincters and rectum.

Aims & Methods: To evaluate symptoms and anorectal function of patients affected by FI, we included 358 patients with FI (77% female (F) and 23% male (M), mean age 63 range 22–92 year) referring to the outpatient unit of Institute of Digestive Pathophysiology of S. Giovanni-Addolorata Hospital, Rome, Italy from January 2006 to December 2016. Clinical presentation (history, symptom profile and severity) and anorectal physiological evaluation (digital examination, manometry, rectal sensory testing, bulbom evacuation test) were analyzed. The manometric parameters obtained with conventional ARM and HR-ARM were: resting pressure, squeeze pressure, rectal compliance, rectal sensation and the anorectal pattern during the defecatory maneuvers.

Results: 114 out of 358 patients (32%) reported both FI and difficulty evacuating stool. Additionally, 77% with anorectal incontinence UI (47%). Proctological surgery (n 122, 34%), pelvic surgery (n 77, 21%) and traumatic anal or vaginal history (n 114, 40%) were statistically associated with FI (p < 0.05). Normal manometric parameters were found in 16 patients (4%). Manometric alterations observed were: internal anal sphincter (IAS) dysfunction: 228 (64%); isolated external anal sphincter (EAS) dysfunction: 274 (76%); combined sphincter dysfunction IAS and EAS: 198 (55%); isolated dysdynergic defecation: 100 (28%); rectal hypersensitivity: 130 (36%).

Conclusion: In our study, in accordance with the literature, we observed a female prevalence in FI. FI is significantly associated with previous proctological/pelvic surgery and traumatic anal/vaginal delivery. Furthermore, patients with FI referred difficulty evacuating stools, too. In fact in patients with dysdynergic-type constipation, the FI may be confused with an encopresis. Finally we observed these prevalent manometric alterations: combined dysfuction IAS and EAS, and rectal hypersensitivity. Manometric findings could help physicians to identify appropriated patients for a biofeedback therapy.

Introduction: Bile acid malabsorption (BMA) is a common and frequently under-investigated cause of chronic diarrhea. Most of the cases of chronic diarrhea after excluding organic disorders are labelled as functional diarrhea or irritable bowel syndrome (IBS). The most commonly used diagnostic test is Selenium homocholic acid taurose (SeHCAT) scan due to its sensitivity, specificity, safety and low cost. However this test is not frequently used in the algorithm for the diagnosis of chronic diarrhea.

Aims & Methods: We aimed to evaluate the usefulness of SeHCAT scan in evaluating patients with chronic diarrhea and identify potential risk factors associated to BMA. We retrospectively reviewed all patients who had SeHCAT scan between June 2014 and October 2016 in a University Hospital. BMA was defined as SeHCAT retraction of less than 15%. We collected the following variables: demographic characteristics, IBS-D Rome III criteria, duration of diarrhea (months), stool culture, parasite investigation of stool specimens, background of comorbid gastrointestinal and other comorbid conditions, positive HLA-DQ2 and DQ8 haplotype.

Results: 137 patients referred to clinic for chronic diarrhea underwent SeHCAT testing over the reviewed period. 42M; 95F, median age 46 y (95% C.I 44.0–50.1), median BMI 25.34kg/m2 (95% CI 24.0–27.00), 70.4% of patients met IBS-D Rome III criteria, median duration of diarrhea 48 months (95% CI 43.0–59.24). Background of co-morbid gastrointestinal conditions 45.3% (62/136), other co morbid conditions 55.3% (75/136). History of previous positive stool culture for parasites and parasitic-association of stool specimens, percentage of positive HLA-DQ2 and DQ8 haplotypes were 27.8% (35/126) and 10.2% (13/127), respectively. SeHCAT test was positive for BMA in 48.9% (67/137); 25.4% (mild 10–15%); 31.3% (moderate 5–10%), and 43.3% (severe ≤ 5%). Patient characteristics between positive and negative SeHCAT test were similar (Table 1). Interestingly, patients with SeHCAT test exhibited in approximately 30% of FGID patients consulting for severe bloating. In the non-responders the vast majority (68%) failed the BET. Multiple regression analysis demonstrated that BET (successful or failed) as a dependent variable, was significantly related to bloating severity. No relationship was demonstrated for abdominal girth changes, FGID diagnosis and straining questionnaire. Conclusion: In this prospective, multicenter trial simple diet advise was of benefit in approximately 30% of FGID patients consulting for severe bloating. In the non-responders outcome disability was prevalent and related with subjective bloating perception. The study is ongoing, but our data may support bowel retraining as potential treatment option for functional bloating.

P1784 INTAKE OF FERMENTABLE Oligo-, Di- and Mono-Saccharides and Polyols (FODMAPs) INCREASES THE RISK OF IRITABLE BOWEL SYNDROME (IBS) IN INDIVIDUALS EXPOSED TO PSYCHOSOCIAL STRESS IN THE COMMUNITY: RESULTS OF A LARGE, PROSPECTIVE, POPULATION BASED STUDY

Introduction: The cause of IBS is uncertain; however, food intake shares many features with this condition. Consumption of FODMAPs has been shown to induce IBS-type symptoms (Shephard 2008) and clinical trials have shown that a low FODMAP diet can improve symptoms in IBS patients (Harms 2014). However, FODMAP intake is not higher in IBS than in health (Bohn 2013) and it is not proven that the outcome of low FODMAP diet is better than standard dietary advice in this condition (Bohn 2015). Recent, experimental research has shown that psychological factors are associated with increased postprandial symptoms in IBS patients (Zhu 2013, Van Oudenhove 2016). This study was designed to assess the relative importance of, and interaction between, psychiatric disease, social stress and diet in the aetiology of IBS in the general community.

Aims & Methods: This population-based study tested the hypothesis that high FODMAP intake increases the risk of IBS more in individuals with psychiatric disease and/or life event stress than other members of the community. Subjects aged 16–74 were randomly selected from five South-Chinese communities. All subjects completed questionnaires by face-to-face inquiry with investigators including demographic information, gastrointestinal symptoms (Rome III), dietary intake (food frequency chart validated in Chinese community), psychiatric disease (HADS), life event stress (LES) and quality of life (SF-8).

Results: From 1999/211/5 (94.7%) members of the community who completed study questionnaires, 117 (5.3%) had IBS by Rome III criteria. The IBS group ingested less lactose than the "No-IBS" group (P = 0.024). Intake of other FODMAPs was similar in both groups (P = 0.346). Compared to the "No-IBS" group, individuals with IBS had a greater likelihood of depression (OR 1.5 (0.97–2.32); p = 0.05), anxiety (2.84(1.64–4.39), p < 0.001), recent life event stress (1.5(1.03–2.20); P = 0.03) and medical and/or surgical co-morbidity (OR 2.9(1.30–5.45), P < 0.001). The IBS group also had lower quality of life (P < 0.001). Joint risk analysis identified high intake of total FODMAP intake as a risk factors for IBS only in subjects with psychiatric disease and/or life event stress (table). Similar effects were seen for individual symptoms, in particular stress (table). Similar effects were seen for individual symptoms, in particular stress (table).

Conclusion: FODMAP intake was similar in IBS and No-IBS groups in the community (lactose intake was lower in IBS subjects, likely due to avoidance of dairy products (Long 2017)). However, as expected, IBS patients in the community had a greater likelihood of psychiatric disease, life event stress and clinical co-morbidity. Joint effects analysis demonstrated that high FODMAP intake alone was not associated with abdominal symptoms; however, IBS was more common in those with a high FODMAP intake and concomitant psychosocial factors known to increase visceral sensitivity to digestive Znu (Zhu 2013). Clinical Trials: NCT0268597

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A large proportion of patients with irritable bowel syndrome (IBS) suffer from anxiety or depression, but the associations with pathophysiological findings and overall symptom reporting are not clear.

Aims & Methods: We included 772 patients with IBS (Rome III criteria) who attended a university hospital-based outpatient clinic specialized in functional GI disorders between 2005 and 2015. The patients underwent examinations to investigate ooro-anal transit time (OATT) and visceral sensitivity (rectal balloon distension and a lactulose challenge test), and they also completed questionnaires to assess anxiety and depression (HAD), overall IBS symptoms (IBS-SRS), bowel habits (BSF), quality of life (IBS-QOL), extraintestinal somatic symptoms (PHQ-12), sense of coherence (SOC), fatigue (MFI), GI-specific anxiety (VSI) and physical and sexual abuse.

Results: Based on validated HAD cut-off levels (≥8), anxiety and depression were present in 55% and 26% of the IBS patients, respectively. More women were anxious (p = 0.001), but for depression no gender differences were detected (p = 0.76). IBS patients with anxiety or depression were younger (p < 0.001), and more commonly reported sexual and/or physical abuse (p < 0.001) than IBS patients without anxiety or depression. The presence of anxiety or depression did not differ between IBS subgroups based on the predominant bowel habit (p = 0.41, p = 0.18). For an overview of comparisons of data from questionnaires and pathophysiological examinations, see table 1. Both the presence of anxiety and of depression were associated with reports of more severe GI and extraintestinal symptoms, GI-specific anxiety, fatigue, and lower sense of coherence. Regarding pathophysiological examinations, the findings were more inconsistent. OATT was similar between groups, as was stool form and frequency. Visceral sensitivity tended to be higher in patients with anxiety, and depressed patients reported more severe pain during the lactulose challenge.
Conclusion: The presence of anxiety and depression seems to clearly potentiate the already substantial disease burden in IBS patients. However, the association with other pathophysiologically findings is less distinct. This group of patients with complex and severe symptoms will benefit from a holistic management approach.

Introduction: Irritable bowel syndrome (IBS) and lactose intolerance may co-exist and readily cause diagnostic confusion due to similar symptomatology (1,2).

Aims & Methods: This study aim to examine the incidence of lactose intolerance in healthy controls and in subjects diagnosed with IBS based on Roma III criteria, as an effort to investigate the association between IBS and lactose intolerance. The patient population consisted of individuals between 18 and 80 years of age who attended between June-December 2013. Patients diagnosed with IBS based on Roma III criteria comprised the IBS group, and subtypes of IBS. Control subjects were healthy volunteers over 18 years of age with no IBS-like symptoms. All participants ingested 25 g of lactose dissolved in 250 ml of water within 5 minutes after 8 hours of fasting, in order to evaluate the lactose intolerance via hydrogen breath test (0, 15, 30, 60, 90, and 120 minutes). Additionally, symptoms arising during the test were assessed.

Results: Of the total 200 participants, 100 (50%) were in IBS and 100 (50.0%) were in control group. There were 133 females (66.5%), and the mean age was 40.5±12.3 years. Of the total 70 patients (35.0%) with lactose intolerance, 47 (47.0%) were in IBS and 23 (23.0%) were in control groups (p = 0.001). Symptoms related to IBS were more common in participants with lactose intolerance in both groups (p = 0.001, p = 0.001 respectively). A comparison of the two groups with regard to symptomatology after the test showed the presence of complaints in 35 (35.0%) patients in IBS group as compared to 24 (24.0%) subjects among controls (p = 0.092). The incidence of lactose intolerance in patients with IBS subtypes of diarrhea-predominant IBS, constipation-predominant IBS, mixed IBS, and unspecified IBS were 27 (57.4%), 7 (4.9%), 10 (21.3%), and 6 (4.4%), respectively, with no significant differences (p = 0.161, p = 0.124, p = 1.000, and p = 0.661 respectively).

Conclusion: A significantly increased frequency of lactose intolerance was found among IBS patients than in controls. In additional, symptoms associated with lactose intake occurred at a higher frequency in IBS patient, although the difference was insignificant.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

While the above text provides a comprehensive account of the study's findings and methodologies, it is important to consider the implications of these results for both clinical practice and future research. The identification of lactose intolerance as a contributing factor in IBS highlights the need for personalized dietary interventions in managing symptoms. Furthermore, the study's findings underscore the importance of comprehensive symptom assessment in diagnosing and treating IBS patients. The use of hydrogen breath tests as a diagnostic tool for lactose intolerance can aid in identifying individuals who may benefit from lactose-restricted diets. This approach not only improves symptom management but also reduces the overall disease burden in IBS patients. However, the effectiveness of such interventions requires further investigation to establish their long-term efficacy and patient satisfaction.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The population prevalence of Rome IV functional gastrointestinal disorders (FGIDs) and their cumulative effect on health impairment is unknown. We sought to address this issue.

Aims & Methods: An Internet-based health survey was completed by 5931 of 6300 general population adults from three English-speaking countries (2100 each from US, Canada, and UK). The survey included questions on demographics, medication, surgical history, somatisation, quality of life, doctor-diagnosed organic GI disease, and criteria for the Rome IV FGIDs. Comparisons were made between those with Rome IV FGIDs against non-GI and organic GI disease controls.

Results: The number of subjects having symptoms compatible with a FGID was 2083 (35%) compared to 3421 (57.7%) non-GI and 427 (7.2%) organic GI disease controls. The most frequently met diagnostic criteria for FGIDs was bowel disorders (n = 1665, 28.1%), followed by gastroduodenal (n = 627, 10.6%), anorectal (n = 440, 7.4%), oesophageal (n = 414, 7%), and gallbladder disorders (n = 10, 0.2%). On average, the 2083 individuals who met FGID criteria qualified for 1.5 FGID diagnoses, and 742 of them (36%) qualified for FGID diagnoses in more than one anatomic region. The presence of FGIDs in multiple regions was associated with increasing somatisation, worse mental and physical quality of life, greater use of medical therapies, and a higher prevalence of abdominal surgeries; all p < 0.001, see table. Notably, individuals with FGIDs in multiple regions had worse somatisation and quality of life scores than organic GI disease controls.

Conclusion: Roughly a third of the general adult population fulfils diagnostic criteria for a Rome IV FGID. Bowel disorders are the predominant FGID in this population. FGID diagnoses in multiple regions are involved and this overlap is associated with increased health impairment. Study Support: The Rome Foundation

Disclosure of Interest: All authors have declared no conflicts of interest.

While the study provides valuable insights into the prevalence and cumulative effect of FGIDs on health impairment, the findings highlight the complexity of managing FGID patients. The identification of FGID overlap in multiple anatomic regions underscores the need for comprehensive care strategies that address both gastrointestinal and psychological symptoms. The study’s results also emphasize the importance of considering individual variability in symptom expression and the potential for tailored therapeutic interventions. However, further research is required to validate these findings and to explore the role of psychological factors in the development and management of FGIDs.
Introduction: Although correlations between features of irritable bowel syndrome (IBS) have been reported, these were based on between-person rather than within-person variation. We investigated the longitudinal within-person correlations between features of IBS.

Aims & Methods: We used a longitudinal cohort of 276 IBS patients, who filled out questionnaires annually over five years on the following features: gastrointestinal (GI) symptom severity (GSS), quality of life (QOL), GI specific anxiety (VSI), general anxiety and depression (HADS), coping resources (CRI), and sense of coherence (KASAM). For each participant, scores were centered on their own mean, and within-person correlations were computed for all pairs of features.

Results: Aggregate within-person correlations are shown in figure 1. Within-person correlations were strong for the triad GI symptom severity, GI specific anxiety, and QOL (r = 0.47 to 0.64). Another set of features was comprised of general anxiety, depression, coping resources, and sense of coherence (r: 0.39 to 0.57). Within-person correlations between the two sets were weak (r: 0.00 to 0.37). However, within-person correlations tended towards bimodal distributions across the population, especially for GI symptom severity and depression (r = 0.6 for half of participants, and r = 0.4 for the other half).

Conclusion: Here we show that, within individual IBS patients, GI symptom severity is strongly associated with GI specific anxiety and QOL, but not with the other four psychological features. The presence of negative within-person correlations in some individuals may imply a lack of relation, but could also signal long-term causative processes.

Results: From the 6300 individuals who completed the survey, 369 were excluded due to inconsistent responses, leaving 5931 (49.2% female; mean age 47.4 ± 14.5 years) to be included for analysis (1949 US, 1994 UK, 1998 Canada). 305 (5.1%) of these fulfilled Rome IV diagnostic criteria for IBS, after 36 individuals were excluded due to organic disease with GSS ≥3. Compared to the non-IBS population, the IBS population was younger (mean age 44.7 ± 14.5 years; p = 0.004) and predominantly female (66%; p < 0.001). Apart from reporting more frequent GI point difference) subscales (Table). Patients with GSS ≥3 also had a lower EQ-5D index score compared to those with GSS <3 (0.67 vs 0.72) (Table). Women reported a slightly lower mean total IBS-QOL score compared to men, but had a notably lower score (14-point difference) on the body image subscale (Table). No difference in mean EQ-5D score was observed between sexes. IBS-QOL total and EQ-5D index scores were similar between patients aged <65 and ≥65 years, though the younger subgroup generally had lower scores on the IBS-QOL, including on the food avoidance and sexual subscales (Table).

Conclusion: Among this patient population, IBS-C patients with higher symptom severity reported greater impairments in HRQoL. These results indicate that symptom severity may be an important consideration for disease management and emphasise the need for IBS-C treatments that improve both symptom burden and quality of life.

symptoms, IBS subjects also reported more somatic symptoms; 103 (34%) had abdominal pain at least 3 times/week, 232 (76%) subjects reported sensation of bloating at least 3 times/month, and 232 (76%) scored > 7 on PHQ-12, indicating high somatic symptom burden (p < 0.001 for all). They also had poorer self-rated overall health, more general body pain, and more health-related impairment of social activities (p < 0.001 for all). See table 1 for details. IBS subjects also reported more frequent visits to the doctor compared to the non-IBS population, both for non-GI and GI related problems; 241 (79%) vs. 3133 (56%) reported more frequent visits to the doctor compared to the non-IBS population, (p < 0.001 for all). IBS subjects also reported higher frequency of visits to gastroenterologists, gynaecologists and surgeons in secondary care; p < 0.001 for all. The use of medication for pain (both subscribed and over the counter), GI related symptoms, depression and anxiety was increased amongst subjects with IBS, as was the rate of abdominal surgery (p < 0.001 for all), appendectomy excluded. See table 1 for details.

Conclusions: Individuals fulfilling the Rome IV criteria for IBS in the general population have increased GI and non-GI healthcare utilization in primary and secondary care, excess non-GI symptom burden and impaired QOL.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Although most cases of colon ischemia (IC) are mild and self-limiting, when severe it implies high mortality rates. We aimed to evaluate the risk prediction and clinical classification of disease severity proposed by American College of Gastroenterology (ACG) guidelines (2015), to provide a management algorithm for these patients and select the level of care.

Aims & Methods: A retrospective multicenter study was conducted on adult patients with definite IC (clinical, colonoscopic, pathologic and culture criteria), between 2013 and 2016. Data was collected on clinical presentation, comorbidities, organ failure, management and outcome. Each case was classified according to ACG guidelines after assessment of the number of risk factors (gender, systolic blood pressure <90 mmHg, heart rate >100 beats per min, abdominal pain without rectal bleeding, BUN >20 mg/dl, Hgb <12 g/dl, LDH >350 U/l, serum sodium <136 mEq/l (mmol/l), WBC >15 x10^9/cmm). Patients were then classified as mild (0 risk factors (RF)); moderate (1–3 RF), and severe (≥3 RF) risk factors or any of the following: peritoneal signs, pneumatosis or portal venous gas, gangrene on colonoscopic examination and pan-colonic or isolated right-colon ischemia involving on imaging by coloscopy or computed tomography.

Results: 349 cases with the clinical diagnosis of IC were analyzed. 193 patients met the inclusion criteria of definitive diagnosis of IC (62.7% females; mean age 72 years ±13). ACG classification of mild, moderate and severe disease was attributed respectively to 21% of patients (0 intra-hospital deaths), 45% (2 deaths) and 34% (12 deaths). The number of ACG RF was: 40% with 0 RF, 8% with 1, 9% with 2, 15% with 3, 16% with 4, 8% with 5, 4% with 6 and 1% with 7. No patient with 0 or 1 RF died. Only patient with 2 RF died. The remaining 13 deaths were verified by expert label 3 RF. The univariate analysis revealed a statistical correlation between RF and intra-hospital or 30-day mortality as well as the need for surgery (mean = 4.06, sd = 1.85). ACG classification presented high predictive accuracy for in-hospital and 1-month mortality with an AUROC of 0.86 (p<0.001), respectively. For a cutoff of 2 ACG RF, the sensitivity (SE) for death was 100%, specificity (SP) 52%, with a positive predictive value (PPV) of 14% and negative predictive value (NPV) of 100%. For 3 ACG RF the results were: SE 93%, SP 61%, PPV 16% and NPV 99%, 3 or more risk factors had an odds ratio of 20.2 (confidence interval (CI) 2.59–158) for intra-hospital mortality and 18.42 for 1-month mortality (CI 2.34–144).

Conclusion: No patient in this cohort with less than 2 ACG RF died, suggesting that the ACG classification as mild disease may include 0 and 1 risk factor without changing the prognosis. Short-term mortality risk increases significantly in patients with at least 3 ACG RF.

Disclosure of Interest: All authors have declared no conflicts of interest.

EXPERIENCE WITH A NOVEL CLINICAL PATHWAY FOR FUNCTIONAL GASTROINTESTINAL DISORDERS

E. C. Linedale1, A. Mikodza-Walsh2, P.R. Gibson2, J. M. Andrews3

Introduction: Despite diagnostic criteria and effective management options for functional gastrointestinal disorders (FGID), confidence in managing these disorders in primary care is low, and long waiting lists for specialist care are common. New models which efficiently transfer specialist-held expertise to primary care practitioners is needed.

Aims & Methods: We aimed to explore and describe the patient and primary healthcare provider (PHCP) experience of a novel non-specialist-dependent algorithm-based approach to the diagnosis and management of FGID (ADAM-FGID). Consecutive patients triaged to the ‘routine waitlist’ of an Australian public hospital Gastroenterology Department over 2 years, with non-specific gastrointestinal symptoms (no alarms) were randomised to waitlist control or the ADAM-FGID algorithm (2:1). Algorithm patients were screened for organic disease with an alarms-based questionnaire and panel of routine blood/stool tests. When patients had clinical alarms or abnormal tests, data were reviewed by a gastroenterologist and, if appropriate, prompt gastroenterologist appointment offered. All others were classified using Rome III criteria. and received a letter explaining their FGID diagnosis and dietary/psychological management options. Waitlist control patients were not screened.

Results: 89 patients were participated. 35 had clinical alarms warranting gastroenterologist review and 45 were diagnosed with FGID (9 excluded). At 6 week follow up: 35/36 FGID respondents had read the feedback survey at study completion. A larger scale randomised controlled trial of this new clinical pathway for FGID (ADAM-FGID) (9 excluded). At 6 week follow up: 35/36 FGID respondents had read the feedback survey at study completion.

Conclusion: In colonoscopy-associated perforation, immediate endoscopic clipping decreases the possibility of operation and shows better clinical outcomes, and early surgical approach decreases complex operation rate. Especially, early operation need be considered in diagnostic perforation regardless of endoscopic clipping.

Disclosure of Interest: All authors have declared no conflicts of interest.

Abstract No: P1796

Aims & Methods: We aimed to compare the cost-effectiveness of annual FIT and colonoscopy every 5 years, to reduce CRC mortality, in FDR with colorectal cancer CRC, as these individuals are considered at higher risk of developing CRC than average-risk individuals. However, this practice has a low adherence and remains opportunistic. Recently, it has been suggested that annual fecal immunocological testing (FIT) might be a valid alternative to colonoscopy in this setting. However, there are scarce data regarding cost-effectiveness of these strategies from the perspective of healthcare services.

Aims & Methods: This study was aimed to compare the cost-effectiveness of annual FIT and colonoscopy every 5 years of patients with CRC. A Markov model was constructed to simulate the efficacy and cost of annual FIT (cut-off 10 µg Hgb/g feces) or colonoscopy every 5 years of patients with CRC.
previously unscreened FDR, starting at age 40 years and ending at age 75. A g/g for FCP respectively. The model was adjusted to the incidence of CRC in Spain and real prevalence of advanced adenoma and CRC in the familial-risk population (http://dx.doi.org/10.1371/journal.pmed.1002080.g001). The main outcomes were quality-of-life (QALY) gained compared with no screening, lifetime burden of colonoscopy, lifetime incidence of colonoscopy complications, and the incremental cost-effectiveness ratio (ICER). We applied a willingness-to-pay threshold of €25,000 per QALY gained. Data from a prospective EuroQol survey carried out on 920 Spanish patients at different disease stages were used for QALY measurement. Sensitivity analysis was performed to evaluate the robustness of the model.

**Results:** In a hypothetical cohort of 10,000 asymptomatic FDR, annual FIT and colonoscopy every 5 years cost-effectiveness over no screening. Taking no screening as either FIT or colonoscopy every 5 years was 1989 and 4472 euros/QALY, respectively. Compared to no screening, annual FIT and colonoscopy every 5 years reduced CRC mortality by 59% and 81%, respectively. The annual FIT strategy saved 33% of colonoscopies and was associated with a lower number of complications compared to colonoscopy every 5 years. The results were robust in sensitivity analyses.

**Conclusion:** Assuming a 50% adherence, annual FIT is less costly than colonoscopy every 5 years for CRC screening and reduces mortality in the familial-risk population. These data suggest that FDR of patients with CRC could be included in organized statewide FIT-based screening programs.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Fecal occult blood test (FOBT) is a non-invasive and easily performed test which has demonstrated to reduce CRC incidence and mortality in colonoscopy (Thermo Fisher Scientific, Waltham, United States). Reference cut-off and included in the final analysis. FOBT was performed by SENTi FIT 270 test (Sentinel Diagnostics, Milan, Italy) and FCP by the ElA Calprotectin immunoassay (Thermo Fisher Scientific, Waltham, United States). Reference cut-off levels for FIT were 117 ng/ml for fecal FIT and 90 ng/g for FCP respectively. The diagnostic accuracy of FIT and FCP were evaluated by a logistic regression model. CRC, advanced adenoma, IBDA and angiodysplasia were considered as relevant pathology. Positive and negative predictive values, sensitivity and specificity were calculated. MedCalc 19.5.3 (MedCalc Software, Belgium) was used for the ROC curve analysis.

**Results:** 171 patients (42.7% female; median age 62 years, IQR: 51–68) were included. 37 (21.6%) had relevant colonc pathology. The most frequent indications for colonoscopy were previous episode of rectal bleeding in 71 (42%) patients, change of bowel habits in 28 (16%) and anaemia in 22 (13%). The diagnostic accuracy of FIT, FCP and combination of both are summarized in table 1.

<table>

**Introduction:** Procedural sedation is considered an integral part of gastrointestinal endoscopy in many countries. The use of sedation does, however, vary internationally and can present patient safety concerns. It has been questioned whether trials assessing patient safety in endoscopy can be generalized worldwide and how differences in sedation practices and adverse events might impact outcomes. It has been questioned whether trials assessing patient safety in endoscopy can be generalized worldwide and how differences in sedation practices and adverse events might impact outcomes.

**Aims & Methods:** We conducted an international survey to examine procedural sedation practices and the incidence of adverse events (AEs) during procedural sedation in France, Germany, Italy, UK, and USA. Data collection from providers (nurses, physicians, and anesthesiologists) was via online surveys.

Respondents were screened to assure that they had the expertise and experience to complete the survey. The survey covered topics such as guidelines, sedation agents, monitoring, patient throughput, and AE incidence, treatment, and outcomes as defined by World SIVA. Data analysis took a global approach with subgroup analysis by location.

**Results:** 101 providers completed the survey, with 20 responses per country, excepting the USA with 21. More than 62% of respondents were gastroenterologists, and 14% were anesthesiologists. The main sedation agents used were midazolam (93 respondents), propofol (90), fentanyl (75), ketamine (57), and meperidine (15). Respondents from France reported higher ketamine and lower fentanyl use than other countries (p < 0.003). Standard of care monitoring was generally reported to be comprised of pulse oximetry plus blood pressure and/or heart rate. Capngrophy use varied by country, and was standard of care for 46% of respondents (ranging from 15% in Italy to 67% in the US). The most desired property of a monitoring modality across all countries was one that “provides an early warning of patient compromise”.

**Conclusion:** Sedation practices are relatively consistent across countries, as are the occurrence of adverse events. Pulse oximetry monitoring is almost universally used during sedation, while capngrophy use is more variable. Said severe oxygen desaturation events were 63, 63, 52, 67, and 0 of 9 who routinely use it (p < 0.005). Providers also differed in their reported adverse event incidence. Gastroenterologists most commonly reported mild oxygen desaturation to occur, while anaesthesiologists and nurses reported hypotension to be the most common AE experienced during procedural sedation (Table).
Results:
 Thirty-two subjects (41% males), aged 31–74 years and with a mean BMI of 26, were included in the analysis. Indications for colonoscopy included family history of CRC (55%) and polyp surveillance (44%). No serious adverse events were reported. The Pure-Vu System was found to be safe and effective in cleaning inadequately prepared colon which may help to improve the overall quality of colonoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The success of colonoscopy depends on the quality of the bowel preparation, which is estimated to occur in as many as 25% of colonoscopy procedures. The MOTUS GI Pure-Vu™ System (Tirat Carmel, Israel) is an FDA cleared device designed to improve visualization in an inadequately prepared colon which may help to improve the overall quality of colonoscopy.

Aims & Methods: This study aims to evaluate the performance of the Pure-Vu System in cleaning a poorly prepared colon, assess the system’s usability, patient satisfaction and safety. Forty-seven cases were planned to be enrolled at three clinical sites, of which 32 had completed the study so far. Pure-Vu was used in subjects with a partially prepped colon after 2x10 mg Bisacodyl, diet restrictions (no dried fruit, seeds or nuts) starting 2 days before the procedure and a 24-hour clear liquid diet prior to the colonoscopy. Study endpoints were: (1) Safety, 2) Improvement of colon cleaning level as per the Boston Bowel Preparation Scale, whereas data on patient experience with the validated Gastronet questionnaire (2). Data on complication rates were collected from the National Health Fund database and Personal Identification Number Registry.

Results: Overall, on the program level, all minimum standards for colonoscopy key performance measures were met. Rate of adequate bowel preparation was 92.1% for the whole program, ranging 80.9–99.2% per individual center, with 7 centers (29.2%) not reaching minimum standard of 90% and 9 centers (37.5%) reaching the target standard of 95%. Cecal intubation rate was 97.4% (range 93.4–99.4%), with all centers reaching minimum standard of 90% and only one center not reaching target standard of 95%. Adenoma detection rate was 29.9% (range 19.1–39.1%), with 7 centers (29.2%) not reaching minimum standard of 25%. Appropriate polypectomy technique was applied in case of 90.9% 6 to 9 mm polyps (range 64.3–100%) with only 2 centers not reaching minimum standard of 80% and 48.2% of 4 to 5 mm polyps (range 0–100%) with only 6 centers reaching minimum standard of 80%. Target standard of 90% was reached in 15 centers for polyps 6 to 9 mm in diameter and only 2 centers for polyps 4 to 5 mm in diameter. For the whole program, 7-day hospitalization rate after screening colonoscopy was 0.3% (122 cases) and 30-day all-cause mortality was 0.02% (9 cases). Gastronet questionnaire coverage is assumed to be 100%, however the response rate was 65.3% (range 5.6%-81.8%), with painful colonoscopy rate of 19.2%. No minimum standard is set, however target standard of 90% of procedures with measured patient’s experience was not met. Appropriately post-polypectomy surveillance, based on the European guidelines, was proposed in 95.4% of cases (range 84.9-99.7%). Target standard of 95% was met in 15 centers, the minimum standard is not set.

Conclusion: Monitoring ESGE performance measures for colonoscopy is feasible in colonoscopy programmatic screening setting. 6 of 7 performance measures were easy to monitor with PCSP database, however monitoring complications needs further development to avoid extracting data from external registries. PCSP meets proposed minimum standards on program level, however some centers need additional interventions to meet the quality standards. Applying appropriate polypectomy technique for polyps ranging 4 to 5 mm in diameter with an inadequately prepared colon may help to improve the overall quality of colonoscopy.
is currently the biggest issue in PCSP and further training is needed to reach minimum standards for this performance goal.

P1805 VALIDATION OF THE “FAILURE TO PROVIDE ADEQUATE RELIEF” (F-PAR) SCALE IN A SPECIALIST CLINIC SETTING

V. Passananti, N. Zarate Lopez, A. V. Emmanuel
GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassananti@gmail.com

Introduction: Treatment of chronic idiopathic constipation is somewhat empiric, but based on step-wise approach[1]. If first-line conservative treatment (lifestyle advice and laxatives) do not relieve symptoms sufficiently, secondary approaches with prokinetic or secretagogue drugs are used before considering hospital-based care (biofeedback, psychosocial support, transanal irrigation (TAI), surgery). Nevertheless, patients are often dissatisfied with care[2] and fail to progress to adequate levels of therapy. The 5-point Failure to Provide Adequate Relief (F-PAR) scale[3] was developed to facilitate the recognition of when to move from one step to the next.

Aims & Methods: The aim of this study was to validate F-PAR in a tertiary clinic setting. We studied 403 consecutive consultations of 331 patients (262 women, mean age 41) in our specialist clinic. All fulfilled Rome III/IV diagnostic criteria for chronic constipation. Immediately prior to each face-to-face clinical assessment by one of 2 experienced physicians, participants completed the F-PAR scale; patients were seen blind to the F-PAR result. Standard clinic assessment was undertaken to identify efficacy of the current management as the gold standard.

Results: The 403 consultations, clinical assessment identified inadequate relief with current therapy was identified in 200. Neither duration nor type of treatment were correlated with relief. The table stratifies, by clinical gold standard, each item of the F-PAR and in the lower panel the total number of F-PAR items replied to positively.

<table>
<thead>
<tr>
<th>Adequate relief (Clinical)</th>
<th>Inadequate relief (Clinical)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bowel frequency inadequate</td>

<tr>
<td>Stool hardness</td>
<td>3 21</td>
</tr>
<tr>
<td>Onset other symptom</td>
<td>2 57</td>
</tr>
<tr>
<td>Current therapy poor tolerable</td>
<td>8 80</td>
</tr>
<tr>
<td>0 FPAR replies</td>
<td>187 1</td>
</tr>
<tr>
<td>1 FPAR replies</td>
<td>10 41</td>
</tr>
<tr>
<td>2 FPAR replies</td>
<td>4 67</td>
</tr>
<tr>
<td>3 FPAR replies</td>
<td>2 22</td>
</tr>
<tr>
<td>4 FPAR replies</td>
<td>0 8</td>
</tr>
<tr>
<td>5 FPAR replies</td>
<td>0 9</td>
</tr>
</tbody>
</table>

Conclusion: Our findings showed that the F-PAR with only five questions can be considered sufficient to provide clinical evidence of treatment failure. The use of standardized process to investigate the efficacy of treatment may reduce the time and improve the quality of managing for the chronic constipation patients.

P1807 THE DUODENAL MUCOSA retaining a DIVERSE MICROBIOTA FOLLOWING BOWEL PREPARATION

E. Shanahan1, A. Shah1, A. Do2, P. Ghaseemi3, T. Hansen1, N. Koloski1, M. Morrison1, G. Holtmann2

Contact E-mail Address: e.shanahan@uq.edu.au

Introduction: The microbiota inhabiting the gastrointestinal (GI) tract plays an essential role in gut health. Although mucosal biopsies are increasingly used for microbiota studies, these are subject to variations introduced through sampling technique and patient preparation. The impact of bowel preparation on the mucosa-associated microbiota (MAM) is of particular interest given it results in complete emptying of bowel contents via laxative ingestion. Although bowel preparation does not appear to induce long term changes to stool microbiota [1], it can induce short-term changes to the colonic MAM [2]. While improvements in clarity of the small intestine after bowel preparation have been reported [3], the impact on the upper GI microbiota is currently unknown. Given patients may undergo both upper GI endoscopy and colonoscopy consecutively, a subset of endoscopy patients will have consumed bowel preparation prior to their procedure, representing a potential bias in MAM analyses. Therefore, this study aimed to assess the impact of bowel preparation on the duodenal MAM.

Aims & Methods: Individuals undergoing upper GI endoscopy, with or without concurrent colonoscopy, were recruited consecutively with ethical approval. Individuals underwent upper GI endoscopy following overnight fast (n = 58), or both upper endoscopy and colonoscopy following polyethylene glycol bowel preparation (n = 48). Participants were undergoing screening for iron deficiency anaemia or GI symptoms with no evidence of mucosal disease/inflammation (n = 58), or with diagnosed Crohn’s disease (n = 18). Duodenal biopsies were obtained and gDNA extracted. Amplicon libraries of the 16s rRNA gene were sequenced (Illumina MiSeq). Sequencing of reagent controls enabled exclusion of
non-duodenal sequences. Bioinformatics and statistics were performed in qiime and Calypso.

Results: A diverse microbiota was observed in duodenal mucus samples from all subjects, following overnight fasting or bowel preparation. Overall the duodenal microbiota was dominated by the genus Streptococcus, followed by Prevotella, Veillonella and Neisseria. Microbial diversity within samples was not significantly different with and without bowel preparation (Chao1 metric). Principal coordinates analysis (weighted UniFrac) revealed substantial overlap between the two groups, and no significant clustering was observed (ADONIS) based on whether patients had undergone overnight fasting or bowel preparation. Similar findings were obtained when these analyses were repeated with exclusion of the Crohn’s disease population.

Conclusion: This study reveals a diverse duodenal MAM is retained following bowel preparation. The comparison of overnight fasting and bowel preparation indicates these differences in patient preparation do not substantially alter the duodenal MAM. Thus patients undergoing concurrent upper GI endoscopy and colonoscopy can be included in study cohorts investigating the upper GI MAM without risk of a substantial confounding effect.

P1808 PERFORMANCE OF GLASGOW-BLACKFORD, ROCKALL, AND AIMS65 SCORES TO PREDICT OUTCOMES AND TO IDENTIFY THE LOW-RISK GROUP AFTER UPPER GI BLEEDING IN PATIENTS WITH CANCER

M. C. Franco1, S. Jang2, B. D. C. Martins1, T. Stevens1, V. Jairath1, R. Lopez1, J. J. Varg3, A. Barkun4, F. Maluf-Filho1

Introduction: Upper gastrointestinal bleeding (UGIB) in patients with cancer presents a unique and difficult challenge as these patients are at higher risk for rebleeding and mortality. Currently available prognostic scoring systems for UGIB for the general population have produced variable accuracy in their validation studies. An effective method of stratification for cancer patients to identify the high-risk group for early hospital-based intervention and death could enhance the outcomes of this specific population.

Aims & Methods: The primary aim of this study was to compare the Glasgow-Blatchford score (GBS), Rockall score (RS) and AIMS65 score for predicting ICU admission, blood transfusion, hemostatic therapy, rebleeding, and in-hospital mortality in cancer patients with UGIB. The secondary aim was to assess the above cited scores in correctly identifying low-risk patients that can be effectively managed as an outpatient. An IRB-approved prospective study was conducted at the Cancer Institute of Sao Paulo, Brazil. Consecutive patients with known cancer admitted with UGIB were enrolled. Pre-endoscopic clinical parameters pertinent to the scoring systems, hemostasis techniques, and outcomes were collected into a prospective registry. Patients were followed for at least 30 days or until the day of discharge, whichever was longer. The low-risk group was defined as those without blood transfusion, hemostatic therapy (by endoscopy, radiotherapy, angiographic or surgical intervention), rebleeding or mortality in 30 days. Multiple logistic regression with receiver operating characteristics analysis was done to assess the predictive ability of each scoring system for the above outcomes.

Results: From April 2015 to May 2016, 394 consecutive patients were screened, while 259 patients met the inclusion criteria. A total of 243 patients were considered for the final analysis, after excluding 16 patients due to missing data or lost to follow up (Table 1). Predicting outcomes: The AIMS65 score (area under curve (AUC) 0.79; p = 0.04) was significantly better than GBS (AUC 0.79; p = 0.04), both the total and clinical RS (AUC 0.71 and 0.66; p < 0.001 for both). The GBS best predicted the need for blood transfusion (AUC 0.82, sensitivity 71% and specificity 80% for GBS ≥ 12) compared with the other prognostic scores. All scores performed poorly in predicting the need for hemostatic therapy and risk of rebleeding. The AIMS65 score best predicted in-hospital mortality (AUC 0.84) compared to the GBS (AUC 0.75; p = 0.004), both the total and clinical RS (AUC 0.70 and 0.69; p < 0.001 for both). Among patients rebleeding at EGD, there was no difference in 30-day mortality if the etiology of bleeding was tumoral or non-tumoral disease (38.1% vs 31.9%; p = 0.46). Identifying low-risk group: With GBS score of 0 as the cut-off value, its specificity was 100% with sensitivity of 5.8%. When GBS was ≥ 2, its specificity was maintained at 100%, while sensitivity was increased to 23.5%. This change increased the proportion of the patients from 1% to 5% without erroneously discharging high-risk patients. In comparison, when an AIMS65 value of 0 was chosen as definition of low-risk, this tool misclassified 20 patients who needed hospital interventions (specificity of 53% and sensitivity of 89.5%). Finally, head-to-head comparison between GBS vs. RS, and GBS vs. AIMS65 scoring system revealed GBS to be superior to both the clinical RS (p < 0.001) and AIMS65 (p = 0.001) in correctly identifying low-risk patients.

Aims65 1.7 ± 1.2

Glasgow-Blatchford 10.8 ± 4.2

Conclusion: The AIMS65 score was superior to other scoring systems in predicting in-hospital mortality and ICU admission in patients with cancer and UGIB, whereas the GBS was superior for predicting the need for blood transfusion. All scores performed poorly in prediction of hemostatic therapy and rebleeding. The GBS was superior in accurately identifying low-risk patients. Furthermore, the cut-off ≤ 2 in GBS score displays increased sensitivity without compromising specificity, effectively increasing the number of patients who can be safely managed as an outpatient.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopists are more frequently performing endoscopic resection (ER) in patients on antiplatelet or anticoagulant therapy and nowadays patients have increasingly started taking direct oral anticoagulant (DOAC) therapies, including direct anti-Xa and thrombin inhibitors. Major guidelines recommend the cessation of anticoagulants before ER and heparin bridging therapy (HBT) for high thrombotic risk cases, although these are still controversial. A recent study has suggested that HBT may be associated with a higher post-endoscopic resection bleeding (PEB) rate in patients on anticoagulants.

Aims & Methods: This study aimed to evaluate the effect of anticoagulants on PEB rate. This was a retrospective study based on medical records from three hospitals. PEB was defined as bleeding that occurred 6 h to 10 days after ER, which required endoscopic hemostasis. We reviewed 108 gastric tumors including adenoma and early cancer in 97 patients on anticoagulant therapy who underwent endoscopic submucosal dissection (ESD) in our hospitals between June 2008 and February 2016. Further, we reviewed 69 colorectal polyps including adenoma and early cancer in 69 patients on anticoagulant therapy who underwent ER in our hospitals between October 2013 and September 2016. ER included polypectomy, endoscopic mucosal resection (EMR), and ESD. Patients were divided into two groups: those prescribed warfarin and patients prescribed DOAC. The management of antithrombotics was based on the Japanese Gastroenterological Endoscopy Society guidelines published in 2005 and 2012. The anticoagulants used during the study period were warfarin, dabigatran, rivarxaban, apixaban, and edoxaban. Warfarin was discontinued 4–5 days before ER, whereas the others were stopped 24–48 h prior to the procedure. For patients at a high thrombotic risk, intravenous unfractionated heparin was administered after ceasing anticoagulants.

Results: Warfarin and DOAC were prescribed to 73 (75%) and 24 (25%) patients, respectively. Apixaban was administered to 1 (1%), dabigatran to 12 (12%), rivarxaban to 11 (11%) patients. There were no significant differences between the DOAC and warfarin groups in terms of clinical characteristics or
Although endoscopic hemostasis is usually effective in controlling gastrointestinal (GI) hemorrhage, some have difficulty in achieving successful hemostasis depending on the location and severity of hemorrhage. NEXPOWDER® (Next Biomedical, Incheon, South Korea) is a biocompatible hemostatic powder designed for controlling hemorrhage in patients with post-endoscopic resection ulcers (41 ESD induced ulcers and 5 EMR induced ulcers), 2 patients with peptic ulcers and 5 EMR induced ulcers, 8 patients with peptic ulcers and 3 patients with other causes. 1. Success rates of hemostasis in acute bleeding were 96.6% (55/57) of NEXPOWDER® group, 2. Re-bleeding rate on second-look endoscopy at 1 or 3 days after the procedure, 3. Persistent rate of hydrogel on ulcer base at follow-up endoscopy, and 4. Clogging rate of catheter during spraying powder. The NEXPOWDER® was delivered by newly developed spraying device through a catheter clogging during endoscopic application. The endoscopic application of NEXPODWER® is effective for the several types of acute GI bleeding. This effective hemostatic action of NEXPODWER® might be achieved by physical barrier of mucodhesive and persistent hydrogel on ulcer base. And new powder delivering device shows low rate of catheter clogging. In addition, a newly developed powder delivering device shows low scattering and targeted spraying properties onto bleeding site.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1811 CLINICAL FEATURES OF DELAYED BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC NEOPLASMS IN HIGH-RISK AND LOW-RISK PATIENTS
Gastroenterology, Osaka General Medical Center, Osaka/Japan
Contact E-mail Address: taktakakkun@gmail.com

Introduction: Antithrombotic drugs are administered to patients undergoing endoscopic treatment at high risk for thromboembolism. However, antithrombotic drugs have been also known as a cause of delayed bleeding associated with endoscopic treatment, including endoscopic submucosal dissection (ESD). We previously reported the clinical features of postpolypectomy bleeding associated with heparin bridge therapy (1), and then various risk factors of delayed bleeding after endoscopic treatment have been reported.

Aims & Methods: The aims of the present study are to investigate the risk factors of delayed bleeding after gastric ESD and to clarify the clinical features of delayed bleeding in high-risk and low-risk patients. The endoscopic treatment of consecutive patients who underwent ESD for gastric neoplasms in Osaka General Medical Center between January 2009 and December 2016 were retrospectively investigated. Independent risk factors of delayed bleeding were analyzed by using a multivariate analysis by logistic regression model, and three predictors of delayed bleeding were selected. Patients were categorized into a high-risk group or low-risk group for bleeding, and the clinical features of post-procedural bleeding in each group were investigated.

Results: A total of 717 patients with 781 gastric neoplasms were identified. Mean age was 74.6, and 71.6% was male. With regard to comorbidity, the proportion of hypertension, diabetes, chronic liver disease, and hemodialysis was 50.2%, 19.2%, 2.7%, and 6.1%, respectively. Total 188 patients have taken oral anticoagulants, and of them, 50 patients treated by gastric ESD under heparin bridge therapy. Two-thirds lesions were located in gastric body and median tumor size (range) was 15 (3–80) mm. En-bloc resection was achieved in 751 lesions (96%), and no uncontrollable bleeding occurred. Forty-nine patients (6.8%) experienced delayed bleeding after gastric ESD. Hospital stay was significantly longer in bleeding cases than in non-bleeding cases [median hospital stay (range) 11 (3–25) vs. 9 (9–25), p = 0.007]. A univariate and multivariate analysis showed heparin bridge therapy, antiplatelet therapy, and hemodialysis as independent risk factors for delayed bleeding. We defined patients with heparin bridge therapy, antiplatelet therapy, and hemodialysis as a high-risk group for bleeding, and the remainder as a low-risk group. The incidence of delayed bleeding was significantly higher in the high-risk group than in the low-risk group (14.3% vs. 3.6%, p < 0.001). Severe bleeding requiring transfusion and recurrent bleeding were more often in the high-risk group than in the low-risk group. Median onset (range of delayed bleeding was PODI (0–16) in the high-risk group and POD6 (0–15) in high-risk group. No thromboembolism occurred in each group.

Conclusion: Bleeding high-risk patients with heparin bridge therapy, antiplatelet therapy, and hemodialysis should be carefully observed after gastric ESD while early hospital discharge is acceptable for bleeding low-risk patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There are few studies of the efficacy of parenteral ferric carboxymaltose (FCM) treatment in acute gastrointestinal bleeding (GIB) of different origins. Few data are available on its use to treat anaemia post-acute haemorrhage.

Aims & Methods: To determine the efficacy and safety of FCM treatment in patients with acute GIB not associated with portal hypertension. A retrospective descriptive 3-year study of patients with acute GIB (anaemia with evident bleeding and/or hemodynamic instability) treated with FCM as part of our hospital’s habitual clinical practice.

Results: Analysis of 84 patients admitted with acute GIB (69.0% male, mean age 68.0 years [SD 6.9]), with a Charlson index ≥3 in 67.1% of cases (≥5 in 31.6%). 15.5% had previously suffered acute GIB due to peptic ulcer. There were 86 hospital admissions for acute GIB; 93.8% were upper GIB (above the angle of Treitz). The most frequent clinical presentation was melena, in 76.7% of cases. 25.6% presented hemodynamic instability at admission. The mean Glasgow-Blatchford index score was 16.1 (SD 2.7) and the mean Rockall score post-endoscopy was 4.2 (SD 1.7). The most common causes of bleeding were: 36.0% duodenal ulcer, 29% gastric ulcer, 9.3% gastritis/errosions, and 7.3% angiodysplasia of the colon. The mean Hb at admission was 9.0 g/dL (SD 2.2)
and the mean of the lowest Hb during admission was 7.6 g/dL (SD 1.3). The most common total dose of FCM administered was 1000 mg. During admission, a mean Hb increase of 0.8 g/dL (SD 2.3) was observed in a mean period of 5.7 days (median: 4.0) after treatment with FCM, with an increase of 4.2 g/dL (SD 2.6) 30 days after acute GIB. After FCM administration, the mean Hb increased significantly (p < 0.0001) in patients >75 years (2.1 g/dL [SD 1.7]), in patients with Charlson index ≥ 3 (1.9 g/dL [SD 1.6]), and when Hb level during admission was <10 g/dL (2.0 g/dL [SD 1.7]). No adverse reactions were observed.

Conclusion: In patients with acute GI bleeding the administration of ferric carboxymaltose improves Hb levels promptly and safely, especially in patients of advanced age and with associated comorbidities. Disclosure of Interest: All authors have declared no conflicts of interest.

Results: 431 patients have been included in this study. 24.8% of patients were >75 years old. The following differences have been observed by comparing the two groups of patients (over and below 75 years old): female 47.7% vs 25.3% (p < 0.001); antplatelet use 40.2% vs 20.1% (p < 0.001); oral anticoagulants use 20.6% vs 7.7% (p < 0.001); NSAIDs use 22.5% vs 33.6% (p = 0.133); smoke- smoking 25.1% vs 35.2% (p < 0.001); alcohol consumption 17.8% vs 45.3% (p < 0.001); one or more comorbidities 77.6% vs 62% (p = 0.005); high risk endoscopic stigmata 61.7% vs 64.4% (p = 0.724); multiple ulcers 41.1% vs 31.8% (p = 0.099); need for blood transfused 39.5% vs 58% (p = 0.832); hospitalization duration 8.4 ±1.6 vs 7.8 ±6.0 days (p = 0.382); rebleeding 10.3% vs 11.4% (p = 0.745); need for surgery 2.8% vs 4.6% (p = 0.589) and in-hospital mortality 13.1% vs 6.2% (p = 0.021). In most of the cases (88.2%), the cause of death was other than hemorrhagic shock (92.9% vs 85.0%, p = 0.484). Using multivariate analysis, three out of these factors were identified as representing independent factors significantly associated with the age over 75 years old: oral anticoagulants use (OR = 2.40, 95%CI:1.24–4.62, p = 0.009), antplatelet use (OR = 2.33, 95%CI:1.43–3.81, p = 0.001) and in-hospital mortality (OR = 2.09, 95%CI: 1.72–4.47, p = 0.048).

Conclusion: The use of oral anticoagulants and antplatelet was significantly higher in older patients, compared to the younger group. Elderly patients with peptic ulcer bleeding do not have a different rebleeding, need for surgery, need of transfusion or hospitalization mortality. Conclusion: The increase in life expectancy and the increased use of antiplatelet and anticoagulants use, smoking, alcohol consumption, presence of comorbidities.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Peptic ulcers are the most frequent cause of upper gastrointestinal bleeding. In different population based surveys regarding all-cause UGIB, mortality ranges between 3% and 14%.

Aims & Methods: The aim of this study was to assess in-hospital mortality in patients with peptic ulcer bleeding and to evaluate the risk factors associated with mortality. In this prospective study we enrolled all patients diagnosed with peptic ulcer bleeding and treated in a medical center over a period of 24 months (January 2015–December 2016). Patients were divided into two groups - those who died and those who survived - and the following parameters were compared: age, signs of hemodynamic instability (hypotension, tachycardia, presence of comorbidity) and Charlson index. The mortality of patients with a single ulcer (Forrest IA, IB, IIA, IIB) was quantified as high risk endoscopic stigmata, while Forrest IIC and III were considered as low risk endoscopic stigmata).

Results: The study included 431 patients. In-hospital mortality rate was 7.9%. The following differences have been observed by comparing patients who died and those who survived: age >75 years 41.2% vs 23.4% (p = 0.036); hypotension 17.6% vs 2.3% (p < 0.001); tachycardia47.1% vs 21.4% (p = 0.001); one or more comorbidities 94.1% vs 63.5% (p = 0.001); high risk endoscopic stigmata 79.4% vs 62.2% (p = 0.070); multiple ulcers 41.2% vs 33.5% (p = 0.473); Rockall score ≥ 5 points 94.1% vs 46.9% (p < 0.001); Blatchford score ≥ 10 points 91.2% vs 66.2% (p = 0.005); hemoglobin < 9.5 g/dL 70.6% vs 41.1% (p = 0.002); INR ≥ 2.5 17.6% vs 5.8% (p = 0.022); creatinine ≥ 1.5 mg/dL 38.2% vs 10.8% (p = 0.001); rebleeding 20.6% vs 10.3% (p = 0.123); need for blood transfusion 82.4% vs 56.4% (p = 0.006); need for surgery 11.8% vs 3.5% (p = 0.063). In most cases (88.2%), the cause of death was other than hemorrhagic shock. Using multivariate analysis, three out of these factors were identified as representing independent factors significantly associated with in-hospital mortality: tachycardia (OR = 2.83, 95%CI:1.21–6.58, p = 0.016), Rockall score ≥ 5 (OR = 6.65, 95%CI:1.46–30.16, p = 0.014) and creatinine ≥ 1.5 mg/dL (OR = 1.25, 95%CI:1.25–7.73, p = 0.014).

Conclusion: The in-hospital mortality rates in patients with peptic ulcer bleeding was 7.9%. Tachycardia, Rockall score ≥ 5 and creatinine ≥ 1.5 mg/dL were the independent risk factors significantly associated with in-hospital mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The interaction between gut microbiota and enteroendocrine cells alterations is believed to play an important role in the pathophysiology of irritable bowel syndrome (IBS). The densities of the duodenal enteroendocrine cells are abnormal in IBS patients, which appears to be caused by a reduced stem cell density and their differentiation into endocrine cells (1). Aims & Methods: The aim is to investigate the effects of faecal microbiota transplantation (FMT) on the differentiation of the stem cells into endocrine cells as detected by neurogenin 3, the stem cells as detected by Musashi 1 and the enteroendocrine cells in the duodenum of patients with IBS. The study included 16 IBS patients according to Rome III criteria and four patients were excluded. The remaining patients (n = 12, 4 females and 8 males, age range 20–44 years) were divided according to the cause of IBS into PI-IBS patients (n = 6) and idiopathic IBS (n = 6) and received FMT donated from their relatives. The patients completed the IBS-symptom severity scoring system (IBS-SSS) before and 3 weeks after FMT. The patients underwent pastascopes with biopsies taken from the descending part of the duodenum at baseline and 3 weeks after FMT. The biopsies were immunostained for neurogenin 3, Musashi 1 and all types of duodenal enteroendocrine cells, and quantified by computerized image analysis.

Results: The score of IBS symptoms as assessed by IBS-SSS was significantly reduced 3 weeks after (240.2 ± 33.6) compared to before (326.6 ± 22.3) receiving FMT, P = 0.009. The scores of IBS-SSS before and 3 weeks after FMT for PI-IBS patients were 286.8 ± 27.8 and 210.4 ± 41, respectively (P = 0.052), and for idiopathic IBS are 352 ± 34 and 270.3 ± 54, respectively (P = 0.034). The densities of neurogenin 3, Musashi 1 and endoenterocrine cells in the duodenum of IBS patients before and 3 weeks after receiving FMT are presented in Table 1. Conclusion: Faecal microbiota transplantation improved the symptoms in IBS patients, both PI and idiopathic. This improvement was associated with a change in the enteroendocrine cell density. The changes in the enteroendocrine cell density does not appear to be caused by changes in the stem cells or their early progenitors, but rather by changes in the differentiation progeny as detected by changes in neurogenin 3.

Introduction: Globus pharyngeus, a sensation of a lump or tightness in the throat, is a well-defined clinical symptom that is usually long-lasting, difficult to treat, and has a tendency to recur. More than half of globus patients suffered from probable psychological disorders, such as anxiety and depression 1. Antidepressants are used in the treatment of functional gastrointestinal disorders (FGIDs) and showed a promising efficacy. Our study manifested that low-dose amitriptyline is well tolerated and effective for general globus pharyngeus patients 2. Our anterior study had ever speculated that AMT could modify brain-gut axis function, up-regulating brain-gut peptides, reducing the visceral sensitivity and regulating the secretory and motory functions of the gastrointestinal tract 3, so that gastrointestinal symptoms as well as emotional well-being could be significantly improved. As we known, serotonin (5-hydroxytryptamine, 5-HT) is an important factor in gut function, playing key role in intestinal peri-stalsis, secretion, and sensory signaling in the brain-gut axis 4. Several studies have investigated the association between SLC6A4 and functional gastrointestinal disorders, including IBS and FD. Besides, the association between various complex behavioral traits and disorders were also studied, including anxiety, major depression, suicide, smoking behavior, alcohol dependence. A single gene (SLC6A4), located on the human chromosome 17q11.2, 17q12, is coded by serotonin transporter (5-HTT). The polymorphism of this gene is characterized by the insertion or deletion of the 44-bp sequence and this is related to the different transcriptional activity of the gene. Allele with 44-bp insertion (short allele) is characterized by a three times lower transcriptional activity than allele with 44-bp insertion (long allele). Compared to other FGIDs, the researches about globus are rare. The pathogenesis of globus pharyngeus is still unknown.

To the best of our knowledge, our findings are the first to establish an association between SLC6A4 gene polymorphism and globus pharyngeus. Aims & Methods: 84 patients diagnosed with globus according to Rome III and 160 healthy controls were genotyped for 5-HTTLPR polymorphism by PCR amplification and agarose gel electrophoresis. All globus patients were studied with high-resolution esophageal manometry pre-therapy. Globus patients were randomized into paroxetine group; amitriptyline group for 6-week treatment, and were asked to complete the following questionnaires pre- and post-therapy: Glouce Edinburgh Throat Scale (GETS), Pittsburgh Sleep Quality Index, Hamilton Rating Scale Anxiety, Depression. Treatment response was defined as ≥ 50% reduction in GETS scores. Results: The significant difference was shown in globus performed S/S genotype by anxiety with compared to without (X2 = 14.579, P = 0.006). The L-S genotype had higher frequency between high upper esophageal sphincter pressure (≥104 mmHg) and non-high upper esophageal sphincter pressure patients (X2 = 14.433, P = 0.006). There was significant association between the S/S genotype and the response to antidepressants treatment, while patients with sleep disorders or depression not. Conclusion: A significant association was observed between S/S genotype of SLC6A4 polymorphism and globus pharyngeus, suggesting that SLC6A4 is a potential candidate gene involved in the pathogenesis of globus pharyngeus. Of these, 91 (61%) had peristaltic reserve on outflow obstruction on HRM. Conclusion: MRS identifies peristaltic reserve better than RDC and has higher diagnostic value of esophageal HRM. Aims & Methods: Hospital Episode Statistics (HES) includes demographic and diagnostic data for all English hospital admissions. The Health Improvement Network (THIN) database includes primary care records of 7% of the UK population, representative of national demographics. Both were searched for incident cases and THIN for prevalent cases of achalasia. Results: There were 10,509 and 711 new achalasia subjects in HES and THIN respectively. The incidence per 100,000 person years in THIN was 1.99 (95% CI 1.87-2.11) and 1.53 (1.42-1.64) per 100,000 person years in THIN. The prevalence measured in THIN was 27.1 (25.4-28.9) per 100,000 population. Table 1: Annual incidence and prevalence of achalasia

Conclusion: The incidence of oesophageal achalasia was approximately 15 to 20 per 1 million population. There were approximately 17,500 patients with achalasia in UK. In 2015 the above data represents the largest published epidemiological investigation of achalasia. The variation of findings between the databases likely results from differences in coding practice and marginally different population structures.

Disclosure of Interest: All authors have declared no conflicts of interest. References

Results: 14 patients (9 male) fulfilled inclusion criteria. 7 were treatment-naïve and 7 had undergone prior esophageal myotomy (3 myotomy, 4 dilatation). Mean resting LES pressure was 14.6 ± 7.4 mmHg. In all patients, and mean and median IRP values for ten 5 mL water swallows were non-raised (mean 9.1 ± 4.3 and 8.7 ± 4.5 mmHg respectively). Of the 7 treatment-naïve patients, 5 demonstrated PEP on MWS, 3 on solid swallows and 6 had a positive TBE at 5 minutes. In treatment-experi- enced patients, 5 had PEP on MWS, 1 on solid swallows and all had a positive TBE. Of the 13 who had resistance to flow on TBE, 10 (77%) also had resistance demonstrated during MWS and/or solid swallows. Mean height of the 5-minute column of barium at baseline was 16.5 ± 8.9 cm. Patients have (so far) under- gone therapy based on these findings; one per oral endoscopic myotomy and 7 pneumatic dilatations. The median baseline ES was 7.5 (IQR: 5–8). The median ES at minimum 3 months (range 3–15 months) following treatment was 1 (IQR 0–4) (P < 0.001 cf. baseline). Similarly, there was significant improvement in TBE findings post-therapy (mean 5-minute column height 3.5 ± 4.1 cm; P = 0.04 cf. baseline).

Conclusion: A normal IRP for water swallows does not preclude a diagnosis of achalasia. The addition of free drinking/solids during HRM or the TBE can identify pathology that might have been missed with standard 5 mL water swal- lows alone as normal, clinically relevant swallowing behavior is reproduced. Patients treated based on this algorithm exhibit excellent treatment outcomes, validating this approach. Further, the close correlation of HRM adjunctive test- ing with TBE supports its routine inclusion in clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The timed barium esophagram (TBE) is an objective measurement of esophageal (3 myotomy, 4 dilatation) and symptomatic relief used in the assessment of achalasia. Post-therapy corre- lation of the maximum height of the residual barium column has been found to correlate imperfectly with short-term symptomatic outcomes, but carries long- term prognostic implications. We hypothesize that the size of the barium column may be more accurate than height, firstly, by demonstrating improvement in esophageal width that often occurs post-therapy, but also by correcting for artificially higher height values due to esophageal (longitudinal) contraction occurring during a single image. We aimed to compare the correla- tion of TBE outcome measures of height and SA with symptom improvement post-therapy.

Aims & Methods: Inclusion criteria were achalasia patients who underwent ther- apy between August 2015–5 and had TBE and Eckardi score (ES) performed at baseline and post-therapy. With TBE upright single images were acquired at 1.2 and 5 minutes following ingestion of 100–200 mL of low- density barium sulfate. Barium height was measured between the gastro-esopha- geal junction and the superior extent of any residual barium column. After manually defining the column boundaries, software was used to calculate SA (AGFA IMPAX surface area tool (Figure)). Adequate symptom relief was defined as reduction in ES ≤ 3. On TBE, metrics of adequate emptying evaluated were i) post-therapy column height < 5 cm, ii) > 50% reduction in column height from pre to post-therapy and iii) > 50% reduction in column SA from pre to post-therapy. Associations between symptom improvement and TBE measures of emptying were assessed using Pearson’s correlation (R). Paired t-tests com- pared TBE measures before and after therapy.

Results: 18 patients (9 male; 6 Type I, 11 Type II, 1 Type III) were included. 11 had dilatation and 7 endoscopic myotomy. Reductions with therapy of both mean 5-minute barium column height (14.7 ± 8.7 to 7.9 ± 6.0 cm; P = 0.01) and mean 50% reduction in column height (4.2 ± 3.5 to 2.4 ± 2.6 cm; P = 0.02) were noted. Symptoms also improved with treatment; median baseline ES of 7 (IQR 5.25–8) improved to 0 (IQR 0–1) post-therapy. Only 2 patients had inadequate symptom relief and are awaiting further treatment. However there was poor concordance between post- therapy barium column height and symptomatic relief (i.e. post-therapy column > 5 cm despite ES ≤ 3 or vice versa), and the correlation (R) between these two variables was poor (Table). Similar poor concordance was seen when adequate emptying was defined by > 50% reduction in column height, but > 50% reduc- tion in SA correlated significantly with R = 0.42, p = 0.01). No standard HRM parameters or TBO findings correlated with Eckardt score.

Conclusion: In TBE performed on achalasia patients post-therapy, reduction in SA of the residual barium column compared with baseline values parallels symptomatic relief more closely than reduction of column height.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Nutrients present in the gastrointestinal tract can alter the initiation and progression of gas movement and are the subject of some debate. The current study was designed to explore the effect of gastric nutrients on gas transport and symptoms.

Aims & Methods: We aimed to determine the effect of gastric nutrients on trans- port of gastric gas, and its relationship with abdominal symptoms. In 7 healthy volunteers without gastrointestinal symptoms (4 women and 3 men, age-range 21–25 yrs), a mixture of non-absorbable gases was infused into the stomach, 5 cm caudal to the lower margin of the LES, at 25 mL/min during 60 min (Total gas infused: 1500 mL). In each subject two gas infusion tests were performed on separate days, with simultaneous infusion of nutrients (Nutriderm 1.5 Kcal/ml, total 315 Kcal) or saline. Belching, by an esophageal multilumen impedance manometry catheter, rectal gas evacuation, via a rectal tube connected to a manometer, and symptoms. Nutrients have several effects on gastric and intestinal motor function that could modulate gas transport and symptoms.

stop. Gastric nutrients reduced significantly rectal gas evacuation (56 resp. 62 mm, p = 0.02), increased the number of defecated stools (3.3 ± 1.3 vs. 3.4 ± 1.5, p = 0.018 vs saline), and increased gastric emptying clearance (score 2.7 ± 0.6, p = 0.030) that decreased during the 30 min following infusion stop (score 1.6 ± 0.7, p = 0.042 vs infusion stop). By contrast to epigastric perception, abdominal perception was only somewhat higher during gas infusion versus nutrients (score 2.6 ± 0.5) than during saline (score 2.1 ± 0.5; p = 0.100 vs nutrients).

Conclusion: Gastric nutrients modulate transit of gastric gas, by reducing gas propulsion to the distal gut, and enhancing retrograde gas evacuation via belching.

P1827 MODIFICATIONS OF THE ECKARDT SCORE PARAMETERS AFTER PERORAL ENDOSCOPIC MYOTOMY

M. Barret1, S. Lebanel1, M. Gaudric1, M. Guillaumot1, A. Oudjidi, M. Dhogue1, V. Abihot1, A. Chryssostalis1, R. Coriat1, S. Chaussade1, F. Prat1
1Gastroenterology, Cochin Hospital, Paris/France
2Radiology, Cochin Hospital, Paris/ France

Aims & Methods:
Currently, the Eckardt score is the clinical score that is the most widely used to assess the treatment of achalasia, clinical success being defined by a score below 4. However, POEM might not equally improve all four parameters of the Eckardt score.

Results:
Between March 2013 and July 2016, 62 POEM procedures were performed on 59 patients (Male/female 33/26; Median age ± SD 47 ± 17, range 15–77). Median (IQR) follow-up time was 8 (3–13) months. Achalasia was diagnosed for a median (IQR) of 24 (13–62) months, and 42% of the patients had received a previous treatment, by botulinum toxin injection (8%), pneumatic dilatation (32%), or Heller myotomy (7%). Achalasia subtype types I/II/III in 37%/47%/15% of cases. Median Eckardt score and integrated resting pressure were 7 (6–8) and 21 (18–23) mmHg, respectively. An anterior myotomy was done in 60% of cases, and a posterior myotomy in 40% of cases. Median myotomy length was 70 (50–110) cm, and hospital stay was 3 (2–4) days. Severe complications occurred in 5% of cases (1 pleural effusion requiring drainage, 2 pneumonias with more than 10 days of hospital stay). Success rates were similar between patients treated by anterior or posterior myotomy (92% vs 93%, p = 1), or between treatments of naïve or pretreated patients (88% vs 96%, p = 0.32). Six patients treatment failures were treated by redo POEM in 3 cases, pneumodilatation in 2 cases, and esophagectomy in one case. Median Eckardt score varied from 7 (6–8) to 1 (0–2) at 3 months and 2 (0–3) at 12 months (p < 0.0001). Dysphagia score varied from 3 (1–4) to 0 (0–1) and 1 (0–3) (p < 0.0001), while regurgitation score varied from 2 (1–3) to 0 (0–1) and 0 (0–1) (p < 0.0001), chest pain varied from 1 (0–2) to 0 (0–1) and 0 (0–1) (p = 0.006), and weight loss from 2 (1–3) to 0 (0–0) and 0 (0–0) (p < 0.0001). At three months, median (range) drop of the integrated dysphagia score was 1 (0–2) to 0 (0–0) and 0 (0–0) (p = 0.0001), while regurgitation data, STW 5 is well suitable also in self-medication. Additional insights can be expected from additional sub group analyses, as the evaluation of sub groups with specific predominant symptoms.

8Dept. Of Gastroenterology, Academisch Med. Centrum Amsterdam, Amsterdam/Netherlands

Aims & Methods: Experience from physicians/surgeons treating these disorders was sought through the International Manometry Working Group.

Results: 13 patients with portal hypertension from 6 international centres have been collected; mean age 61 ± 9 years. The median pre- therapy Eckardt score was 7 (IQR 6–9), 9/13 (69%) patients had a barium swallow and 12/13 (92%) had oesophageal physiology studies performed. There were 3 Type I, 6 Type II, 2 Type III achalasia and 2 with oesophageal-gastric outflow obstruction. Varices were identified endoscopically in 7 patients, radiologically in 5 and in 1 patient varices were first noted during surgical myotomy. 2 patients had grade 3 varices, 3 had grade 2 and 3 had grade 1 varices (grading not provided for the rest). Cirrhosis was due to alcohol in 7 patients, non-alcoholic steatohepatitis in 3, cryptogenic in 2 and 1 had hepatitis C cirrhosis. 75% were Child-Pugh A and 25% were Child-Pugh B. Patients had diverse treatments for their achalasia.

Achalasia is a chronic condition presenting with dysphagia, regurgitation, chest pain and/or weight loss. Management options include Heller’s myotomy, Botox, pneumatic dilatation and Per-Oral Endoscopic Myotomy (POEM). Treatments carry risks of bleeding and perforation. Concomitant portal hypertension with varices is very rare and achalasia treatment in this context has only been described in single case reports.

PI830  THE NATURAL HISTORY OF ACHALASIA: EVIDENCE OF A CONTINUUM–THE PATTERN–EVOLUTIVE STAGING THEORY
Dept. Of Surgical, Oncological And Gastroenterological Sciences, University Hospital of Padova, Padova/Italy

Contact E-mail Address: m.costantini@unipd.it

Introduction: Esophageal achalasia is classified into three clinically relevant patterns at High Resolution Manometry (HRM) and according to Chicago Classification. Currently, it is unclear whether they represent distinct entities or are part of a disease continuum.

Aims & Methods: The aims of this study were: a) to test the hypothesis that the three manometric patterns represent different stages in the evolution of esophageal achalasia and b) to investigate whether manometric patterns change after Laparoscopic Heller-Dor (LHD). We evaluated the patients who had a diagnosis of achalasia and underwent LHD as first treatment from 1992 to May 2016. Symptoms were scored using a detailed questionnaire for dysphagia, food-regurgitation, and chest pain; barium swallow, endoscopy, and esophageal manometry (conventional or High Resolution technique) were performed, before and 6 months after surgical treatment. All conventional manometric tracings, before 2010, were reviewed and re-classified according to the manometric-pattern classification, whereas after 2010 the HRM data were prospectively collected.

Results: Five-hundred and eleven consecutive achalasia patients (M:F = 239:272) were classified as having pattern I, 241 (47.2%) had pattern II, and 39 (7.6%) had pattern III. Demographic and clinical data showed that pattern III cases had a shorter duration of symptoms, a more incidence of chest pain, and a less dilated gullet (p < 0.001). Further, all patients with a sigmoid-shaped mega-esophagus (radiological grade IV) had pattern I achalasia. One patient with diagnosis of pattern III achalasia, who refused any treatment evolved to pattern II at a follow-up manometry performed for a progressive worsening dysphagia after 36 months. At a median follow-up of 30 months (IQR 12–56), the outcome of surgery was positive in 479 patients (91.7%).

Conclusion: Healthy stomach was found in 21.2% patients. Prevalence of CAG increased with patient’s age in both sexes as well as the use of PPIs (p = 0.0001). Table 1 shows the serum biomarkers values divided according to five categories: healthy stomach (H), GER, HP, CAG, and PPIs therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Table 1: Changing manometric patterns after LHD. *5 patients had a recovery of peristalsis (all patients had a pattern II before LHD).

<table>

<td>8 (48.3%)</td>
</tr>
</tbody>
</table>

Conclusion: The data of this study strongly support the hypothesis/theory that the different manometric patterns of achalasia could represent different evolutive stages of the disease - where pattern III is the earlier stage, pattern II an intermediate, stage and pattern I the end stage.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI831  ROLE OF A SERUM BIOMARKERS PANEL (GASTROPEAN) IN NON-INVASIVE DIAGNOSIS OF UPPER GI DISEASE: A PRIMARY CARE POPULATION OF NORTH-EAST ITALY

Introduction: The development of non-invasive methods to detect the presence of H. pylori, and to estimate the extent and severity of gastritis, have reduced the need for diagnostic endoscopy in asymptomatic individuals. However, it is not known whether the use of non-invasive diagnostic methods is effective in dyspeptic patients.

Aims & Methods: To use a non-invasive blood test with four stomach-specific biomarkers to assess the prevalence of different stomach conditions: gastrosophageal reflux disease (GERD), H. pylori (HP) infection, chronic atrophic gastritis (CAG), and the efficacy of proton pump inhibitor (PPI) therapy in a primary care population. A cohort of 2583 dyspeptic patients (male 36%, mean age 44.0 yrs, range 6-95) was selected in a primary care population and examined with a panel of biomarkers [Pepsinogen-I (PG-I) and -II (PG-II), amidated gastrin-17 (G-17), and HP IgG (Biohit, Finland)]. A standard questionnaire, including upper gastrointestinal symptoms and PPI use, was administered. Exclusion criteria were dysphagia, anemia, weight loss and vomiting. CAG patients underwent to endoscopy and histological examination.

Results: Healthy stomach was found in 21.2% patients. Prevalence of CAG increased with patient’s age in both sexes as well as the use of PPIs (p = 0.0001). Table 1 shows the serum biomarkers values divided according to five categories: healthy stomach (H), GER, HP, CAG, and PPIs therapy.

Conclusion: The combination of data on the levels of PG-I, PG-II, G-17 and HP IgG allow to diagnose different pathological conditions such as HP, and non HP-related gastritis, the appropriateness of PPI administration, GERD and CAG, a precancerous condition.

Disclosure of Interest: All authors have declared no conflicts of interest.

Table 1: Serum biomarkers values divided according to five categories: healthy stomach (H), GER, HP, CAG, and PPIs therapy.

Aims & Methods: The aim of the additional data analysis of a previous randomised placebo-controlled trial was to explore post-treatment effects that occurred after continuation of therapy after a 4-week randomised placebo controlled treatment with Menhacarin® with regard to disease-specific symptoms and QoL in FD patients. After the 4-week randomised placebo-controlled treatment period, patients were allowed to continue the treatment. The treatment was given in a double-blind fashion and allocation of treatment followed the initial randomisation. 114 adult FD outpatients were initially treated and received twice a day one enteric-coated Menhacarin capsule or a matched placebo capsule for 4 weeks. Fifty-four of them participated in the optional follow-up phase and received Menhacarin (34) or placebo (20) for further 8 weeks according to their original randomization. The results of these 54 patients are reported here. Outcomes were assessed utilising the validated self-rating Nepean Dyspepsia Index (NDI). Intra-individual differences between baseline and week 4/week 12 for NDI sub-scores for pain (sum of the NDI items ‘pain or ache in upper

Disclosure of Interest: All authors have declared no conflicts of interest.
abdomen, 'discomfort in upper abdomen', 'cramps in upper abdomen' and 'bloating in upper abdomen') and discomfort in 30% of the NDI items 'pressure in upper abdomen' and 'fullness after eating or slow digestion') and for QoL by NDI total score were compared and descriptively tested by means of Wilcoxon-Mann-Whitney U-tests.

Results: After the initial 4 weeks, 54/114 patients opted for an extension of the treatment. Interestingly, 34 out of 52 patients had been on active therapy while only 20 had received placebo. Until week 4, the NDI sub-score for pain had decreased by 7.5 ± 3.9 points during Menthacarin treatment as compared to 5.1 ± 4.9 points during placebo (p = 0.0371). After the follow-up, overall reduction for Menthacarin (8.7 ± 4.9 points) was also significantly better as compared to placebo (5.1 ± 4.9 points, p = 0.005). The NDI sub-score for discomfort had decreased for week 4 by 5.3 ± 2.1 points during active therapy as compared to 1.2 ± 2.1 points during placebo treatment (p = 0.0003). For the 12-week therapy, the score had declined by 3.7 ± 2.5 points and 1.3 ± 2.6 for Menthacarin and placebo, respectively (p = 0.0014). Overall QoL improvement was better for active medication for 4 and 12 weeks as compared to placebo.

Conclusion: After 4 weeks of randomised double-blind, placebo-controlled treatment with either Menthacarin or placebo, patients who received active medication are more likely to opt for a continuation of therapy as compared to patients on placebo. The gain over placebo remained significant even after 12 weeks of treatment. Menthacarin is a proprietary combination of essential oils of specified quality from Mentha × piperita L. (90 mg Peppermint oil WS® 1340) and Carum carvi (50 mg Caraway oil WS® 1520).

Introduction: The introduction of proton pump inhibitors (PPIs) into clinical practice has revolutionized the management of acid-related diseases. Studies in primary care and emergency settings suggest that PPIs are frequently inappropriately prescribed or used in clinical conditions with little benefit.

Aims & Methods: To evaluate the role of Gastropanel in relation to the appropriateness of PPI-therapy prescription. 2833 dyspeptic patients (male 36%, mean age of 44.0 yrs, range 6–95) with no alarm symptom (i.e., dysphagia, anemia, weight loss and vomiting) from a primary care population were included in the study. For each patient a blood sample was collected for serum Pepsinogen I (PG-I) and G-17 values according to the response to PPI therapy.

Results: Among 1015 patients under PPI therapy up to three months before the values of PG-I and G-17 values according to the response to PPI therapy.

Conclusion: An appropriate prescription of PPI should be preceded by the assessment of gastric functional status. In particular, patients with HP infection should be eradicated before PPI therapy, while CAG patients should not receive PPI therapy because they are no responders. Patients who do not respond to PPI therapy should be further investigated (compliance, diagnosis).

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1834 DUODENAL ACID PERFORATION INCREASES DUODENAL PERMEABILITY AND ACTIVATES DUODENOGASTRIC REFLEX, INDEPENDENTLY FROM MAST CELL ACTIVATION**

Introduction: We recently reported that functional dyspepsia patients show impaired duodenal integrity, associated with low-grade inflammation (Vanheel, Gut 2014). A potential cause underlying this phenomenon may be the increased duodenal acid exposure that has been demonstrated in some of these patients.

Aims & Methods: Our aim was to evaluate the effect of duodenal acid perfusion on duodenal permeability in healthy volunteers and to investigate whether mast cell activation is required for acid-induced impairment of mucosal integrity. As it has already been shown that duodenal acid activates duodenogastriic reflex pathways, we also assessed intragastric pressure (IGP). This study consisted of 2 parts, each including 10 healthy volunteers. 1) An infusion tube was positioned in the second part of the duodenum and a high resolution manometry probe was positioned in the stomach to measure IGP. HCl 0.1N or saline was infused in the duodenum during 30 min (5mL/min) in a randomized, double-blind manner. Duodenal biopsy specimens were obtained after infusion to measure transepithelial electrical resistance (TEER) and paracellular passage (fluorescein-labeled dextran, 4kDa) in Ussing chambers. Expression of cell-to-cell adhesion proteins (claudin 1–4, occludin, zonula occludens 1–3, β-catenin, E-cadherin, desmocollin-2, desmoglein-2) in biopsies was evaluated by PCR, western blot and/or immunofluorescence. The number of mast cells and eosinophils was counted using immunohistochemistry for tryptase and eosinophil major basic protein respectively, and by evaluating the expression of these proteins using PCR and expression of the expression of these proteins using PCR and expression of the expression of these proteins using PCR and expression of the expression of these proteins using PCR.

Results: IGP was significantly lower during acid perfusion compared with saline perfusion (p = 0.003). Acidification also resulted in decreased TEER (p = 0.005), increased passage (p = 0.007) and lower protein expression of claudin 3 (p = 0.0006). No difference in mast cell (p = 0.34) and eosinophils (p = 0.34) counts were detected, but an increased protein expression of tryptase (p = 0.0008) was found after acid perfusion. In the placebo and the DSCG group, acidification induced a similar drop in IGP (p = 0.68). There was also no difference in TEER (p = 0.70) and passage (p = 0.21) after acid perfusion between both pretreatments.

Conclusion: Duodenal acid perfusion in healthy volunteers disrupts epithelial integrity and activates an inhibitory duodenogastric reflex. Although this effect seems to be independent from mast cell activation, increased duodenal acid exposure in functional dyspepsia is a potential pathophysiological mechanism contributing to abnormalities in duodenal and gastric structure and function observed in patients with functional dyspepsia.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastric acid secretion is believed to decrease in the aging stomach, but the number of elderly patients on proton pump inhibitor (PPI) therapy is significantly increased. Aims & Methods: Our aim was to evaluate the effect of acid secretion and atrophic gastritis on duodenal biopsies from elderly patients and to investigate whether the number of elderly patients on proton pump inhibitor (PPI) therapy is significantly increased.

increasing. Pepsinogen I (PGI) <30 ng/mL; PGI/PGII <3 and gastrin-17 (G17) >10 pmol/L are non-invasive serological markers to surmount to explore gastric function, with a negative predictive value for chronic atrophic gastritis (CAG) of 96%.

Aims & Methods: Aim of the study was to evaluate gastric function by means of serology (PGI, PGII, G17 and IgG-antibodies against Helicobacter pylori) in very elderly patients, including centenarians. A total of 379 patients were prospectively enrolled (M = 126, F = 253, mean age = 83.6 ± 8.7, range: 70–106). They were divided into four groups: 132 subjects with an age between 70 and 79 years old (first group), 111 subjects between 80 and 89 (second group), 76 subjects between 90 and 99 (third group) and 25 subjects between 100 and 106 (fourth group). Demographics and drug intake, particularly the PPI intake, were collected. For all patients, serological markers were determined in fasting blood samples using Medtronic (Minneapolis, MN, USA) and Unisensor (Attikon, Switzerland) catheter. Normal values for both systems were: PGI: 30–120 μg/L; PGII: 2–15 μg/L; PGI/PGII ratio: >3; G17: >1–9 pmol/L; H.p.-IgG: <30 EU).

Results: In the first group (age 70–79), 18.2% of the subjects showed H. pylori infection (PGI >80 μg/L, IgG against H.p. >30 EU), 22.7% had CAG (PGI <30 μg/L and PGII <3) and 53.8% were under PPI therapy. 16.9% of the patients on PPI therapy had CAG. In the second group (age 80–89), 32.9% of the subjects showed H. pylori infection, 8.9% had CAG and 48.6% were under PPI therapy. 8.5% of the patients on PPI therapy had CAG. In the third group (age 90–99), 22.4% of the subjects showed H. pylori infection, 10.5% had CAG and 48.7% were under PPI therapy. 8.1% of the patients on PPI therapy had CAG. In the fourth group (age 100–106), 44.0% of the subjects showed H. pylori infection, 16.0% had CAG and 72.0% were under PPI therapy. 16.7% of the patients on PPI therapy had CAG.

Conclusion: Acid secretion is preserved in most of the elderly and very elderly subjects, even in centenarians. Serological markers may be helpful to identify patients affected by CAG in which the administration of PPI is inappropriate, especially in the elderly.

P1836 THE PSYCHOLOGICAL CHARACTERISTICS OF REFLUX HYPERSONSITIVITY-A PILOT STUDY BASED ON SCL-90 QUESTIONNAIRE AND 24 HOUR PH-IMPEDEANCE MONITORING

K. Wang, Z. Xu, Z. Xia, Y. Ge, L. Duan
Department Of Gastroenterology. Peking University Third Hospital, Beijing/China

Contact E-mail Address: duanlp@bjmu.edu.cn

Introduction: Reflux hypersensitivity (RHV) was lately defined as a functional esophageal disorder by the Rome IV workshop. The clinical and psychological characteristics are still unknown.

Aims & Methods: The aim of this study was to assess the reflux and psychological characteristics of RHV. Patients who underwent 24 h pH-impedance monitoring were screened from Jan 1st 2011 to Nov 31st 2015. The patients with heartburn or chest pain ≥2 days/week for more than 6 months were enrolled. Healthy volunteers (HV) were enrolled too. All subjects fulfilled the SCL-90 questionnaire, underwent gastroscopy to exclude upper gastrointestinal diseases and underwent HRM test to exclude main motility disorders. The patients for normal esophageal mucosal but overload acid, weakly acid or non-acid reflux were diagnosed as non-erosive reflux disease (NERD). The patients with normal esophageal mucosal but overload acid, weakly acid or non-acid reflux were diagnosed as functional heartburn (FH). The reflux and psychological characteristics are compared among NERD, RHV and FH.

Results: Total 231 patients were enrolled. 107 were NERD (48.25 ± 1.18 yrs, M:F = 55:52), 92 were FH (48.30 ± 1.27yrs, M:F = 98:83), 32 were RHV (48.41 ± 2.36yrs, M:F = 48:28). 28 HVs (47.21 ± 2.27, M:F = 8:20) were enrolled as normal control. NED’s depressive, anxiety, Reactive facets, impulsivity and senseless thought were all higher than FH, NERD and HVs (p < 0.05). The acid reflux and weak acid reflux are both higher in NERD than that in FH, RH and HV (p < 0.01). The total scores of SCL-90 of the first group of patients were significantly higher than NERD/HV (n=120), 133.15 ± 3.68 vs. 108.61 ± 4.51, p = 0.004. SF(HV, 133.15 ± 3.68 vs. 108.61 ± 4.51, p = 0.003; RHV/HV, 142.67 ± 8.91 vs. 108.61 ± 4.51, p = 0.002).

Conclusion: All authors have declared no conflicts of interest.

P1837 HIGH-RESOLUTION ESOPHAGEAL MANOMETRY: EVALUATION OF NEW SYSTEMS FOR THE ACQUISITION AND ANALYSIS

Introduction: High-Resolution Manometry (HRM) has recently became the gold standard for the evaluation of esophageal motility. A new classification of esophageal motility disorders (Chicago Classification, v. 3.0) has been developed, based on the findings from a given hardware and software. Different systems for HRM and new features of the existing ones have recently been developed.

Aims & Methods: In this study we aimed to evaluate a new solid-state HRM system and a new 3-D catheter and system for the study of lower esophageal sphincter (LES). Fifteen healthy volunteers (7 m, 8 f, median age 27) underwent two consecutive Esophageal HRM studies by using two different solid state systems (ManoScan, Medtronic, Minneapolis, USA and Medica SpA, Italy with Unisensor AG, Atikon, Switzerland catheter). The studies were performed in a random order using the standard protocol. Furthermore, a new 3-D catheter for the study of sphincters was evaluated in 12/15 volunteers.

Results: Table 1 reports the findings obtained with the Medica system compared to the consolidated Medtronsic system. The data of the 3-D evaluation are also reported. The data are expressed as medians (and 5th-95th percentiles).

Conclusion: Significant differences were recorded in most of the considered parameters obtained by the two HRM systems. This is particularly relevant in the evaluation of the LES relaxation, the cardinal point in the hierarchical approach of the Chicago Classification, probably due to different analysis used by the two systems (the lowest residual pressure vs IRP). Furthermore, the differences found in the measurement of the LES resting pressure and abdominal length may rely either on the different technology (3-D vs linear transducers) or on the different algorithms and thresholds used. The latter may probably also apply to the differences found with the two systems in the duration of the esophageal contractions and in the new contractile parameters (i.e.: DCl and DL) introduced by the Chicago Classification. This study emphasizes the need for a careful validation of any new system for motility disorders manometry. The acquisition of new sets of normal values, to be used to compare the data measured in patients, is therefore mandatory. The conclusions of our study may represent the reference normal values for other esophageal laboratories that are using the HRM systems and devices we tested here.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** Proton Pump Inhibition-response esophageal eosinophilia (PPI-REE) is a condition characterised by symptoms of esophageal dysfunction in the setting of eosinophilic inflammation on esophageal biopsies responding to a course of 5 weeks of PPI therapy. Recent data collected by using esophageal high resolution manometry (HRM) documented that patients with PPI-REE present frequently motility abnormalities, mostly weak peristalsis and hypotensive esopahgogastric junction (EUGJ). Data on the effect of PPIs in improving these motor abnormalities are lacking.

**Aims & Methods:** We aimed to prospectively compare HRM features of patients with PPI-REE before and after a course of PPI therapy. Consecutive patients with symptoms suggestive of EoE underwent upper endoscopy to assess the presence of at least 15 eos/hpf on esophageal biopsies at mid/proximal esophagus and, thereafter, patients with symptoms suggestive of EoE were treated with twice-daily PPIs for at least 8 weeks. Thereafter, patients repeated upper endoscopy and PPI-REE was identified in case of less than 15 eos/hpf and a 50% decrease from baseline. Patients with PPI-REE underwent HRM at the time of diagnosis (off-PPI) and after the course of PPIs (on-PPI). Patients with achalasia and absent peristalsis were excluded (Chicago Classification v.3).

**Results:** Twenty-eight patients [23M:5F; mean age 33] reporting dysphagia (93%), bolus impaction (68%) and chest pain (25%) were diagnosed with PPI-REE. After the diagnosis and secretory therapy, most of the patients reported complete resolution of esophageal symptoms directly linked to esophageal infiltration (p < 0.001), namely dysphagia, bolus impaction and chest pain. Compared to HRM features at baseline, HRM after PPI therapy showed that patients with PPI-REE had higher median EUGJ resting pressure [baseline 11 (3–34) vs. post-PPI 17 (3–13); p < 0.05], greater mean distal contraction integral [1094 (483–5281) vs. 2634 (495–6450); p < 0.01], and less frequent panesophageal pressurization [6 (21%) vs. 0 (0%); p < 0.02]. No differences were observed in terms of distal latency and rate of different EUGJ subtypes (p > 0.05). As to the manometric diagnoses, after PPI therapy patients with PPI-REE showed a reduced rate of ineffective motility or fragmented peristalsis [16 (57%) vs. 7 (25%); p = 0.02] and increased frequency of normal peristalsis [9 (32%) vs. 18 (64%); p = 0.03]. No differences were observed in terms of frequency of distal esophageal spasm and outflow obstruction diagnoses (p > 0.5).

**Conclusion:** In most PPI-REE patients, PPI therapy restores the impairment of esophageal function assessed by ineffective and fragmented peristalsis, thus favouring the return to a normal motility pattern. This finding, paralleled with symptoms improvement in the same subjects, seems to emphasize the important role of inflammation linked to the eosinophilic infiltration of the esophageal wall in inducing motor dysfunction and related symptoms.

**Introduction:** Eosinophilic Esophagitis (EoE) is a chronic immune disease of the esophagus, which is characterized by a predominant eosinophilic inflammation. EoE is mainly found in children and adolescents. Recent data from different centers have established that eosinophilic esophagitis (EoE) is an increasing diagnosis in adults. It is characterized by esophageal symptoms and histologically characterized by a predominant eosinophilic inflammation. EoE has been found in patients with atopic conditions. However, recently an association with IgG4 but not with IgE has been reported. Gastroesophageal reflux disease (GERD) is the most important diagnostic differential diagnosis of EoE. In this study we measured systemic serum IgG4 and IgE levels of EoE patients before and after a topic steroid therapy, correlated them to esophageal IgG4-positive plasma cells and compared them to GERD patients.

---

**Results:** In total, 119 patients were diagnosed with EoE and included in this study. The median age at onset of symptoms was 29 years (IQR 9, 15-42) and the median age at diagnosis was 38 years (IQR 23, 51 years), leading to a median diagnostic delay of 6.5 years (IQR 2-14 years). The median delay in diagnosis between first contact in the hospital and diagnosis was 1 year 3 months (IQR 2-14 years). The incidence of patients newly diagnosed with EoE increased steadily over a period of 11 years. Criteria for the microscopic diagnosis of EoE varied between pathologists in each hospital. Initial treatment included topical corticosteroids (30.3%), proton pump inhibitors (PPIS) (29.4%) or a combination of both (10.1%). A follow-up treatment included PPIs (76.0%), topical corticosteroids (59.6%) or a combination of both (45.4%).

**Conclusion:** Diagnostic and therapeutic discrepancies between daily clinical practice and recommendations for diagnosis and management of esophageal eosinophilia and eosinophilic esophagitis. Moreover, therapeutic strategies were utilized in the participating centers. Our results show that apart from developing guidelines, efforts should be undertaken to implement them in daily clinical practice.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Aims & Methods: Serum levels of IgG4 and IgE of 19 EoE patients were measured before and after 8 weeks of therapy with budesonide (1 mg twice a day). Biopsies were taken from the esophagus before and after therapy for histological and immunohistochemical evaluation. 14 patients with GERD without histological proof of eosinophilic granulocyte infiltration were taken as a control group. Serum levels of IgG4 of 19 EoE patients were measured before and after eight weeks of therapy with budesonide (1 mg twice a day). Biopsies were taken from the esophagus before and after therapy for histological and immunohistochemical evaluation. 14 patients with GERD without histological proof of eosinophilic granulocyte infiltration were taken as a control group.

Results: Serum IgG4 levels of EoE patients were significantly higher than in GERD patients (mean: 121.0 mg/dL vs. 71.2 mg/dL, p = 0.034). In contrast, no significant difference of IgE levels in EoE and GERD patients was observed. In EoE patients, the percentage of eosinophils in histology was decreased at a significant level after topical steroid therapy (mean: 51.9 eosinophils/high power field [hpf] vs. 6.4 eosinophils/hpf p < 0.001). After lower therapy levels of IgG4-serum-levels could be measured (mean: 121.0 mg/dL vs. 104.2 mg/dL p = 0.034). In the control group we did not show a significant difference. The eosinophilic biopsies of EoE patients showed a high number of IgG4-positive plasma cells (mean expression of 27.4 IgG4-positive plasma cells of 46.3 stromal plasma cells hpf).

Conclusion: EoE patients show higher systemic IgG4- but not IgE-serum levels compared to GERD-patients. These elevated levels normalize under effective topical steroid therapy. Additionally high local expression of IgG4-positive plasma cells can be seen in EoE patients. These findings might be further evidence for a possible IgG4-association of EoE.

P1841 SYSTEMATIC REVIEW: HEALTH-RELATED QUALITY OF LIFE IN CHILDREN AND ADULTS WITH EOSINOPHILIC ESOPHAGITIS: MEASURE INSTRUMENTS AND DETERMINANT FACTORS

A. J. Lucendo Villarín, L. Arias-González, J. Molina-Infante, A. Arias
Dept. De Gastroenterología, Hospital General de Tomelloso Dept. of Digestive Health Dept. of Gastroenterology, Tomelloso/Spain

Contact E-mail Address: ahucendo@vdafone.es

Introduction: Measurement of Health-related quality of life (HRQoL) with generic or specific instruments has been increasingly used in patients suffering from EoE to support both research and clinical care. Generic instruments aim at measuring the overall HRQoL of patients across several conditions, being useful when comparing across different conditions and economic health outcomes. Disease-specific instruments assess domains specific to a given disease and are considered more sensitive to changes in the patient’s health state. An up-to-date systematic review will provide a useful resource for researchers and EoE specialists to ensure they can select an appropriate HRQoL measure for patients in their practice in order to identify correctable factors determining an impaired perception and to improve treatment outcomes.

Aims & Methods: We aim to systematically review the current HRQoL measures for patients with EoE and to appraise their measurement properties using a robust evaluation methodology checklist. We also sought to identify disease-specific determinant factors for HRQoL in children and adults with EoE, and the effect of investigations and interventions on HRQoL. A search strategy was designed to identify and retrieve all documents dealing with the effect of investigations and interventions for EoE on HRQoL. A search was designed to identify and retrieve all documents dealing with the effect of investigations and interventions for EoE on HRQoL.

Results: Of the 596 references identified, data was collected from 34 studies including a total of 1,842 individual patients. Three disease-specific HRQoL measures in EoE covered different aspects of patients’ lives and developed in EoE-specific patient samples. Details of the measurement properties, respectively, are shown in the Table. The PedsQL inventory (including parent and child report forms) and the Peds-QoL module were the generic and specific instruments respectively used in children, while the SF-36 and EoE-QoL-A were the most used questionnaires in adults. The effect of EoE on HRQoL of affected children and adolescents, which manifest in the normal development of their daily activities, their physical health and their mental status, with parents generally underestimating the impact of the disease regarding children declared HRQoL. Regarding determinant factors, age was not associated with HRQoL. Number and severity of symptoms negatively correlated with child-reported and Parent proxy-reported PedsQoL score and family impact score. Disease duration was identified as a risk factor for a low SF-36 score. EoE impacts on a number of domains including frustration, anxiety and the effect of treatment on symptoms and esophageal inflammation, the effect of treatment on the symptoms, the effect of treatment on esophageal inflammation, compatibility of therapy with lifestyle, possible side effect, and recommendation therapy. Additionally high local expression of IgG4-positive plasma cells can be seen in EoE patients. These findings might be further evidence for a possible IgG4-association of EoE.

Conclusion: Adult EoE patients consider both effect of medication on symptoms as well as inflammation as most important criteria, when choosing EoE therapy. EoE patients appear to be ‘satisfied’ with PPI, STC, and dietary therapy and ‘very satisfied’ with STC, if diet therapy is taken twice daily.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1842 TREATMENT SATISFACTION OF ADULT EOSINOPHILIC ESOPHAGITIS PATIENTS

Introduction: Available treatment options for adult EoE patients include drugs (proton-pump inhibitors [PPI], swallowed topical corticosteroids [STC]), food elimination diets, and esophageal dilation. Knowledge about patients’ view regarding the different therapeutic options is very limited.

Aims & Methods: We aimed to systematically assess adult EoE patients’ satisfaction with different EoE-specific treatment modalities. We first created a questionnaire that included items that queried general demographic characteristics (7 items), EoE-specific patient history and presence of atopic disease (8 items), past and present EoE-specific therapy (9 items), concomitant medication use (7 items), important considerations for choice of therapy (2 items), as well as treatment satisfaction with various therapies recalled over a period of 12 months (assessed using the validated “Treatment Satisfaction Questionnaire for Medication” [TSQM], 52 items). The TSQM consists of 14 items falling into 4 scales: effectiveness (3 items), side effects (5 items), convenience (3 items), and overall satisfaction (5 items). The score for each TSQM scale ranges from 0 (dissatisfied) to 100 (satisfied). In analogy with other conditions, a score above 66.6 and 83.3 identifies patients that are ‘satisfied’ and ‘very satisfied’ with therapy, respectively.

Results: Patient response rate was 73.5% (108/147). Mean patient age at inclusion was 48.8 years, 73.8% of patients were male, and mean disease duration (from the time of diagnosis to the time of enrollment) was 6.8±5.1 years. In the last 12 months, 11.1%, 48.1%, 10.2%, and 28.7% of patients reported to have suffered from symptoms of asthma, rhinoconstrictivity, eczema, and food allergy, respectively. In the last 12 months, 25.0%, 2.7%, 77.8%, 1.9%, 19.4%, and 13.0% were treated with PPI, STC in the form of a spray, STC in the form of a powder, STC in the form of a spray, diet, and esophageal dilation, respectively (37.0% patients received more than one treatment). ‘Satisfied’ and ‘very satisfied’ patients receive any treatment. We identified the following considerations as important for the choice of therapy: the effect of the treatment on the symptoms (88.9%), the effect of treatment on esophageal inflammation (75.9%), possible side effects (69.4%), ease of therapy use (90.5%), and recommendation of therapy (89.0%) (patients could choose more than one). Patient treatment satisfaction, respectively, with lifestyle, possible side effect, and recommendation therapy (46.3%). When asked about single most important criterion for the choice of therapy, 48.5%, 33.7%, 11.9%, 3.0% and 2.0% of patients chose the effect of treatment on symptoms and esophageal inflammation, the effect of treatment on the symptoms, the effect of treatment on esophageal inflammation, compatibility of therapy with lifestyle, possible side effect, and recommendation of the physician, respectively. The TSQM scales scores as well as average TSQM values for patients on PPI, STC, and diet are shown in Table 1.

Conclusion: Adult EoE patients consider both effect of medication on symptoms as well as inflammation as most important criteria, when choosing EoE therapy. EoE patients appear to be ‘satisfied’ with PPI, STC, and dietary therapy and ‘very satisfied’ with STC, if diet therapy is taken twice daily.

Introduction: Measurement of Health-related quality of life (HRQoL) with generic or specific instruments has been increasingly used in patients suffering from EoE to support both research and clinical care. Generic instruments aim at measuring the overall HRQoL of patients across several conditions, being useful when comparing across different conditions and economic health outcomes. Disease-specific instruments assess domains specific to a given disease and are considered more sensitive to changes in the patient’s health state. An up-to-date systematic review will provide a useful resource for researchers and EoE specialists to ensure they can select an appropriate HRQoL measure for patients in their practice in order to identify correctable factors determining an impaired perception and to improve treatment outcomes.

Emotional impact was the only dimension with a significantly worse score in patients under dietary restrictions.

Conclusion: HRQoL is a relevant outcome that should be considered in clinical practice and research of EoE. Further validation studies in several languages and populations are required to support the use of disease-specific HRQoL measures.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: In this study, we aimed to systematically assess the nature of subepithelial histologic alterations, analyze their relationship with epithelial histologic findings, adverse features, and symptoms, and evaluate the diagnostic impact of subepithelial eosinophil counts in patients with an epithelial peak eosinophil count of <15/hpf. We prospectively included in this cohort study adult EoE patients who underwent assessment of clinical, endoscopic, and histologic disease activity using scores.

Results: We included 200 EoE patients (mean age 43.5±15.7 years, 74% males) with a median peak count of 36 intraepithelial eosinophils/hpf [IQR 14-84]. The following histologic features were identified in the subepithelial layer: eosinophilic infiltration (median peak count of 20 eosinophils/hpf [IQR 10–51]), eosinophil degranulation (43%), fibrin (82%), and lymphoid follicles (56%). Peak intraepithelial eosinophil counts were higher, identical, and lower when compared to the subepithelial layer in 62%, 5%, and 33% of patients, respectively.

Subepithelial histologic activity correlated with epithelial histologic activity (rho 0.331, p < 0.001), endoscopic severity (rho 0.208, p = 0.003), and symptom severity (rho 0.179, p = 0.011). Forty percent (21/52) of patients with <15 intraepithelial eosinophils/hpf had subepithelial peak counts of <15/hpf.

Conclusion: In one-third of patients subepithelial peak eosinophil counts are higher than epithelial eosinophil counts. Systematic assessment of subepithelial eosinophil counts can aid in diagnosing EoE in additional 40% of all patients with epithelial eosinophils <15/hpf.

PI846 BELCHING PATTERNS IN PATIENTS WITH ISOLATED PATHOLOGICAL UPRIGHT REFLUX AND PATHOLOGICAL BIPOSITTIONAL REFLUX
Contact E-mail Address: j.conchillo@mumc.nl
Introduction: Belching is a commonly occurring symptom in patients with gastro- esophageal reflux disease (GERD). Belching may also reflect reflux. It is unknown whether GERD patients with isolated pathological upright reflux (UP) have belching patterns that are different from GERD patients with pathological bipo- sittonal reflux (BIP).
Aims & Methods: Aim of this study was therefore to evaluate the belching pat- terns of UP reflux patients as compared with BIP reflux patients. We included 50 consecutive patients with pathological reflux and typical symptoms who under- went 24-h-pH-impedance monitoring at the Maastricht University Medical Centre from 2015 to 2017. Patients referred for excessive belching were excluded. A group of 25 UP reflux patients (10 male, mean age 52.9 years (range 22-77)) and 25 BIP reflux patients (11 male, mean age 47.9 years (range 18-77)) were evaluated. All pH-impedance tracings were analysed manually. We classified belches according to: a) physiological mechanism: supragastric vs. gastric; and b) their temporal relationship with a liquid reflux episode: isolated belch, preceding or during a liquid reflux episode. Symptom-assessment analysis was performed to assess a relationship between reported symptoms and reflux episodes.
Results: BIP patients showed higher acid reflux time (17.8±2.4% vs. 7.3±0.6%, p<0.001) and higher number of total reflux episodes (121±9 vs. 97±8, p=0.05) than UP patients. Notably, both the proportion of reflux episodes with belches of any type and the proportion of belches preceding liquid reflux were higher in UP patients than in BIP patients (51.7±3.6% vs. 32.1±3.7%, p<0.001 and 27.3±3.1% vs. 17.8±2.9%, p=0.03, respectively). No difference was found in the proportion of both supragastric and gastric belches between groups. During 24-h pH-impedance monitoring UP patients reported more symptoms (21±6 vs. 12±3, p=0.16) and had more positive symptoms with belches (60.2±7.1% vs. 39.0±6.6%, p=0.03) than BIP patients. Of the total number of belches that were detected using 24-h pH-impedance, more belches were experienced in UP patients than in BIP patients (24.8±6.4% vs. 11.1±2.5%, p=0.06).
Conclusion: In our study, GERD patients with isolated pathological upright reflux had more often (symptomatic) belches than GERD patients with pathological biposittional reflux. Therefore, examination of belching patterns can assist diagnostic and therapeutic strategic planning in GERD patients who are refrac- tor to medical therapy.

PI847 IS REFLUX DURING NAPS WORSE THAN DURING NIGHT-TIME SLEEP?
C. Teruel Sánchez-Vegazo, M. J. De Higéz Ruiz, A. Albillos gastroenterología, Hospital Ramón y Cajal, Madrid, Madrid/Spain
Contact E-mail Address: cteruelvegazo@yahoo.es
Introduction: Gastroesophageal reflux in the recumbent period is related to a higher risk of developing oesophageal lesions (severe esophagitis or Barrett oes-ophageus). The only study to date that analysed reflux during daytime naps sug-gests that it is worse than that which occurs during the night-time sleep. Our objective was to determine if reflux during naps is more severe than during night-time sleep.
Aims & Methods: Between February 2015 and November 2016 patients that underwent ambulatory 24-hour oesophageal pH monitoring at our motility unit were screened. Those who slept an afternoon nap in the recumbent position in the 45 to 60 min of night-time sleep, with pathological acid exposure (deMeester score >14.72) were included. We excluded those patients with pre- vious foregut surgery or sleep apnea, those taking sleeping medication and those who were in recumbent position more than twice during the study. All studies were reviewed by the same investigator. Number of refluxes, number of refluxes per hour, reflux duration and oesophageal acid exposure (AET) time were compared between the two recumbent periods. Correlation between AET and meal-to-bed time was analysed, both for naps and night-time sleep.
Results: A total of 32 patients were selected (59.4% women, mean age 51.31±14.59, median BMI 26.48 (range 21.63-38.71)). Indication was typical GERD symptoms in 68.8% and atypical symptoms in 32.3%. Oesophageal manometry revealed normal oesophageal body motility in 65.6%, inefficient peristalsis in 28.1%, and a median lower oesophageal sphincter pressure of 8 mmHg (range 1–24). Median nap duration was shorter than that of the night-time sleep: 108 mins (range 30-375) vs 454 mins (range 240-593) (p=0.00). Median meal-to-bed time was also shorter for naps: 30.5 mins (range 4-185) vs 110.5 mins (range 9-247) (p=0.00). Median number of refluxes per hour and median recumbent AET were similar in both periods: 1.71 (range 0–26.5) vs 1.85 (range 0–12.8) (p=0.45) and 1.55 (range 0-61) vs 5.9 (range 0-36.1) (p=0.57), respectively. 87% of total reflux event took place during the

PI848 TREATMENT WITH PROTON PUMP INHIBITORS (PPI) DOES NOT REDUCE ACIDIC LARYNGOPHARYNGEAL REFLUX (LPR) DESPITE REDUCING DISTAL ACIDIC GASTROESOPHAGEAL REFLUX AND IMPROVING SYMPTOMS IN PATIENTS WITH LPR

Introduction: PPI improve LPR symptoms in many patients. It is implicitly assumed that this effect is due to reduction of acidic LPR by PPI. Here we tested this assumption. We evaluated LPR and distal gastroesophageal reflux by using simultaneous pH/impedance monitoring in laryngopharyngeal segment and in distal esophagus before and after PPI treatment.
Aims & Methods: Patients referred for suspected LPR were screened and those with positive reflux finding score (RFS > 7, determined by ENT physician) and/or positive reflux symptom index (RSI ≥13) and at least one acidic LPR episode during 24h-pH-impedance study were enrolled. The RSI, RFS and dual pH/impedance study of LPR and distal reflux were performed before and after 3 months therapy with PPI twice a day. Appropriate distance between pH sensors was chosen based on manometrically determined LES and UES so that the proximal pH sensor was positioned 1 cm above UES and distal sensor was posi- tioned 4-6 cm above LES. By definition each LPR event was preceded by reflux detection in the distal esophagus.
Results: 18 patients (11M/7F, 31 ±10yrs) completed the study. In this group the PPI treatment substantially reduced the symptoms of LPR. Reflux finding score (RFS) was decreased by 40% from 9±1 to 5±1 (P<0.01). The number of distal acidic reflux episodes was reduced from 17±2 to 3±1 (P<0.01). Surprisingly, acidic LPR was not decreased by PPI treatment. The number of LPR with pH < 5.0 was 2±0.5 vs 3±1, P=NS, and the number of LPR episodes with pH < 4.0 was 0.7±0.1 vs 0.6±0.2, P=NS. Surprisingly, the number of acidic LPR episodes with pH = 5.0–6.0 was even increased (14±2 vs 21±3, P<0.05) leading to an increase in the overall number of LPR episodes by approximately 50% from 16±2 to 24±3 (p<0.05). PPI treatment did not decrease laryngopharyngeal time the pH was less than 4.0 (p=NS) and did not alter the composition of laryngopharyngeal reflux (P=NS).
Conclusion: Proton pump inhibitor treatment does not reduce acidic laryngo- pharyngeal reflux despite substantially improving symptoms in patients with objectively established LPR. This suggests that PPI treatment influences some aspects of pathogenesis of LPR symptoms that are not readily detected by laryngopharyngeal pH/impedance monitoring.

Introduction: Menthol is widely used as a food flavourant. In general, it is considered as a trigger of gastroesophageal reflux symptoms. It has been assumed that menthol reduces the tone of the lower esophageal sphincter (LES) as a consequence of direct effect on the smooth muscle of the LES. Evidence has provided that menthol sprayed on the gastric mucosa significantly suppresses gastric acid secretion and motility. However, there is no evidence of the impact of menthol on the esophageal peristalsis and LES tone.

Aims & Methods: The aim of the study was to evaluate the effect of the menthol infusion into the esophagus on the esophageal peristalsis and lower esophageal sphincter pressure in healthy volunteers. High-resolution manometry and the parameters of esophageal pressure topography were used to quantitatively evaluate the certain components of esophageal motility. 13 healthy volunteers without out esophageal symptoms were enrolled. High-resolution manometry with a thin silicon tube attached were placed transnasally so that the distal end of the tube was 5 cm above the LES. After a 5 min. adaptation period the measurement was performed in the supine position according to the protocol as follows: in 10 volunteers recording 10 water swallows of 5 ml and 3 x 3 water swallows of 10 and 15 ml after that a 20 min. infusion challenge with 3 mM menthol 8 ml/min. was carried out and subsequently the water swallows in order described above were repeated. HRM tracings were manually analyzed using Medical software and Parameters used in this study in the Chicago classification (v3.0) were evaluated. Integrated relaxation pressure (IRP), nadir LES pressure and distal contractile integral (DCI) values from 5 ml, 10 ml and 15 ml swallows before and after menthol infusion were used for statistical analysis. Statistical analysis:

Results: None of the subjects had any motility disorder defined by the Chicago Classification v3.0. Few volunteers reported only mild cold sensation during the infusion challenge. None of the subjects had any motility disorder defined by the Chicago Classification v3.0. 

Paired parametric tests were used for statistical analysis. distal contractile integral (DCI) values from 5 ml, 10 ml and 15 ml swallows before and after menthol infusion was not significant (p > 0.05). However, difference of IRP in 10 ml and 15 ml swallows was not significant (p > 0.1, p > 0.5, respectively). Average DCI pressure (5 ml swallows) was 737.8 ± 116.2 mmHg before and after menthol infusion, respectively (p > 0.5). We found no difference in DCI in 10 ml and 15 ml swallows before and after menthol infusion. Menthol seemed to have had only a marginal insignificant effect on IRP and DCI in rapid swallow test.

Conclusion: We quantified the effect of menthol on the esophageal function and LES pressure in healthy volunteers using high resolution manometry. The analysis of HRM tracings revealed that menthol has no effect on particular parameters of the esophageal motility and esophageal peristalsis.

Introduction: Due to a negative feed-back mechanism, gastrin-17 (G17) can be considered a mirror of acid secretion: the lower G17 values, the higher gastric acid secretion. Some studies suggest serum G17 low levels as a marker of acid-related conditions, like Gastroesophageal Reflux Disease (GERD). Aim of the study was to evaluate the property of low levels of G17 in GERD diagnosis, compared in clinical and concomitant clinical GERD gold-standards (typical symptoms, esophagitis at endoscopy, a positive DeMeester score at pH-metry).

Aims & Methods: We evaluated 777 consecutive patients (518 males and 259 females), aged 36-99 years, referred for gastroesophageal reflux disease suspicion. We collected all clinical data and non-invasive tests. All patients underwent upper GI endoscopy and esophagitis was classified according with Los Angeles score. One hundred and seventy-out 221 patients which underwent 24h pH-metry showed a positive DeMeester score for acid gastroesophageal reflux. Summarizing, 700 out of the 777 subjects included in the study showed at least one of the criteria (clinical, endoscopic or functional) accepted to support the diagnosis of symptomatic gastroesophageal reflux disease (GERD).

Conclusion: By using low levels of G17 as a non-invasive marker of GERD, in more than 90% (700 out of 777 pts) the diagnosis of reflux disease was confirmed, according with the current clinical or instrumental gold standard criteria, supporting the use of this simple method to identify subjects with suspected GERD almost when typical symptoms are lacking or a NERD picture is find.

Conclusion: Our data indicate that HRM can be useful in detecting GERD, with our predictive model allowing a high level of suspicion for reflux disease. In particular the role of the EGJ-CI in GERD pathophysiology has been
P1854 GORD Patients are frequently Dissatisfied on Long-term PPI Therapy (Aiming at the reasons) and Management in Routine Clinical Care (Lopa II Study)

J. Labenz1, G. Labenz2, M. Müller3, D. Stephani4, E. Wilke4

Aims & Methods: The LOPA II study is a prospective, multicenter, observational study conducted in 17 general practice clinics. Patients with chronic GORD, taking PPI therapy for at least 1 year, and not satisfied with their treatment were asked to complete a questionnaire. Patients were asked about the reasons for their PPI therapy satisfaction, as well as the frequency of symptoms at least twice per week despite PPI. A total of 20% were dissatisfied with their treatment. Few patients had received specific GORD diagnostics or recommended other options (<10%).

Results: 510 consecutive patient responses were collected within one year. Patients suffered from GORD an average of 9.6 years and prescribed PPI therapy for an average duration of 7.9 years. 70% were dissatisfied or very dissatisfied with their PPI therapy (GerdQ score of 1 or 2). 83% reported heartburn or regurgitation at least 2 days in the prior week (53% 4–7 days). 49% reported using additional medication other than their prescribed PPI at least 2 days per week (34% 4–7 days). In patients dissatisfied on PPI, most cited insufficient symptom control (87%) for dissatisfaction. In addition, 31% cited concerns with long-term use of drugs and 27% the need for daily medication. 92% of patients satisfied with their current condition, frequency of symptoms in the last week, whether they had previously received diagnostic evaluation or surgical consultant related to GORD, whether they plan to consult a reflux specialist for further diagnostics, and reason for dissatisfaction with their current medication treatment. “Lost Patients” were defined as those with a satisfaction score of 1 or 2 on a 5-point Likert scale (1: very dissatisfied; 2: dissatisfied; 3: somewhat dissatisfied; 4: somewhat satisfied; 5: very satisfied). GerdQ score at least 8, and have not previously received specialized GORD diagnostics.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1855 Prevalence and Pathophysiology of Gastroesophageal Reflux Disease in Patients with Autoimmune Gastroitis

G. Maddalo1, V. Pilotto2, E. Savarino2, C. Orlando3, M. Fassan2, D. Basso3, M. Rugge3, F. Farinati2

Aims & Methods: The study was aimed to define the prevalence of reflux symptoms in AIG patients, to evaluate the serological, histological and clinical differences in AIG patients with or without reflux symptoms and to investigate the pathophysiology behind these symptoms. One hundred and fifty AIG patients were enrolled and 87 were included in the study: 29 AIG patients with reflux symptoms (AIG-R) and 58 without (controls), selected with similar age and sex distribution. AIG-R underwent pH-impedance (pH/I) and high resolution manometry (HRM). Serum biomarkers, EGDS, histology and anamnestic data were evaluated in both groups. Statistics was performed as indicated.

Results: AIG-R were 19% overall and 28% of them showed endoscopic esophageal lesions, with more frequent hiatal hernia than in controls (p < 0.02). pH/I diagnosed acid reflux, esophageal hypersensitivity and a normal pattern in 7%, 28% and 66% respectively. The number of non-acid reflux (NAR) was higher when compared with acid ones (p < 0.0001), moreover NAR and NAR proximal extension were associated with endoscopic lesions (p < 0.03 and p < 0.05, respectively). HRM revealed normal pattern in 62% of patients, minor peritardis disorders in 24%, and outflow obstruction in 14%. According to the new Rome IV criteria, 55% of patients presented “functional esophageal disorders” (Rome IV-IN). No differences were detected in serological marker and clinical presentation. AIG-R presented lower antrum gastritis (p < 0.001) and a trend towards lower corpus gastritis (p = 0.07) when compared with controls. The two patient with acid GERD were an OLGA 0 with mild gastrin increase and an OLGA I with short segment Barrett’s esophagus. Lower OLGA stages, lower corpus atrophy (p < 0.02) and more frequent response to PPI (p < 0.05) were associated with Rome IV-OUT status.

Conclusion: AIG-R patients are not uncommon despite the hypo-achlorhydria. Acid reflux is rare in AIG, while motility and “functional” disorders are frequent. Lower corpus atrophy and OLGA stage in Rome IV-OUT patients, with an at least partly preserved fundic gland, is likely related to lower prevalence of symptoms. Treatment should consider use of proton pump inhibitor drugs only in specific patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1856 Diet is more effective than Antacids in Relieving Reflux Symptoms in Mild GERD

M. Furnari1, S. Cento2, S. Tolené2, M. Frassoni3, E. Savarino2, L. Frassoni2, E. Marabottis2, G. Bodini4, V. Savarino4, N. De Bortol2, S. Marchi2, P. Minale2

Aims & Methods: To firm these preliminary data.

Results: After investigations 261 patients out of 500 (52.2%) were excluded because of IBS (140), colic disease (6), nickel atopy (25), lactose intolerance (60), SIBO (10), and allergy to other foods (20). The remaining 239 patients were diagnosed as affected by mild GERD (median age 47; BMI 24; 132F/107M; no erosive reflux disease) and were included in our interventional prospective study. Among them, 101 (42%) patients were assigned to the intervention group (dietary therapy), and 138 (58%) were assigned to the control group (medical therapy). Diet for patients was carefully designed following a structured diet regimen, tailored on the metabolic need of the patient. In patients with mild GERD, diet completely prevented reflux symptoms (p<0.01) and was effective in 94.9% of them. No differences were noted between responders and not responders in terms of BMI, age and gender. Diet was more effective than antacids treatment in reducing reflux symptoms in mild GERD patients (p<0.01).

Conclusion: A structured diet regimen, tailored on the metabolic need of the patient, appear more effective than antacids alone in relieving reflux symptoms in patients with mild GERD. Further controlled studies are mandatory to confirm these preliminary data.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1857 Interim Results of a Prospective Multicenter Registry of Lower oesophageal sphincter (Los) Function in Patients with Gastro-oesophageal Reflux Disease

J. Labenz1, A. Leodolter2, J. Pedersen3, A. Nieponice4, R. Weise5, N. Bouvy5, S. Schoppmann6, C. Gutt7, A. Madisch8

The LOPA II study is a prospective, multicenter, observational study conducted in 17 general practice clinics. Patients with chronic GORD, taking PPI therapy for at least 1 year, and not satisfied with their treatment were asked to complete a questionnaire. Patients were asked about the reasons for their PPI therapy satisfaction, as well as the frequency of symptoms at least twice per week despite PPI. A total of 20% were dissatisfied with their treatment. Few patients had received specific GORD diagnostics or recommended other options (<10%).

Aims & Methods: Our study was aimed to define the prevalence of reflux symptoms in AIG patients, to evaluate the serological, histological and clinical differences in AIG patients with or without reflux symptoms and to investigate the pathophysiology behind these symptoms. One hundred and fifty AIG patients were evaluated and 87 were included in the study: 29 AIG patients with reflux symptoms (AIG-R) and 58 without (controls), selected with similar age and sex distribution. AIG-R underwent pH-impedance (pH/I) and high resolution manometry (HRM). Serum biomarkers, EGDS, histology and anamnestic data were evaluated in both groups. Statistics was performed as indicated.

Results: AIG-R were 19% overall and 28% of them showed endoscopic esophageal lesions, with more frequent hiatal hernia than in controls (p < 0.02). pH/I diagnosed acid reflux, esophageal hypersensitivity and a normal pattern in 7%, 28% and 66% respectively. Introduction: Safety and efficacy of electrical stimulation of the lower esophageal sphincter (LES) using the EndoStim® LOS Stimulation System (Nijmegen, The Netherlands) has been demonstrated in clinical trials up to > 5 years. Data on outcomes in routine clinical practice is growing.

Aims & Methods: An ongoing, prospective international multicenter web-based registry collecting data in patients with refractory GERD symptoms, treated with ES-LOS in clinical practice. Data is collected at baseline and at routine follow-ups for 5 years. Demographics, adverse events, GERD symptoms, GORD health related quality of life (GORD-HRQL) scores, use of proton pump inhibitors (PPI) and physiological data (oesophageal pH, manometry) are collected when available.

Results: 180 patients at 13 sites in Europe and Latin America have been enrolled. Follow-up data up to 2 years is available. Median (IQR) age at the time of implant was 51 (41–60), 57% were male. All patients were taking prescription PPI at baseline. At their last follow-up between 6 and 24 months post op, 70% (84/121) were completely off PPI (p < 0.001). Median (IQR) composite GORD-HRQL score improved from 23 (17–29) preoperatively to 3 (4–15) at 6 months, 7 (2–12) at 12 months, and 5 (4–15) at 24 months (p < 0.001 at all time points, n = 154, 121, 66, 33 at baseline, M6, M12, M24, respectively). Oesophageal pH testing post-op was performed by a few sites either as standard of care or in protocol-specified subgroups. Median (IQR) 24-hour oesophageal acid exposure improved from 8.2% (4.6–18.4) at baseline to 4.7% (1.4–14.5) at 6 months (p = 0.26) and 3.6% (1.0–5.8) at 12 months (p = 0.04) (n = 120, 39, 10 at baseline, M6, M12, respectively). The proportion of patients with moderate to severe regurgitation decreased from 64% at baseline to 22.5% after 6 and 13.4% after 12 months. Extra-oesophageal symptoms (recurrent cough, pneumonitis, shortness of breath) and sleep disturbances also decreased substantially. Overall, dysphagia and gas were less common at 12 months than preoperatively. Four serious adverse events were reported in one patient. One myocardial infarction related sudden death at 11-month post-op, not related to the device or procedure; 1 event of asymptomatic electrode erosion into the oesophagus detected during routine endoscopy and the device safely removed during laparoscopic fundoplication; and 2 events of gastrointestinal perforations in 1 patient requiring hospitalization, possibly related to the device, were reported.

Conclusion: ES-LOS is safe and effective in treating patients with refractory GERD symptoms despite PPI in routine clinical practice. ES-LOS should be considered as initial treatment option for refractory GERD patients.

Introduction: Radiofrequency ablation (RFA) with or without endoscopic resection (ER) is an established endoscopic treatment of early Barrett’s esophagus (BE) related neoplasia (BORN). After successful treatment, follow-up is still required as recurrences may occur. The aim of this prospective single-center case series was to assess the long-term efficacy of endoscopic treatment (RFA with or without ER) for BORN. Main outcomes were complete remission of neoplasia (CR-N) and intestinal metaplasia (CR-IM) and recurrence of IM (R-IM) and neoplasia (R-N).

Aims & Methods: A total of 99 consecutive patients with BORN have been treated from 2009 to 2019, 82 patients (75 men, mean age 64, range 22–91) completed the treatment and were included in this analysis. The patients had been followed up during 296 patient-years (mean 3.4 years, range 0.5–6). Thirty-three patients were diagnosed with adenocarcinoma (35%), 24 patients with high-grade dysplasia (26%) and 30 patients with low-grade dysplasia (34%). Prior to RFA, ER for visible lesions was performed in 57 patients (60%). Mean length of the Barrett’s esophagus (BE) was 4.6 cm (range 1–13 cm). After treatment, the patients have undergone regular endoscopic surveillance with multiple biopsies. Remission was defined as complete remission of IM (CR-IM) and complete remission of neoplasia (CR-N) and intestinal metaplasia (CR-IM) and recurrence of IM (R-IM) and neoplasia (R-N).

Results: We included 92 patients with BE (at least CM1), who had a baseline VLE scan, followed by RFA and had no prior ablative therapy. These patients were divided in three patient groups: without prior EMR and treated with only RFA, with prior EMR and treated with only RFA and with combined RFA and EMR. All patients who had any ablative therapy prior to baseline VLE. The primary outcome was the percentage reduction of Prague length after the first treatment. Secondary outcomes were: 1. complete remission of intestinal metaplasia (CRIM) during 12 months after baseline procedure, 2. complete remission of dysplasia (CRD) during 12 months after baseline procedure, and 3. number of RFA treatments necessary for complete response of intestinal metaplasia. We estimated the thickness of BE mucosal layers, by measuring the distance between the esophageal surface to the deepest edge of the lamina propria. In order to do so, we developed an algorithm (ImageJ software; imagej.nih.gov/ij/) that automatically adjusts every clockwise image into a high-resolution vertical scan with enhanced contrast. We used two measurement protocols: subjective, by drawing a line from the surface to the edge of the lamina propria (LP) and by plotting a grayscale density plot at the same location, using the sharp drop off in density to measure the thickness of the tissue.

Conclusion: We included 92 patients with BE at least CM1, who had a baseline VLE scan, followed by RFA, and had no prior ablative therapy. These patients were divided in three patient groups: without prior EMR and treated with only RFA, with prior EMR and treated with only RFA and with combined RFA and EMR. All patients who had any ablative therapy prior to baseline VLE. The primary outcome was the percentage reduction of Prague length after the first treatment. Secondary outcomes were: 1. complete remission of intestinal metaplasia (CRIM) during 12 months after baseline procedure, 2. complete remission of dysplasia (CRD) during 12 months after baseline procedure, and 3. number of RFA treatments necessary for complete response of intestinal metaplasia. After a median of 20 months: small Barrett island (n = 3), HGD (n = 22), EC (n = 27). Worst pathology pre-RFA (after any ER) was: non-dysplastic IM (n = 9), LGD (n = 27), HGD (n = 32). Median FU was 85 months (IQR 58–96) with a median of 7 FU endoscopies per patient. Recurrence of long-term follow-up (FU). Primary outcome: recurrence of HGD-EC; recurrence of endoscopically visible Barrett’s mucosa. Secondary outcomes: Buried Barrett’s glands; IM in biopsies obtained distal to a normal appearing neo squamocolumnar junction (neo-SCJ); need for retreatment; sustained CE-IM and CE-NEO at last FU.

Results: 68 patients were included (55 men, median 64 yrs, median BE C5M6). In 53/68 patients ER was performed (worst pathology: low-grade dysplasia (LGD) (n = 40), LGD-HGD (n = 13), HGD (n = 23)). Worst pathology pre-RFA (after any ER) was: non-dysplastic IM (n = 9), LGD (n = 27), HGD (n = 32). Median FU was 85 months (IQR 58–96) with a median of 7 FU endoscopies per patient. Recurrence of HGd-EC was found in 3 patients (2%): one patient with a T1mE2 AEC 3 cm away from the neo-SCJ 10 months and one patient had a visible lesion at the neo-SCJ with HGD after 22 months, both were treated successfully with ER. Recurrence of endoscopically visible Barrett’s mucosa was seen in 22 patients (32%) after a median of 20 months: small Barrett island (n = 10), BE tongue (n = 9), ec-SCJ (n = 2), Broad (n = 2). In patients Buried Barrett’s glands were detected (overall 34/48 FU endoscopies, 0.7%). IM in a normal appearing neo-SCJ was found in 19 patients (28%), and this was not reproduced in 84%. In 2 patients LGD without IM was found in the neo-SCJ. Eleven patients had a local recurrence of Barrett’s mucosa (n = 5), six patients had additional ER (1x T1m2, 1x HGD, 2x LGD, 2x visible Barrett’s islands), RFA for LGD without IM in the neo-SCJ (n = 1). CE-NEO and CE-IM (excluding IM in the neo-z-line) at the last FU endoscopy was seen in 100% and 96% respectively.

Conclusion: With 7-years of follow-up, this study presents the longest published follow-up data on RFA for BE with HGD/Ec to date. Our long-term outcomes show that after successful RFA recurrence of HGd-EC is rare (3%). Recurrence of endoscopically visible BE was found in 32% of patients, however it was confined to small islands or tongues <1 cm in the vast majority of patients.

Disclosure of Interest: All authors have declared no conflicts of interest.
for lepin. The association did not differ according to subgroups defined by BMI (p-interaction for leptin=0.82). We also observed that adiponectin was not associated with BE. However, we observed an OR of 0.41; 95%CI 0.17, 0.99 comparing extreme quintiles of IGFBP-3 (p-interaction=0.11). Among both women and men, we did not observe any other significant associations between inflammatory or metabolic biomarkers and adenocarcinoma of the esophagus.

Conclusion: There was little evidence that pre-diagnostic inflammatory or metabolic biomarkers are associated with risk of BE.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1866 OUTCOMES OF TREATMENT OF PATIENTS WITH EARLY-STAGE ADENOCARCINOMA OF THE ESOPHAGUS WITH INCipient SUBMUCOSAL INVASION, RETROSPECTIVE ANALYSIS OF 19 CASES FROM A TERTIARY REFERRAL CENTER IN THE UK

Introduction: Endoscopy mucosal resection (EMR) is an established diagnostic and treatment tool in the management of Barrett’s oesophagus (BO) with early neoplasia, however it is not enough evidence on the outcomes of the patients, in whom the EMR’s histologic assessment identifies early-stage adenocarcinoma of the esophagus with incipient submucosal invasion (pT1b sm1).

Aims & Methods: We have conducted a retrospective analysis using our electronic database for endoscopic procedures for patients with BE, who underwent EMR from October 2010 to December 2016. We investigated the size of the EMRs, the complication rates of the EMRs, the histological features and the resection margins of the EMR specimens and also the outcomes with the mortality.

Results: A total of 99 patients underwent 134 EMR procedures, and the histology identified early adenocarcinoma with incipient invasion of the submucosa in 25 patients. 23 (92%) were male, the mean age at the EMR was 71 years (SD: 8.1). In all 25 EMR 9 (36%) patients had a single piece, 7 (28%) patients 3 piece and 4 (16%) patients 4 piece EMR. The median length of the circumferential and maximum extent of the BO segments were 2 and 5 cm respectively (interquartile range (IQR) 2–4). We observed 6 (24%) intra-procedural bleedings and 2 (8%) patient needed admissions with post procedural bleeding and 1 (4%) of them required transfusion. Stricture was endoscopically detectable but not causing any symptoms in 1 (4%) patient and another patient (4%) had slight dysphagia post EMR, but did not need dilatation. Histology showed lymphovascular invasion in 6 (25%) patients and vascular invasion in 1 (4%) patient. Of all 25 early adenocarcinomas 7 (28%) were reported as poorly differentiated, 11 (44%) as moderately differentiated and 3 (12%) as well differentiated. In 4 (16%) cases differentiation was not reported. All resection margins were reported as being clear from dysplasia or cancer. There were 10 (60%) patients with clear radial and or deep margin of the EMR specimen, of these 9 (60%) had oesophagectomy and in the histologic assessment of these specimens, lymph node involvement was observed in 2 cases (22.2% of all oesophagectomies and 9.5% of all surviving and currently cancer-free patients). There was no residual cancer in 3 (33.3%) of the surgical specimens. Radical radio-chemotherapy was given in 1 (6.7%) patient and 3 (33.3%) patients did not have radical treatment for clinical reasons. There were 10 (40%) patients without cancer invasion of the EMR resection margins, of these 4 (40%) had oesophagectomy and 1 (10%) radical radio-chemotherapy. The histologic assessment of these surgical specimens showed residual cancer in 3 (30%) cases and high-grade dysplasia in 1 (10%) case. Of the 25 patients 5 (20%) met the criteria and had radio frequency ablation of the residual Barrett’s oesophagus. Of the 13 (52%) patients who had had oesophagectomy 1 (7.7%) patient died of the deterioration precipitated by the oesophagectomy, and sadly in this case the oesophagectomy specimen did not show residual cancer. Of the 12 (48%) patients who had not had oesophagectomy 3 (25%) died since their EMR, 1 (8.3%) of cardiac arrest, 1 (8.3%) of chronic obstructive pulmonary disease and 1 (8.3%) of advanced oesophageal cancer, 18 months after the EMR, and the 9 (75%) surviving patient are all doing well. We diagnosed 9 (75%) patients with cancer invasion of the submucosa. Of the median survival of all 21 (84%) patients currently alive is 25 months (range: 2–68 months; SD: 22.2).

Conclusion: Early detection of esophageal cancers can significantly reduce the years of potential suffering for patients with BE. A new prototype endoscopic method incorporating the endoscopyduce function into a magnifying endoscope has been designed. Previously, Inoue et al have published a pilot trial on evaluating the use of this endoscopyctoscope in various types of benign and malignant pathologies. We designed a study that evaluated the potential of this new endoscope. A new endoscopic method incorporating the endoscopyduce function into a magnifying endoscope has been designed. Previously, Inoue et al have published a pilot trial on evaluating the use of this endoscopyctoscope in various types of benign and malignant pathologies. We designed a study that evaluated the potential of this new endoscope.

Results: From July 2015 to March 2017, forty-four patients were included in the study. Seventeen of the forty-four (38.6%) patients had histological confirmed cancer of the esophagus. There were sixteen patients who had normal finding and nine patients with esophagitis. The positive predictive value for malignancy (ECA 4 and 5) was 89.5%; the negative predictive value was 100%. Sensitivity was 100% and specificity was 92.6%. Similar findings were noted with IPCL on malignancy. The positive predictive value for malignancy (IPCL 4 and 5) was 100%; the negative predictive value was 100%. Sensitivity was also similar at 100% and specificity 92.6% respectively. To compare the diagnostic accuracy of endoscopyctoscopy and magnifying NBI, the McNemar test was performed. The McNemar chi-squared statistic is NaN, and the McNemar chi-squared statistic was 0.5, meaning that the two tests have the same diagnostic accuracy.

Conclusion: Endoscopyctoscopy had a high positive predictive value and sensitivity for esophageal malignancy. Its diagnostic accuracy was comparable to magnifying NBI. It may be helpful as an adjunct for better characterization of esophageal lesions. However, further studies on interobserver variability is required.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic resection for early esophageal cancer is considered to be a high-risk factor for superficial esophageal cancer. But there are few reports of endoscopic resection for this cancer, and the outcome is unclear. In our hospital, we have performed over 1300 Per-Oral Endoscopic Myotomy procedures for esophageal achalasia and related esophageal diseases. In this process, we diagnosed 10 superficial esophageal cancers in patients with achalasia. We performed endoscopic resection for all cases and report relatively long-term outcome.

Aims & Methods: We aimed to evaluate clinicopathological findings and outcomes of endoscopic resection for 10 achalasia-associated superficial esophageal cancer. This is a case series study at our hospital. Between August 2010 and February 2017, 10 achalasia patients with superficial esophageal cancer underwent endoscopic resection. We performed in all cases upper gastrointestinal endoscopy, using lugo’s solution and narrow band imaging, and we included all patients that had early cancers that were eligible for endoscopic resection in this series. At 2 and 12 months after treatment, we performed follow-up endoscopy in all cases. After this, we performed long-term endoscopic follow-up every year. In the case that the tumor invasion depth is to the muscularis mucosa (MM) on histopathology, we performed endoscopic follow-up every 6 months and CT scan.

Results: There were 6 men and 4 women and their average age was 61.7 years. 8 patients were diagnosed with lesions before POEM. We performed endoscopic resection (ESD/EMR,9/1) in all cases after POEM. None of the patients had a severe adverse event. The mean tumor diameter was 30mm (range: 5–80mm). The pathological diagnosis was 8 SCC, 2 high grade intraepithelial neoplasia. Out of the SCC cases, 7 were found with superficial lesion with depth of Tis-EP to T1a-LPM, and 1 with depth of T1a-MM, without lymphatic invasion(0) or venous invasion(v0). Follow-up surveillance mean was 32 months (range: 1–
Venous involvement of EP and SEP were 0% and 2.9% (1/35), respectively. The LNM was found in one of two patients who had SEP SCC without an additional therapy. 6. Local recurrent rate was 0%. 7. LNM rate of EP and SEP was 0% and 5.7% (2/35), respectively. One of two patients who had LNM was a 76-year-old male. He had SEP SCC without lymph duct involve- ment. A cervical LNM was diagnosed 6 months after ESD. Lymph node dissec- tion (CRT) was performed for the patient. The patient died of other disease without recurrence of pharyngeal SCC. The other patient also had a cervical LNM and treated by lymph node dissection + CRT. The patient is alive without recurrence for 10 years after ESD. 8. Prognosis No patients died of pharyngeal SCC or ESD.

Conclusion: ESD is a safe and useful treatment for superficial esophageal SCC. However, surveillance of LNM is important for the patients who had SEP SCC.

Discourse of Interest: All authors have declared no conflicts of interest.

P1870 OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL PHARYNGEAL SQUAMOUS CELL CARCINOMA
T. Oyama, A. Takahashi
Endoscopy, Saku Central Hospital Advanced Care Center, Nagano/Japan

Contact E-mail Address: oyama@cercl.or.jp

Introduction: Superficial pharyngeal squamous cell carcinoma (SCC) has been increasing in Japan. And, such SCC could be treated by endoscopic submucosal dissection (ESD). However, the outcome of pharyngeal ESD is unknown. Aims & Methods: The aim of this study is to clarify the outcome and prognosis of pharyngeal SCC treated by ESD. 89 pharyngeal SCC in 68 patients treated by ESD from Jan. 2006 to 2014 in Saku Central Hospital Advanced Care Center were enrolled in this retrospective study. The patients treated from 2004 to 2009 were followed up without TA injection (Non-TA), and the follow-up period of TA injection was performed for the patients after 2009 (TA group). The number of patient in Non-TA and TA group was 16 and 28, respectively. Age of both groups was 65 (30-83) and 61 (42-82) years old. The length of circumferential resection was 75 (50-10) and 76 (55-111) mm, respectively. There was no significant difference in the background of both groups. Fifity mg TA was injected into submucosal layer just after ESD, and TA injection was repeated in two-weeks interval. Fifteen mm endoscopic balloon dilatation (EBD) was performed when the scope couldn’t pass the ESD ulcer. The primary endpoint was the number of balloon dilatation. The secondary endpoints were duration from ESD to ulcer healing, and the difference between Barrett’s esophagus adenocarcinoma (EAC) and squamous cell carcinoma (SCC).

Results: 1. Number of EBD in Non-TA and TA group were 20 (13-33) and 5.1 (0-23), respectively (p = 0.01).2. Duration from ESD to ulcer healing were 10 (3-25) and 7.3 (4-32) weeks, respectively. (p = 0.47) 3. Complications; Perforation rate due to ESD was 6.3% (1/16) and 3.6% (1/28). Both patients were treated by conservative therapy.

Conclusion: Three factors were significantly associated with longer hemostatic time. The difference between Barrett’s esophagus adenocarcinoma (EAC) and squamous cell carcinoma (SCC). All authors have declared no conflicts of interest.

P1872 EXPLORATORY STUDY OF PREDICTIVE BIOMARKER FOR INFECTIVE CHEMORADIOTHERAPY FAILURE: IDENTIFICATION OF SPECIMENS OF PATIENTS WITH ESOPHAGEAL SQUAMOUS CELL CARCINOMA
Gastroenterology And Endoscopy, National Cancer Center Hospital East, Kashiwa/Japan

Contact E-mail Address: ktakashima@east.ncc.go.jp

Introduction: Superficial esophageal squamous cell carcinoma (ESCC) is a common disease in Japan. However, the treatment is quite controversial. Our institutional guidelines recommend the endoscopic resection for ESCC. However, only 30% of ESCC cases are eligible for endoscopic resection. The long term outcomes of patients who underwent ESD from 2004 to 2016 in Saku Central Hospital Advanced Care Center were recommended to perform as surveillance after ESD, and these examinations were recommended for patients with lymph node metastasis (LNM). However, surveillance of LNM is important for the patients who had SEP SCC. All authors have declared no conflicts of interest.

2. Pathology, Exploratory Oncology Research And Clinical Trial Center, National Cancer Center Hospital East, Kashiwa/Japan
Introduction: While definitive chemoradiotherapy (CRT) showed high efficacy for esophageal squamous cell carcinoma (ESCC), approximately 40% of patients develop local failure, resulting in poor long-term survival. However, there is no definitive biomarker which is useful to predict survival outcome after CRT for ESCC. Several studies have investigated the correlation of expression of CD24, cytoplasmatic podoplanin (PDpn), and cytokeratin 4 (CK4) with prognosis of patients with various malignant tumors who underwent surgical resection. However, it remains unclear whether the expression of these proteins can predict the outcome of CRT for patients with ESCC.

Aims & Methods: The aim of this study was to clarify the predictive values of expression of CD24, CK4, and PDpn for ESCC patients who received CRT. Among patients with ESCC who received CRT or curative esophagectomy with extended lymph node dissection (OPe) as an initial treatment between 2005 and 2016 at our institution, patients were selected on the following criteria: clinical stage II, III (UICC-TNM classification 6th edition), age of 75 years old or younger, ECOG Performance Status 0–1, and no prior or concurrent other cancers. The method of immunohistochemistry (IHC) was utilized to examine the protein expression of CD24, CK4, and PDpn in pretreatment biopsy specimens of ESCC. The cut-off values for CD24, CK4, and PDpn expression were used hazard ratio for overall survival (OS). The prognostic factor of CD24, CK4, and PDpn expression were statistically analyzed. OS was calculated from the date of CRT or OPe to the date of death or last follow-up, using the Kaplan-Meier method. The survival predictors identified by univariate analysis was assessed by multivariate analysis using a Cox’s proportional hazards model. Results: 148 ESCC patients (CRT group, n = 83; OPe group, n = 65) were analyzed. In the CRT group, 40 patients had stage II and 45 patients had stage III, and the 5-year OS was 52%. In the OPe group, 32 patients had stage II and 33 patients had stage III, and the 5-year OS was 66%. By univariate analysis, there were no statistically significant differences for OS in differences between the CRT and OPe group. The cut off value for CD24, CK4, and PDpn expression were 20%, 10%, and 20%, respectively. While the expression equal to the cut off value or more was defined as strong, the expression less than the cut off value was defined as weak. The frequency of strong protein expression was 50% for CD24, 12% for CK4, 65% for PDpn, respectively. In the CRT group, the OS of patients with strong CD24 expression was significantly better than that of patients with weak CD24 expression (P = 0.015; strong/weak 5-year OS: 65%/43%). On the other hand, for patients with strong CD24 expression was poorer OS comparing with patients with weak expression in the OPe group, however there was no significant difference (P = 0.286; strong/weak 5-year OS: 57%/74%). As for patients with strong CK4 expression, there was no significant difference between CRT group and OPe group (P = 0.446). However, there was significant difference between CRT and OPe group in patients with weak CD 24 expression (p = 0.009). There were also no significant differences of the OS based on expression of CK4 or PDpn between the CRT and OPe group, respectively. Multivariate analysis of the strong CD24 expression in ESMGDI (P = 0.012; HR = 2.787; 95% CI: 1.253–6.200) as an independent variable for favorable outcome. Conclusion: CD24 expression was significantly associated with the survival outcome in ESCC patients after CRT or OPe when they were treated CRT. In conclusion, weak CD24 expression might be a useful predictive biomarker of poor outcome for CRT in ESCC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1873 ENDOSCOPIC TREATMENT OF PATIENTS WITH HIGH-RISK EARLY ESOPHAGEAL CANCER
M. Koller1, J. Krajcova1, J. Maluska1, E. Honsova1, A. Paredo2, T. Harustik2, D. Kedotova2, Z. Vackova1, J. Spicak2, J. Martinove1
1Clinical And Transplant Pathology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
2Department Of Hematopathology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Introduction: Endoscopic treatment is a standard therapeutic approach for patients with T1a early esophageal cancer (EEC). In patients with ‘high-risk’ T1a early esophageal cancer, with cancer grading or invasion to submucosal tissue (T1b), endoscopic treatment might be curative in selected patients with ‘high-risk’ EEC.

Aims & Methods: The aim of this study was to assess outcomes of endoscopic treatment in patients with ‘high-risk’ EEC. ‘High-risk’ cancer was defined as any cancer with sm invasion or mucosal cancer with at least one of following: poor differentiation (G3/G4), invasion to blood (A+) or lymphatic vessels (L+) and high tumor cell dissociation (TCD3). The main outcome measurement was tumor-free survival. A single-center, retrospective analysis of prospectively collected data. Patients with EEC underwent endoscopic resection (ER) or endoscopic submucosal dissection (ESD). Based on histopathological staging, patients with ‘high-risk’ features were referred for surgery (ER). Patients who underwent endoscopic treatment consisted of continued sessions of ER and/or radiofrequency ablation if necessary. The patients have been followed up for a median of 39 months (range 2–156).

Results: A total of 56 patients with ‘high-risk’ EEC underwent endoscopic treatment: 21 patients (41%) had T1a cancer with ‘high-risk’ features and 35 patients (59%) had T1b cancer with sm invasion (sm1: 15, sm2: 9, sm3: 11). 45 patients had adenocarcinoma (EAC), 11 patients had squamous carcinoma (SCC); 19 (41%) were referred for curative endoscopic treatment (both patients had sm3 invasion, A+, L+) and these patients are undergoing oncological treatment. All remaining patients with CLR (n = 33) have experienced neither local relapse nor generalization. One patient had to undergo surgery due to esophageal perforation. Tumor-free survival was 89% (CI 79–99%) in patients treated endoscopically and esophageal related mortality was 0% (0/37). Among 19 patients who were referred for esophagectomy, one patient presented with tumor generalization revealed during the operation. The remaining 18 patients underwent esophagectomy; local residual of malignancy were present in 5/18 patients (28%). Lymph node (LN) metastases have not been detected in any patient among the 337 examined LNs. Surgery related mortality was 6% (1/18).

Conclusion: Endoscopic treatment provides long-term remission or cure in a considerable number of patients with ‘high-risk’ EEC and it may thus represent a valid alternative to surgery. Broadening of indications for radical endoscopic treatment of early EEC should be reconsidered.

3. V globally, there is no convincing evidence whether the expression of these proteins can predict the outcome of CRT for patients with ESCC.

Aims & Methods: The objective of this study was to determine the predictive value of the expression of CD24, CK4, and PDpn using multivariate analysis using a Cox’s proportional hazards model. Results: Among patients with ESCC who received CRT or curative esophagectomy with extended lymph node dissection (OPe) as an initial treatment between 2005 and 2016 at our institution, patients were selected on the following criteria: clinical stage II, III (UICC-TNM classification 6th edition), age of 75 years old or younger, ECOG Performance Status 0–1, and no prior or concurrent other cancers. The method of immunohistochemistry (IHC) was utilized to examine the protein expression of CD24, CK4, and PDpn in pretreatment biopsy specimens of ESCC. The cut-off values for CD24, CK4, and PDpn expression were used hazard ratio for overall survival (OS). The prognostic factor of CD24, CK4, and PDpn expression were statistically analyzed. OS was calculated from the date of CRT or OPe to the date of death or last follow-up, using the Kaplan-Meier method. The survival predictors identified by univariate analysis was assessed by multivariate analysis using a Cox’s proportional hazards model. Results: 148 ESCC patients (CRT group, n = 83; OPe group, n = 65) were analyzed. In the CRT group, 40 patients had stage II and 45 patients had stage III, and the 5-year OS was 52%. In the OPe group, 32 patients had stage II and 33 patients had stage III, and the 5-year OS was 66%. By univariate analysis, there were no statistically significant differences for OS in differences between the CRT and OPe group. The cut off value for CD24, CK4, and PDpn expression were 20%, 10%, and 20%, respectively. While the expression equal to the cut off value or more was defined as strong, the expression less than the cut off value was defined as weak. The frequency of strong protein expression was 50% for CD24, 12% for CK4, 65% for PDpn, respectively. In the CRT group, the OS of patients with strong CD24 expression was significantly better than that of patients with weak CD24 expression (P = 0.015; strong/weak 5-year OS: 65%/43%). On the other hand, for patients with strong CD24 expression, there was no significant difference between CRT group and OPe group (P = 0.446). However, there was significant difference between CRT and OPe group in patients with weak CD 24 expression (p = 0.009). There were also no significant differences of the OS based on expression of CK4 or PDpn between the CRT and OPe group, respectively. Multivariate analysis of the strong CD24 expression in ESMGDI (P = 0.012; HR = 2.787; 95% CI: 1.253–6.200) as an independent variable for favorable outcome. Conclusion: CD24 expression was significantly associated with the survival outcome in ESCC patients after CRT or OPe when they were treated CRT. In conclusion, weak CD24 expression might be a useful predictive biomarker of poor outcome for CRT in ESCC patients.

Introduction: Preoperative Neutrophil to Lymphocyte Ratio (NLR) has been proposed as a prognostic marker in several solid tumors (Templeton 2014). A retrospective prospective study of 60 patients showed the prognostic relevance of NLR as a predictor of response in esophageal cancer patients treated with chemoradiotherapy. The aim of this study is to assess the NLR prognostic strength in a retrospective series of two high-volume centers.

Aims & Methods: A retrospective review of two prospective esophageal cancer database was conducted. Neutrophil to lymphocyte ratio was defined as the prechemoradiotherapy serum neutrophil count divided by lymphocyte count. We dichotomized the NLR data using as cut-off values 2.5 and 3 respectively. Univariable logistic regressions were performed to determine the effect of NLR on response after neoadjuvant treatment. Survival curves were constructed with Kaplan Meier method and compared with the long rank test.

Results: We included 280 patients. The analysis of NLR as predictor of pathology-complete response (pCR) showed a OR of 0.93 (95% CI 0.51–1.746, p = 0.901) and 1.161 (95% CI 0.647–2.081, p = 0.617) considering as cut-off values 2.5 and 3 respectively. In our large series, NLR did not result as a predictive marker neither in terms of Overall Survival nor in terms of Disease Free Survival (p = 0.997 and p = 0.672 respectively).

Conclusion: Our results did not confirm NLR as a significant marker of pCR. Moreover, the survival analysis did not reveal significant differences using NLR as pre-treatment prognostic marker. The heterogeneity of treatments, the com-

CORM-2 was accompanied by a significant decrease in plasma levels of IL-1ß and TNF-α, when comparing to vehicle-control group. The expression of IL-1ß, TNF-α, and HO-2 was detected in vehicle control group and these effects were ameliorated by treatment with CORM-2. The gastric mucosal MPO activity and themucosal content of MDA + 4HNE in gastric mucosa were elevated in vehicle-control group and these effects were significantly inhibited by CORM-2. CORM-2 in subchronically administered CO decreases the length of pre-existing gastric ulcerations by the mechanism involving an increase in gastric microcirculation at ulcer margin, the inhibition of inflammatory response as manifested by the attenuation of enhancing synthesis of the proinflammatory markers IL-1ß, TNF-α, COX-2 and iNOS as well as by antiangiogenesis properties of CORM-2 releasing CO limiting lipid peroxidation.

P1878 PROTON PUMP INHIBITORS INAPPROPRIATE USE IN PATIENTS ADMITTED IN A TERTIARY GREEK HOSPITAL CREATES SIGNIFICANT DIRECT COSTS BURDEN AND EXPOSURE OF PATIENTS TO THE RISK OF UPPER GASTROINTESTINAL COMPLICATIONS

Introduction: There is evidence of proton pump inhibitors (PPIs) misuse in the community and in the hospitals causing significant direct and indirect costs burden for the health care system.

Aims & Methods: We aimed to evaluate the frequency of inappropriate PPIs administration in hospitalized patients, to measure the direct in-hospital costs of PPIs inappropriate use and to calculate the number of patients exposed to the risk of upper gastrointestinal (UGI) complications due to medication underuse. This was a prospective, cross-sectional, prescription-indication drug-utilization, chart-review study in hospitalized patients with follow-up until discharge, in a tertiary hospital in Athens, Greece. We recorded data of all patients admitted (intensive care, cardiac, psychiatric, pediatrics and obstetrics day clinic admission were excluded) during three consecutive on-call days of the hospital in March 2017 regarding PPIs utilization before admission, during hospitalization and at discharge. PPIs cost was calculated for intravenous use and the number of patients at risk of UGI complications due to PPIs underuse for 1 year period, using a simulation model.

Results: We included data from 470 patients admitted age 67 ± 19 yrs; 32.5% were pre-senile, 67.5% were registered as inpatients and 69.5% were discharged. PPIs overutilization was detected in 15.7%, 41.3% and 12.6% of the patients before admission, during and after the admission, while medications underutilization was detected in 10.2%, 8.1% and 9.5% of them, respectively. Admission at internal medicine and orthopedics clinics was associated with the highest unadjusted ORs (1.68 [95%CI 1.63–1.72] and 1.68 [1.59–1.78]) for PPIs misuse, 0.80 of the 193 over treated patients received PPIs (80% of them od, 20% bid) while the rest were treated with PPIs per os (90% of them od, 10% bid) during discharge. PPIs overutilization length of hospitalization. This accounts for 1460 PPI iv and 344 PPI per os doses inappropriately given during the observation period. Taking into account in our simulation model that there are 90 on-call days of our hospital per year, we calculated the number of hospital costs of PPIs overuse for 1 year period, using a simulation model.

Conclusion: Hospitalization does not represent an opportunity for optimization of PPIs utilization. On the contrary, the frequency of PPIs inappropriate use during hospitalization is higher than that observed during admission, causing significant direct costs for the hospital and exposing patients to the risks of UGI complications.

Introduction: PPIs are becoming increasingly used in a large proportion of the outpatients population. The trend of change in the prevalence with increasing length of PPI exposure over 5 years is not known. Theoritical risk of FGP seems to be very low but not HO-2 was detected in vehicle control group and these effects were ameliorated by treatment with CORM-2. The gastric mucosal MPO activity and the mucosal content of MDA + 4HNE in gastric mucosa were elevated in vehicle-control group and these effects were significantly inhibited by CORM-2. CORM-2 in subchronically administered CO decreases the length of pre-existing gastric ulcerations by the mechanism involving an increase in gastric microcirculation at ulcer margin, the inhibition of inflammatory response as manifested by the attenuation of enhancing synthesis of the proinflammatory markers IL-1ß, TNF-α, COX-2 and iNOS as well as by antiangiogenesis properties of CORM-2 releasing CO limiting lipid peroxidation.

P1880 ENDOCUTLSE RESECTION OF ADVANCED AMPULLARY ADENOMAS: A SINGLE-CENTER 14-YEAR RETROSPECTIVE COHORT STUDY S. E. Van Der Wiel, J.W. Poley, M.J. Bruno, A.D. Koch

Department Of Internal Medicine and Gastroenterology, Erasmus University Medical Center, Rotterdam/Netherlands

Contact E-mail Address: s.vanderwiel@erasmusmc.nl

Introduction: Adenomas of the ampulla of Vater are rare. Endoscopic ampullectomy has been recognized as a safe and reliable treatment of selectve tumors of the ampulla of Vater and is associated with lower morbidity and mortality rates than surgical resection. However, the success rates for endoscopic ampullectomy are limited. Aims & Methods: The aim of our study was to evaluate the technical success, complications and recurrence of endoscopic resection for treating patients with ampullary adenomas with intraductal extension (AIE), and patients with lateral spreading adenomas (LSA). Results: During study period 1525 patients (mean age 59.2 years, 53% male) were admitted at our tertiary 500 beds hospital in Athens, Greece. We recorded data of all patients referred to the Erasmus Medical Center, Rotterdam, for endoscopic resection of the more advanced ampullary tumors were retrospectively identified. Cases were selected by using ENDOBASE and we provided a search in the our local PALCA database. We included patients with a histological diagnosis of adenoma. Endoscopic resection was performed by 5 experienced endoscopists. Endoscopic success was defined as complete excision of the adenoma, irrespective of the number of attempts, and in the absence of recurrence. All patients underwent endoscopic follow-up. Early and late complications were registered.

Conclusion: We included 84 patients, 56 patients (67%) had an adenoma confined to the ampulla (ACA), 17 patients (20%) had a LSA and 11 patients (13%) were treated for adenomas that demonstrated growth pattern with intraductal extension. Fifty-five percent of the patients were men and the median age was 65.4 years (range 32–89). The median lesion size was 24.6mm (range 5–80) for patients with ACA, 34.8 mm (range 23–50) for LSA and 16.3 mm (range 10–20) for patients with an AIE (P = 0.039). Complications occurred in 26 patients (30.9%), of which hemorrhage was most seen in 17.9%, followed by perforation in 5.9% of the patients. Complications were equally divided over these three groups (P = 0.775). The mean follow-up duration was 31.1 months (range 0–129) for ACA, 23.1 months (range 0–127) for LSA and 11.9 months (range 0–37) for IEA (P = 0.136). Endoscopic resection was curative in 87.5% of patients with a localized adenoma, 82.3% in patients with a lateral spreading adenoma and in only 9.1% of patients with an intraductal extended tumor (P < 0.000). Recurrence occurred in 9 patients (10.7%), 5 of them had a localized adenoma, 3 patients had a lateral spreading adenoma and 1 patient with an intraductal extended adenoma (P = 0.875).

Conclusion: Endoscopic ampullectomy is a safe and successful treatment in patients with adenomas with or without a lateral spreading growth pattern. Incidence of an intraductal extended adenoma endoscopic success rates are significantly lower.

Disclosure of Interest: All authors have declared no conflicts of interest.
Lesion larger than 3 cm without finding of ulcer, U of stomach, and age negative and UL negative. And, 152 of 263 UL negative lesions were 3 cm or less in size, and 207 lesions were judged as UL positive whereas the other 263 were assessed as negative and UL negative. 

Aims & Methods: The aim of this study was to evaluate the factors associated with the technical difficulty of ESD for early gastric cancer (GC) which met expanded indication criteria using data from JCOG0607. The major inclusion criteria of JCOG0607 were as follows: 1) histopathologically proven intestinal adenocarcinoma; 2) cT1aN0M0; 3) lesion without finding of ulcer (UL negative) and >2 cm in size, or UL positive and ≤3 cm in size; 4) age >75. ESD were performed by certified endoscopists or under the supervision of certified endoscopists. Multivariable analysis was performed to investigate the clinical factors associated with technical difficulty of ESD.

Results: From November 2014 to October 2015, a total of 470 patients (pts) (male/female: 385/85, median age 65-y (range: 40–75)) were enrolled from 29 institutions. Tumor location was upper (U) of stomach in 71, middle in 255, and lower in 144 pts, respectively. The median tumor size was 2.5 cm (range: 0.5–13), and 207 lesions were judged as UL positive whereas the other 263 were assessed as UL negative. And, 152 of 263 UL negative lesions were 3 cm or less in size, and the other 111 of them were larger than 3 cm. Median procedure time was 79 min (range: 14–462), and it took 120 min or longer in 127 pts. 12 pts developed perforation and the procedure took 120 min or longer in 31 of them. Therefore, 130 pts (27%) were classified in difficult case group. The proportion of difficult case was 23.2% (48/207) in UL positive and ≤3 cm cases, 18.4% (28/152) in UL negative and ≤3 cm, and 48.6% (54/111) in UL negative and >3 cm, respectively. Multivariable showed UL negative and >3 cm (vs. UL negative and ≤3 cm, odds ratio, 4.66; 95% confidence interval, 2.59–8.37, p < 0.0001) was the most significant factor associated with technical difficulty, and U of stomach, and age ≤60 were also associated with difficulty.

Disclosure of Interest: All authors have declared no conflicts of interest.

2 Endoscopy, Kobe University Hospital, Kobe/Japan

Contact E-mail Address: valencia.0001@gmail.com
Introduction: Endoscopic submucosal dissection (ESD) is widely used as a standard treatment for superficial tumors in the GI tract and its safety has been established. Opportunities for elderly patients to undergo ESD for gastric cancer is increasing due to the continued improvement in life expectancy. However, short-term and long-term outcome of ESD for elderly patients is still uncertain due to the high risk of complications and possible increased risk of complications related to ESD in this population.

Aims & Methods: Therefore, we investigated the safety, efficacy and short-term outcome of gastric ESD for patients over 80 years old. Additionally, we evaluated the long-term outcome of non-curative resections according to both age groups. 1056 lesions in 886 patients treated with ESD between January 2011 and December 2015 in our hospital were retrospectively reviewed. They were classified into two groups; elderly group >80 years old (246 lesions in 201 patients) and non-elderly group >79 years old and younger (810 lesions in 685 patients). The patient demographics, lesion characteristics, short-term ESD outcome, complications (perforation, postoperative bleeding, postoperative delirium, pneumonia), were evaluated and compared between the two groups. Concerning the long-term outcome of non-curative ESD, cases performed between 2011 and 2013 were assessed.

Results: The median age was 83 years old (range: 80-92) in the elderly group and 70 years old (range: 36-78) in the non-elderly group. The mean number of patients in the non-elderly group was significantly higher in the elderly group (30.9% vs. 17.0%: p < 0.0001). Comorbidities were significantly higher in the elderly group including heart disease (24.8% vs. 10.5%: p < 0.0001), lung disease (13.6% vs. 7.4%: p = 0.002) and diabetes (3.3% vs. 1.0%: p = 0.05). Tumor location was not significantly different between the two groups. Median specimen and tumor size were the same in both groups with no significant difference: 43 mm and 15 mm, respectively. The en bloc resection rates (96.3% and 97.8%) and the curative resection rates (82.5% and 84.6%) were not significantly different. The perforation rates were not statistically different (2.44% and 3.21%). However, the postoperative bleeding rate (5.28% vs. 2.72%: p = 0.05), postoperative delirium (2.0% vs. 0.25%: p = 0.009) and pneumonia (2.0% vs. 0.25%: p = 0.009) were significantly higher in the elderly group. In multivariate analysis, age over 80 was not an independent risk factor for postoperative bleeding, however it was the independent risk factor for postoperative delirium and postoperative pneumonia. Nineteen elderly patients and 54 non-elderly patients with non-curative resections were followed-up for 3 years after ESD for the long-term outcome analysis. The percentage of patients who underwent additional surgery after ESD was 26.3% (5/19) and 51.8% (28/54) respectively (p = 0.05). Neither disease specific death nor progression to advanced gastric cancer was found in each age group. Overall survival rate 3 years after ESD was 94.4% and 87.2% respectively (p = 0.11).

Conclusion: ESD is a safe and effective treatment for early gastric neoplasia even in patients over 80 years old. However, because postoperative delirium and postoperative pneumonia were observed more often in the elderly patients, more careful attention to these conditions during perioperative care may be necessary. Elderly patients over 80 years, with non-curative resections, underwent less frequent additional surgery without any impact on the disease specific death and global mortality.

P1886 GASTRIC INTESTINAL METAPLASIA OUTCOMES: RESULTS FROM A 17 YEAR TERTIARY CENTRE UPPER GI SURVEILLANCE PROGRAMME IN IRELAND

M. Mc Nally1, I. Cretu1, A. O’Connor1
1 Trinity Academic Gastroenterology Group, Naas General Hospital, Kildare/Ireland

Contact E-mail Address: maiarealn@gmail.com
Introduction: Adenocarcinoma of the stomach is the second leading cause of cancer related death in the world. Gastric intestinal metaplasia (GIM) is an important intermediate stage in the gastric cancer cascade through a series of well-defined precursor lesions including nonatrophic gastritis, multifocal atrophic gastritis, intestinal metaplasia, and dysplasia. The prevalence of GIM is unclear in many parts of the world and few studies have evaluated the rate of progression to gastric cancer in patients with GIM. There is a lack of clarity in
published guidelines regarding appropriate surveillance of patients with GIM and have widely disparate management in the context of this premalignant condition.

**Aims & Methods:** This study aimed to analyze surveillance practice and characterize the natural history of this premalignant condition by identifying all patients with GIM on an upper GI surveillance programme and reviewing follow up data. This is a retrospective study of patients with GIM who are currently enrolled in an upper GI surveillance programme. Patients with a history of GIM identified at any time during an 18-year surveillance period (from 1998 to 2016) were included in the study. Patient characteristics, endoscopic data including biopsy and follow-up histology, rates of Helicobacter pylori infection, Barrett’s oesophagus association and outcomes were reviewed.

**Results:** 160 patients (including those with Barrett’s oesophagus, GIM and family history of gastric cancer) were enrolled on the surveillance programme. 42 patients with GIM were identified—20 females (47.6%) and 22 males (52.3%). The mean age at which GIM was first diagnosed was 60.6 years (range from 17.9 to 71.5 years). 15/42 patients (35.7%) had co-existent Barrett’s oesophagus and Helicobacter pylori was identified in 6/42 (14.3%). The follow-up period ranged from 1.2 to 17.3 years. 27 patients had repeat gastroscopies following initial diagnosis. 15 patients are still awaiting a repeat gastroscopy. A large degree of variability in the number and frequency of follow-up gastroscopies was observed. The average interval of follow-up gastroscopies was 3.3 years per person. 14/27 patients (51.8%) had no evidence of GIM on most recent gastroscopy, 7/27 patients (26%) had repeat findings of persistent focal GIM, 5/27 patients (18.5%) progressed to extensive GIM. No cases of dysplasia were recorded but 1 patient (3.7%) developed gastric cancer.

**Conclusion:** This study suggests a low apparent risk of progression of gastric intestinal metaplasia in a small western cohort. Further studies may be necessary to address if the applicability of published surveillance guidelines can be generalized to regions with low gastric cancer prevalence.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Previously we reported that direct family history of gastric cancer (GC) as a risk factor of gastric cancer and genotypic polymorphism of TGFBI (transforming growth factor-B1) was associated with the development of GC in the first-degree relative of GC. The aim of this study is to investigate relationship between stage of gastric cancer and genetic polymorphism of TGFBI regarding first-degree relative of GC.

**Aims & Methods:** From January 2006 to March 2017, 1090 gastric cancer patients were enrolled at Seoul National University Bundang Hospital in whom stage of GC was obtained from surgery, endoscopic submucosal dissection (ESD), endoscopic mucosal resection (EMR), and computed tomography (CT). Patients were divided according to presence of GC and PET-CT images. 203 patients (18.6%) had direct family history of GC and 887 (81.4%) did not have. Genotype of TGFBI-509 was measured by the polymerase chain reaction restriction fragment length polymorphism. Relationship between TGFBI polymorphism and stage or GC tissue issue type was analyzed.

**Results:** Proportion of stage I & 2 was statistically higher in the group with direct family history of GC (170, 83.7%) than without direct family history (600, 74.4%). (P=0.005). When GC stage was analyzed regarding direct family history and TGFBI genetic polymorphism the ratio of gastric cancer stage I to TGFBI-509 T carrier was significantly higher than that of stage II or higher (P=0.008), only in male. However, this difference was not found in female. In addition no significant difference was found in GC patients without direct family history. Lauren classification and TGFBI genotype did not show any statistically significant results even in the group with direct family history.

**Conclusion:** Family history of GC affects the stage of GC and the genotype of TGFBI-509 could be underlying mechanism in case of male. Survival analysis is undergoing.

**Table:** Differences of gastric cancer stage according to TGFBI-509 polymorphism and family history (Hx) of gastric cancer

Introduction: ESD is the one of the options of treatment even for lateral spreading (LS) esophageal squamous cell carcinoma that the ESMGD has special features under the endoscopic ultrasonography (EUS). The typical ultrasonic images of EUS could help diagnosis ESMGD.

Aims & Methods: In order to investigate the clinical value of EUS for diagnosing Gastrointestinal stromal tumors (GIST) accompanied by early esophageal cancer, which were suggested by conventional endoscopy or biopsy, this study retrospectively analyzed the consecutive patients with early esophageal cancer diagnosed in the Endoscopy Center at the Affiliated Drum Tower Hospital, Nanjing, China from September 2009 to November 2019. The clinical data of 519 patients were included in this study, and all of them had already underwent EUS combined with Endoscopic Submucosal Dissection (ESD). The EUS preoperative examinations were compared with the results of postoperative pathology from ESD.

Results: According to the pathologic results of ESD, 371 (72.1%) patients (319 males and 148 females, with a mean age of 67.5±4.5years) had been diagnosed with early esophageal cancer with different invasive depth. Out of 519 patients, about 478 patients were not found ESMGD by both examinations. Besides, postoperative pathology confirmed that 40 patients were identified with ESMGD, 34 patients of which were completely consistent with the preoperative diagnosis of EUS. Approximately 98.7% (512/519) of ESMGD were diagnosed exactly by EUS. Another six patients were estimated as false negative inaccurately, including two squamous cell carcinoma and four high-grade intrapithelial neoplasia. One case was regarded as ESMGD by EUS while confirmed not by pathology. Therefore, the EUS values for sensitivity and specificity for the diagnosis of ESMGD were 85.0% (34/40) and 99.8% (474/476) respectively. Furthermore, the positive predictive value was 97.1% (34/35), and the negative predictive value was 98.8% (478/484).

Conclusion: The esophageal submucosal gland duct involvement is a kind of lateral spreading superficial esophageal histologic pattern located in the thickened mucosa. EUS has a satisfactory diagnostic accuracy for ESMGD as well as good sensitivity and specificity.

Introduction: Few major international guidelines consider pepsinogen tests as the best available non-invasive tests to detect precancerous lesions (in particular, - corpus atrophy) in the stomach mucosa. Gastrin-17 (G-17) has been suggested as an alternative marker for antrectomy and different tests are used in Europe and Asia.

Recommendations from the European Commission expert group consider the need for additional studies before any screening with biomarkers can be recommended for implementation.

Aims & Methods: Generally healthy 40–65 years aged participants of the GISTAR pilot study referred for upper endoscopy according to the pilot study protocol were enrolled. Pepsinogen (Pg) I and II were assessed from plasma samples by two methods-ELISA (Biohit Plc.) and latex-agglutination (Eiken Chemical Co.) test systems. G-17 and IgG group antibodies to H.pylori infection were assessed by Biohit Plc. ELISA test systems. The following cutoff values were considered characteristic for atrophy: Pg I-II < 3 for ELISA, Pg I-II < 3 and PgI < 70 mg/ml for latex-agglutination, and G-17 >1 pmol/l (in a plasma sample obtained in fasting condition). Biopsies were sampled and read by two independent pathologists according to the updated Sydney system. OLG and OLGIM scoring systems were also applied. Cancer, dysplasia, OLGIM III-IV taken together were considered high-risk lesions.

Results: Altogether 1044 subjects (55% females, mean age =52, 67.7% with positive H. pylori antibodies) were included to the study. The sensitivity and specificity for detecting moderate to severe atrophy in the corpus for Biohit ELISA test was 47.2% and 92.3%, but for Eiken latex-agglutination test 81.1% and 62.1%, respectively. The corresponding values for G-17 to detect atrophy in the antrum were 29.2% and 58.9%. High-risk lesions were detected by Biohit ELISA pepsinogen test system with 22.8% sensitivity and 91.6% specificity. Recommendations from the European Commission expert group consider the need for additional studies before any screening with biomarkers can be recommended for implementation.

Introduction: Normally, resided within the submucosal layer of esophagus, each esophageal submucosal gland will culminate in a single duct. The esophageal submucosal gland ducts (ESMGD) can traverse the subepithelial connective tissue and access to the mucosa, and deliver the mucus secretions to the esophageal lumen. However, the clinicopathological features of the esophageal submucosal gland duct involvement (ESMGD) and its precursor lesion have not been comprehensively evaluated so far, and the series study focusing on endoscopic features of this lesion has not been reported widely. While since the 1990s, the esophageal lesions presumed to originate from ESMGDs had been described constantly in various case reports. Currently, in addition to the gold standard of histopathology, almost no more useful modality could be applied to this lesion. In our study, we considered that the ESMGD had a correlation with esophageal gland cancer, and we suspected that the ESMGD had special features under the endoscopic ultrasonography (EUS). The typical ultrasonic images of EUS could help diagnose ESMGD.

Aims & Methods: In order to investigate the clinical value of EUS for diagnosing Gastrointestinal stromal tumors (GIST) accompanied by early esophageal cancer, which were suggested by conventional endoscopy or biopsy, this study retrospectively analyzed the consecutive patients with early esophageal cancer diagnosed in the Endoscopy Center at the Affiliated Drum Tower Hospital, Nanjing, China from September 2009 to November 2019. The clinical data of 519 patients were included in this study, and all of them had already underwent EUS combined with Endoscopic Submucosal Dissection (ESD). The EUS preoperative examinations were compared with the results of postoperative pathology from ESD.

Results: According to the pathologic results of ESD, 371 (72.1%) patients (319 males and 148 females, with a mean age of 67.5±4.5years) had been diagnosed with early esophageal cancer with different invasive depth. Out of 519 patients, about 478 patients were not found ESMGD by both examinations. Besides, postoperative pathology confirmed that 40 patients were identified with ESMGD, 34 patients of which were completely consistent with the preoperative diagnosis of EUS. Approximately 98.7% (512/519) of ESMGD were diagnosed exactly by EUS. Another six patients were estimated as false negative inaccurately, including two squamous cell carcinoma and four high-grade intrapithelial neoplasia. One case was regarded as ESMGD by EUS while confirmed not by pathology. Therefore, the EUS values for sensitivity and specificity for the diagnosis of ESMGD were 85.0% (34/40) and 99.8% (474/476) respectively. Furthermore, the positive predictive value was 97.1% (34/35), and the negative predictive value was 98.8% (478/484).

Conclusion: The esophageal submucosal gland duct involvement is a kind of lateral spreading superficial esophageal histologic pattern located in the thickened mucosa. EUS has a satisfactory diagnostic accuracy for ESMGD as well as good sensitivity and specificity.

The expression levels of miR-211-5p were significantly decreased in vitro. miR-211-5p in proliferation, apoptosis, migration of gastric cancer cell lines gastric mucosa by RT-PCR. Furthermore, we investigate the biological role of miR-211-5p was measured in paired primary gastric cancer with corresponding adjacent tissues in non-small cell lung cancer by targeting SRCIN [5]. Therefore, the functional role of miR-211-5p in the development of gastric cancer. The expression level of miR-211-5p was still unclear. We hypothesized that miR-211-5p in proliferation, apoptosis, migration of gastric cancer cell lines in vitro.

Results: The expression levels of miR-211-5p were significantly decreased in gastric cancer and low expression of miR-211-5p correlates with poor prognosis in gastric cancer patients. Ectopic expression of miR-211-5p suppressed proliferation, migration and induced apoptosis in gastric cancer cells in vitro. Bioinformatics and quantitative analysis revealed that FoxC1 might be a target of miR-211-5p. Downregulation of FoxC1 inhibited proliferation and migration of gastric cancer cells and Overexpression of FoxC1 partly abrogated the inhibitory effects of miR-211-5p on gastric cancer cell proliferation and motility.

Conclusion: We hypothesize that miR-211-5p acted as a tumor suppressor by targeting FoxC1 in gastric cancer and miR-211-5p might be a potential target for the treatment of gastric cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

associated, in our series, with a higher incidence of residual/recurrent adenoma, when compared to other recurrent cancers but these results are similar to those reported in the literature. Residual and recurrent duodenal adenomas were successfully treated by EMR in all of them but one. Mortality related to NASDA was absent in our series after a median follow-up of 59 months (range 1–147). Management of severe events after EMR for NASDA requires the availability of interventional radiologists and surgeons with experience in retroperitoneal surgery. In our experience colorectal adenomas was correlated to NASDA (33.3%), colonooscopy is considered part of the pre-EMR assessment when NASDA is diagnosed. A recall system and patient’s compliance to endoscopic follow-up are mandatory to detect recurrences and their prompt treatment.

Introduction: Obestatin is a bioactive peptide with a well-defined function on cell proliferation mediated by the GPR39 receptor. Our data involve this system in several processes located in the stomach: from pepsonogen secretion in healthy stomach to malignant proliferation in gastric adenocarcinomas (1). A key step in obestatin signaling is the transactivation process GPR39-RTK through MMPs activation. This step could imply a key mechanism by which MMPs regulate these diseases. Numerous studies have shown that alterations in the expression or/mutations in members of the family of receptors EGFR/ErbB are present in these diseases. Numerous studies have shown that alterations in the expression and/or mutations in members of the family of receptors EGFR/ErbB are present in these diseases. Numerous studies have shown that alterations in the expression of interventional radiologists and surgeons with experience in retroperitoneal surgery. In our experience colorectal adenomas was correlated to NASDA (33.3%), colonooscopy is considered part of the pre-EMR assessment when NASDA is diagnosed. Aims & Methods: The aim of this study is to analyze whether indomethacin modulates lysosomal function and oxalipatin-induced cell death in these cells. Gastric AGS cells were treated with increasing concentrations of indomethacin for 2, 6 and 20 hours. Lysosomal pH was assessed by using Lysotrack Red and Acidine orange fluorescent probes (static cytomtery). Cathepsin activity was determined by using Omnicathepsin fluorescence substrate. In cells treated with indomethacin for 2 hours LAMP2 immunostaining was also carried out. In another set of experiments AGS cells were treated with increasing doses of the antiinflamatory drug oxaplatin and combined with indomethacin. Cell viability was measured by an MITT assay, the rate of apoptosis/necrosis was analyzed by means of the Apotosis Detection Kit, and autophagy by p62 immoblotting.

Results: Treatment of AGS cells with indomethacin decreased Lysotracker fluorescence in AGS cells after 2, 6 and 20 hours. Indomethacin also produces an acute reduction in lysosome-derived fluorescence of acidrine orange after 2 and 6 hours of treatment. In addition, we observed a significant reduction of cathepsin enzymatic activity in cells treated with indomethacin for 6 or 20 hours. Furthermore, there was an altered distribution of LAMP2-positive dots from the perinuclear position observed in control cells to a peripheral position in cells treated with indomethacin. Taken together, these data suggest that indomethacin inhibits the activity of lysosomal acid hydrolases by increasing lysosomal pH. On the other hand, oxaplatin decreased cell viability in a dose-dependent manner after 48 hours of treatment, and treatment of cells with indomethacin during the last 24 hours further decreased cell viability. In addition, indomethacin also increased the rate of apoptosis and necrosis in AGS cells treated with oxaplatin. Finally, indomethacin blocked the autophagic degradation of p62 protein induced by oxaplatin.

Conclusion: Indomethacin inhibits lysosomal function in gastric cancer cells. This could affect the inhibitory action on autophagy and the resultant increase in susceptibility to cytotoxic drugs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The mechanisms of gastric carcinogenesis, especially of diffuse type of gastric carcinoma (GC) are poorly understood. The cancer stem cells (CSC) represent a particular fraction of cancer cells, considered at the origin of cancer and responsible for its development. The enteric nervous system (ENS) is a newly recognized component of tumor microenvironment and its role in carcinogenesis has been recently suggested. In particular, the role of acetylcholine (ACh), a major neuromediator released by enteric nerves, has been suggested in gastric carcinogenesis but its effect on gastric CSC remains to be established.

Aims & Methods: Our aim was to study the effect of ACh on gastric cancer cells, and in particular its capacity to induce the stem cell phenotype, and to study the mechanisms involved. Adenocarcinoma gastric epithelial cells MKN-45 were first cultured in adherent conditions in the presence of ACh (0.1-10-5M), before being cultured in non-adherent condition in order to favour expansion of CSC and formation of tumorspheres (T). The effect of ACh on T formation was evaluated under microscope by quantifying the number and size of T. ACh was applied to the System snapshot file in INCell analyzer 2200/6000. The involvement of different cholineergic (muscarinic and nicotinic) receptors in ACh-induced responses was studied by pharmacological approach using selective agonists and antagonists. The expression of CSC markers (CD44, ALDH) and EMT markers (Snail, Zeb1) was measured by flow cytometry, RT-qPCR and immunofluorescence. Statistical analysis was performed using two-way ANOVA test, Kruskal-Wallis test, or two-way non-parametric ANOVA test using SPSS16.0 software.

Results: ACh at concentrations of 0.1 and 1mM significantly increased the number and size of T as compared to control conditions (p < 0.001).

Conclusion: This study shows that ACh induces CSC properties of gastric cancer cells of diffuse type via activation of muscarinic and nicotinic pathways. It also suggests that ENS may be a new actor in gastric carcinogenesis.

Introduction: CpG Island Methylation Phenotype (CIMP) has been identified as a distinct molecular subtype of gastric cancer, yet associations with survival are conflicting. A meta-analysis was performed to estimate its potential prognostic significance.

Aims & Methods: A systematic review of Embase, Medline, PubMed, PubMed Central and Cochrane databases related to CIMP in gastric was performed and the primary outcome measure was cumulative 5-year survival.

Results: A total of 967 patients from 10 studies were included, and the median rate of tumour CIMP-H was 40.9% (range 53.6-62.7%). Pooled analysis suggested that specimens exhibiting CIMP-H were associated with poorer 5-year survival (OR 1.49, 95% CI 1.11-2.10, p < 0.005).

Conclusion: There was significant heterogeneity in the gene panels used to identify CIMP which may explain the survival differences. Consensus regarding CIMP methodology would be welcome to better facilitate the assessment of its prognostic validity.

Introduction: The BreathDx/Hp lab breath test (UBT) system provides several advantages over other 13C breath analyzers for the detection of Helicobacter pylori (H. pylori), including: higher accuracy, operator independence and immediate results. However, there are occasions when mailing or transporting saved breath samples may be preferable to real time analysis, especially in centers requiring a large quantity of automated analyses where continuous sampling from a single patient can provide a bottle neck preventing multiple other users from accessing the device.

Aims & Methods: To evaluate the sensitivity and specificity of a new BreathDx/Hp Lab System (Exalenz Bioscience Ltd, Modin, Israel), a 13C-UUBT system using breath sampling bags, for the diagnosis of H. pylori in a multi-center international clinical study. A total of 257 subjects with evaluable results for UBT and biopsy [rapid urease testing (RUT) and histology] were enrolled into two study groups: 189 native subjects with unknown H. pylori status were included in the pre-therapy group, and 68 subjects who had completed pre-therapy therapy and post-therapy sample. The post-therapy group was assessed for the stability of the breath samples in the breath sample bags, each pair of breath sample bags was analyzed at a different time point up to 14 days after collection. Analytical studies were conducted to evaluate the reproducibility and repeatability of the 13C-UBT results using a cut-off of 5 Delta Over Baseline (DOB).

Results: Among the pre-therapy subjects evaluated with the composite results from the two biopsy based methods (RUT and histology)/immunohistochemistry (IHC), 86 results (37 positive, 49 negative) matched those of the UBT resulting in an overall agreement of 98.3% (95% CI: 95.2%; 99.7%) with a sensitivity of 100% (95% CI: 90.6%; 100.00%) and specificity of 97.9% (95% CI: 94.0%; 99.3%). The overall agreement between the UBT and the biopsy diagnosis in the post-eradication therapy cohort (55 negative, 13 positive) was 98.5% (95% CI: 92.1%; 100.00%). The sensitivity of the UBT in this cohort was 92.3% (95% CI: 66.7%; 98.6%) and its specificity was 100.0% (95% CI: 93.3%; 100.00%). The overall validity evaluated in sample size of 191 (45 positive, 146 negative) subjects from the pre-therapy cohort was excellent, with positive agreement in 97.8% (95% CI: 88.43, 99.61)) and negative agreement in 100.0% (95% CI (97.44, 100.0)). Similarly there was uniformly high overall reproducibility of the test results over different batches, when analyzed on different days and under different storage conditions.

Conclusion: The validation studies of the BreathDx/Hp Lab System described above show it is a highly accurate and dependable method for the diagnosis of H. pylori infection. Based on the current study, BreathDx/Hp Lab System received on November 2016 U.S. Food and Drug Administration (FDA) marketing clearance for H. pylori bacterium detection.

Disclosure of Interest: H. SHIRIN: Haim Shirin received grants and stock from a single patient can provide a bottle neck preventing multiple other users from accessing the device.

Aims & Methods: In this study, we investigated whether activation of gGlu-HMRG fluorescence was suppressed in H. pylori culture solution which was co-incubated with an inhibitor of GGT (GGTTop). Furthermore, we applied gGlu-HMRG to biopsy specimens which were taken from antrum and corpus of stomach in H. pylori positive patients (n = 13) and H. pylori negative patients (n = 14). We then observed the increase of fluorescence intensity over time (1 min, 5 min, 10 min, 15 min). Fluorescence intensity was quantified by Image J2 software (National Institutes of Health, Rockville, Maryland).12

Results: Activation of gGlu-HMRG fluorescence was detected in WT strain, but was not in ggt mutant strain. Activation of gGlu-HMRG fluorescence was inhibited by GGTTop. There was significant difference of the increase of fluorescence intensity between H. pylori positive and negative both in antrum corpus of stomach (antrum p = 0.0008, corpus p = 0.047).

Conclusion: GGT-activated fluorescent probe can be useful for H. pylori infection diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1903 SEROLOGICAL CHANGES AFTER EQUIVOCA
HELICOBACTER PYLORI-SEROLOGY TEST FINDINGS DEPEND ON THE GASTRIC SECRETING ABILITY
J.H. Kim, S. Lee, S.P. Lee, J.H. Kim, I. Sung, H.S. Park, C.S. Shim Internal Medicine, Gastroenterology, Konkuk University Hospital, Seoul/Korea, Republic of
Contact E-mail Address: kjhcess@gmail.com

Introduction: The serum anti-Helicobacter pylori (H. pylori) IgG and serum pep- sinogen (PG) assays are widely used for gastric cancer screening. An equivocal serology test finding indicates IgG titers or the positive and negative results. We then observed the increase of fluorescence intensity over time (1 min, 5 min, 10 min, 15 min). Fluorescence intensity was quantified by Image J2 software (National Institutes of Health, Rockville, Maryland).12

Results: Of the 7,178 subjects who underwent the serum assays and UGI endo-
scopy on the same day, 274 (3.8%) subjects showed an equivocal H. pylori serology test finding. Of the 98 followed-up subjects, 58 (59.2%) showed sero- positive finding at the mean follow-up period of 30.6±12.4 months. Subjects with seroconversion showed a higher initial serum PG I (p = 0.023) and PG II (p = 0.036) levels than the subjects without seroconversion.

Conclusion: An equivocal H. pylori serology test finding is not rare (3.8%) in Korean adults, and 60% of the equivocal subjects showed seroconversion within 3 years. Higher seroconversion rates in the subjects with high PG I and PG II levels suggest that intact gastric secreting ability play a role for the survival of H. pylori. Therefore, equivocal subjects with increased serum PG levels should be considered as a potential seropositive subjects.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: γ-glutamyltranspeptidase (GGT) is a cell surface-associated enzyme that is not highly expressed in normal cell. However GGT is overexpressed in various type of human cancers. It is known that Helicobacter pylori (H. pylori) also produce GGT. Urano et al have developed an enzymatically activatable fluorescent probe, γ-glutamyl hydroxymethyl rhodamine green (gGlu-HMRG) which is fluorescent under acidic pH and normal cellular environment, but turns to be highly fluorescent upon reaction with GGT13. Aim of this study is to consider if gGlu-HMRG can be useful for diagnosing infection H. pylori.

Aims & Methods: In this study, we investigated whether activation of gGlu-HMRG fluorescence detects a wild-type of H. pylori (WT) and a ggt gene disrupted mutant of H. pylori (ggt mutant). In addition, we investigated whether activation of gGlu-HMRG fluorescence was suppressed in H. pylori culture solution which was co-incubated with an inhibitor of GGT (GGTTop).

Results: Of the 7,178 subjects who underwent the serum assays and UGI endoscopy on the same day, 274 (3.8%) showed an equivocal H. pylori serology test finding. Of the 98 followed-up subjects, 58 (59.2%) showed sero-positive finding at the mean follow-up period of 30.6±12.4 months. Subjects with seroconversion showed a higher initial serum PG I (p = 0.023) and PG II (p = 0.036) levels than the subjects without seroconversion.

Conclusion: An equivocal H. pylori serology test finding is not rare (3.8%) in Korean adults, and 60% of the equivocal subjects showed seroconversion within 3 years. Higher seroconversion rates in the subjects with high PG I and PG II levels suggest that intact gastric secreting ability play a role for the survival of H. pylori. Therefore, equivocal subjects with increased serum PG levels should be consid- ered as a potential seropositive subjects.

**Introduction:** Several *H. pylori* (HP) infection-related gastric findings (mucosal atrophy, metaplastic change, diffuse redness, spotty redness and nodular change of the antrum etc.) are so important sign of HP infection on endoscopic examination. On the other hand, we have confused with various newly endoscopic findings as coronary reflux and map-like redness etc. were seen on the stomach eroded atom. On this time, we have found out a new other ultimate useful finding showing HP infection related gastritis at gastric cardia (EG junction) including present and post HP infection. The endoscopic image of gastric cardia is the first gastric view through the esophagus on each endoscopic examination.

**Aims & Methods:** Our aim of this study is to elucidate possibility of judgement with only this cardiac endoscopic view about presence or absence with HP infection. We have found out so useful and specific cardiac image (We call Whale Shark Sign: WSS) closely related to HP infection. We have examined the presence of WSS on 4,268 cases that have been able to overviewed on their endoscopic profiles. We have judged the presence of HP infection with serum HP antibody titers on each case. The 3,233 cases their serum HP antibody titers were measured from Jan. 2012 to Oct. 2016. A total of 2,810 patients (HP positive) were enrolled. Fisher’s exact test was used in all statistical analyses. The judgement of HP present or past infection was done more than serum HP antibody 3 U/ml to avoid false negative results.

**Results:** Mean age of patients was 52.4 years old. In case of WSS positive, all their serum HP antibody titers showed more than cut-off level (3 U/ml). This means that the presence of WSS closely related to HP related gastritis. The positive predictive value (PPV) of WSS was surprisingly high (98%). According to this high PPV, we can think WSS positive cases are high risk of gastric carcinoma. This WSS mean that the presence of irregular gastric mucosal surface pattern and the presence of lymphoid hyperplasia, that showing HP infection or gastritis stomach. Especially presence of lymphoid hyperplasia at gastric cardia is most important specific sign of HP related gastritis. This lymphoid hyperplasia at gastric cardia were recognized small round whitish nodules on white light endoscopy. And this was more emphasized with image-enhanced endoscopy (Narrow Band Imaging; NBI), it looks like Whale Shark. This WSS sign is very simple and easy for every gastroenterologist. It is so useful to know gastric cancer risk at gastric entrance (cardia) with the presence of very easy simple sign.

**Conclusion:** We have been able to judge the presence of HP infection with only cardiac endoscopic images (WSS), we should take care of seeing the presence of WSS sign. Since this sign is very easy and simple, everyone will be able to judge the presence of HP infection and gastric cancer risk.

**Introduction:** The diagnosis of *Helicobacter pylori* (H. pylori) infection is currently made by means of non-invasive (Urea Breath Test or HpSA) or invasive (gastric biopsy or culture) methods. Serological assessment of H. pylori infection by using levels of IgG is not recommended. Pepsinogen II (PGII) is validated in the literature as a non-invasive marker of gastritis. The aim of this study was to assess in a population of dyspeptic patients the clinical availability of PGII determination in singling out subjects infected by H. pylori in comparison with non-infected ones.

**Aims & Methods:** A cohort of 880 consecutive dyspeptic patients (F 439; mean age 55.5 yrs; range: 29.83-74 yrs) were enrolled in the study. Exclusion criteria: previous surgery, previous H. pylori eradication therapy, concomitant PPI. In all patients the diagnosis of H. pylori infection was made by means of upper GI endoscopy and at least one of these two methods: UBT, HpSA. All patients underwent blood sample for determination of serum levels of PGII (Bohlt Oyj; Finland; normal values: 2-15μg/l). In a group of 670 pts a course of antibiotics (triple, concomitant or sequential therapy) to cure H. pylori infection was performed and PGII levels tested at baseline (T0) and after two months (T1) from the end of the antibiotic therapy. The search for the most appropriate cut-off of PGII in diagnosis of H. pylori infection was assessed by using the ROC curve method.

**Results:** 430 out of 860 dyspeptic patients (F 245;mean age 52.3 yrs; range 32-69 yrs) showed an H. pylori-related gastritis (group 1) in comparison with 430 (F 261;mean age 57.3 yrs; range 38-74 yrs) resulted negative for H.p infection (group 2). The mean value of PGII in group 1 was 20.9+1.485 μg/l, opposite to 7.2+0.985 μg/l in group 2; p<0.0001. 415 out of 670 patients treated with antibiotics schedules were cured from H.p infection, opposite with 255 non-eradicated ones. In the group 1, C. miraglia1, S. scida1, A. violi1, M. franceschi2, G. baldassarre3, M. rugge4, P. crafa5, A. tursi6, G. brandimarte7, L. franzoni8, N. dal bo9, R. cannizzaro10, C. scarpignato2

Introduction: The Urea Breath Test (UBT) is considered the gold standard non-invasive test for detection of Helicobacter pylori infection in Ireland. In Ireland, eradication rates for standard clarithromycin-based triple therapy have fallen below the 80% deemed acceptable for a given treatment. With this in mind, it is important to optimise management of H. pylori infection. It has been suggested that the DOB value is reflective of the amount of bacteria present in the stomach and could predict whether the infection is eradicated.

Aims & Methods: The aim of this study was to determine whether there is an association between DOB and eradication of H. pylori infection in an Irish cohort. Treatment naïve adult patients undergoing UBT were included. Patients were deemed to be H. pylori positive if a Delta Over Baseline (DOB) value of > 20 % was obtained. Positive patients were categorised into low (< 16%), intermediate (16-35 %), and high (> 35 %) DOB groups. A random subset of positive patients was given clarithromycin-based triple therapy for 7 days. A follow-up breath test was performed at least 8 weeks post-treatment to confirm eradication of H. pylori in all patients. The three DOB groups were compared with respect to age, gender and eradication rates.

Results: Out of 860 of UBTs assessed (mean age 43.1 ± 14.8 years, 39% male), 289 (33.6%) were positive (mean age 43.1 ± 14.9 years, 41.9% male). Of the total positive patients, 91 (31.5%) returned for a follow-up UBT to confirm eradication of H. pylori. When patients were categorised into low, intermediate and high UBT groups, there was no significant difference in age and gender between groups (p = 0.06 for age and p = 0.3 for gender). Eradication rates in the low, intermediate and high UBT groups were 70.5%, 63.0% and 50.0% respectively (p = 0.3). Patients were then categorised according to eradication status. When eradication was successful, the average DOB value was significantly higher in the low DOB groups compared with the high DOB groups (p = 0.03, 95% CI 0.69 to 17.5). 46 (50.5%) patients were given clarithromycin-based triple therapy for 7 days. When this subset of patients was categorised into low, intermediate and high UBT groups, eradication rates were 76.5%, 72.2% and 66.7% respectively. When these rates were compared to respective rates in those whose treatment was not known, no difference was observed. The subset was also categorised according to eradication status. When eradication was successful, the average DOB value was lower, at 22.0% compared with when eradication was unsuccessful (p = 0.6). Similarly, when these DOB values were compared to respective values in whose whose treatment was not known, no difference was observed.

Conclusion: As the DOB value increases in the UBT, the eradication rate of H. pylori decreases, regardless of treatment regimen. When categorised according to eradication status, the DOB value was significantly lower when eradication was unsuccessful (20.6 % vs 29.8%, p = 0.03). The DOB value could be a useful value in stratifying patients with H. pylori infection; especially as histology and antimicrobial resistance information is unavailable in patients undergoing non-invasive testing for H. pylori infection.

P1908 COMPARISON OF THE EFFICACY BETWEEN BISMUTH AND ALTERNATING RIFAXIMIN ON SECOND-LINE QUADRUPLE REGIMEN OF HELICOBACTER PYLORI ERADICATION

Digestive Disease Center, Institute For Digestive Research, Soochunhyang University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: junsarok@schm.ac.kr

Introduction: Bismuth is a heavy metal which has antimicrobial activity through inhibiting bacterial biofilm formation. Therefore, bismuth is one of the attractive agents in the treatment of Helicobacter pylori (H. pylori) infection which is highly susceptible to bismuth. So the Korean guideline preferably recommends the regimen contains bismuth for the patients who failed on H. pylori eradication with the primary regimen consists of proton pump inhibitors, amoxicillin, and clarithromycin therapy. Rifaximin is one of derivatives of rifamycin with antimicrobial activity against H. pylori. It can achieve high concentrations within the gastrointestinal tract and remains active in acidic environment. So rifaximin has been studied as a treatment for persistent H. pylori infection. Rifaximin has been prescribed for replacing the bismuth of the regimen concurrently uses PPI, metronidazole, and tetracycline in Soochunhyang University Hospital, Seoul for a while. So we reviewed the clinical outcomes of the 2 different regimens.

Aims & Methods: From May 1st 2003 to October 31st 2015, six thousand and five hundred ninety-five patients were treated their H. pylori infection in Soochunhyang University Hospital, Seoul. And their prescriptions and result of eradication were retrospectively reviewed on the medical records. The patients had clarified pre-and post-eradication result, which can be assured by the rapid urease test performed within 10 days of eradication were enrolled. And statistical analyses were performed to the patients who had second-line treatment to compare the efficacy of the bismuth containing regimen and the rifaximin containing one.

Results: During the periods over 12 years, two thousand and seven hundred and forty-two patients were prescribed the standard triple eradication regimen and two thousand and eighty-nine (78.11%) patients showed the successful treatment result. One hundred twenty-six (4.10%) treatment failure group were consecutively treated with second-line regimen. Thirty-five patients were prescribed the bismuth-containing regimen and 34 (97.14%) of them showed successful eradication result. Other 91 patients were treated with the rifaximin-containing regimen and showed 92.31% of eradication rate. The treatment success rates are not different significantly in statistics.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1909 COMPARISON OF 10-DAY STANDARD TRIPLE THERAPY AND LEVOFLOXACIN BASED THERAPY FOR HELICOBACTER PYLORI ERADICATION: RANDOMIZED CONTROLLED TRIAL

Introduction: Standard triple therapy (STT) has been widely used in Helicobacter pylori (H. pylori) infection, but eradication rate is decreasing because of clarithromycin resistance. Recently, Levoflaxacin-based therapy (LBT) has been evaluated to overcome the low eradication rate of standard triple therapy and reported eradication rate over 80%. Aims & Methods: We compared the efficacy and safety of STT group and LBT group for Koresians. Between April 2014 and April 2016, 49 patients in the STT group (amoxicillin 1 g bid, clarithromycin 500 mg bid and omeprazole 20 mg bid for 10 days) and 48 in the LBT group(levofloxacin 500 mg bid, amoxicillin 1 g bid,
P1910 TREATMENT OF HELICOBACTER PYLORI INFECTION: WILL TAILORING THERAPY FIRST TIME OVERCOME INCREASING FAILURE OF STANDARD TRIPLET THERAPY?

Trinity Academic Gastroenterology Group, Trinity College Dublin, Dublin/Ireland

Contact E-mail Address: dbrennan9@tcd.ie

Introduction: In Ireland, Helicobacter pylori infection has become increasingly resistant to commonly used antibiotics, such as clarithromycin. Concurrently, eradication rates for standard clarithromycin-based triple therapy have fallen below the 80% deemed acceptable for a given treatment. Aim: The aim of this study was to compare eradication rates of standard clarithromycin-based triple therapy with those of tailored therapy based on antimicrobial susceptibility as a first-line treatment for H. pylori infection. Treatment-naïve adult patients undergoing endoscopy were prospectively recruited. Biopsies from H. pylori-positive patients (assessed by CLO test) were processed for sensitivity testing by E-testing and genotyping by the GenoType HelicoDR assay (Hain). Patients randomly received either clarithromycin-based standard triple therapy or tailored treatment based on antibiotic sensitivities, for 7-14 days. A follow-up breath test was performed at least 8 weeks post-treatment. Results: To date 889 patients have undergone endoscopy and 186 (21%) were H. pylori positive. Infected patients were significantly younger (mean age 53 vs 49 years, p = 0.002) and tended to be male (43% vs 53%, p = 0.02). Of 186 H. pylori-positive patients, 112 (60%) were treatment naïve. Culture of H. pylori was successful in 57% (64/112) of samples and primary clarithromycin resistance was 47% (30/64) by E-test. Genotypic resistance data was available for 93% (104/112) patients and 55% (61/114) strains were clarithromycin resistant. Thus far, 99 (88%) treatment naïve patients have been enrolled in the study; 92 (93%) have completed the study. Of these, 45 (46%) have received standard triple therapy and 54 (54%) have received tailored therapy. In the tailored arm, 25 (46%) patients received standard triple therapy, 14 (26%) received levofloxacin-based triple therapy, 13 (22%) received a PPI and combination of antibiotics based on their sensitivities (e.g. levofloxacin, clarithromycin, rifampicin, tetracycline or metronidazole), and 3 (6%) bismuth quadruple therapy. The eradication efficacy of tailored therapy by intention-to-treat analysis was higher at 74% (40/54) compared to 67% (n = 30/45) for standard therapy (p = 0.5). The eradication efficacy by per-protocol analysis was also higher, at 82% (40/49) for tailored versus 70% (30/43) for standard therapy (p = 0.2). Patients in each arm were further categorised by clarithromycin resistance status, phenotypically by E-test or genotypically by the GenoType HelicoDR assay. Of note, in clarithromycin resistant patients, tailored therapy achieved a better eradication rate per protocol analysis than standard triple therapy (83% vs 57% per protocol, p = 0.09). Conclusion: Those who are sensitive to clarithromycin, standard clarithromycin-based triple therapy achieves an acceptable eradication rate of approximately 81%. However, a high primary clarithromycin resistance rate was observed in this study (47%). In those who are resistant to clarithromycin, prescribing a regimen based antibiotic susceptibilities increases eradication rates to 83%, compared to those treated with standard triple therapy (57%, p = 0.09).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1912 ARE PROBIOTICS USEFUL AS ADJUVANTS IN ERADICATION THERAPY OF HELICOBACTER PYLORI INFECTION?

Introduction: Helicobacter pylori (Hp) successful eradication has been considered since it contributes to several gastrointestinal disorders. Sequential therapy has been used widely as the first approach in Hp eradication therapy (HpET). However, its failure is 10-45%. The addition of probiotics has been considered because of potential benefit in the improvement of efficacy and reduction of side effects during HpET. Aims & Methods: We aimed to evaluate the effect of probiotics, as adjuvants to sequential HpET on treatment efficacy, side effects and patient compliance. This was a prospective study of total of 1159 patients followed in a gastroenterology outpatient clinic. Selected patients undergone Hp screening for unexplained gastrointestinal symptoms or disorders with HpET indication. Comparing patients under sequential therapy (10-day treatment of 5 days of pantoprazole + amoxicillin followed by further 5 days of pantoprazole + clarithromycin + metronidazole)G1-n=85 and patients with additional supplement of Lactobacillus reuteri probiotics therapy 2tab/day in previous two weeks and during treatment (G2-n=77), since it was approved for this indication. Screening Hp test and indication, eradication rate, auto-reported side effects and patient compliance were evaluated. The overall HpET screening Hp test, 147(55.5%;147/265) were positive, being the majority obtained by gastric biopsy (86.0%;n=228). The mean age was 58.6±15.8 years with female predominance (60.8%;n=161). The main indications for Hp screening were dyspepsia (27.9%), epigastric pain (24.2%), gastroduodenal peptic ulcer disease (19.2%) and gas-troesophageal reflux disease (15.8%). At gastric biopsies, chronic gastritis was present in 61.5% (n=163), gastric atrophy in 17.0% (n=45) and intestinal metaplasia in 7.9% (n=21), with Hp mild colonization in most cases (58.5%;76/130). Eradication rate was significantly higher in patients who had probiotic supplement (G1-74.1%n=G2-92.2%;p=0.002;OR = 4.132). No significant difference was verified between two groups in relation to side effects (G1-15.3%n=G2-9.1%;p=0.094) or patient non-compliance (G1-2.4%n=G2-
P1913 THE IMPACT OF CLOSTRIDIUM BUTYRICUM MIYAIRI-588 ON HELICOBACTER PYLORI ERADICATION THERAPY

Departement Of Gastroenterology And Hepatology, Kyoto Prefectural University of Medicine, Kyoto, Japan

Contact E-mail Address: shunt02@koto.kpu-m.ac.jp

Introduction: As a country with high incidence of gastric cancer, the elimination of Helicobacter pylori (HP) is useful strategy for the prevention of gastric cancer in Japan. And the eradication therapy for HP-infected gastritis was approved as an insurance indication since 2013, and virtually all HP-infected patients were simultaenously eradicated by the therapy using proton pump inhibitor (PPI)/amoxicillin (AMPC)/clarithromycin (CAM) has been used as a regime for the primary eradication therapy. Since HP has rapidly acquired the resistant character against CAM, the eradication rate has gradually been decreasing. Recently, PPI/CAM, a novel probiotic, has been used as an alternative eradication therapy. Successful rate of HP eradication was 81.7% in the PPI group, 89.8% in the VPZ group and 94.9% in the MBM group. The eradication rate in VPZ group was not significantly higher than that of PPI group, and there was no significant difference between 3 groups.

Aims & Methods: The objective of this study is to compare, in Morocco, an eradication therapy using probiotics, _Clostridium butyricum_ Miyairi-588 (MBM) on PPI-based triple therapy comparing the eradication rate and side effect with VPZ-based triple therapy. From January 2015 to December 2016, patients who received HP primary eradication therapy in our hospital were retrospectively evaluated. They were divided into 3 groups: 1) patients who received PPI + AMPC + CAM therapy (PPI group), 2) patients who received VPZ + AMPC + CAM therapy (VPZ group), 3) patients who received PPI + AMPC + CAM + MBM therapy (PPI + MBM group), and the eradication rate and side effects were evaluated. A study on the number of patients enrolled in this study were 468: 150 cases in the PPI group, 271 cases in the VPZ group and 47 cases in the PPI + MBM group. Successful rate of HP eradication was 81.7% in the PPI group, 89.8% in the VPZ group and 89.1% in the PPI + MBM group. The eradication rate in VPZ group was significantly higher than that of PPI + MBM group. The rate of side effect was 17.4% in the PPI group, 10.0% in the VPZ group and 19.1% in the PPI + MBM group, and there was no significant difference between 3 groups.

Results: The number of patients enrolled in this study were 468: 150 cases in the PPI group, 271 cases in the VPZ group and 47 cases in the PPI + MBM group. Successful rate of HP eradication was 81.7% in the PPI group, 89.8% in the VPZ group and 89.1% in the PPI + MBM group. The eradication rate in VPZ group was significantly higher than that of PPI + MBM group. The rate of side effect was 17.4% in the PPI group, 10.0% in the VPZ group and 19.1% in the PPI + MBM group, and there was no significant difference between 3 groups.

Conclusion: This study shows that _Clostridium butyricum_ Miyairi-588 can have additive effects in PPI-based triple therapy for HP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1915 “CONCOMITANT” OR “SEQUENTIAL” THERAPY FOR THE ERADICATION OF HELICOBACTER PYLORI: WHICH REGIMEN COMES FIRST IN MOROCCO?

Introduction: The eradication of Helicobacter Pylori remains crucial because of its constantly evolving data. The recent recommendations of Maastricht V stipulate that the concomitant quadritherapy and the bismuth quadruple therapy are more efficient than the sequential therapy because of a higher rate of eradication (90% vs 82%), but with more important side effects. The aim of our study is to investigate the effects of the Saccharomyces boulardii supplementation to the sequential therapy on Helicobacter pylori eradication rate and associated therapy side effects.

Aims & Methods: One hundred ninety nine patients with Helicobacter pylori infection documented on a histological study of gastric biopsies were enrolled from May 2013 to May 2016, on a single center, prospective, controlled and randomized study, performed in the Gastro Entérology II department on the military hospital of Rabat. Using a permuted block randomization, our patients were assigned to one of the following groups: a control group receiving the standard sequential therapy, and an experimental group receiving in addition to the sequential therapy Saccharomyces boulardii 20 mg orally and daily during the ten days of regimen. All the patients were reviewed in the end of the therapy to evaluate the adherence to treatment and the incidence and severity of side effects. The eradication of Helicobacter pylori was evaluated by _13C-urea breath_ test 4 to 6 weeks after the end of the protocol. Statistical analysis was performed by the software SPSS 20.0. A model of logistic regression was performed to analyse the effects of Saccharomyces boulardii supplementation on eradication rate and side effects.

Results: There was no significant difference between the two groups on age (middle age = 44.3 ± 13.8years vs 43.1 ± 13.2years), gender (sex ratio M/F = 1.15 vs 1.05), medical antecedents, smoking, endoscopic and histological data. In Intention To Treat ITT and Per Protocol PP analysis, the eradication rate was significantly higher in the experimental group (86.6% ITT, 87.5% PP), comparing to the control group (78.2% ITT 74.7% PP), p = 0.02. Moreover, the Saccharomyces boulardii supplementation allowed a significant reduction of the incidence of overall side effects (RR = 0.26, IC95% [0.14–0.47], p < 0.001), and the incidence of antibiotic-associated diarrhea (RR = 0.70, IC95% [0.28–2.0], p < 0.001). The incidence of nausea and vomiting, dizziness, asthma and metallica toxicity was also lower in the experimental group, although the differences were not statistically significant. In the multivariate analyse, the Saccharomyces bouardii supplementation was associated with an optimization of the eradication rate (RR = 2.4, IC95% [0.19–1.09], p = 0.02), and with a reduction of the antibiotic-associated diarrhea AAD (RR = 0.07, IC95% [0.02–0.26], p < 0.001). Conclusion: Our study shows that the Saccharomyces boulardii treatment during sequential therapy in Helicobacter pylori regimen is associated with a significant reduction of side effects and particularly the antibiotic-associated diarrhea, and allows an optimization of the eradication rate of Helicobacter pylori.

P1916 PROSPECTIVE COMPARATIVE STUDY OF TWO FIRST-LINE REGIMENS FOR HELICOBACTER PYLORI ERADICATION: 14-DAYS NON-BISMUTH QUADRUPLE OPTIMIZED CONCOMITANT THERAPY VERSUS 10-DAYS BISMUTH-CONTAINING QUADRUPLE THERAPY USING A TREATMENT CAPSULE

Department Of Digestive Diseases, Miguel Servet University Hospital, Saragossa/Spain

Contact E-mail Address: jaledo@telefonica.net

Introduction: The Maastricht V/Florence Consensus Report recommends bismuth quadruple or non-bismuth quadruple concomitant therapies as first-line treatments for _H. pylori_ infection, in areas where clarithromycin resistance is high (>15%), Head-to-head studies between both therapies are needed. Aims & Methods: We aimed to compare compliance, efficacy and adverse effects of two first-line _H. pylori_ eradication therapies in a high clarithromycin resistance setting.
area, and in clinical practice. A prospective study was performed in a Spanish center recruiting consecutive naïve adult patients, candidates to H pylori eradication. Omeprazole 40mg, Clarithromycin 500mg, Amoxicillin 1g and Metronidazole 500mg, all drugs b.i.d, for 14 days (OCAM); or Omeprazole 20mg b.i.d and 3-in-1 capsule with Bismuth 140mg + Tetracycline 125mg + Metronidazole 125mg. 3 capsules q.i.d, for 10 days (3–1-OBMT) were prescribed according to physician criteria. Compliance was assessed by striking the consumed doses in a patient filled template, and adverse effects using a specific questionnaire with a 1–3 intensity scale. Efficacy was determined by 13C-urea breath test. A descriptive study and analysis of efficacy by intention to treat (ITT) were performed. Cases with poor therapeutic compliance (<80%) or no available data were excluded in per-protocol (PP) analysis. Chi2, Student’s t, and Mann-Whitney U tests with significance level p < 0.05 were applied. The payment was approved by the Ethics Committee.

Results: 216 patients (63.43% women; mean age 51.53 - range 19-84 years) were included. OCAM were prescribed in 103 and 3–1-OBMT in 113. No differences in age, sex and functional dyspepsia as indication to eradicate were observed between groups. Main indications for treatment were functional dyspepsia (39.35%), gastroduodenal ulcer (19.44%) and non-investigated dyspepsia (13.89%). Compliance was <80% in 11 patients and unknown in 7. The efficacy outcome was unavailable in 9 subjects. Compliance >80% was observed in 91% with OCAM and in 93.53% with 3–1-OBMT (p=0.64). The ITT rates were 82.52% vs 85.84% (p = 0.63), and PP 89.47% vs 96.04% (p = 0.13), for OCAM and 3–1-OBMT respectively. The outcomes of adverse effects (frequency, number, duration and intensity) are shown in the Table.

Conclusion: A high clarithromycin resistance area, 14-days OCAM and 10-days 3–1-OBMT regimens achieve high and similar compliance and efficacy rates, but 3–1-OBMT provides a superior safety profile.

Introduction: We have detected a large increase of urea breath test (UBT) requests for Helicobacter pylori (Hp) diagnosis by primary care physicians (PCP). In this way, most Hp-infected patients are now being managed at primary care level. However, little is known about outcomes of Hp infection by PCP.

Aims & Methods: 1. To evaluate and compare the eligibility of UBT indications, treatment regimens and eradication rates between PCP and gastroenterology specialist (GS). 2. To evaluate the effect of introduction of specific counselling to PCP in the management profile of Hp infection. First, we prospectively evaluated the effect of introduction of a specific counselling to PCP to increase the adherence to appropriate treatment regimens (71% vs 35%; p <0.0001) and eradication rates (78% vs 57.1%; p < 0.0001) were observed in the PCP group after the implementation of specific counselling based on national guidelines.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1918 VALPROATE AND CHIR 99021 AMELIORATES RADIATION-INDUCED INTESTINAL EPITHELIAL INJURY IN MOUSE MODEL
Y. Kim, J.S. Shin
Internal Medicine, Division Of Gastroenterology, Korea Cancer Center Hospital, Seoul,Korea, Republic of

Contact E-mail Address: younjo282@gmail.com

Introduction: Radiation-induced gastrointestinal syndrome (RIGS) stems from the clonogenic loss of crypt cells and vill depopulation and results in mucosal barrier disruption, bacterial invasion, inflammation and sepsis. Valproate (VPA) is the one of the popular anti-convulsants, recently its Notch signal modulatory effect has been reported. Notch signal pathway is the one of the important pathways to maintain intestinal stem cells and to differentiate to secretory cells such as goblet cells. Moreover, It has been reported that combination of VPA and CHIR 99021 (GSK3B inhibitor) has powerful proliferatory effect for intestinal stem cells, such as Lgr 5+ cells. One of the major difficulties for RIGS studies is the fact that crypts are not easily accessed and cultured with traditional means. Ex vivo culture techniques for single crypt or a stem cell derived enteroid, with essential features of the in vivo tissue architecture, have been recently developed. Thus, we have adopted the 3D-cultured enteroids for RIGS ex-vivo model, and proved the effect of VPA and SCFAs for RIGS.

Aims & Methods: We have adopted the 3D-cultured enteroids for RIGS ex-vivo model, and proved the effect of VPA and SCFAs for RIGS. To culture enteroid, ten centimeters segments of jejunum were procured from 9–13 week-old C57BL/6 mice. Crypts were isolated by EDTA chelation, suspended in Matrigel and grown in culture media containing epidermal growth factor, noggin, R-spondin 1. After 1 day in culture, the enteroids were treated (or not) 3 mM CHIR 99021 (GSK3B inhibitor) and 1 mM VPA. On day 3, the enteroids were irradiated as a dose dependent manner. The evaluation of irradiated enteroids was performed by measuring MITT assay, budding efficiency of enteroid, and EdU staining. On post-irradiation Day 2 and Day 7, RT-PCR was performed.

Results: Enteroid from mouse had multiple crypts (‘budding’) with well-differen- tiated goblet, Paneth cells, +4 stem cells (quiescence stem cells, BM1 is expressed), Lgr5+ stem cells. In the response of radiation, irradiated enteroid decreased proliferation rate in a dose dependent manner, as measured by MITT assay. Enteroids budding efficiency of enteroids. Irradiated enteroids with VPA +CHIR 99021 could maintain their +4 stem cells even in 10 Gy of irradiation, lethal dose of mouse intestinal epithelium, and they were able to proliferation. Combination of VPA + CHIR 99021 did not have an effect on paneth cells, enteroid, Paneth cells and goblet cells.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1921 REVIEW OF SERVICE PROVISION OF NATIONAL INSTITUTE FOR HEALTH AND CARE EXCELLENCE (NICE) RECOMMENDED QUALITY STANDARDS FOR CELIAC DISEASE AT A BIG DISTRICT GENERAL HOSPITAL

F.K. Shaikh, D. Vani, M. Sprakes, F. Greenhalgh
Gastroenterology, Mid Yorkshire Hospitals NHS Trust. Wakefield/United Kingdom

Contact E-mail Address: shaikhd17@yahoo.com

Introduction: In the UK, 1 in 100 people are affected with coeliac disease. NICE published quality standards (QS134) for coeliac disease in October 2016 based on NICE guidelines NG20 (September 2015). This quality standard covers the recognition, assessment and management of coeliac disease in children, young people and adults. The quality standard is expected to contribute to improvements in the diagnosis of coeliac disease, growth in children and young people, health-related quality of life, incidence of osteoporosis, intestinal lymphoma, vitamin D deficiency, and iron deficiency.

Aims & Methods: We audited our departmental practices against NICE quality standards for coeliac disease. It is a retrospective data analysis of patients, 16 years and above, with positive coeliac serology from April 2016 to September 2016. All patients were source of referral, value of issue transglutaminase (tTG) antibodies, type of referral (new or follow up), timing of OGD (less than or more than 6 weeks), whether or not seen by dietician, offer of annual review, and DEXA scan.

Results: There are 209 first-degree relatives of CD patients. In total 95 cases were confirmed from patient records. All variables were compared between screen-positive relatives and screen-negative relatives.

Conclusion: The incidence and prevalence of coeliac disease in our study are 30.28 per 100,000 and 0.072 per 100,000 persons-years in our study. Thirty-four patients were positive for celiac serology which corresponds to the prevalence of CD in first degree relatives of 1%.

Disclose of Interest: All authors have declared no conflicts of interest.

Introduction: In nonresponsive celiac disease (NRCD) the symptoms and duodenal histology do not improve, despite a gluten-free diet (GFD). NRCD is characterized by persistent villous atrophy and mucosal inflammation despite strict GFD, long-term complications and progression. Additionally, NRCD is associated with increased seroreactivity to microbial antibodies.

Methods: We analyzed serum microbial markers in nonresponsive celiac disease (NRCD) and gluten-sensitive enteropathy (GSE). We compared NRCD patients to GSE patients. We also compared NRCD patients to GFD responsive celiac patients served as CD controls (58 samples at diagnosis and 55 on GFD). We hypothesized that chronic infection with persistent villous atrophy and mucosal inflammation despite strict GFD and negative celiac serology (NRCD group). Corresponding GFD responsive patients served as CD controls (58 samples at diagnosis and 55 on GFD)

Introduction: Celiac disease affects 1-2% of the population, but due to diverse presentation most patients remain unrecognized. Diagnostic efficiency could be improved by screening of at-risk groups, but long-term benefit of this approach is unclear. To shed light to this issue, we compared a variety of celiac disease-related and other parameters in large cohorts of adult patients diagnosed in childhood either because of clinical suspicion or by screening.

Aims & Methods: A questionnaire about current health and lifestyle, adherence to gluten-free diet (GFD) and follow-up of celiac disease was sent to 564 adults with celiac disease diagnosis. Further, the participants fulfilled validated Gastrointestinal Symptom Rating Scale (GSRS) and Psychological General Well-Being (PGWB) surveys for symptoms and quality of life. Clinical and histological presentation at diagnosis and other relevant medical data were confirmed from patient records. All variables were compared between screen-detected and clinically detected patients.

Results: Altogether 235 (42%) adults completed the questionnaires. At diagnosis, screen-detected patients (n = 49) were older (11.3 vs 8.8 yr, p = 0.016) and had lower vitamin D (25.7% vs 39.5%, p < 0.001) compared to clinically detected patients (n = 186). They also had a trend to have less often total villous atrophy (18% vs 32%, p = 0.075) and anemia (18% vs 32%, p = 0.072). The groups did not differ in gender, current age (median 26.5 vs 28.5 yr, p = 0.21), time from the diagnosis to referral, experience of persistent symptoms or concern about health, clinical symptoms, strict GFD (74% vs 80%, p = 0.161), lifestyle restrictions caused by GFD, presence of celiac disease-related complications, physical activity, fertility or GSRS and PGWB scores. However, screen-detected patients smoked less (4% vs 15%, p = 0.037) and had more often celiac disease in relatives (78% vs 58%, p = 0.011).

Conclusion: Diagnostic approach and presentation of celiac disease in childhood do not seem to affect the long-term health outcomes or attitude towards the disease in adulthood. Lack of difference in the dietary adherence and lifestyle recommendations gives further support for active screening and early diagnosis of celiac disease.

Disclose of Interest: All authors have declared no conflicts of interest.

United European Gastroenterology Journal 5(5S)
80 healthy blood donors as non-CD controls. Kruskal-Wallis test was used to compare antibody titers and Dunn-Bonferroni for post hoc pairwise comparisons.

**Results:** At least one serum microbial marker was positive in 80% of NRCD patients, in 97% of untreated and 87% of treated CD patients and in 44% of non-CD controls. NRCD patients had the highest frequency of ASCA positivity (64% vs 52%, 20% and 0%, respectively) and also significantly higher ASCA IgA (median 14.5 U/ml) and IgG (32.5 U/ml) titers than treated CD patients (7.0 U/ml, 13.0 U/ml and non-CD controls (4.5 U/ml, 5.8 U/ml). There was no difference in ASCA rates between NRCD and untreated CD. The frequencies of ASCA were 62% in non-CD treated and 86% in untreated CD (86%, 59%, respectively), while 12 titers were higher in NRCD (median absorbance 0.76) and untreated (1.0) and treated (0.83) CD than non-CD controls (0.32). OmpW was elevated in untreated (1.1) and treated (0.84) CD patients compared with non-CD controls (0.79).

**Conclusion:** Seropositivity and high titers of ASCA were associated with NRCD and might thus serve as additional follow-up tool for histological recovery in CD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** High levels of reactive oxygen species (ROS) and impaired antioxidant defense systems lead to oxidative stress (OSx) and tissue injury in different intestinal and extraintestinal conditions, including celiac disease (CD). A possible effect of gluten ingestion on intracellular oxidative imbalance has been suggested. Aims & Methods: The first aim of the study was to investigate the effects of OSx in CD, evaluating the levels of ROS and oxidative damage biomarkers in sera of naïve patients (N-CD), coeliac patients on a gluten-free diet (GFD) including responders (CD-GFD) or non-responders (NRCD) to dietary treatment. The second aim was to look for new serological biomarkers corresponding to morphological/functional alterations detected in biopsies according to Marsh-Oberhuber classification. Finally, a possible correlation between ROS production and/or biomarkers of OSx and/or hematological data was investigated. Analysis were conducted on small intestinal biopsy specimens and peripheral blood samples of celiac patients (N-CD, CD-GFD and NRCD). The methods included Electron Paramagnetic Resonance (EPR) technique for ROS detection, High Performance Liquid Chromatography (HPLC) analysis of erythrocytes glutathione (GSH), enzymatic assays for oxidative damage biomarkers (lipid per-oxidation measured by thiobarbituric acid-reactive substances (TBARS) method; protein oxidation, measured by a protein carbonyl (PC) assay kit; total antioxidant capacity (TAC), measured by an enzymatic kit; nitric oxides metabolites) as a marker of gut inflammation.

**Results:** Overall, blood samples and biopsies from 54 patients affected by CD were collected (44 F; median age 43.98 ± 13.44 years; range 19–80; 17 N-CD, 18 CD-GFD and 19 NRCD). Hemoglobin and haematocrit levels were significantly lower in NRCD and CD than in CD-GFD group (p < 0.05). In our study, a significantly increased production of ROS, lipid peroxidation and oxidized protein levels, plasma nitrate concentrations were reported in NRCD and N-CD compared to CD-GFD. On the contrary, the TAC and GSH levels were significantly decreased in N-CD and NRCD groups compared to CD-GFD. Data are summarized in Table 1. A significant direct relationship between Marsh subtypes and ROS production rate R2 = 0.19; p < 0.001, TBARS (R2 = 0.20; p < 0.001) and PC (R2 = 0.17; p < 0.001) was found by Pearson’s product-moment correlation while an inverse correlation between Marsh subtypes and TAC (R2 = 0.23; p < 0.001) and GSH (R2 = 0.34; p < 0.0001) was identified. In all groups of patients, at higher ROS production rate levels corresponded to greater plasma TBARS concentrations and lower erythrocytic GSH levels.

**Conclusion:** Several defense mechanisms are implied in maintaining the cell integ- rity and tissue homeostasis. According to our results, the presence of higher levels of ROS, oxidative damage biomarkers and nitric oxides metabolites in naïve and CD patients responding to GFD, the pro-oxidant/antioxidant balance seems to be greatly recovered.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1924 CIRCULATING EXTRACELLULAR VESICLES, A NOVEL MECHANISM OF ENDORCINE CELLULAR CROSS-TALK, ARE INCREASED IN NEWLY DIAGNOSED CELIAC DISEASE PATIENTS**

K. Ethynakis, G. Bologna, P. Lantuzi, C. Pipino, A. Milano, F. Laterza, P. Simeone, A. Bonitaitis, A. Pandolfi, M. Marchisio, S. Misica, M. Neri Department Of Medicine And Ageing Sciences And Center For Excellence On Ageing And Translational Medicine (cesi-mes), # G. D’Annunzio# University and Foundation, Chieti/Italy

**Contact E-mail Address:** effkan78@gmail.com

**Introduction:** Extracellular vesicles (EVs) have been recently hypothesized to represent a major peripheral mechanism of cellular cross-talk. EVs carry surface receptors and proteins characteristic of their cells of origin and shuttle molecules (proteins, RNAs, microRNAs) potentially controlling physiological and patho- logical systemic processes. Recent studies have demonstrated an increased number of circulating EVs in a variety of conditions characterized by multi-organ impairment and/or damage such as insulin-resistance, atherosclerosis and obesity. Celiac disease (CD) is an immune-mediated inflammatory enteropathy,a dietetic change can modify inflammatory and anti-inflammatory molecules in genetically susceptible individuals. It is frequently associated with a variety of systemic conditions both autoimmune and potentially immune-mediated in nature. Aims & Methods: The aim of this study was to assess and characterize patterns of circulating EVs in newly diagnosed CD patients. We enrolled consecutive adult anti-ITG positive, biopsy proven CD patients. Circulating EVs were identified untouched on whole blood samples by a no-lyse/no-wash method, combined with EVs volumetric count (FACSVerse, BD), based on a novel six-colour flow cytometry panel, in order to identify and enumerate both the whole EV compartment and different EV subpopulations. Data are expressed as mean ± SD and statistical differences were evaluated by means of T-test. Results: We evaluated 12 EV subpopulations (mean age 42.9 ± 19.1 vs. 40.8 ± 15.9 years, F/M = 4:1) at diagnosis and 12 age- and sex-matched healthy controls. Histology was considered positive for lesions of grade ≥1 according to the Corazzi-Villanacci classification. Mean anti-ITG levels at diagnosis were 6.9 ± 3 times ULN. Mean number of total circulating EVs was significantly higher in CD than in controls (59859 ± 72482 vs 14383 ± 1008 EV/microl, p = 0.035). Subgroup analysis showed that EpCAM + EVs, of epithelial origin, and CD41+ platelet-derived EVs were not significantly different between CD and controls (894 ± 1004 vs. 548 ± 1237 and 3052 ± 1563 vs. 1734 ± 1610 respectively, p = ns). On the contrary, CD45 + EVs, of leucocyte origin, showed a significantly higher frequency compared on controls (460 ± 492 vs. 119 ± 150 p = 0.026).

**Abstract No:** P1923

Data on levels of ROS and oxidative damage biomarkers in sera of naïve patients (N-CD), coeliac patients on a gluten-free diet (GFD) including responders (CD-GFD) or non-responders (NRCD) to treatment.

P1925 COELIAC DISEASE AND REPRODUCTIVE DISORDERS: IS THERE ANY CORRELATION

H. Boutilalka, I. Benelbarhdadi, F.Z. Ajana
Medecine C, Ibn Sina University Hospital, Rabat-Morocco

Contact E-mail Address: hanaeboutilalka@gmail.com

Introduction: The coeliac disease is an autoimmune enteropathy induced by the ingestion of gluten in genetically predisposed individuals. It causes intestinal and extraintestinal problems. Extraintestinal findings are observed in many systems. The prevalence of extraintestinal findings in CD patients is not clearly known and the correlation between them has not been yet obviously explained. There is also no data in the literature regarding the association of patient's reproductive organ (PFO) and celiac disease, which is 10–25% common in the general population. We performed an echocardiography study to determine the frequency of accompanying cardiovascular findings in our patients with celiac disease. In this article, we aimed to share the frequency of the PFO detected in celiac patients with high results.

Aims & Methods: We prospectively recruited cases of clinically suspected CD patients also, and it can lead to false-positive diagnoses. Our aim was to establish the frequency of these disorders in the coeliac disease and their evolution under gluten-free diet.

Results: About 241 patients suffering from coeliac disease, 58 patients presented reproductive disorders, either 28.9%. Recruiting 53 women and 5 men, with a sex ratio M/F of 10/6. The mean age was 32.25 years ranging from 13 to 59 years old. The diagnosis of coeliac disease was based on: Histology (severe or partial villous atrophy with intraepithelial lymphocytosis exceeding 30%), the antieti-body antibodies and/or antigliadin antibodies positive. The reproductive disorders were never isolated but always associated with digestive or extradigestive signs at the time of the diagnosis of coeliac disease. These disorders were: primary amenorrhea in 11 cases (19%), secondary amenorrhea in 13 cases (22.4%), Metrorrhagia in 12 cases (20.6%), absence of development of secondary sexual characters in 8 cases (12.5%), spontaneous abortion in 7 cases (10.9%), menometrorrhagia in 4 cases (13.8%), primary sterility in 3 cases (8.6%), precocious menopause in 6 cases (10.3%), premature labour and/or IUGR in 3 cases (5%), primary amenorrhea in 2 cases (3.4%), and intrauterine Fetal death IUFD in one case (1.7%). All our patients benefited from a gluten-free diet. 15 patients were excluded from the study, 2 patients died, and 12 patients were lost to follow-up. Of the 102 patients stayed, the evolution of the reproductive disorders under gluten-free diet was good in 26 cases (90%), with normalization of the cycles in 15 cases, The cycle was returned in 6 cases, development of secondary sexual characters in 2 cases, fertility was returned in one case, and there was normalization of the cycles in 1 case. A baby was delivered in a baby in term after a repeated premature delivery. The evolution was good in 3 cases as regard missed abortion four years after the gluten-free diet in 1 patient, and amenorrhea continued in 2 cases.

Conclusion: The reproductive disorders related to the coeliac disease were frequent and variable. In our study, these disorders well responded to the gluten-free diet in 90% of cases, and these disorders were reversible under gluten-free diet.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1926 SEVERITY OF MUCOSAL DAMAGE AND TISSUE TRANSGLUTAMINASE ANTIBODY LEVELS CORRELATE WELL IN ADULT CELIAC DISEASE IRRESPECTIVE OF CLINICAL FEATURES

Introduction: Celiac disease (CD) is a chronic imune-mediated enteropathy that occurs in genetically predisposed individuals. The clinical phenotypes ranges from classical gastrointestinal manifestations to only atypical signs, which are regressive with a gluten-free diet. The classic form is actually a manifestation of severe CD histopathology. GI and non-GI symptoms are not reliable predictors of disease activity, which are regressive with a gluten-free diet. The classic form is actually a manifestation of severe CD histopathology. GI and non-GI symptoms are not reliable predictors of disease activity, which are regressive with a gluten-free diet.

Aims & Methods: We prospectively recruited cases of clinically recommended CD patients diagnosed with CD hospitalized at the Institute of Gastroenterology and Hepatology, “St. Spiridon” Hospital, Iasi between January, 2012- December, 2016 admitted with symptoms of abdominal disturbances (diarrhoea, heartburn, nausea, vomiting, regurgitation, abdominal pain). Demographic, clinical, serological, and histological characteristics of individuals with CD were reviewed.

Results: The study group included 81 adult patients with a female: male ratio of 3.1, 60(71.1%) female patients, mean age 40.02 ± 12.14 years. A total of 46.1% patients presented with gastrointestinal (GI) complaints and 51.9% of patients presented mostly with non-GI manifestations, and advanced age of symptom onset in the latter category (38ys ± 47ys). Marphototherapeutic classification was used to assess mucosal injury and Marsh 3c lesions were found in 25 (30.9%) cases. When assessing the serological parameters, IgA anti-transglutaminase (IgA-tTG) antibody (61.45±7.465 u/mL vs 162.02±106.179 u/mL, P = 0.001) and IgA anti-gliadin antibodies (IgA-AGA) levels (61.83±69.41u/mL vs 77.15±71.02 u/mL, P = 0.001) correlated with intestinal villous atrophy (Marsh 3b and 3c) in CD patients by Spearman rank correlation. Among symptomatic, abdominal distention and diarrhea were associated with abnormal histology. Hemoglobin levels were evaluated and anemia was diagnosed in 61.7% patients among patients with elevated IgA-tTG levels (r = 0.516, P = 0.004), IgA-AGA (r = -0.301, P = 0.006) and Marsh 3b-3c lesions (r = 0.008). Among biological markers included in the statistical analysis, low iron levels (cut off 30 mg/dl), hypocholesterolemia and low protein levels were associated with Marsh 3 b lesions (P = 0.008) and elevated IgA-IgA titers (r = -0.384, P = 0.001).

Conclusion: We prospectively recruited cases of clinically recommended CD patients also, and it can lead to false-positive diagnoses. Our aim was to establish the frequency of these disorders in the coeliac disease and their evolution under gluten-free diet.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1927 USEFULNESS OF BULB BIOPSY SAMPLES IN CELIAC DISEASE DIAGNOSIS IN ADULTS

D.V. Balaban1, A. Popp2, J. Taavola1, K. Laurila1, M. Mäki1, M. Jinga1

2Center For Child Health Research, University of Tampere and Tampere University Hospital, Tampere/Finland

Contact E-mail Address: vbalaban@yahoo.com

Introduction: Celiac disease (CD) is a chronic imune-mediated enteropathy that occurs in genetically predisposed individuals. The clinical phenotypes ranges from classical gastrointestinal manifestations to only atypical signs, which are regressive with a gluten-free diet. The classic form is actually a manifestation of severe CD histopathology. GI and non-GI symptoms are not reliable predictors of disease activity, which are regressive with a gluten-free diet. The classic form is actually a manifestation of severe CD histopathology. GI and non-GI symptoms are not reliable predictors of disease activity, which are regressive with a gluten-free diet.

Aims & Methods: We prospectively recruited cases of clinically recommended CD patients diagnosed with CD hospitalized at the Institute of Gastroenterology and Hepatology, “St. Spiridon” Hospital, Iasi between January, 2012- December, 2016 admitted with symptoms of abdominal disturbances (diarrhoea, heartburn, nausea, vomiting, regurgitation, abdominal pain). Demographic, clinical, serological, and histological characteristics of individuals with CD were reviewed.

Results: The study group included 81 adult patients with a female: male ratio of 3.1, 60(71.1%) female patients, mean age 40.02 ± 12.14 years. A total of 46.1% patients presented with gastrointestinal (GI) complaints and 51.9% of patients presented mostly with non-GI manifestations, and advanced age of symptom onset in the latter category (38ys ± 47ys). Marphototherapeutic classification was used to assess mucosal injury and Marsh 3c lesions were found in 25 (30.9%) cases. When assessing the serological parameters, IgA anti-transglutaminase (IgA-tTG) antibody (61.45±7.465 u/mL vs 162.02±106.179 u/mL, P = 0.001) and IgA anti-gliadin antibodies (IgA-AGA) levels (61.83±69.41u/mL vs 77.15±71.02 u/mL, P = 0.001) correlated with intestinal villous atrophy (Marsh 3b and 3c) in CD patients by Spearman rank correlation. Among symptomatic, abdominal distention and diarrhea were associated with abnormal histology. Hemoglobin levels were evaluated and anemia was diagnosed in 61.7% patients among patients with elevated IgA-tTG levels (r = 0.516, P = 0.004), IgA-AGA (r = -0.301, P = 0.006) and Marsh 3b-3c lesions (r = 0.008). Among biological markers included in the statistical analysis, low iron levels (cut off 30 mg/dl), hypocholesterolemia and low protein levels were associated with Marsh 3 b lesions (P = 0.008) and elevated IgA-IgA titers (r = -0.384, P = 0.001).

Conclusion: We prospectively recruited cases of clinically recommended CD patients also, and it can lead to false-positive diagnoses. Our aim was to establish the frequency of these disorders in the coeliac disease and their evolution under gluten-free diet.

Disclosure of Interest: All authors have declared no conflicts of interest.
recommendations. Paraffin embedded biopsy samples were assessed for villous height (VH) and crypt depth (CrD) and VH:CrD ratio revealed a critically low sensitivity, either due to a sensitivity problem with this serology in the pediatric population or secondary to a suboptimal IgA band expression of the POCT.

Disclosure of Interest: All authors have declared no conflicts of interest.

POCT QUALITY STANDARDS: COELIAC DISEASE: A RETROSPECTIVE EVALUATION IN A SINGLE SPECIALIST CLINIC
M. Fitzpatrick1, S. Nichols2, E. Soilleux2, S. Travis3

Introduction: Quality standards in coeliac disease management were recently published by the National Institute for Health and Care Excellence3. These specify a new 6-week target for the time from referral to endoscopy, which was previously covered by the 16-week referral to treatment (RTT) pathway2. They also state that all newly-diagnosed patients should discuss a gluten-free diet with a specialist dietician. We retrospectively evaluated practice in the Oxford University Hospitals NHS Foundation Trust coeliac clinic against these criteria, and against national guidelines (duodenal bulb sampling at endoscopy and screening for nutritional deficiency)1.

Aims & Methods: The medical records of 110 patients referred to our clinic between September 2015 and September 2016 were examined. The date of referral and endoscopy were recorded, along with relevant demographic, clinical and laboratory information. Data were collected and analysed in Microsoft Excel.

Results: Eighty-five patients (68% female, median age 34) were seen with suspected or newly-diagnosed coeliac disease; of whom 76 (89%) were referred with positive coeliac serology and would be subject to the 6-week target. Six patients declined or delayed endoscopy, and endoscopy or referral information were not available for 4 patients. For the remaining 66 patients, median time from referral to endoscopy was 12 weeks (SD 37 days), with 59 patients (89%) referred within 18 weeks, but only 11 patients (17%) within 6 weeks (Figure 1). Duodenal bulb biopsies were taken at endoscopy in 31 patients (44%). A diagnosis of coeliac disease was made in 74 (87%) of all patients referred, of whom 67 (90%) were referred to a specialist dietician. Haematocrits (iron studies, vitamin B12 and folate) were measured in 67 patients (90%), bone densitometry was measured in 51 patients (69%) and all patients were offered a follow-up appointment in the coeliac clinic. Iron deficiency was found in 31 patients (45%) of patients tested, folate deficiency in 12 patients (18%), vitamin B12 deficiency in 5 patients (8%) and vitamin D deficiency in 23 patients (38%). Osteoporosis was diagnosed in 5 patients (10%) and osteopenia in 10 patients (20%).

Conclusion: Appropriate dietician referral, specialist follow-up and screening for nutritional deficiency and bone disease occur within the Oxford coeliac disease service. Compliance with recommended biopsy protocols was only 44%. Whilst most referrals met the previous 18-week RTT pathway, few would have met the new quality standards.

Disclosure of Interest: M. FitzPatrick: Michael FitzPatrick is supported by an Oxford-Celgene Research Fellowship funded by Celgene Corporation.

Introduction: We previously reported that small-bowel capsule endoscopy (CE) is effective in diagnosing small-bowel lesions with occult obscure gastrointestinal bleeding (OGB) (Gastroenterol Res Pract. 2013). However, there is no consensus regarding the management of occult OGB patients without bleeding source identified.

Aims & Methods: We aimed to consider management of occult OGB patients based on the long-term outcomes. A total of 357 consecutive occult OGB patients (203 men; mean age: 59.7 years) who underwent CE at Hiroshima University Hospital before March 2016 and whose entire small-bowel could be observed and followed-up by CE for at least 12 months, were enrolled. We examined each patient to confirm the positive CE findings rate, the detection rate of bleeding source lesions, the details of bleeding source lesions, the overt
bleeding rate with or without treatment, the rate of anaemia exacerbation (hemoglobin levels 0 g/dL), 5 year overall survival rate (OS), and 5 year disease specific survival rate (DSS). Occult OGB is defined as recurrent or persistent iron deficiency anaemia with or without a positive faecal occult blood test and no bleeding findings by esophagogastrroduodenoscopy and colonoscopy.

Results: The rate of positive CE findings was 44% (157/357) and the detection rate of bleeding source lesions was 27% (98/357). All of the treated bleeding source lesions (Group A) were as follows: angioectasia 61 patients (Yamamoto classification Type 1a 37 patients, Type Ib 24 patients), non-specific ulcers 15 patients, hereditary non-polyposis colorectal cancer 5 patients, hemangiomas 5 patients, Crohn’s disease 3 patients, primary cancer 2 patients, metastatic cancer 2 patients, gastrointestinal stromal tumour 2 patients, malignant lymphoma 2 patients, others 3 patients. Lesions that were not regarded as bleeding source lesions (Group B) were as follows: angioectasia 25 patients (Type 1a without oozing 25 patients), erythema 31 patients, others 3 patients. There were no patients with overt bleeding in Group B. Although 6 patients (10%) had anaemia exacerbation in Group B, none of these patients were diagnosed as having a bleeding source lesion. On the contrary, in both Group A and Group B was 90%. DSS in Group A was 99% and in Group B it was 100%. One patient in Group A died of a primary small-bowel cancer.

Conclusion: Conclusion: Long-term outcomes with occult OGB patients were good except malignant tumor, because overt bleeding and/or anaemia exacerbation did not occur within the follow-up period. Thus, occult OGB patients without bleeding source lesions, including Type 1a angioectasia without oozing, and erythema, are unnecessary to follow-up with CE in occult OGB patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Small bowel capsule endoscopy (SBCE) is a very useful method of investigating iron-deficient anaemia, or occult gastrointestinal (GI) bleeding. It can also detect the causes of anaemia or bleeding, such as angioectasia, small bowel Crohn’s disease, polyps, lymphoma, and malignant lesions. There is however a need to improve the diagnostic yield, particularly where resources and access to capsule endoscopy are restricted. Faecal immunochromatographic test (FIT) has an established role, in investigating large bowel bleeding, and is incorporated into a number of bowel cancer screening programmes.

Aims & Methods: The aim of our study was to investigate whether FIT could help predict likelihood of small bowel bleeding or other significant pathology at time of small bowel capsule endoscopy. This was a prospective pilot study, performed at our centre from September 2016-April 2017. Indications for enrolment were patients referred for SBCE with the indication of anaemia or occult GI bleeding.

Baseline patient characteristics were obtained including age, gender, history of renal disease, transfusion requirements and use of antiplatelet/anti-coagulants. Patients were asked to return one completed FIT for further analysis. A cut of 50 ng/ml was chosen as this is the standard cut-off used, in the Irish National Bowel Cancer Screening programme.

Results: A total of 40 patients were enrolled, mean age 55.4 years (range 18-77), 64% were female. A total of 27.6% of patients were on anti-platelet agents or anti-coagulants. 34% of patients had a blood transfusion within the last year. Mean Hb for the cohort was 12.8 g/dL (range 7.8-15.9 g/dL). The average FIT reading was 459 ng/mL (range 0-4426 ng/mL). 30% of patients had a FIT level >50 ng/mL. 46% of patients, had positive findings at SBCE. 9/12 (75%) of patients, with a FIT level >50 ng/mL had positive findings at capsule endoscopy compared to 5/28 (17.8%) for FIT level <50 ng/mL, p value =0.002, 95% C.I. 0.29-0.86 O.R. 10.16. These included 4/12 (33%) new cases of Crohns, 3/12 (25%) angiodysplasia, 3/12 (33%) non-HBD enteritis, 1/12 (16.7%) small bowel tumour and 1/12 (16.7%) melanoma, with no clear source. In addition there was a good correlation between FIT and Haemoglobin levels. 60% of patients with FIT >50 ng/mL were anaemic (Hb <11.5 g/dL), compared to 17% with FIT <50 ng/mL, p value =0.02 95% C.I. 0.09-0.76 O.R. 1.4. Combining Hb and FIT levels, was also informative and predictive of small bowel pathology. 83% of patients, who were anaemic and had a FIT >50 ng/mL had clinically significant findings at SBCE compared to 21% pick up rate in patients with normal Hb and FIT levels, p value =0.03 95% C.I. 0.22-0.83 O.R. 0.05. Overall the sensitivity for a FIT >50 ng/mL for detecting small bowel pathology was 83% with a specificity of 92%, giving a positive predictive value of 83.3% (95% C.I. 56.5-95%). Platelet levels were not predictive of a positive FIT, as 16.7% of patients with a FIT >50 ng/mL were on anti-platelet agents, compared to 83.3% who weren’t.

Conclusion: FIT is useful at predicting clinically significant small bowel pathology at the time of capsule endoscopy. It may help better identify and prioritise patients who would best benefit from referral.

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: VCE detected small bowel lesions in 71% in our cohort. There is a high prevalence of PHE in patients with decompensated cirrhosis. Vascular lesions are the most common finding in the small bowel of this population. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Small-bowel capsule endoscopy (SBCE) have been useful in managing obscure gastrointestinal bleeding. We previously reported that the use of omeprazole and diclofenac was associated with an increased risk of nonsteroidal anti-inflammatory drug (NSAID)-induced small-bowel injury (Aliment Pharmacol Ther 2014). However, the etiology and temporal development of drug-associated small-bowel bleeding (SBB) has not been well characterized.

Aims & Methods: The aim of this study is to determine the risk of drugs associated with overt SBB using a case-crossover design. The Japanese Association for Capsule Endoscopy developed a prospectively recorded database of outpatients and inpatients that underwent SBCE at 18 medical centers in Japan, and data were collected from 1052 patients with obscure gastrointestinal bleeding (OGIB) between December 2010 and June 2016. This database includes patient characteristics, drugs used, SBCE findings, and final diagnosis. Drugs used were identified during a “case period” 4 weeks before the overt SBB, and a “control period” 24-5 weeks before the overt SBB. Drug adherence was classified into 4 groups: 1) 100%, 2) 50% or higher, 3) lower than 50%, and 4) 0%. Using conditional logistic regression, odds ratios (ORs) and 95% confidential intervals (CIs) were estimated using Mantel-Haenszel estimator in discordant cases.

Results: Of 1052 patients with OGIB (male/female: 678/374, age of onset: 64.8 ± 12.7 years, 45.2%: 21.5%, 29.7%, 17.3%) and colon (n = 133), 346 patients on 346 drugs which could be identified 24 weeks before overt SBB were analyzed. ORs (95% CIs) of enteric-coated aspirin (n = 51), warfarin (n = 27), clopidogrel (n = 24), and loxoprofen (a propionic acid derivative, n = 21) were 5.7(1.3-24.3), 3.70(1.0-14.5), 4.1(1.3-13.6), and 18.0(2.3-139.6). Aspirin-associated SBB was caused by aspirin-induced injuries, angiodysplasia, Meckel’s diverticula, and polyps. Loxoprofen-associated SBB was caused by mostly loxoprofen-induced injuries.

Conclusion: Enteric-coated aspirin, clopidogrel, and loxoprofen were identified as drugs causing overt SBB during a relatively short period after administration. Disclosure of Interest: All authors have declared no conflicts of interest.

P1935 META-ANALYSIS REVEALS SIMILAR REBLEEDING RATES AMONG EASTERN AND WESTERN POPULATIONS UP TO FIVE YEARS AFTER INDEX VIDEO CAPSULE ENDOSCOPY

EXAMINATION FOR OBSCURE GASTROINTESTINAL BLEEDING

G. Tzatzios, P. Gkolfakis, G. D. Dimitriadis, K. Triantafyllou

2nd Dept of Internal Medicine And Research Institute, National and Kapodistrian University of Athens, Medical School, Athens/Greece

Contact E-mail Address: ktriantis@med.uoa.gr

Introduction: Video capsule endoscopy (VCE) is the first-line diagnostic modality for obscure gastrointestinal bleeding (OGIB) investigation and different re-bleeding rates have been published among Western and Eastern studies.

Aims & Methods: Aim of this meta-analysis was to examine the differences in re-bleeding rates in patients with OGIB after index VCE, as measured in Western and Eastern studies. A comprehensive literature search in MEDLINE was conducted to identify all studies examining re-bleeding rate after VCE for OGIB. Meta-analysis assessed the pooled proportion of re-bleeding events after VCE for OGIB according to study’s origin (Western vs. Eastern) as the primary end point. Pooled relative risks for re-bleeding vs. negative index VCE and after longer (>24 months) vs. short (<24 months) follow-up in the two study origins, comprised the secondary endpoints. Study outcomes effect sizes were calculated using RevMan 5.3 software random effect model and they are presented as random-effects model. Publication bias was examined with funnel plots inspection.

Results: Thirty-eight (14 Eastern and 24 Western) studies were included in the analysis with 5197 patients followed from 6 to 52 months. We detected significant heterogeneity with no evidence for publication bias in the meta-analyzed studies. While the overall, pooled rate of re-bleeding after VCE was 25%/29%/27%, I² = 93%, similar re-bleeding rates were detected among Eastern and Western populations [22%/28%], I² = 93% vs. [28%/35%], I² = 95%. The re-bleeding risk after positive vs. negative VCE was 1.20(0.58-2.61), I² = 77% and 1.90(1.40-2.53), I² = 71% in Western and Eastern studies, respectively. For studies with long-term follow-up, no significant difference in the OR of re-bleeding after positive vs. negative index VCEs was detected either in the East [2.03(0.64-4.9), I² = 71%] or in the West [2.7(0.81-5.0), I² = 98%].

Conclusion: Our analysis shows that patients undergoing VCE for OGIB have similar re-bleeding rates in the East and in the West, regardless of the length of the follow-up. An increased re-bleeding risk after positive vs. negative index VCE was noted only in studies originating from the East.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1936 LONG-TERM OUTCOMES AFTER NEGATIVE DOUBLE-BALLOON ENTEROSCOPY FOR SUSPECTED OVERT SMALL BOWEL BLEEDING (OBSCURE-OVERT GASTROINTESTINAL BLEEDING)

R. Hashimoto1, T. Matsuda2, M. Nakahori3

1Dept. Of Gastroenterology, Sendai Kosei Hospital, Sendai, Japan

Contact E-mail Address: rinhashimoto@gmail.com

Introduction: There are very few reports about long-term outcomes in patients with negative balloon assisted enteroscopy for suspected overt small bowel bleeding (obscure-overt gastrointestinal bleeding).

Aims & Methods: The aim of this study is to evaluate long-term outcomes and risk factors of re-bleeding after negative double balloon enteroscopy (DBE) for suspected overt small bowel bleeding. We investigated 297 patients undergoing DBE for suspected overt small bowel bleeding between December 2004 and April 2016 at Sendai Kosei Hospital. Prospectively collected data were reviewed, and 83 patients (27.9%) showed negative results in the first antegrade and/or retrograde DBE. For these patients, letter and telephone interviews were conducted in April 2017. As a result, a cohort of 64 patients could be followed. The primary outcome measurement is overt rebleeding and necessity for clinical assessment after negative DBE.

Results: The observation was performed in 19 of 64 patients (29.7%) with 76 months follow-up period. The mean period during the first DBE and the first rebleeding episode was 11.6 months(2day-48months). Three patients showed rebleeding after more than three years of the first DBE. At the time of rebleeding, emergent endoscopy including DBE (within less than 48 hours) and/or contrast-enhanced computed tomography (CECT) was performed in all patients. The bleeding source was identified in 17 of 19 patients (89.4%). The bleeding source were duodenum (n = 8), jejunum (n = 7) and colon (n = 2), respectively. One
patient died due to uncontrollable duodenal bleeding. Blood transfusion before the first DBE was associated with rebleeding (odds ratio 22.5, n = 0.0005), but total endoscopy rate, use of capsule endoscopy, use of anti-thrombotic agents and use of NSAIDs were not associated with rebleeding.

**Conclusion:** Rebleeding after negative DBE for suspected overt small bowel bleeding was rare. Blood transfusion before the first DBE may predict rebleeding. Emergent endoscopy including DBE and concomitant CECT use could help the diagnosis on re-bleeding.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1937 DOES DISCONTINUATION OF ANTITHROMBOTIC AGENTS AFFECT DIAGNOSTIC YIELD OF SMALL BOWEL CAPSULE ENDOSCOPY IN PATIENTS WITH OBSCURE GASTROINTESTINAL BLEEDING?**

T. Watanabe1, S. Shimada1, Y. Nadanori1, K. Otsuji1, F. Tanaka1, Y. Nagami1, N. Kama1, H. Yamagami1, T. Tanigawa1, M. Shibata1, T. Miyazaki2, S. Nakamura1, Y. Fujiiwara1

2Dept. Of Inflammatory Bowel Disease, Division Of Internal Medicine, Hyogo College of Medicine, Nishinomiya/Japan

**Contact E-mail Address:** watanabet@med.osaka-cu.ac.jp

**Introduction:** Capsule endoscopy (CE) is a useful and noninvasive modality for investigation of the small intestine, and currently, it has become the first-line method for the therapy of obscure small bowel bleeding (OSBB). Use of antithrombotic agents including antiplatelets and anticoagulants is associated with gastrointestinal bleeding. Antithrombotic users account for a large portion of patients with OSBB, and those with OSBB often undergo CE. It should be noted that some patient with over OSBB discontinue antithrombotic agents at the time of CE, which may affect endoscopic findings.

**Aims & Methods:** To examine the effect of discontinuation of antithrombotic agents on the diagnostic yield of CE, and to assess the predictive factors associated with positive CE findings in patients using antithrombotics who develop overt OSBB. Between March 2004 and December 2015, 130 consecutive patients (75 male; mean age, 71.9 years) taking antithrombotics who underwent CE for overt OSBB were enrolled, whereas patients who underwent double-balloon endoscopy prior to CE were excluded. Findings were considered positive if the observed lesions could explain the bleeding, while findings including isolated red spots and a single small polyp were considered negative. The primary endpoint was the diagnostic yield of CE findings between patients who continued and those who discontinued antithrombotic agents. Furthermore, a propensity score analysis was performed to reduce the effects of selection bias and potential confounding factors. The secondary endpoint was to assess the predictive factors for the positive CE findings by using multiple logistic regression.

**Results:** Of the 73 patients who continued antithrombotic agents, 36 (49.3%) patients had positive findings in the small intestine (ulcer/erosion [n = 24], angioectasia [n = 7], tumor [n = 4], and blood pooling [n = 1]), while of the 57 patients who discontinued these agents, 35 (61.4%) patients had positive findings (ulcer/erosion [n = 17], angioectasia [n = 11], tumor [n = 3], and blood pooling [n = 4]). The rates of positive CE finding did not differ between the two groups. Even after propensity score matching, discontinuation of antithrombotic agents did not affect the positive CE finding. In multivariate analysis, the lowest hemoglobin level before CE examination was an independent predictive factor associated with positive CE findings. The odds ratio per 1 g/dl increase in the lowest hemoglobin (OR 1.05, 95% confidence interval 1.01-1.09). However, other factors, including sex, age, and discontinuation of antithrombotic agents, were not associated with positive CE findings.

**Conclusion:** Discontinuation of antithrombotic agents did not affect the diagnostic yield of CE with overt OSBB, and lowest hemoglobin level was associated with positive CE findings.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1938 EFFICACY OF REBAMIPIDE TO PREVENT LOW-DOSE AASPIRIN-INDUCED SMALL INTESTINAL INJURY**

S. S. Vylov

Gastroenterology, Peoples Friendship University of Russia, Moscow/Russian Federation

**Contact E-mail Address:** svylov@mail.ru

**Introduction:** Long-term use of low-dose aspirin (LDA) is associated with development of peptic ulcers, gastrointestinal bleeding, enteropathy. For prevention of LDA-induced small intestinal mucosal injury, enteropathy, subjects comprised undergoing lifelong low-dose aspirin therapy prescribed by cardiologist. Patients with a high-risk of gastrointestinal bleeding were excluded. This trial was performed as a randomised open-labelled clinical study with the permission of an institutional review board. The trial was included 100 patients (50 cases in each group) received gastro-coated low-dose aspirin (90 mg). The Group PPI received LDA plus pantoprazole 40 mg, the Group RBD received plus rebamipide 300 mg. Before starting therapy, we checked the background characteristics of each patient (H.pylori, use of LDA, NSAID, bismuth, PPI; and endoscopic findings). Gastroscopy and capsule endoscopy were performed, and the fecal occult blood reaction and fecal calprotectin levels were measured before, two and four weeks after drug administration. After the therapy, we have asked physicians and patients about medication compliance and side effects. Capsule endoscopy was then repeated. The primary endpoint was the change in the number of mucosal breaks from baseline to 4 weeks. The secondary endpoints were the rates of side effects.

**Results:** The fecal calprotectin levels increased significantly in Group PPI, they did not increase in Group RBD. The mean number of small intestinal injuries by capsule endoscopy in Group PPI increased significantly up to 3.9 after 4 weeks of LDA treatment. There was not detected new small intestinal injuries in Group RBD. Stomach ulcer, bleeding or stenosis were not found in any subjects. There were no significant differences in the presence of fecal occult blood in both groups. There were no significant side effects in Group RBD.

**Conclusion:** In conclusion, rebamipide is effective and sufficient for preventing mucosal injury of the small intestine induced by low-dose aspirin. These results show the gastroprotective and enteroprotective effects of rebamipide, suggesting that it may be a good choice in low-dose aspirin users with gastrointestinal toxicity that is not suppressed by acid suppressants alone.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P1940 VALIDATION OF A SCORE CHART TO PREDICT THE RISK OF CHRONIC MESENTERIC ISCHEMIA: A DISCRIMINATIVE AND USEFUL TOOL IN CLINICAL DECISION-MAKING

Aims & Methods: Patients suspected of CMI referred to two Dutch specialized centers were included consecutively from January 2014 to August 2016. After diagnostic work-up of medical history taking, mesenteric CT-angiography and/or conventional catheter angiography, and a functional test for detecting mucosal ischemia using either tonometry or visible light spectroscopy, all patients were discussed in a specialized CMI multidisciplinary meeting resulting in an expert based consensus diagnosis. All CMI suspected patients. This score chart consists of patient characteristics and anatomic observation in the general population but not necessarily related. Harki et al(1) designed a score chart to predict the risk of CMI based on a cohort of CMI suspected patients. This score chart consists of patient characteristics (female 1 pt, weight loss 1 pt, cardio-vascular disease 1 pt) and radiologic evaluation (50–70% celiac artery (CA) stenosis 1 pt, >70% CA stenosis 4 pts, 50–70% superior mesenteric artery (SMA) stenosis 1 pt and >70% SMA stenosis 3 pts). A total score of 0–2 pts predicts an absolute risk of CMI of 0–21%, 3–6 pts a risk of 22–79%, we aimed to validate this prediction model in a prospective large multicenter patient cohort.

Aims & Methods: Patients suspected of CMI referred to two Dutch specialized centers were included consecutively from January 2014 to August 2016. After diagnostic work-up of medical history taking, mesenteric CT-angiography or MR-angiography, and a mucosal ischemia test (visible light spectroscopy or tonometry), all patients were discussed in a specialized multidisciplinary meeting resulting in an expert based consensus diagnosis. All patients with a CMI consensus diagnosis were planned for treatment (revascularization) or non-occlusive ischemia (NOMI) due to decreased cardiac output or hypoxia-oxygenation. The diagnosis of CMI remains challenging as chronic abdominal pain is common and mesenteric artery stenoses are frequently observed in the general population but not necessarily related. Harki et al(1) designed a score chart to predict the risk of CMI based on a cohort of CMI suspected patients. This score chart consists of patient characteristics (female 1 pt, weight loss 1 pt, cardio-vascular disease 1 pt) and radiologic evaluation (50–70% celiac artery (CA) stenosis 1 pt, >70% CA stenosis 4 pts, 50–70% superior mesenteric artery (SMA) stenosis 1 pt and >70% SMA stenosis 3 pts).

A total score of 0–2 pts predicts an absolute risk of CMI of 0–21%, 3–6 pts a 22–46% risk and ≥7 pts a risk of ≥79%. We aimed to validate this prediction model in a prospective large multicenter patient cohort. Aims & Methods: Patients suspected of CMI referred to two Dutch specialized centers were included consecutively from January 2014 to August 2016. After diagnostic work-up of medical history taking, mesenteric CT-angiography or MR-angiography, and a mucosal ischemia test (visible light spectroscopy or tonometry), all patients were discussed in a specialized multidisciplinary meeting resulting in an expert based consensus diagnosis. All patients with a CMI consensus diagnosis were planned for treatment (revascularization) or non-occlusive ischemia (NOMI). A definitive diagnosis of CMI was made if successful treatment resulted in durable symptom relief. The score chart to predict the risk of CMI was computed for each patient.

Results: A total of 246 patients were included and consensus diagnosis of CMI was made in 108 (44%) patients, which resulted in 96 (39%) patients with a definitive diagnosis of CMI after a positive response therapy. A definitive diagnosis of CMI was made in 9% of the patients with low risk, in 40% of the patients with intermediate risk and in 94% of the patients with high risk of CMI according to the score chart, respectively. Etiology and vascular lesions are shown in the table. The discriminative ability of the score chart was strong (C-Statistic 0.87).

Conclusion: The score chart for CMI based on patient characteristics and anatomic observation is a reliable tool to discriminate the risk of CMI and useful for clinical decision-making, for example to adopt a wait-and-see policy in patients with a low risk and immediate vascular intervention in patients with high risk of CMI. Disclosure of Interest: All authors have declared no conflicts of interest.

P1941 LONG-TERM SYMPTOM RELIEF AFTER REVASCULARIZATION IN PATIENTS WITH SINGLE ARTERY CHRONIC MESENTERIC ISCHEMIA

Aims & Methods: Data were collected from all 97 consecutive patients with gastrointestinal symptoms and a single mesenteric artery stenosis referred to the outpatient clinic of our tertiary care institution for analysis of CMI between January 2006 and October 2010. All patients underwent a standardized diagnostic work-up for CMI at baseline consisting of medical history taking and physical examination, imaging of the gastrointestinal arteries with either CT- or MR-angiography and/or conventional catheter angiography, and a functional test for detecting mucosal ischemia using either tonometry or visible light spectroscopy. All cases were discussed in a multidisciplinary meeting attended by a vascular surgeon, interventional radiologist and gastroenterologist, all specialized in CMI, leading to an expert based consensus diagnosis. Patients with consensus diagnosis of CMI underwent surgical or endovascular revascularization. The primary outcome was clinical response to revascularization, defined as relief of presenting symptoms as experienced by the patient.

Results: Consensus diagnosis of CMI was obtained in 62/97 patients and all consensus patients were revascularized. Isolated CA stenosis was present in 55/ 62 patients (89%) (31 vascular disease; 24 median arcuate ligament syndrome, MALS) and isolated atherosclerotic SMA stenosis in 7 patients. After a mean follow-up of 5.5 ± 3.0 years, 42/62 patients (68%) experienced sustained symptom relief. Responders to revascularization had a BMI increase during follow-up in contrast to the non-responders (+0.43 ± 2.5 versus −1.06 ± 2.4 kg/m², p = 0.033). Response to revascularization was not related to lesion localization (CA 67% versus SMA 71%, p = 0.825) or lesion etiology (MALS 63% versus vascular disease 71%, p = 0.483). See table.
A substantial proportion of patients with clinical symptomatic angiooagulants). Anaemia and/or overt bleeding resolved spontaneously in 24 patients between index and repeat endoscopy was 21 weeks. A total of 48 patients were detected but left untreated during the index endoscopy. Median time endoscopies with APC in patients with angiodysplasias who were left untreated
treat endoscopic detected angiodysplasias difficult.

Technique: The aim of this study is to investigate the need for repeat endoscopies with APC in patients with angiodysplasias who were left untreated during the index endoscopy performed for iron deficiency anaemia or overt bleeding. We initiated an international, multicentre cohort study to collect clinical, laboratory and endoscopic data from angiodysplasia patients. Cases were identified through a systematic search in endoscopy reports from 2010–2015 with inclusion criteria was endoscopic detection of angiodysplasia in patients with iron deficiency anaemia or overt bleeding resulting from gastrointestinal angiodysplasia. In the minority of patients active bleeding angiodysplasias are seen during endoscopy, but in contrast non-bleeding angiodysplasias can be an incidental finding. This can make the decision whether to treat endoscopically detected angiodysplasias with APC difficult.

Aims & Methods: The aim of this study is to investigate the need for repeat endoscopies with APC in patients with angiodysplasias who were left untreated during the index endoscopy performed for iron deficiency anaemia or overt bleeding. We included 39 patients. Thirty-two were females (82.1%) and the mean age was 43.6 years. Median follow-up was 37 months (range 18–57). In 52% of the cases (n = 103) APC treatment for bleeding angiodysplasia(s) was performed at the index endoscopy. Repeat endoscopy with APC was necessary in 17 patients (18%) in whom angiodysplasias were detected but left untreated during the index endoscopy. Median time between index and repeat endoscopy was 21 weeks. A total of 48 patients (51%) who received a purely diagnostic index endoscopy were in need of other treatment modalities (e.g. iron supplementation, blood transfusion, stop anti-inflammatory agents). Anemia and/or overt bleeding resolved spontaneously in 24 patients (26%).

Conclusion: A substantial proportion of patients with clinical symptomatic angiodysplasia bleeding do not receive APC at the index endoscopy and continue to be dependent on iron supplementation, blood transfusion or undergo repeat endoscopy with APC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1942 UNDERUTILIZATION OF ENDOSCOPIC ARGON PLASMA COAGULATION FOR TREATMENT OF BLEEDING GASTROINTESTINAL ANGIODYSPLASIAS: AN INTERNATIONAL MULTICENTRE COHORT STUDY

K. Grooteman1, M. Mathurewicz1, G. Holleran2, E. Van Geenen1, D. Menen2, K. Chhita1, H. Bachir2, G. Kharrasse1, A. El Mekkaoui1, 1Gastroenterology And Hepatology, Radboudumc, Netherlands, Nijmegen/Netherlands 2Department of Clinical Medicine, Trinity College, Dublin/Ireland

Contact E-mail Address: karingrooteman@gmail.com

Introduction: Endoscopic argon plasma coagulation (APC) is the first-line treatment in patients with iron deficiency anaemia or overt bleeding resulting from gastrointestinal angiodysplasia. In the minority of patients active bleeding angiodysplasias are seen during endoscopy, but in contrast non-bleeding angiodysplasias can be an incidental finding. This can make the decision whether to treat endoscopically detected angiodysplasias with APC difficult.

Aims & Methods: The aim of this study is to investigate the need for repeat endoscopies with APC in patients with angiodysplasias who were left untreated during the index endoscopy performed for iron deficiency anaemia or overt bleeding. We initiated an international, multicentre cohort study to collect clinical, laboratory and endoscopic data from angiodysplasia patients. Cases were identified through a systematic search in endoscopy reports from 2010–2015 with inclusion criteria was endoscopic detection of angiodysplasia in patients with iron deficiency anaemia or overt bleeding resulting from gastrointestinal angiodysplasia. In the minority of patients active bleeding angiodysplasias are seen during endoscopy, but in contrast non-bleeding angiodysplasias can be an incidental finding. This can make the decision whether to treat endoscopically detected angiodysplasias with APC difficult.

Conclusion: A substantial proportion of patients with clinical symptomatic angiodysplasia bleeding do not receive APC at the index endoscopy and continue to be dependent on iron supplementation, blood transfusion or undergo repeat endoscopy with APC.

P1943 DIGESTIVE INVOLVEMENT IN SYSTEMIC DISEASES: A UNIVERSITY HOSPITAL EXPERIENCE

W. Khannoussi1, K. Chita1, H. Bachir2, G. Kharrasse1, A. El Mekkaoui1, S. Hamza2, H. B. Alaoûn1, K. Serraj2, Z. Ismaili3, 1Hepato Gastroenterology, Centro Hospitalar do Algarve, Faro/Portugal 2Clinical Pathology, Centro Hospitalar do Algarve, Faro/Portugal 3Gastroenterology, Centro Hospitalar do Algarve, Portimão/Portugal

Contact E-mail Address: wkhannoussi@yahoo.com

Introduction: Digestive manifestations in systemic diseases including vasculitis and granulomatosis is broad and can affect any segment of the digestive tract and related organs. The clinical symptoms are not specific and it can be challenging for diagnosis. The other difficulty remains the interference of digestive side effects of medication used.

Aims & Methods: We aimed to review various digestive manifestations of systemic diseases. This was a retrospective study from Feb 2009 to Sep 2016 in internal medicine and gastroenterology departments. The exclusion criteria was incomplete data considering the diagnosis of the systemic disease.

Results: We included 39 patients. Thirty-two were females (82.1%) and the mean age was 43.6 ± 11.3 years. The mean BMI before surgery was 41.6 ± 7.5 kg/m². There was a significant decrease in BMI after surgery and, on average, the mean total body weight loss was 34% and the mean excess BMI loss was 90%. Before

Patients symptoms and clinical findings were: Abdominal pain in 32 cases (22.9%), Nausea and vomiting in 7 cases (5%), stool modification 15 cases (10.7%), jaundice in 4 cases (2.9%), dyspepsia in cases (7.1%), hepatomegaly in 4 cases (2.9%), splenomegaly in 8 cases (5.7%), ascitis in 13 cases (9.3%), digestive bleeding 17 cases (12.1%). Laboratory findings: elevated liver enzymes in 13 cases (15.9%), alkaline phosphatase elevation 15 cases (19.2%). Radiological findings: 17 ascitis (14.4%), 12 digestive thickening (10.6%), 6 hepatomegaly (5.8%), 14 splenomegaly (11.8%), 2 portal cavernoma (1.6%), 3 portal thrombosis (2.5%), 4 esophageal distension (3.4%), acaulcus cholecystitis in 2 cases (1.6%), 2 portal hypertension (1.6%), steatosis in 3 cases (2.5%), 3 hepatic angiomia (2.5%), acute pancreatitis in 2 cases (1.6%), 2 mesenteric ischemia (1.6%), 1 badd chiari (0.8%), 1 hepatic carcinoma (1.8%). Upper gastrointestinal Endoscopy findings: hiatus hernia in 3 cases (8.6%), esphagitis in 11 cases (31.4%), esophageal varies in 2 cases (5.7%), Gastritis in 2 cases (5.7%), duodenitis in cases 16 cases, ulcers in 3 cases (8.6%), 4 celiac disease (11.42%). Lower GI endoscopy: Crohn’s disease in 1 case (8.3%), ulcerative colitis in 1case (8.3%), 1 hyperplastic polyps (6.3%), 2 colitis (16.6%). Esophageal manometry: motility disorder in 4 cases. The most used drugs were immunosuppressive drugs, steroids and hydrocholeaurine, all causing digestive side effects mainly abdominal pain.

Conclusion: The digestive involvement is around 10% of cases in the most represented systemic diseases, the main symptom is abdominal pain probably related to medication, and clinical manifestations are mainly non specific but we found some association with celiac disease and IBD. Liver involvement was noticed in 15% of cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1944 CHANGES IN LEVELS OF VITAMIN D IN OBSESE PATIENTS SUBMITTED TO BARIATRIC SURGERY

A. Vaz1, R. Guerreiro2, D. Sousa1, P. Queirós1, T. Gago1, J. Roseira1, H. Guerreiro1 1Gastroenterology, Centro Hospitalar do Algarve, Faro/Portugal 2Clinical Pathology, Centro Hospitalar do Algarve, Faro/Portugal

Contact E-mail Address: anam_vaz@hotmail.com

Introduction: An association between obesity and vitamin D deficiency has been reported in several studies. This may be explained, among other things by the sequestration of the fat-soluble vitamin D in the adipose tissue. Bariatric surgery, including Roux-en-Y gastric bypass (RYGB) is an effective treatment for more extreme cases of obesity, promoting significant weight loss and consequently reduction in some obesity-related health problems. However, the problem of vitamin D deficiency doesn’t seem to be solved after RYGB and can even be exacerbated by the changes in digestion and absorption of this nutrient after the surgery.

Aims & Methods: The aim of this study was to analyze the prevalence of vitamin D deficiency (VDD) and vitamin D insufficiency (VDI) in a population of obese patients, before and after being submitted to RYGB. We included patients patients selected to undergo RYGB for obesity. We measured anthropometric variables as BMI and serum levels of 25-hydroxyvitamin D (25(OH) D) before and 1 year after the procedure. VDD was defined as serum 25(OH) D <20 ng/mL and VDI as serum 25(OH)D concentrations between 20–30 ng/mL. Levels of 25(OH) D >30 ng/mL were considered normal.

Results: We included 39 patients. Thirty-two were females (82.1%) and the mean age was 43.6 ± 11.3 years. The mean BMI before surgery was 41.6 ± 7.5 kg/m². There was a significant decrease in BMI after surgery and, on average, the mean total body weight loss was 34% and the mean excess BMI loss was 90%. Before
bariatric surgery, 52.3% of patients had VDD and 36.8% had VDI. After surgery, the number of VDD increased to 71.1% (p = 0.0079). The mean levels of 25(OH)D decreased significantly from 19.8 ng/mL before surgery to 16.6 ng/mL after surgery (p < 0.05). There was no correlation between the amount of weight loss and the changes in the levels of 25(OH)D in our study.

**Conclusion:** There is a high prevalence of vitamin D deficiency in obese patients eligible for bariatric surgery. The level of deficiency tends to increase after RYGB. This population of patients should, therefore, be offered an adequate level of vitamin D supplementation, especially after the procedure.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1946 INTRAGASTRIC BALLOON: A CRITICAL VIEW IN NON ELECTIVE BARIATRIC SURGERY PATIENTS**

R.J.F. Fernandez1, E. Usuy2, C.F. Dietstel1, S. Barrichello1, A. F. Texeira1, M. Galvao Neto3

1Dept. Of Bariatric Endoscopy, Endogastro Rio, Rio de Janeiro/Brazil
2Dept. Of Gastroenterology, Usuy Clinic, Florianopolis/Brazil
3Bariatric Endoscopy, Gastro Obeso Center, Sao Paulo/Brazil

**Contact E-mail Address:** ricfittipaldi@hotmail.com

**Introduction:** Bariatric surgery is established as an excellent therapy for obesity. However, lower degrees of overweight without surgical indication also impact on patients’ health and quality of life, and the intragastric balloon (IGB) may be a treatment option.

**Aims & Methods:** We aimed to assess the efficacy of excess weight treatment with an IGB in patients with overweight and grade I obesity at EndogastroRio Clinic. A total of 717 patients were analyzed. A liquid filled IGB was used. The patients had initial body mass index (BMI) between 27 and 34.9 kg/m². The level of significance was set at p < 0.05.

**Results:** 615 patients were women. 131 patients had overweight and 586 had grade I obesity. Mean age was 37.97 years (17-75). Weight loss results and treatment success rates are shown on table 1. Percent excess weight loss (%EWL) was higher in overweight group (p < 0.0001) and percent total body weight loss (%TBWL) was higher in the grade I obesity group (p = 0.0009). 96 (73.28%) overweight patients and 132 (22.52%) grade I obesity patients reached a normal BMI (< 25 kg/m²).

**Conclusion:** Endoscopic treatment of obesity with an IGB shows to be an excellent therapeutic option to non elective patients for bariatric surgery according to BMI criterion.

**Disclosure of Interest:** M. Galvao Neto: I declare that I have received personal fees from FRACTYL LABS, GI WINDOWS, APOLO ENDO SURGERY, GI DYNAMICS, ETHICON ENDO SURGERY, not related to the present study. All other authors have declared no conflicts of interest.

**P1947 SPATZ³® ADJUSTABLE INTRAGASTRIC BALLOON TREATMENT: A BRAZILIAN MULTICENTRIC EXPERIENCE**

R.J.F. Fernandez1, C.F. Dietstel1, M. Galvao Neto5, A. F. Texeira1, E. Usuy2, S. Barrichello3

1Dept. Of Bariatric Endoscopy, Endogastro Rio, Rio de Janeiro/Brazil

4Dept. Of Bariatric Endoscopy, Gastro Obeso Center, Sao Paulo/Brazil
5FRACTYL LABS

**Contact E-mail Address:** ricfittipaldi@hotmail.com

**Introduction:** Intragastric balloons (IGB) are already used worldwide in the treatment of overweight and obesity, with established success. The Spatz³® adjustable balloon brings the possibility of balloon volume control during all the treatment, possibly reducing the risk of early removals due to intolerance and greater weight loss when compared to traditional IGBs.

**Aims & Methods:** We aimed to analyze the initial 25 months results regarding weight loss and complications with Spatz³® adjustable intragastric balloon in Brazil. In this retrospective longitudinal study were included patients submitted to Spatz³® adjustable IGB treatment between October 2014 to April 2017 in four private clinics in Brazil. The IGB Spatz³® was filled with a standard volume of 600 ml that was downward or upward adjusted when necessary. The patients presented a minimum body mass index (BMI) of 27 kg/m². Were analyzed the complications of Spatz³® treatment and BMI reduction, percent total body weight loss (%TBWL) and percent excess weight loss (%EWL). Data were analyzed using descriptive statistic and the Student t test. The level of significance was set at p < 0.05.

**Results:** 422 patients underwent implant Spatz³® balloon in the period. The complications (14.28%) at the present study were: early balloon removal (6.89%), gastric ulcer (3.94%), spontaneous deflation (1.48%), gas production inside the balloon (0.98%), gastric perforation (0.23%) and Malory Weiss Syndrome (0.23%). There was no death at the present study. Twenty-eight patients underwent downward adjustment due to intolerance (mean volume reduction: 162.86 mL) and all of then kept in the treatment (no early removals). 180 patients have completed the treatment (minimum 9 months of gastric balloon stay). The BMI decreased from 37.69 to 31.51 kg/m² (p < 0.0001), body weight decreased from 107.67 to 90.16 kg (p < 0.0001) and excess weight dimished from 36.79 to 19.27 kg (p < 0.0001). Eighty-six patients underwent upward adjustment. The adjustment resulted in a further mean weight loss of 4.2 kg (< 9 to 20 kg), the range of upward volume was 281.73±66.58 ml (100–420 ml) and the moment of the procedure was 7.06 ± 1.64 months. The group of patients that did the upward adjustment don’t have a higher %TBWL, %EWL or a higher BMI reduction when compared to the group that did not (p = 0.4413, p = 0.9245, p = 0.2729, respectively).

**Conclusion:** This study shows that Spatz³® IGB treatment is an effective procedure for weight reduction, without mortality but with higher morbidity rates when compared to traditional IGBs. Even more, the downward adjustment treatment may be effective in preventing the early balloon removal. Although the upward adjustment does not show to be able in providing a greater weight loss.

**Disclosure of Interest:** M. Galvao Neto: I declare that I had received personal fees from FRACTYL LABS, GI WINDOWS, APOLO ENDO SURGERY, GI DYNAMICS, ETHICON ENDO SURGERY, not related to the present study. All other authors have declared no conflicts of interest.
Patients’ body mass distribution had a clear improvement, with a significant increase in the percentage of Fat-Free Mass. A significant reduction of the basal metabolic rate of 1893.24 to 1694.67 was noted. Endoscopic approach with gastric balloon provides a significant weight loss and helps patients acquiring healthy habits

Introduction: Endoscopic methods, especially the intragastric balloon (IGB), have been shown to be effective for the treatment of excess weight.

Aims and Methods: We aimed to assess the efficacy and complications of excess weight treatment with a non adjustable IGB. A liquid-filled IGB with a volume of 600 to 700 ml was used. Treatment success rate (%EWL > 25) was 93.0%, as follow: overall weight was 99.0%, grade I obesity was 95.83%, grade II obesity 93.65% and grade III obesity 86.09%. Percent EWL was higher in the overweight group (OVW) (131.54% EWL) followed by grade I obesity (G1O) (95.83%) and grade II obesity (G2O) (93.65%) and grade III obesity (G3O) (50.61%) and grade IV obesity (G4O) (45.45%) sequentially (p < 0.0001). Percent EWL was also higher in women (69.71% EWL) than in men (53.39% EWL) (p < 0.0001).

Results: A total of 5874 patients were analyzed. The incidence of complications was 7.32% (n=430), as listed below: 299 (5.09%) early IGB removal, 58 (0.98%) absence of weight loss or weight gain. The incidence of gas production inside the balloon was 0.20% (n = 12) and the incidence of leakage was 0.54% (n = 32); pregnancy was 0.32% (n = 19); gastric perforation was 0.06% (n = 4); Upper digestive bleeding was 0.01% (n = 1); pancreatitis and esophageal perforation was 0.01% each (n = 1). Of the 5444 remaining patients, 4081 (74.9%) were women and 1363 (25.1%) were men. Mean age was 38.38 years. The patients showed a significant weight loss, with a significantly lower final BMI (mean: 30.08 ± 5.06 kg/m2) than the initial BMI (mean: 36.94 ± 5.67 kg/m2) (p < 0.0001). Mean BMI reduction was 6.85 ± 3.06 kg/m2, (range: 0.25–29.79). Mean percent total body weight loss (TBWL) was 18.42 ± 7.25% and mean percent excess weight loss (EWL) was 65.66 ± 36.24% (range: 3.99–336.14). The weight loss in kilograms was 19.13 ± 8.86. The treatment success rate (%EWL > 25) was 93.0%, as follow: overall weight was 99.0%, grade I obesity was 95.83%, grade II obesity 93.65% and grade III obesity was 86.09%. Percent EWL was higher in the overweight group (OVW) (131.54% EWL), followed by grade I obesity (G1O) (76.67%), grade II obesity (G2O) (50.61%) and grade III obesity (G3O) (45.45%) sequentially (p < 0.0001). Percent EWL was also higher in women (69.71% EWL) than in men (53.39% EWL) (p < 0.0001).

Results are better shown in table 01.

Disclosure of Interest: All authors have declared no conflicts of interest.
Hypersensitivity and intestinal inflammation aggravated by certain FODMAPs (Fermentable Oligosaccharides, Disaccharides, Monosaccharides, and Polyols) and abdominal complaints. A diet low in FODMAPs can reduce symptoms in patients with IBS but mechanisms were poorly understood.

Aims & Methods: We aim to explore the role of FODMAPs in triggering IBS symptoms by investigating visceral sensitivity, intestinal inflammation, and short chain fatty acid (SCFA) stress in induced IBS mouse models. Fructo-oligosaccharide (FOS) as one of the most frequently exposed FODMAPs in daily life was used in the study. Mice were subjected to water avoidance stress (WAS condition; 1 h/day for 10 days) or sham stress (basal condition; 1 h/day for 10 days) with oral gavage of saline or FOS. The effects of FOS were compared with saline-administered mice in WAS condition. In basal condition, no difference of visceral sensitivity, intestinal inflammation and SCFA production was observed between saline and FOS-administered mice compared with saline-administered mice in WAS condition. In WAS condition, increased visceral sensitivity and mucosal mast cell (12.3 ± 2.61 vs. 8.33 ± 3.55, P < 0.01) were observed in FOS-administered mice compared with saline-administered mice. In WAS condition, cytokine expression was mediated by FOS with increased IL-23 (2.11-fold, P < 0.01) in ileum and IL-1b (2.45 ± 1.55-fold, P < 0.05) in colon compared with saline. In addition, the average concentrations of acetate (2.48 ± 0.02 vs. 1.04 ± 0.10, P < 0.01), propionate (0.48 ± 0.09 vs. 0.33 ± 0.09, P < 0.05) and butyrate (0.19 ± 0.03 vs. 0.09 ± 0.03, P < 0.05) significantly increased in FOS-administered mice compared with saline-administered mice in WAS condition. In basal condition, no difference of visceral sensitivity, intestinal inflammation and SCFA production was observed between mice treated with FOS or saline.

Conclusion: Oral gavage of FOS leads to both an increase in visceral sensitivity and gut inflammation in stress induced IBS mice. These effects are linked with the production of SCFA in the gut which involved in the regulation of sensitivity and intestinal immune activation. These findings support the hypothesis that visceral hypersensitivity and intestinal inflammation aggravated by certain FODMAPs may be responsible for IBS symptom generation, and indicate an alternative mechanism of the efficacy of the low-FODMAP diet for IBS patients.

Conclusion: The outcomes were educational and enjoyable for all age groups. The interactive approach and the environment out of health-care centres facilitated population to feel comfortable and eager to learn, as well as clinical cases simulation provided a valuable entertaining experience. This strategy of raising public awareness of GI diseases seems promising, we are refining the model for a national campaign.

Introduction: Total gastrectomy can profoundly influence patients’ nutritional status due to the altered anatomical route for nutrients. The optimal nutritional route after total gastrectomy is still under debate.

Aims & Methods: The aim of the review was to determine the optimal nutritional route after total gastrectomy. The search was performed from 1950 to 2015 via PubMed, Cochrane Library and Embase. Articles focusing on randomized controlled trials dealing with the optimal nutritional route after total gastrectomy were included for data analysis.

Results: A total of 62 studies were included in this meta-analysis. The meta-analysis revealed that patients who received TPN compared with JEN (OR 4.59, 95%CI 1.74–12.10, p = 0.01) had a significantly higher mortality rate. There was a trend towards greater mortality in patients who received TPN compared with JEN (OR 2.95, 95%CI 1.13–7.68, p = 0.02) and TPN decreased weight loss significantly (p = 0.0001 and p = 0.05 respectively) but there was no change in gut transit, HFD induced short -term memory (p = 0.02), whereas VAD compromised spatial learning (p = 0.04). HFD rats were more anxious in OFT (p < 0.01).

Conclusion: HFD-induced alterations in memory and anxiety were not affected by VAD but VAD blunted effect of HFD on water intake and faeces weight, suggesting that their operating mechanisms are different. VAD by itself impaired spatial memory that requires further investigation.

Introduction: Patients on home parenteral nutrition (HPN) are exposed to a lifelong risk of catheter-related bloodstream infections (CRBSI), which threaten catheter and patient survival. Both taurodilnine 2% and saline 0.9% solution are used as catheter lock solutions (CLS) to prevent CRBSI. The optimal agent however, remains unclear. We hypothesized that taurodilnine as CLS is superior to saline in preventing CRBSI in HPN patients.

Aims & Methods: We hypothesized that taurodilnine 2% as CLS is superior to saline 0.9% in preventing CRBSI in HPN patients. This multicenter double blind trial randomly assigned HPN patients to use either the CLS taurodilnine 2% or saline 0.9% for one year. Primary outcome was the number of CRBSI/1000 catheter days. Secondary outcomes included time to CRBSI or catheter removal due to CRBSI, number of catheter removals due to CRBSI, exit-site infections, catheter occlusions, and (serious) adverse events.

Results: Of 102 randomized patients enrolled as modified intention-to-treat population. With taurodilnine, 5 CRBSI occurred during 15318 catheter days. In the saline arm 18 CRBSI occurred over 12493 catheter days. CRBSI/1000 catheter days were 3.33 (95%CI 1.44 in the taurodilnine and saline groups, respectively). The relative risk, 0.25; 95% CI 0.07 to 0.73; P = 0.002. The cumulative proportion of CRBSI-free patients after one year was 88% in the taurodilnine group and 49% in the saline group (P = 0.002). The number of catheter removals due to CRBSI was two (4%) in the taurodilnine group and eight (16%) in the saline arm (P = 0.049). The cumulative proportion of patients without a catheter removal due to CRBSI was higher in the taurodilnine group (P = 0.025). Exit-site infection and catheter occlusion rates were similar in both groups. Except for occurrence of CRBSI (P = 0.002), there was no difference in (serious) adverse events between groups. Drug-related adverse events were rare and generally mild to moderate.

Conclusion: Taurolidnine 2% decreased the risk for CRBSI by more than four fold in HPN patients compared to saline 0.9%. Given its favorable safety profile and lack of evidence for altering microbial susceptibility, taurolidnine locking therefore seems a key strategy to prevent CRBSI.

Introduction: Patients with severe intestinal failure depend on lifelong home parenteral nutrition (HPN) support. Repeated central venous catheter (CVC) loss due to complications, including mechanical damage, compromises vascular access. It remains unclear whether repair of damaged CVCs is an effective strategy to extend catheter life, avoid surgical replacement and maintain venous access.

Aims & Methods: The objective of this study was to characterize patients who underwent catheter repair and to evaluate effects on catheter survival and describe complications. This study concerns a retrospective analysis of all catheter repairs that were performed in HPN patients at the Radboud University Medical Center between January 2000 and May 2017. Primary endpoint was the difference in catheter survival in the presence or absence of catheter repair. To this end, a non-parametric survival analysis was performed. Secondary outcomes included localization of catheter damage and frequency of repair-related complications within 1 month after catheter repair.

Results: A total of 50 repairs in 38 CVCs of 32 HPN patients were included in the analysis. 16 CVCs (32%) were damaged at the distal end, near the screw thread of the catheter, 25 CVCs (50%) at the junction between the rigid and flexible part of the catheter, and 9 CVCs (18%) at the flexible part of the catheter. The mean time to catheter repair after placement was 2.2 years (95% CI 1.5–5.2). The mean catheter survival after repair was extended by 1.4 years to 3.6 years (95% CI 2.69–4.46; p = 0.01). No repair-related complications occurred within 1 month after catheter repair.

Conclusion: Repair of damaged CVCs significantly extends catheter life in HPN patients and maintains venous access. Catheter repair is a safe procedure.

Introduction: Catheter-related complications (CRCs) in home parenteral nutrition (HPN) patients are a threat to both catheter and patient survival. Taurolidine 2%, an antimicrobial catheter lock solution (CLS), is an effective agent for the prevention of catheter-related bloodstream infections (CRBSIs). Aim & Methods: The aim of this retrospective study was to evaluate long-term clinical outcomes of our HPN patient cohort that uses the CLS taurolidine. Between 2008 and 2016, all adult HPN patients requiring a central venous catheter (CVC) with taurolidine as a CLS were included. CRC incidence rates/1000 catheter days were described. Kaplan-Meier analysis was used to determine the time until a first CRC. Cox proportional hazard analysis was performed to identify risk factors for a first CRC.

Results: In 221 HPN patients, 658 CVCs (418 Hickmans, 172 PACs, and 28 non-tunnelled CVCs) were inserted, comprising 261252 catheter days. Median survival for Hickmans, PACs and non-tunnelled catheters was 175 (43–544), 310 (61–827) and 14 (7–19) days, respectively. During eight years follow-up, 17 CRBSIs occurred. CRBSI occurred in 80 catheter-related complications (CRC). CRBSI and CRO rates/1000 catheter days were 0.74 and 0.34, respectively. In 47% and 32% of patients, at least one CRBSI or CRO occurred, respectively. Median time to a first CRBSI or CRO was 246 (54–817) and 215 catheter days (5–2070). Numerically, but not significantly, CRBSI and CRO rates decreased over time. The sole use of intra-venous fluids was associated with a significantly lower risk for CRBSI (RR 0.32). Twenty patients reported adverse events (5 grade 1, 13 grade 2 and 2 grade 3) which were possibly related to the use of taurolidine.

Conclusion: This study describes the largest cohort of HPN patients to date on long-term taurolidine 2% as CLS. Overall, CRC incidence rates were low when compared with the literature. We found no evidence for a decreased effect of taurolidine over time.

Introduction: Patients with short bowel syndrome (SBS) exhibit substantial disturbances in gut microbiota composition, which implicates significant alterations of intestinal metabolism.

Aims & Methods: The aim of this study was to perform genetic and metabolomic analysis of stool samples collected from SBS patients totally dependent on parenteral nutrition (TPN). We collected 40 stool samples from 8 healthy individuals and 8 SBS patients with TPN. Faecal microbiota composition was assessed by sequencing of variable V4 and V3 regions of 16S rRNA gene using Illumina MiSeq TM platform. Library preparation, template building and template sequencing was performed. RNA was isolated according to manufacturer’s protocol. Obtained data were filtered by quality and length and processed for alpha and beta diversity analyses using QIIME software package. SCFA profile was measured using solid phase microextraction (SPME) coupled to gas chromatography and high resolution mass spectrometry employing time of flight mass analyser (Pegasus GC-HRT; LECO, USA). D-lactate content was determined using Megazyme kit.

Results: Weighted UniFrac analysis revealed significant differences between control and TPN subjects. In healthy controls, most abundant phylum was Firmicutes (64 ± 7.5%), followed by Bacteroidetes (22 ± 9.1%) and Actinobacteria (8.9 ± 4.5%). Proteobacteria were found only in one control sample. In TPN group, Firmicutes reached 66 ± 29% of microbiota but Bacteroidetes were absent and Actinobacteria significantly reduced (1.6 ± 4.1%). Proteobacteria were found in all samples (23.6 ± 15%). The most abundant metabolites in control stool samples were short-chain fatty acids (SCFA): acetate, propionate and butyrate. In the TPN group, lactate predominated significantly, while SCFA were absent in the intestinal content of these patients.

Conclusion: Long-term dependence on total parenteral nutrition results in dysbiosis of the intestine residuum characterized by extinction of Bacteroidetes and appearance of Proteobacteria. This was reflected by the changes in the composition of prevailing metabolites in stool.

P1963 COMPARING RISKS OF ADVERSE EVENTS ASSOCIATED WITH PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (PEG) PLACEMENT BETWEEN DIFFERENT ENDWALL TECHNIQUE AND THE OVERTUBE ASSISTED PULL TECHNIQUE

H. Matsui, H. Inomata, H. Horuchi, N. Tamai, K. Sumiyama

Introduction: Techniques of percutaneous endoscopic gastrostomy (PEG) placement can be divided into two techniques, the pull technique or the introducer technique (IT). Although the differences in procedural safety for the gastrostomy placement, the pull technique, in which the PEG catheter is delivered through the oral cavity and the hypopharynx, is more preferable regarding procedure related adverse events. However, severe peristomal bleedings were observed only in the modified introducer group. Four patients required suture placements and 3 in the pull technique group. Four patients required suture placements and 3

Aims & Methods: In this study, we retrospectively investigated risks of adverse events associated with the modified introducer technique using a blunt cannula compared with the conventional pull technique demonstrated that the modified introducer technique was more preferable regarding procedure related adverse events. Meanwhile, use of an overtube while guiding the catheter into the stomach may reduce the risk of bleeding at the gastrostomy site.

Results: During the study period, 236 PEG placements were done in 234 patients. The average age was 69.3 ± 12.5. The modified introducer technique was applied in 167 procedures (70.8%) and the overtube assisted technique was applied in 69 procedures (29.2%). The average age of the PEG technique was placed aiming for nutrition supports for cancer patients in 132 procedures, cerebrovascular accident in 51 procedures, aspiration pneumonia in 32 procedures, and others such as infection and duodenal ulcer in 21 procedures. Age (the overtube assisted pull technique > the modified introducer group) and gender (the modified introducer group) were significantly different between the two groups (p < 0.05). Overall, adverse events were observed in 19 (8.1%) procedures, although there was no procedure related mortality in the both groups. The risks of clinically significant adverse events were not different between the two groups. There was no significant difference in the types and the rate of adverse events between the two groups. However, severe peristomal bleedings were observed only in the modified introducer technique group. Four patients required suture placements and 3
patients required blood transfusion for the peristomal bleeding. In a univariate analysis, age, the rate of aspiration pneumonia as the reason for the PEG placement were higher in patients encountering adverse events (p < 0.05) (table 1). Also, serum platelet level, serum albumin and the rate of nutrition supports for cancer as the reason of the PEG placement was lower in patients encountering adverse events (p < 0.05). In a multivariate analysis, lower serum platelet level was solely recognized as a relevant predictive factor for adverse events (p < 0.05). The types of the technique used were not relevant to risks of adverse events.

(continued)

**Conclusion:** There was no significant difference in overall risks of adverse events between the modified introducer technique group and the overtube assisted pull technique group. However, the modified introducer technique may be associated with higher risks of severer adverse events. Especially, special care should be taken in patients with lower serum platelet level.
